Waste management regulations clearly define our duty of care and responsibilities for waste. The introduction of environmental taxes (e.g. landfill tax) and the waste hierarchy has encouraged the industry to reduce, re-use and recycle waste. For example, the material we excavate from street works is now used on site or recycled and we also aim to use only recycled materials when backfilling our excavations.

Opportunities continue to be explored to make waste derived products through end-of-waste and quality protocols. Research is also being undertaken into cost-effective methods of re-using chemicals and extracting resources from our waste residues.

Government incentives, such as those that support the increase in the generation of renewable energy, have allowed the industry to invest in innovative treatment processes and sufficient long-term capacity for waste. By securing incentives for a 20 year period this has given the industry the necessary security to implement significant waste management schemes. For example, we treat all of our sewage sludge (remaining after sewage treatment) through two thermal hydrolysis anaerobic digestion plants to generate renewable energy under the Renewables Obligation scheme. The process also significantly reduces the solid material that is beneficially recycled to agricultural land as a fertiliser. We also clean up and enhance the gas generated before directly injecting it to the gas network under the Renewable Heat Incentive scheme - see appendix 3. All of the above is also an example of the circular economy.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

Our aim is to reduce, re-use and recycle waste, generate renewable energy and continue to lead by example as an efficient water and sewerage company in the circular economy. This requires the continued support of Government in setting and securing financial and regulatory incentives so that innovation can continue and we have confidence to invest in new technology, such as advanced resource recovery from wastewater. Environmental regulation change would also allow water companies to co-treat other waste materials for the benefits of customers, the circular economy and the environment.

Appendix 1

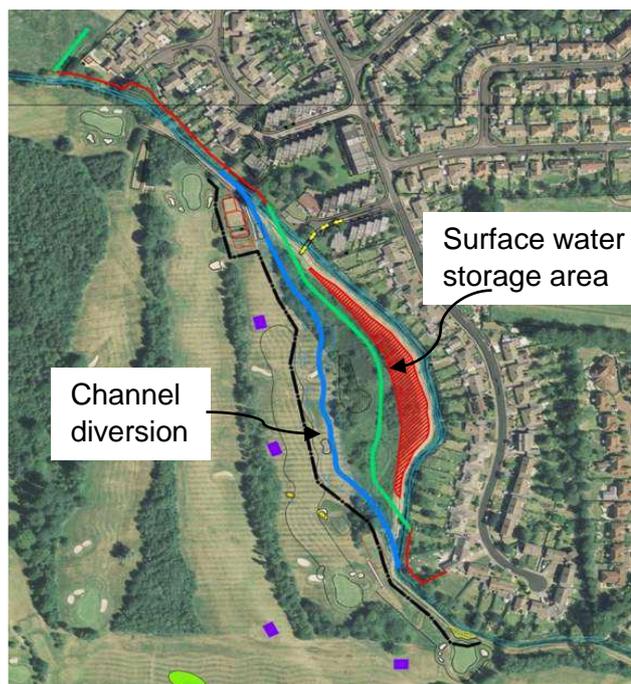

An example of a partnership project which addressed drainage incapacity is Brunton Park an integrated urban drainage scheme.

During heavy rainfall events approximately 100 properties in this residential estate were identified as being at risk of internal flooding from multiple sources – 74 fluvial, 57 surface water and 61 sewer.

Separate studies were carried out by both the Environment Agency (EA) and Northumbrian Water (NW) in conjunction with Newcastle City Council (NCC) to identify the best interventions to reduce flood risk in this area. The common conclusions were that investment in isolation could not successfully deliver the combined reduction in flood risk the community needed.

An integrated option proposed by NW was founded upon sustainable drainage principles and included the diversion of 360m of a main river channel into an adjacent golf course whilst using the original channel to create a 7,500m³ storage area to manage excess surface water flows. The space created, and material excavated, allowed for the creation of a new fluvial flood defence between the river and the community.

Additional components were two kilometres of new surface water and foul sewers with a new underground foul water storage tank. Joint working between the EA, NW and NCC has enabled this integrated and sustainable option to be developed and successfully delivered. By sharing the costs of some components of the scheme, like the channel diversion, the scheme has been delivered with excellent value for money to all partners.

NW led on the scheme design, procurement and delivery (including building the EA's assets) as well as providing a financial contribution. The EA took the role of lead risk management authority to secure the FDGiA contribution to the overall project cost and facilitated land access for working on a main river. NCC provided a financial contribution and supported project delivery.

As well as flood risk reduction this integrated approach also provided:

- Effective and efficient project delivery through alignment of expertise, statutory powers, finance and procurement.
- Cost savings through shared solutions.
- Improved river water quality.
- Improved biodiversity and local amenity (0.5ha of new wetland habitat created).
- Successful community engagement strategy.
- A template for future partnership working.

Appendix 2

An example of slowing the flow through catchment management is at Lound Lakes, in our Essex & Suffolk Water supply area.

Lound Lakes straddle the Suffolk Norfolk border and are nine interconnected water bodies that, along with Fritton Lake, are the local sources of water that we collect, clean and deliver to our customers from Lound Water Treatment Works. They are part of a 280 acre site which we own that is a designated County Wildlife Site.

Working with the Suffolk Wildlife Trust we've created two wetlands with reed bed areas there which have improved the range of habitats in Lound Lakes County Wildlife Site and increased the leisure and educational opportunities for local people.

The wetlands also have a very serious and important role to play in making sure that water quality is maintained in the Lakes. If a catastrophic pollution incident took place in the area (for example from a local farm or the release of oil from domestic premises or a road traffic accident) they can be used to store polluted water. They will give Essex & Suffolk Water valuable time to plan an appropriate response and act to prevent contamination of Lound Lakes.

At the same time the wetlands also benefit water quality generally by increasing the time the water is stored there which means that the sediment and nutrients have time to settle out.

The creation of the wetlands also increases the habitat opportunities for a large range of creatures and in particular for amphibians and bird species such as Reed Warblers, Chiffchaffs and Lesser Whitethroats. It also provides habitat for some of the 22 species of dragonfly that have been recorded at Lound Lakes.

The work was sensitively planned to be in tune with the environment and work commenced at end of August 2015 after nesting birds had fledged. This also allowed the excavator to access the land at its driest. The works settled over winter and filled up to create the wetlands then natural regeneration in spring 2016 provided habitat.

As part of the project we used some of the excavation material to raise a permissive footpath at Bloodmans Corner improving access during the winter period. This provides a perfect vantage point to view the new wetland area and for the public to enjoy the wildlife interest that it attracts.

The way we manage our land at Lound with sensitive grazing using local cattle breeds and the creation of the new wetlands to hold water is a good example of best Sustainable Urban Drainage practice. We have shown how even small areas can be used for effective rural Sustainable Urban Drainage to enhance the environment and slow the flow of water.

Appendix 3

Northumbrian Water (NW) uses the waste customers flush down the toilet, as a fuel, and turns it into electricity and gas which people then use to heat their homes and cook their meals.

We are the first water company in the country to use all of the sewage sludge (the material left over at the end of the sewage treatment process) to produce gas and electricity. We've transformed sewage sludge, from being a waste product that needed a lot of energy to clean up before it could return to the natural environment, into a fuel being used to produce green energy.

Bran Sands

Howdon

We:

- invested £75 million in thermal hydrolysis advanced anaerobic digestion (AAD)
- exceeded our renewable energy target of 20% two years early in 2013
- reduced carbon emissions by 30% towards our target of 35% by 2020
- are annually treating 2,000,000m³ of sludge from 3,000,000 customers and turning it into 10MW of renewable energy
- improved sludge product – safety, odour and value
- reduced transport movements
 - Moving sludge as a cake rather than a liquid as we use 6 regional dewatering hubs
 - Significant reduction in carbon footprint by transporting sludge cake as opposed to liquid
 - 2,000,000m³ liquid sludge = 90,000 tankers
 - 320,000m³ sludge cake = 10,000 trailers
 - Product broken down in the process

This, and other innovations, means our customers have some of the cheapest bills in the industry as it helps save the company millions of pounds in energy bills each year. NW is leading the way in green energy production for the water industry.

Thermal hydrolysis Advanced Anaerobic Digestion (AAD) uses a natural, biological, process which involves taking leftover sludge from sewage treatment and heating it in something similar to a giant pressure cooker. This process breaks down the cell structure of the sludge and kills anything that could cause diseases, releasing more nutrients for energy conversion. (Conventional anaerobic digestion, used by other water companies, does not have this stage so an equivalent amount of sludge would only produce half as much power). The sludge is then fed to billions of bacteria in giant digester tanks.

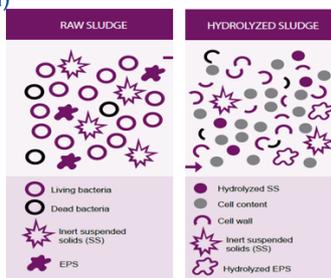

As they eat the sludge the bacteria give off methane and carbon dioxide gases, (similar to us burping and letting off wind), which are collected in two huge golf ball-like biogas storage bags, before being burned in a gas engine to produce electricity and heat. What remains of the sludge after the AAD process is a high quality, safe, odour free fertiliser for farmers.

SLUDGE STRATEGY ADVANCED SLUDGE DIGESTION

Advanced is really a pretreatment stage prior to conventional anaerobic digestion

- Sludge is preheated to 165°C and held at 6Bar for nearly an hour
 - Kills pathogens (e.g. e-coli and salmonella)
- Pressure is then dropped Sludge to ambient
 - This pressure drop causes cell structure to “explode”
 - Exploded cells are easier for enzyme to breakdown
 - More methane
 - More electricity

21 *EPS = Extracellular Polymeric Substances

By 2012 both our Howdon and Bran Sands sites were fully operational converting 100% of our sewage sludge to biogas and then into renewable electricity. At the time, this met 20% of all of NWG’s energy demands and covered more than 40% of all of our waste water treatment costs, which was a great achievement. The AAD plant at Howdon could produce all the sites energy needs.

We’ve made the power from poo process even more efficient by building a pioneering £8m gas to grid plant at Howdon, which is the largest in the water industry. It began producing power in December 2014 when we opened our Biomethane Injection plant at Howdon. It takes renewable biogas from the AAD process and purifies it to an extremely high quality so that it can be injected into the public gas distribution network. With the biomethane injection plant now online a maximum output of 88GWh of renewable energy, sufficient to supply 7,000 homes, can be passed into the grid annually making far more efficient use of the biogas available. The new plant now injects more than 200,000kWh of renewable gas per day into the public gas network.

The gas-to-grid plant delivers a step change in efficiency of over 35% in the use of biogas, equivalent to over 32GWh per year compared to the pre-existing CHP process. That’s 32GWh per annum that does not have to be provided from fossil gas, saving 5,902tonnes CO₂e every year. The plant delivers a £3 million annual efficiency, enabling NW to have some of the lowest bills in the industry.

It's more environmentally friendly in other ways too. Under the previous CHP operation, biogas containing impurities was burnt in gas engines, which released sulphur and nitrogen oxide emissions to atmosphere. These have now largely stopped, as a pre-treatment plant provided for both the CHP and the upgrade plant removes these impurities from the biogas. When the CHP is running on natural gas the exhaust is very much cleaner as the Gas Safety and Management Regulations permit only very low concentrations of sulphur and nitrogen in gas supplied by the public network. The direct environmental advantage of converting the CHP plant to run on natural gas rather than using grid electricity is the CO₂ emission factor which is 2.5 times greater for electricity than for natural gas.

This provides NW with an even more efficient process, generating more than £2.4m additional operational savings per year.

National Infrastructure Assessment Call for Evidence: Nuclear Industry Association response

1. The Nuclear Industry Association (NIA) welcomes this opportunity to respond to the National Infrastructure Commission's call for evidence.
2. NIA is the trade association and information and representative body for the civil nuclear industry in the UK. It represents around 260 companies operating in all aspects of the nuclear fuel cycle, including the current and prospective operators of the nuclear power stations, the international designers and vendors of nuclear power stations, and those engaged in decommissioning, waste management and nuclear liabilities management. Members also include nuclear equipment suppliers, engineering and construction firms, nuclear research organisations, and legal, financial and consultancy companies.
3. As major investors the nuclear new build developers are better placed than the NIA to respond to the detailed questions in the call for evidence and will be making their own submissions. We would however like to take this opportunity to make some broader points.

Overview

4. The NIA strongly supported the creation of an independent National Infrastructure Commission to consider the UK's long term infrastructure needs. Large scale projects are often affected by the political life cycle and an independent NIC should help overcome this issue by providing greater certainty for both the public and investors.
5. The National Infrastructure Assessment should help ensure the UK's infrastructure needs are met effectively, and consequently that UK economic growth is maximised. However in doing this it is important the Assessment does not reinvent the wheel; the UK needs huge investment in new generating capacity, but this is unlikely to be forthcoming without energy policy stability. The Assessment should therefore where possible identify policy changes that build on existing policy measures such as Electricity Market Reform arrangements and National Policy Statements, rather than starting from scratch.

Question 1: What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

6. Nuclear energy will play an important role in meeting the UK’s energy policy objectives in both the short and long term. Three nuclear developers – EDF Energy, Horizon Nuclear Power and NuGen – have plans for 16 GW of new nuclear build in the period to the mid-2020s. This will not only help secure our energy security and climate objectives but bring enormous benefits to the UK economy in terms of jobs, skills and global competitiveness. There will also be significant local economic and social impacts, particularly in terms of employment and expenditure.
7. From an industrial perspective these projects will also help put the UK nuclear supply chain in a position to compete for nuclear business overseas. Nuclear power capacity worldwide is increasing steadily, with over 60 reactors under construction in 15 countries – the highest rate of new build in 25 years. As the UK adjusts to a more globally focussed post Brexit economy this could become particularly important in terms of our industrial strategy.

Question 3: How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

8. As stated above we believe the NIC and the National Infrastructure Assessment can play a key role in ensuring the UK’s infrastructure needs are met as efficiently and cost-effectively as possible, but also need to maintain investor confidence through policy consistency. This means that where possible any changes should build on existing policy measures which have been delivering successfully, for example in the case of the electricity industry the Electricity Market Reform arrangements and National Policy Statements.
9. In terms of interaction with housing, there could be a case for the NIC looking at whether development sites for future housing might impact future potential power station sites. As the NIC will be aware the latter are few in number since new nuclear stations currently planned will be sited on existing nuclear sites, and any further stations beyond these are likely to be on existing or decommissioned sites.
10. Conversely associated infrastructure, including enhanced road, rail and sea links, is an important aspect of large infrastructure projects and could usefully be coordinated – where relevant - in a combined strategy covering nuclear and housing development sites. Whilst Local Enterprise Zones (where relevant) will have a role to play alongside developers the National Infrastructure Commission could also play a key role in coordinating this activity.

Question 5: How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

11. It is clearly important to achieve the right balance between the two to achieve the best value for the consumer. In the case of the nuclear sector the investment forthcoming for

maintaining and life extending existing nuclear stations, and for building new ones, is significantly influenced by the policy framework established by Government to achieve the UK's energy security and low carbon objectives, particularly the EMR arrangements, the Capacity Market, and the Carbon Price Floor. We believe these have generally worked well and should be maintained.

Question 7: What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

12. In the case of the electricity industry the investment required to fund new generation capacity, including new nuclear capacity, is being raised against the background of the EMR arrangements, and it is important these should continue.
13. In terms of taxation Business Rates are a tax on power stations that contribute to local services, and the Government have recently consulted on moving to a system of 100% retention by local government. We strongly support this since it would ensure that local authorities are financially incentivised to attract investment and promote local economic growth and development, and would promote acceptance of new nuclear build.

Question 9: How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

14. Key players in the electricity industry contribute to Government and regulator led initiatives designed to increase resilience across the sector, and again the NIC should attempt to build on these. In the case of nuclear the NIA has set up a Cybersecurity working group with a view to agreeing a coordinated approach to addressing cyber threats across the nuclear supply chain.

Question 10: What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

15. To ensure the greatest possible policy stability we would like to see any review of the planning system and infrastructure governance in the electricity sector to build on and improve the existing framework, including the National Policy Statements and EMR, rather than attempting to replace it.

Energy

Question 20: What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

16. With the potential electrification of heating, transport and industrial processes in the period, achieving a zero carbon power sector by 2050 is an important target if the UK is to meet its objective of reducing carbon emissions by 80% overall.

17. In terms of electricity generation decarbonisation can be achieved through the replacement of current fossil plant by a basket of renewable energy – particularly onshore and offshore windfarms and solar pv – and new nuclear stations, and also, if economically viable, with new CCS equipped gas and coal stations.
18. Given the major uncertainties about the most cost-effective mix of technologies and the pace of transition, for example in battery technology, it is impossible at this stage to predict the most effective option. However in principal low carbon technologies with the lowest cost should provide the greatest market share. Against this background we would expect nuclear to make a significant contribution; with at least 16 GW of new plant if current plans come to fruition, and more if new nuclear technologies such as SMRs are deployed.
19. In terms of policies to achieve decarbonisation, we would reiterate that the current EMR arrangements continue to represent deliver the transition, although they may need to be complimented with further measures in the light of developments.

NIC Call for Evidence – Ofwat Response

Introduction

Our regulatory regime has enabled investment of over £120bn into water and wastewater services since privatisation in 1989. We have been responsible for ensuring that the water industry has delivered significant infrastructure improvements for the long term, in the best interests of customers, society and the environment. We have achieved this through price controls which set incentives for innovation and efficiency and which have evolved to reflect the changing challenges of the sector. Our approach has enabled companies to supply reliable water and wastewater services while delivering substantial improvements for customers and meeting the policy expectations of governments.

We are currently developing our methodology for the 2019 price review, our next periodic review of the sector. This will set out our expectations for company business plans for the period 2020-25. Companies will submit these to us in September 2018. We recognise the crucial role that water and wastewater plays in national infrastructure planning, in particular the impact of regional variations in water availability and the need to provide the most appropriate solutions to those problems. We are now more than ever looking for the industry to deliver the best, not simply the least cost, solution.

We have targeted our response and have therefore not provided an answer to every question.

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

(Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice.

Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.)

Answer:

The highest value infrastructure investments in the water sector are likely to be those interventions which combine high traditional performance with high adaptation potential to a range of future scenarios.

The vast majority of existing water, wastewater and flood related infrastructure has been designed against a very fixed set of future variables – particularly climatic variables. The next generation of resilience infrastructure will need to adopt a different set of value criteria. It will need to deliver resilience against a more uncertain future within the context of affordability and completeness. Delivering against these criteria will require the sector to better embrace innovations and consider genuinely alternative approaches such as upstream management, water demand management, sharing/trading and cross sector collaboration. A broader mix of supply and demand infrastructure options will likely be key to resilience, sustainability and affordability - an over reliance on a single type of infrastructure will lead to higher risk overall. The optimization of existing capacity and the management of demand are likely to be some of the lowest regret investment options. This is likely to also include network interconnectivity where economically attractive as it adds to the overall level of national resilience.

Demand for water services has been relatively stable over the last 20 years, with strong population growth being addressed by better demand management and reducing leakage. Notably demand has fallen in south east England despite strong population growth. Water resources and infrastructure have relatively low average costs relative to other infrastructure, but high marginal costs for new resources, with companies estimating that new water resources have costs hundreds to thousands times that of existing water resources. This reflects the relatively slow pace of technical change in the sector and the usage of low cost marginal resources in earlier developments. These factors suggest that opportunities to make better use of existing resources and networks via demand management, smarter network management and improve network interconnections are likely to have highest value.

The highest value investment needs to be informed by better knowledge of current and future pressures on the existing system. Advanced decision making approaches, developed in other sectors, are now starting to be utilised in water planning. We have encouraged this approach through our joint Water Resource Management Plan (WRMP) guidance and continue to work with the sector to ensure our model of regulation provides the right incentives to enable high value infrastructure investments. In addition we are starting to see a more coordinated regional and national planning approach being developed which is moving away from optimizing on a company basis which may have been the emphasis previously. This approach provides real opportunities to share water more effectively through trades and transfers. We are particularly keen that customer legitimacy (service resilience and

value for money) continues to have a dominant role within decisions on the need and nature of future infrastructure.

Our work with the sector is also making clear that high value infrastructure is more than just a measure of the intrinsic value. We are starting to form a more fully developed understanding of the value associated with capacity, skills, integrated thinking and behavioral change (planning, decision makers and customers). We think the NIC/NIA can provide a step change in thinking by helping to bring together a high value approach to enable truly high value infrastructure.

We continue to consult with the sector on how our model of regulation can set the right incentives for resilience. We have a series of engagements with the sector planned for 2017 and our consultation on the PR19 methodology in July 2017 will provide a key opportunity to shape the regulatory process.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Answer:

Reliable and efficient water and wastewater services are critical to the country's competitiveness. The National Audit Office (NAO) estimated that water abstraction (only one component of the wider water and wastewater value chain) has a value of £72bn given its importance to a range of industries including agriculture and energy¹. Not only can disruption to water and sewerage services have a direct and immediate impact on the industries that depend on them, but they are also important to the environment and preservation and development of our natural capital.

Water companies play a key role in enabling growth. The ability of the water and wastewater services to respond to the needs of sustainable economic growth has room for improvement, particularly in better sharing of resources between surpluses and deficits across company boundaries. We believe that increased interconnectivity across networks will provide important added value by enabling a more responsive service which will aid the development of our economy. Our Water 2020 programme is focusing on the development of both water resource and bio-resource markets to encourage better utilisation of resources through trading and markets. We expect water companies to challenge themselves in putting together the business plans for

¹ NAO Efficiency in Resource Management. 2005: <https://www.nao.org.uk/report/environment-agency-efficiency-in-water-resource-management/>

the next price review to develop innovative solutions to enable sustainable economic growth within this regulatory framework.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Answer:

Planning for sustainable, affordable water and wastewater infrastructure which provides resilience for future generations requires a strong evidence based approach with customer legitimacy through engagement. There is considerable scope for better outcomes from smart sustainable design of new urban development to make best use of existing resources and networks. Smarter design of new development can reduce per capita consumption of potable water by around 50%. Opening the provision of new infrastructure to a broad range of providers ensures that existing monopolies do not prevent the development of more innovative and effective approaches.

The existing processes of WRMPs and our periodic review provide a strong planning process to deliver appropriate, resilient water supply infrastructure. The inclusion of customer engagement as a fundamental concept incorporated within WRMPs and companies' business plans provides the opportunity for customer input which helps shape infrastructure development around customers' needs and expectations.

Despite these strong foundations, we consider that potential exists for further improvements. A better front end approach using integrated thinking and recognising the benefits of behavioral change and cross sector approaches could enhance customer and societal outcomes. An important example is the current planning and design approach between service providers and developers/house-builders. We are starting to see, often through competition, real innovation in water and wastewater service delivery through new working models with significant service and resilience benefits for both customers and the environment, beyond supporting efficient new development. In addition we are also starting to see a more integrated approach for planning and design with local authorities and the Environment Agency on drainage and flooding issues. Again, these approaches are providing evidence of the value for sustainable economic growth through collaboration and better alignment between the key parties involved.

New providers of local infrastructure such as Albion Water demonstrate how integrating sustainable urban drainage, water efficiency and local supply resilience

into a single development can reduce the need for expensive new resources and network development. This also leads to faster development, supporting the Government's home building commitments, as it limits the pressure on the existing network. It also highlights how competition to provide new infrastructure can both foster innovation and enable more resilient and sustainable services.

As well as new developments, there is also a growing need for sustainable drainage investment in existing areas under threat from increased rainfall and surface water run-off. The RainScape projects in Wales, which seek to collect and store rainwater to mitigate stress on the sewerage system during heavy rainfall, provide an example of what can be achieved. It aims to both enhance customer outcomes through improved sewerage services and greater efficiency, while also having a positive impact on the physical environment and wildlife, all without the need for expensive capital intensive investment.

The above examples highlight what can be done. Our regulatory will promote the development of models that bring in new providers with new ideas where appropriate. However we also expect water companies to continue to challenge themselves in how they approach new development and consider a range of innovative solutions.

4. What is the maximum potential for demand management, recognizing behavioral constraints and rebound effects?

(Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for

demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.)

Answer:

Demand management and leakage reduction are particularly relevant to water and wastewater due to the high marginal cost of new resources and infrastructure. Although some progress has been made over recent years, and the overall demand for water has reduced, we believe that there is the potential for a step change in the water sector. We consider that improved demand management could have

significant positive effects in the water sector and beyond. We expect water companies to be at the forefront of driving more efficient demand management over current and future price controls. We outline below further details on the potential scale of the opportunities.

Impact of water demand management:

Current average per capita consumption across England & Wales is 145 liters per person per day (l/p/d). A modest reduction to 130 l/p/d would result in a resilience equivalent of c750 megalitres per day over the whole of England and Wales. New water resources would likely have a less significant impact – for example the Thames Water’s proposed Abington Reservoir would have provided only around 100 megalitres per day. We could learn a lot from cities such as Copenhagen which managed to reduce per capita consumption from 171 to 108 l/p/d between 1987 and 2010, with particularly significant savings being made in apartments (40%)². Reducing per capita consumption is also likely to be one of the most cost effective resilience actions, particularly when the associated energy/carbon benefits are included within an assessment (see below).

Key to unlocking the potential for reductions in consumption are effective customer engagement and participation to encourage behavioral change. As identified by our review of residential retail competition, retailing in the water sector has lagged behind other sectors in its use of technology and levels of customer service. We continue to see a lack of scale across the water industry which we believe is an important barrier to progress. We have adapted our regulatory model to further incentivise water efficiency at PR14 with some notable local successes. One example is that new market entrants will be able to bid to provide demand management services into incumbent Water Resource Management Plans. Companies will be expected to be transparent in their assessment of these bids and to publish their decisions on each bid.

We will build on this at PR19. For example, bilateral trading of water resources linked to the business retail market in England will also provide the potential for water efficiency and demand management gains beyond those that regulation has traditionally been able to achieve.

² <http://www.sustainia.me/resources/publications/mm/CPH%20Beyond%20Green.pdf>

Impact on energy and carbon:

The water and wastewater value chain is energy intensive with an associated carbon footprint of c5.5% of UK carbon emissions, roughly equivalent to the aviation sector³. Consequently, the demand management of water will result in both energy and carbon savings. Some 90% of these savings tend to be in the household, particularly related to hot water use. Consequently, domestic water demand management can yield savings for customers on their water, wastewater and energy bills, as well as contributing to the UK's climate change commitments. This cross sector benefit appears poorly incorporated within planning process and could provide an important opportunity for the NIC.

Impact of wastewater demand management:

A wide range of evidence supports the value of demand management in wastewater and its benefits in terms of offsetting or deferring the need for costly infrastructure. Sustainable Urban Drainage Systems (SUDS) are a primary example of local soft infrastructure providing a cost effective option with real benefits for sustainable economic growth – particularly in house-building. SUDS can be developed to remove surface water from sewerage systems and to minimise water passed forward for treatment by dealing with the problem at source. However, feedback from new entrants and developers suggests that barriers exist within the system which constrain utilization and adoption in England and Wales.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Answer:

The serviceability of existing assets can significantly influence the need for investment in new assets, as well as securing customer support for new investment. Good asset management can reduce or defer the need for new assets and provide a more sustainable outcome for customers and the environment by eliminating the need to constructions projects and their associated environmental impacts. We expect all water companies to focus on embedding effective asset management

³ *Greenhouse gas emissions of water supply and demand management options* (EA 2008)

strategies, policies and processes to ensure their customers get the greatest possible value from existing assets.

Leakage in the water sector provides a good example of the importance of asset management. Currently over 3000 megalitres (or the capacity of about 1200 Olympic sized swimming pools) of water is lost every day as leakage. This represents some 20% of the water abstracted, treated and distributed by the water industry. Since publication of 'Managing Leakage' in 1994 the industry has worked to achieve the 'economic level of leakage' (or latterly a sustainable level of leakage - a derivation of the same that takes into account an element of social and environmental consequences).

We consider that there is considerable potential for further reductions in leakage. Progress on leakage reduction has largely stagnated and we are concerned that innovations by both the supply chain and internationally (mainly new technology) are not being adopted. We introduced outcome incentives to reward reductions in leakage and penalise those who fail to meet their targets last year, so we will consider what further measures are required in the light of experience and performance against targets. Slow progress on managing leakage levels downwards is a particular concern given the public focus on the issue. It is likely to become increasingly difficult to justify to customer the need of new infrastructure schemes whilst a significant proportion of water which customers pay to be abstracted, treated and distributed is lost through leakage.

Quality and availability of data is a key challenge when it comes to effective asset management and optimization across the sector. Historically water companies have struggled to collect reliable data on the operation of their existing assets. This has had a significant impact on both the implementation of robust approaches to asset management, for example drawing on data intensive techniques like reliability centered maintenance, as well as developing robust datasets on asset health. The former can help to extend asset lives through targeted preventative maintenance, while the latter are particularly important for developing things like whole catchment area solutions which require a holistic understanding of complex networks.

There have been some recent examples of progress leading to improved asset management outcomes. For example, the ability to insert cameras in sewers has led to the wastewater industry developing innovative, no dig and minimal invasion spot repairs. Remote sensors in the sewer network can give good 'lead failure' indications of impending loss of serviceability. In contrast, the challenges faced in inserting similar technology to water mains (disinfection, discolouration risk, partially closed valves, etc.) means that typically water mains are renewed in complete lengths – or repaired reactively on failure. There remains significant scope for the industry to

improve remote sensing and failure prediction and to extend asset life and resilience through targeted investment and maintenance.

However, even with good asset management, new infrastructure will continue to play a role. Factors such as climate and demographic change, as well as the age of some of existing assets can in some cases justify the need for new investment. We expect any new investment to be fully justified through cost benefit analysis that considers a wide range of potential options, not simply those that rely on capital expenditure. Our regulatory approach aims to ensure that companies are incentivized to consider their customers' needs when it comes to deciding whether to invest in new assets or maintain or upgrade those that already exist. As noted above, we have implemented a range of outcome delivery incentives which seek to ensure companies deliver good performance for their customers. These financial incentives reinforce companies own performance commitments, set following engagement with their customers. They also reinforce the strong reputational incentives on companies to provide good services for their customers. From PR14 we also assess companies' business plans on a total expenditure (totex) basis, rather than looking specifically at capital or operational costs. This incentivizes companies to consider the best approach to deliver against requirements, whether this involves maintaining existing infrastructure or building new assets. WRMPs are also critical to the development of new infrastructure. In developing their business plans, we expect companies to be able to justify any proposed new asset investment by reference to the WRMPs they have agreed. This helps to minimize the risk of unnecessary investment or stranded assets which would be higher if a less rigorous approach was used.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Answer:

We consider that there is considerable potential for improved collaboration and competition in water supply services. Water abstraction is a case in point - less than half of the water currently licensed for abstraction is actually abstracted, despite the needs of some companies to invest in new infrastructure to meet demand pressures.

As part of PR19 we are proposing to create markets for both upstream water resources and bioresources. In relation to bioresources, evidence shows there is scope for increased optimisation of activities across the companies – and, looking further ahead, greater participation from firms operating in wider waste markets. In relation to water resources, trading is below its optimal level, and taking steps to reduce identified barriers to this could result in significant benefits for customers. We will take a range of steps for PR19 to ensure that markets can develop in these areas. For example we will introduce information platforms, set network access

prices for incumbents to charge new entrants and have separate binding price controls for water resources and bioresources to ensure transparency of the existing appointees' businesses.

In April 2017 the non-household retail market in England will open to competition. This will mean new entrants providing retail supply services to customers, in some cases in competition with existing appointees. This aims to deliver benefits for customers, including by creating the opportunities for increased innovation around providing new services or changing the way existing services are provided. In Scotland (which already has non-household retail competition) examples of innovations from new entrants include: rain water harvesting for large customers to reduce overall consumption, arranging for maintenance to be performed around customer not company needs and enhanced provision of information to customers to spot anomalies in usage trends which could be caused by leaks⁴. There is also scope for participation from third parties in the market for water resources, for example in water resources providers negotiating directly with water retailers as the business market develops.

Finally, we expect companies to develop proposals for using direct procurement for customers for suitable discrete, large-scale (over £100m of whole life totex) projects as part of their business plans for PR19. Water companies currently use a variety of arrangements to provide these services, including self-provision and procuring services from third parties. We think that encouraging companies to include a broader set of arrangements needed to deliver services, specifically the financing of large-scale projects and potentially the operation of new high-value assets, could realise additional benefits for customers. Under a direct procurement framework, the water company would seek bids from third parties and select the best value offer on behalf of its customers. A key difference between direct procurement and current arrangements is that, under a direct procurement arrangement, the service provider is competing to provide finance as well as construction and, where appropriate, operation of the new asset. This provides market evidence on the cost of finance, construction and potentially operations.

These reforms build on our existing approach. For example, through New Appointments and Variations (NAV) we can allow a new or existing water or wastewater company to replace the existing provider of water or wastewater services for defined geographical area. This includes appointing new licensees, for example to serve a new development that does not currently have water or wastewater services. As such we consider it is has been and will continue to be an important

⁴ <http://www.watercommission.co.uk/UserFiles/Documents/Presentation.pdf>

mechanism to enable new entrants to enter the market, which in turns drives innovation across the sector. The example provided in response to question 3 above notes the benefits of Albion Water’s approach to providing services for new developments; this resulted from its appointment through the NAV process.

With respect to collaboration, the opportunity (particularly for greater collaboration between water companies) is considerable. For example, the existing work of the Water Resources South East (WRSE) has already demonstrated the benefits of cross company collaboration. WRSE brings together the companies providing both water and wastewater services in south east England, along with other stakeholders such as central government, the Environment Agency and Consumer Council for Water. Through initiatives like the regional modelling project WRSE then look to identify strategic opportunities for long term resource management across different companies. At the previous planning round WRSE’s combined regional planning approach identified c£500m of deferrable infrastructure investment by sharing resources to increase utilization of available resources.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

(Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.)

Answer:

Water and wastewater services are funded from customer bills. Historically, each monopoly provider would generally bill the customers in its designated area based on the revenues it is allowed to recover, which in turn are set by us at each periodic review. This would apply to allowed revenue for both retail and wholesale services. With the introduction of retail market competition in England from April 2017, for non-household customers, this approach will change as new retail companies will enter the non-household supply market. These retailers will bill customers and then provide the funding for the non-household wholesale services customers receive from the regional monopoly provider(s).

Direct recovery from customers has worked well in terms of delivering required investment and placing customer legitimacy at the heart of the services companies provide. However, the rigidity of the current funding structure has the potential to limit sector innovation in future. Several examples are illustrative:

- Investment required by local water companies to address environmental improvements – which may have wider national benefits- can create tensions with affordability. For example South West Water has undertaken considerable investment for environmental improvements relating to a large stretch of coastal waters. This has resulted in South West Water having the highest bills in England and Wales. The Government has intervened by providing a £50 bill subsidy for South West Water’s customers. The current funding model means that South West Water can only recover its required revenue from its regional customer base. This potentially limits the scope for collaboration between companies within catchment areas or for the evolution of more national initiatives like the potential development of more interconnection and trading across regions.
- The introduction of social tariffs by water companies has helped to support customers in need of assistance with the affordability of their water bills. While there is some question around the role water companies and their customers should play in supporting their customers versus what role Government social assistance should play, the sector funding model has been able to accommodate social tariffs. This could also potentially become relevant if water companies are asked to provide additional services with wider social or environmental objectives, for example flood defense. We note some of the challenges in the energy sector around levies on customer bills to fund subsidies for renewable electricity generation or social programmes such as the Warm Home Discount.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

Answer:

No, the financing model for traditional infrastructure options is robust and we have also encouraged, and will continue to encourage, new and more innovative approaches such as direct procurement for Thames Tideway. There is scope to remove legislative barriers to the use of direct procurement for customers using a project specific licence (as opposed to a contract between the new entrant and

existing appointee). However we consider this would be helpful rather than essential and that the current framework for direct procurement can work effectively.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

Answer:

The water sector has an increasing interest in wider interdependencies both in terms of the opportunities they raise but also the risks they pose. We see the need for more engagement with other sectors by water companies, particularly related to energy, food and telecommunications/cyber security.

We recognise that Ofwat has a role in supporting this work. We also recognise the need to work with other regulators to ensure potential barriers between regulatory regimes are managed and that incentives are suitable aligned. However, we also expect the water industry to work together and collaborate across sectors to address the collective challenges arising from interdependencies. We believe that the NIC could play an important role in helping to identify interdependencies and to facilitate work across different sectors.

As part of our review of business plans for the next price control period we expect companies to provide robust evidence that they understand the risks facing their networks and services. We expect companies to clearly outline how they are planning and are able to deliver a level of resilience that their customers expect and are willing to pay for.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Answer:

It is not obvious that planning arrangements are barrier to significant infrastructure investment in the water sector. We note that major investment is taking place in the sector such as the Elan Valley (£242m) and Thirlmere Link (£300m). The Thirlmere Link required a public inquiry as part of the water resource management planning process and received quick approval. However, we note there has not been a major new reservoir or interconnector constructed in England and Wales since the 1970s,

so it is unclear how the planning system would cope with such proposals. We expect that the provisions of the Planning Act 2008 should be sufficient to ensure that any Nationally Significant Infrastructure Project in water or wastewater can be progressed in a timely manner. We note, for example, that the Development Consent Order for the Thames Tideway Tunnel projects was approved within the indicated timescales. We also consider that Government's approach of publishing National Policy Statements for water and wastewater has been helpful in providing additional certainty on how projects will be appraised. As a regulator setting price controls of the water and wastewater sector we value certainty on future investment as we set cost allowances for companies, including for investment in new infrastructure. We therefore welcome the publication of further National Policy Statements in future. .

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Answer:

Water/wastewater services are inextricably linked to a finite natural environment. We have reached a critical point in the history of water/wastewater management. For many key parts of the country we have now fully utilized available license capacity to abstract from the environment and discharge more to it. For these areas the next generation of water and wastewater infrastructure will likely be more expensive than existing assets. This would raise significant questions around affordability.

The alternative is to work differently with the environment through catchment/upstream management (soft infrastructure). Not only have such approaches been demonstrated to be cost effective, but they are also likely to be increasingly resilient to future shocks. We are aware of a number of companies actively engaging with other stakeholders to manage catchments and to develop no-build (hence cost and carbon efficient) solutions.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: "credible" improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. "Tractable" improvements are those that can generate usable quantitative outputs. "Transparent" improvements are those that do not rely on 'black box' modelling and assumptions.

Answer: Approaches to cost-benefit analysis are generally well established in the water and wastewater regulatory model. The key area for further work in the

forthcoming Business Plans will be how to represent benefits against a more uncertain future. Specifically the resilience agenda will require companies to consider mitigation for high consequence events against a very uncertain probability. It is likely that a less mechanistic set of approaches might need to be adopted if the process is to be credible, tractable and transparent. We will be seeking reassurance that customers are suitably engaged in this process and that companies work towards best value and not necessarily least cost options.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: “demand” includes domestic, commercial, power generation and other major sources of demand.

Answer:

There is a well-established water resource management planning process which looks out 25 plus years as basis for managing supply/demand imbalances. Potential issues relate to optimisation across company boundaries and taking a longer term view (beyond 25 years).

Optimisation across company boundaries concerns the need to look at, for example, regional or catchment based approaches where several companies operate within a defined area. This requires information on potential opportunities to provide water across company boundaries, which in turn requires understanding of potential options to improve demand management, reduce leakage and transfer water from areas with surplus to areas with deficit. Ofwat is promoting the development of market information platform to help reveal the opportunities and enable responses to these opportunities by water companies. This builds on the existing water resource management processes, but recognises that in order to facilitate efficient decision making, companies need a better understanding of potential interest to supply outside their areas.

In terms of longer term thinking, the recent WaterUK report into Long Term Drought Forecasting calls for a ‘twin track’ approach and recognises and advocates the need for Demand Reduction (including water efficiency and leakage) as well as regional

transfers to share resources⁵. The report further recognises that once these options are exhausted then new sources and storage may be required. Current national and international thinking is starting to show a clear consensus that managing demand downwards, catchment based approaches and sharing resources are likely to be some of the most effective long term/sustainable interventions in many situations.

This is not to say that large-scale traditional infrastructure (reservoirs, desalination, wastewater treatment etc.) will not be needed, but that they need to be carefully considered in context and need not be an automatic response. Indeed, demand management and reducing leakage may create valuable opportunities to better understand need for further investment by revealing information about demand and allow time for companies to develop a better understanding of a range of options to meet demand/supply balance.

We are currently working with the sector, under the Water and Wastewater Resilience Action Group (WWRAG), to develop a set of resilience metrics. This will enable comparison of level of resilience within and between companies. It is likely that this work will provide a better understanding of the relative hierarchy of different intervention types, including both hard and soft infrastructure options. However, the most effective interventions are also likely to be influenced by local circumstances. We therefore expect much of the progress in this space to continue to be industry led and would strongly welcome any steps the NIC could take to encourage water companies to focus on effective supply and demand management over the long term.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

Answer:

It is generally recognized that the most effective intervention is to deal with the surface water component of sewerage flows. It is rare that sewerage capacity is overwhelmed by sewerage coming directly from properties. Dealing with surface water can be done by delaying the entry of surface water to the sewer, slowing the

⁵https://dl.dropboxusercontent.com/u/299993612/Publications/Reports/Water%20resources/WaterUK%20WRLTPF_Final%20Report_FINAL%20PUBLISHED.pdf

entry of surface water and/or reducing the volume of surface water entering the sewer, in the extreme, preventing its entry altogether. SUDS are vital to address this and a report in 2011 commissioned by Ofwat suggested that the UK could learn valuable lessons from overseas about SUDS implementation⁶. Following this report, we took a number of steps to help the industry improve outcomes. For example, in collaboration with the Environment Agency, we published a drainage strategy framework in 2013 to help companies, in collaboration with other organisations, to deliver the outcomes customers want⁷, including through SUDS.

Surface water separation/ removal (not necessarily using SUDS) can be a cost-effective option. Northumbrian's scheme in Whitburn is an example. The removal of surface water from a supermarket, its car park and farmland from a sewer in the Whitburn area of Sunderland has resulted in the downsizing of new underground storage tanks that are being constructed to limit the frequency and volume of discharges to the environment when it rains heavily and so maintain compliance with the Urban Waste Water Treatment Directive. At £8 million, the current cost estimate for the project is around half of the previous estimate that Northumbrian Water provided to Ofwat in the course of the last price review (PR14)⁸.

Incentives to encourage householders to disconnect down pipes are in place (i.e. surface water drainage rebates) but lengthy pay-back period hinders their effectiveness. Charging based on impermeable surface area would be more cost-reflective and may incentivise disconnection but experience has shown it can be a politically sensitive issue given the potential impact on certain types of customers with large impermeable surface areas (eg churches). However, four out of 10 wastewater companies have moved to surfaced based charging.

The above examples highlight how companies are making progress to better manage surface water drainage. We expect them to continue to focus on this when considering options and how/whether to invest in new assets.

⁸ See: https://www.nwl.co.uk/media-centre/611_5479.aspx

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Answer:

A whole catchment approach involves managing all the inflows and outflows to the water system in an integrated way. The key to making it work effectively is collaborative or partnership working from water companies and a range of stakeholders, including their customers, within a catchment. Effective catchment management is likely to involve companies working with a range of local and national stakeholders to deliver an integrated and sustainable approach.

There are a number of ways that this coordination could take place, for example:

- Catchment area partnerships – informal or formal collaboration arrangements formed to deliver a whole catchment approach for a defined catchment area. This would effectively create a number of local bodies to manage each catchment with national level coordination through bodies like the Environment Agency.
- More central coordination, for example through establishing a ‘system operator’ role for providing water and wastewater services – this approach would formally bring a greater level of national coordination to catchment management by creating a single system operator for the water and wastewater network.

Both of the above options would have benefits and drawbacks; we do not have a view on which is more appropriate. However we continue to expect water companies to put catchment management at the heart of their business plans for the next price review.

In addition to the organisational challenges of catchment management, there is a number of practical challenges. Diffuse pollution is one of the biggest challenges to improving water quality in England and Wales. Diffuse pollution occurs when small amounts of pollutants – often from many different sources – enter a water catchment across a wide area. On their own, the sources of this pollution can be relatively minor, but across the catchment they can accumulate to significantly affect water quality and to damage the ecosystem.

We recognise the effort and expense that is required to treat raw water to make it good quality drinking water. We further recognise similar effort that is required to treating wastewater such that it will not damage the environment to which it is discharged. Treatment is costly and risks damaging the environment (eg through the use of chemicals). Another concern is that current treatment approaches do not

remove pollutants from the surrounding environment – only from water that is for public use. This means that pollution could remain in the environment where it would continue to affect the wildlife that our rivers and streams sustain.

Upstream catchment management schemes could be a more sustainable way of managing the water cycle and of helping to ensure good quality drinking water. This is because they tackle diffuse pollution at source - before it reaches a water treatment works. They may also help the companies to find more cost-effective ways of meeting their environmental obligations.

These benefits also extend beyond diffuse pollution into flood risk management. An example is South West Water's 'Upstream Thinking' project. This aims to improve water quality in river catchments in the company's area as a way of reducing treatment costs. It also aims to help it manage water volumes during droughts and control run-off during floods.

Water customers could legitimately be expected to pay for those elements of catchment management that bring direct and measurable benefits to them, where schemes for good land management reasons contain measures that produce other benefits, alternative funding sources and contributions should be sought. This is consistent with wider approaches to flood risk management.

The upstream catchment management principles can also be applied to urban environments where surface water run-off and flood risk require a wider range of stakeholders to contribute to identifying, financing and implementing the optimal approach. Some examples of this type of approach are mentioned in our 2013 drainage strategy report discussed above.

There is a further challenge around payments. The catchment management approach may result in the polluter being paid to reduce their pollution. There is a question about the efficiency and fairness of this approach and whether it would be more efficient for the polluter to bear the costs of their impacts on wider society.

Considering natural, social and human as well as economic capital consequences of investment decisions should form part of the understanding of "how much" as well as "who pay".

INTRODUCTION

Ordnance Survey (OS) is Britain's mapping agency, responsible for creating and updating the definitive mapping and geographic information database of Great Britain.

Our core business is focused on the collection, creation, maintenance, management and supply of geographic information to meet the needs of national physical and social infrastructure. We are heavily relied upon by organisations spanning transport, digital communications, energy, water and wastewater, flood risk management, and solid waste sectors in addition to the public sector in delivering against regulatory and policy objectives.

OS data is available to over 4,490 public sector organisations, free at the point of use under the terms of the Public Sector Mapping Agreement and the One Scotland Mapping Agreement¹. Additionally, OS expertise and data is being used to provide infrastructure-related analysis and services in a variety of contexts. Examples of these include:

1. Working with HS2 Ltd to provide a service to assure highly-accurate positioning capability to facilitate the rail construction process. A project to fulfil this has recently been awarded to OS, based on developing enhancements to OS's own satellite positioning infrastructure, OS Net², a highly accurate positioning service built on our geodetic framework. This service is widely used for precision tasks such as machine automation and precision agriculture.
2. Provision of ResilienceDirect³ to the Cabinet Office. This is an online service for the resilience community to share information amongst all Category 1 and 2 emergency responders and agencies for planning, response and recovery, built on a queryable mapping interface.
3. Collaboration with DfT to define and create a new generation of definitive road, path and right of way data, developed and maintained as a combination of OS surveyed content and information sourced from highway authority custodians. The resultant data, released in 2016, is highly interrogable and is enabling improved routing and asset management.
4. Working with the Department of Health to develop a map-based tool to visualise live data on localities' performance and process measures in relation to winter pressures on NHS and social care services, enabling the identification of areas under most pressure and facilitating planning and response actions.
5. Supporting Openreach in developing a flood risk mitigation strategy. A bridge collapse in Tadcaster in 2015 disrupted a trunk cable; we subsequently identified all bridges across Britain which carry Openreach assets together with associated flood risk categories. This information was used to establish mitigation and contingency options.

We support the ambition of the NIC and welcome the opportunity to engage and offer support at a strategic level. Our data and services are woven into the fabric of the national infrastructure and the

¹ <https://www.ordnancesurvey.co.uk/business-and-government/public-sector/mapping-agreements/index.html>

² <https://www.ordnancesurvey.co.uk/business-and-government/products/os-net/>

³ <https://www.ordnancesurvey.co.uk/business-and-government/public-sector/resilience-direct/about.html>

planning, operation and resilience of national infrastructure comprises a central component of our mission and our public task.

We provide national and international services to governments and commercial organisations based on our knowledge, skills and understanding of location data and geography. OS is a government-owned limited company, the entire issued share capital of which is held by the Secretary of State for BEIS, who is represented on the OS board by UKGI.

CALL FOR EVIDENCE RESPONSES

CROSS-CUTTING ISSUES

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

No comment.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

We acknowledge that data issues do not form a direct part of the NIC's scope. However, we suggest that one component of the improving the value of infrastructure is to invest in data as part of Britain's digital infrastructure, which offers opportunities for planning, deploying and operating assets, enhancing international competitiveness; not only by reducing costs but also by positioning the UK as a leader, enabling the export of ideas and skills.

An example of this is BIM (Building Information Modelling) Level 2⁴, a standard for enabling data interoperability and collaborative working. In 2011 the UK government issued a directive that from 2016 all public-sector capital projects would be compliant to BIM Level 2 with the aim of reducing costs by 20%. In 2015 alone, construction savings of £804m were reported⁵. This has been hailed internationally as a far-sighted initiative, and has created export opportunities for UK businesses.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Throughout our response, we will make repeated reference to the value of a common location referencing framework. Everything happens somewhere; infrastructure, or services relating to infrastructure, are inherently geographic or location-based. Making use of location as a common

⁴ Further information about BIM Level 2 is available here: <http://bim-level2.org/en/about/>

⁵ Digital Built Britain: Level 3 Building Information Modelling - Strategic Plan, page 5
https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/410096/bis-15-155-digital-built-britain-level-3-strategy.pdf

reference links otherwise disparate datasets and enables information about people, properties and assets to be identified, analysed and communicated effectively, through a map or otherwise.

Further information about OS core reference data is provided in the Annexe.

Comprehensive and reliable data relating to natural and built assets is essential to effective management and operation. We argue for the creation of a national Digital Built Environment (DBE), recognising data as a key infrastructure capability for managing assets within an open, secure context. Within a DBE, geospatial data provides the framework within which the relationships across human, natural and built environments and systems can be identified, modelled and managed. If properly curated and maintained, a DBE becomes a single version of the truth, with the capability to improve decision-making and reduce costs.

Achieving this requires capturing and describing the real world, including the built environment, in ways that can be usefully consumed by multiple parties for multiple uses, enabling better outcomes in terms of more cost-effective infrastructure (both in terms of planning, construction and ongoing management), and healthier and more resilient places.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

No comment.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

With reference to our response to question 3, this challenge can be addressed by modelling and evaluation through DBE simulation.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

A single version of the truth – a core element of the DBE concept we highlighted in our response to question 3 – is a powerful enabler of both competition and collaboration between infrastructure service providers.

An example of improved competition lies in connections to existing networks, such as broadband fibre and electricity. Taking the latter as an example, Ofgem has implemented measures to facilitate competition in the provision of utility connections. As a consequence, customer connections can now be undertaken by Independent Connection Providers as well as the incumbent electricity network companies. In 2014 Ofgem published results of its findings in relation to issues frustrating

competition⁶. Access to network information was highlighted as being key to a successful open market, together with the adoption of common processes and practices to facilitate data exchange.

Similarly, collaboration requires a shared understanding of what is where. Ensuring that street works are coordinated and executed in an efficient and effective way is a challenge for infrastructure owners in the context of incomplete access to cross-sector asset information, which in many cases is inaccurate or out of date. As a result, numerous asset strikes occur every year (60,000 according to one estimate⁷), often with severe consequences. In addition, street works are not as efficient as they could be, resulting in longer time for the works with corresponding economic impact. Maintaining and sharing a common view of infrastructure data has the scope to significantly reduce this problem.

The deployment of 5G infrastructure represents a major forthcoming challenge (and is discussed further in our response to questions 17 and 18). DCMS is currently funding research⁸ into how to exploit detailed geospatial data to optimise the planning of 5G infrastructure, which will be essential due to the short range and propagation capabilities of mmWave radio signals. A detailed 3D model of the built environment is required to optimise signal coverage; the figure below illustrates how the two potential base station sites (yellow points) enable continuous radio coverage in the street, with the green and blue areas identifying the lines of sight from these locations. Access to a shared facility of this kind could offer major collaboration benefits – and reduced costs – to government and telco operators.

⁷ <http://www.online.co.uk/features/striking-out-underground-cable-strikes#.V6DAkKkRPNI>

⁸ 5G infrastructure planning project led by Ordnance Survey, supported by Met Office and University of Surrey; see <https://www.ordnancesurvey.co.uk/about/news/2016/uk-leading-way-5g-future.html>

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

No comment.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

No comment.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

In our responses to questions 6 and 25 we refer to two examples of infrastructure risk (buried asset strikes and flooding). Planning for resilience requires active collaboration between stakeholders, again dependent on a single version of the truth, built on a common referencing framework. In this regard, we commend the MISTRAL⁹ project being led by the ITRC consortium (which includes OS), which is pursuing a 'system of systems' approach in modelling vulnerabilities.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

We refer to our response to question 3, where we introduced the concept of the Digital Built Environment, or DBE. We suggest that a fully-functioning DBE will offer significantly reduced costs and improved effectiveness for infrastructure planning and governance throughout asset lifecycles by providing an authoritative, independent model of the asset in the context of its surrounding geography.

Realising this will require a level of mandatory participation by infrastructure owners, particularly in terms of submitting data to the DBE in accordance with defined standards. This is already being realised in part through the operation of BIM Level 2, as referred to in our response to question 2; this mandates data interoperability and sharing within the supply chain.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The wealth of attention that has been devoted to concepts such as Natural Capital and Ecosystem Services has enabled much greater rigour in modelling and monitoring environmental outcomes from infrastructure projects than has historically been the case.

We perceive two elements to this challenge:

⁹ <http://www.itrc.org.uk/>

- Minimising and mitigating the adverse impacts of new infrastructure, and
- Designing infrastructure specifically to enhance or protect the natural environment

Infrastructure investments should be considered from a range of perspectives, including ecological habitats, ecosystem services and amenity. One area of major current concern is clean air in cities; we advocate seeking opportunities to plan and utilise green space at key locations within urban contexts to absorb pollutants, encourage the flow of clean air and improve the drainage of surface water. OS is working with the Scottish Government and BEIS to create a greenspace register for the whole of Great Britain which could support this.

We also encourage the adoption of a landscape-scale conservation¹⁰ approach when offsetting habitat loss, thereby helping to build a critical mass of habitat and reduce fragmentation.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

No comment.

TRANSPORT

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

The Atlas feasibility study¹¹, supported by the Government's £100m Intelligent Mobility fund and led by OS, is examining the data and communication requirements that will enable autonomous navigation. Our research is focusing on the growth and development of the underpinning technology, data and supporting infrastructure that Connected and Autonomous Vehicles (CAV) will require.

This research has identified the need for the development of high bandwidth communications infrastructure that can enable the exchange of data between fixed assets (such as traffic lights) and vehicles. It is anticipated that development of CAV will lead to the emergence of new business models and transport patterns.

Whilst CAV will be part of a future interconnected transport system, we believe that there will need to be a comparable investment on a national scale to deliver new mass-transit public transport infrastructure which incorporate bus, trains and metro systems.

¹⁰ https://en.wikipedia.org/wiki/Landscape-scale_conservation

¹¹ <https://www.ordnancesurvey.co.uk/about/news/2016/uk-given-green-light-driverless-cars.html>

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Within our major urban centres vehicle congestion and resultant poor air quality is a significant issue with measurable impacts on both productivity and public health¹². In recent years initiatives such as cycle hire schemes in London and several other cities have enabled the growth of low-impact flexible transport. In London specifically, this has been supported by the development of a growing network of segregated and traffic controlled cycle lanes. This growth of urban cycling has also led to the development of innovative delivery services such as Pedals and Deliveroo. The London experience would suggest that investment in cycling infrastructure should be taken seriously and can enable significant beneficial impacts urban outcomes.

Regarding freight, one of the significant challenges faced by cities is the movement of goods and the impact of HGVs, and to this end there have been suggestions to limit the size or weight of goods vehicles in city centres, or to limit the time period that these vehicles are permitted access. The issue of the movement of goods is difficult, as while it may be preferable to use smaller vehicles for this purpose, smaller permitted vehicles will result in greater numbers, which in turn could add to urban congestion levels.

Precise address location data can play a significant part in improving freight delivery efficiency. A major online retailer reported an immediate 10% improvement in delivery accuracy by exploiting OS's address location information (described in the Annexe) within its delivery operations, with consequent wider benefits in terms of reduced congestion and vehicular emissions.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

No comment.

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

The development of Mobility as a Service (MaaS) platforms and the implementation of road user charging should perhaps be treated as two separate issues. MaaS is focussed on the closer integration of multiple transport modes that can be accessed through a single and integrated system. These MaaS platforms have the capacity to deliver significant improvements in users' access to transport services. Today the deregulation and disaggregation of many aspects of public transport, particularly outside London, has meant that city-wide MaaS services are more challenging to deliver.

MaaS is typically focussed on improving the integration of public transport services. The data that these services collect could form the basis for a road user charging model; however, this would need to be intrinsically linked to the development of high quality and meaningful alternative services that

¹² The causes and impacts of poor air quality are set out in a 2016 report by the Royal College of Surgeons: <https://www.rcplondon.ac.uk/projects/outputs/every-breath-we-take-lifelong-impact-air-pollution>

can offer users convenient, efficient and flexible transportation options and other services such as single-trip insurance models.

DIGITAL COMMUNICATIONS

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

The highest value infrastructure investment will be a combination of 'deep fibre' (sometimes called 'full fibre') and mmWave radio, which is the vision of the emerging 5G world.

This builds on the views of Ofcom, which in a recent consultation¹³ stated:

One of our key proposals is to make a strategic shift to encourage investment in the large-scale deployment of ultrafast broadband networks, including fibre direct to homes and business premises (sometimes called "full fibre"), as an alternative to the predominantly copper-based technologies currently planned by BT. We believe network competition is the most effective spur for continued investment in high quality fibre networks.

The imperatives in this strategic shift are to maximise capacity and coverage, or network bottlenecks will remain.

Location dependency is an issue today; digital connectivity to a large extent depends on where you are. In some rural areas small businesses have relocated to obtain adequate broadband speeds and/or mobile coverage and remain viable. This often precludes remote working and therefore exacerbates the problems of vehicle emissions and transport congestion.

The link between digital connectivity and economic growth is well documented:

- A report by Arthur D Little in 2011 concluded that doubling the broadband speed for an economy increases GDP by 0.3 per cent¹⁴
- A 2011 World Bank report concluded that broadband has a significant impact on growth and deserves a central role in country development and competitiveness strategies¹⁵. This conclusion was reinforced in a 2016 World Bank report¹⁶

The UK is well positioned to take a leading role in the next generation of mobile communications, particularly in opening up mmWave frequencies for 5G use. However, as we discuss in our response to question 18, 5G initiatives and programmes are taking shape in several countries and decisions need to be made at the earliest opportunity to capitalise on this opportunity.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

No. A core problem throughout has been the pace of change, with regulation consistently lagging behind technology. This is partly recognised in the upcoming Digital Economy Bill; however, we have not taken all steps necessary to lead the world in the drive towards 5G.

Our recommendation is that a UK taskforce of representative experts from all sectors should be formed with the explicit task of driving 5G investments in rapid timeframes, and where possible seeking to explain to the wider community where technology aggregation possibilities might exist.

For a 5G network to evolve we need two fundamental improvements; in the costs of infrastructure deployment, and in predictability of the available revenues to facilitate long-term business planning. We also need to assess the needs of those in what has become the rural information underclass.

On the cost side, we need cheaper fibre and work is already in hand in the UK to enable this. In a densified network, the numbers of radio access points will be significantly higher; by a factor of hundreds of thousands in some locations if mmWave frequencies are used. As alluded to in our response to question 6, geospatial data has a vital role in optimising infrastructure locations, both in terms of signal propagation through the built and natural landscape, and also by identifying other factors such as land ownership, planning consents and environmental risks. Good use of geospatial data has the capability to significantly reduce costs.

On the revenue side, data is increasingly available which can enable demand for radio capacity to be modelled over the space and time. This data is typically derived from records linked to addresses, or derived from crowdsourced methods such as mobile device tracking. To generate the greatest interoperability value, data records of this type need to be tied to persistent unique identifiers, such as the Unique Property Reference Number for addresses or the Unique Street Reference Number for road segments (more information about these identifiers is provided in the Annexe).

The current regulatory regime is still focused on 'fixed' and 'mobile' as separate entities. The market is already moving beyond this (as the BT-EE tie up demonstrates), and despite moves to release spectrum more quickly, we are aware of significant industry concerns that the fine vision set out by Ofcom (including in its capacity as leaders in BEREC) will not be translated into action (for instance spectrum auctions and data sharing) quickly enough. In the meantime, the USA will be releasing the 28GHz band in spring 2017, South Korea will deploy proto-5G systems in 2018, and Tokyo will fully deploy 5G by 2020 in time for the Olympics.

ENERGY

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

No comment.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

No comment.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Low carbon vehicles, and especially electric vehicles, present new challenges for an electricity grid already struggling with the integration of distributed and intermittent generation. The additional complicating factor of mobile demand, generation and storage all present issues and opportunities.

Grid balancing is a preferable approach than network reinforcement, which can create local overload. Local demand for charging electric vehicles can be highly unpredictable, but conversely significant opportunities exist in utilising electric vehicles as local storage units. This is essentially a problem of balancing supply and demand across time and space, and optimising the solution is therefore highly dependent on using a common location referencing framework. The challenge in this example is to be able to integrate physical (actual location) and logical (systems architecture) views of the electrical grid; this has proved a major issue for electricity networks.

Findings from the Low Carbon London study between UKPN and Future Transport Systems¹⁷ showed, amongst many things, that confidence in having access to charging points is critical to the adoption of electric vehicles. By integrating the logical and physical representation of the network to create a holistic view of the system, service providers will be able to dynamically manage demand and supply through feeds from sensors, social media, smart meters and other data sources whilst ensuring that users will be able to charge electric cars at any time at in any location.

WATER AND WASTEWATER (DRAINAGE AND SEWERAGE)

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

No comment.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

No comment.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Please refer to our response to question 26.

¹⁷ See <http://www.ukpowernetworks.co.uk/internet/en/news-and-press/press-releases/Electric-vehicle-lease-scheme-launched-in-London.html>

FLOOD RISK MANAGEMENT

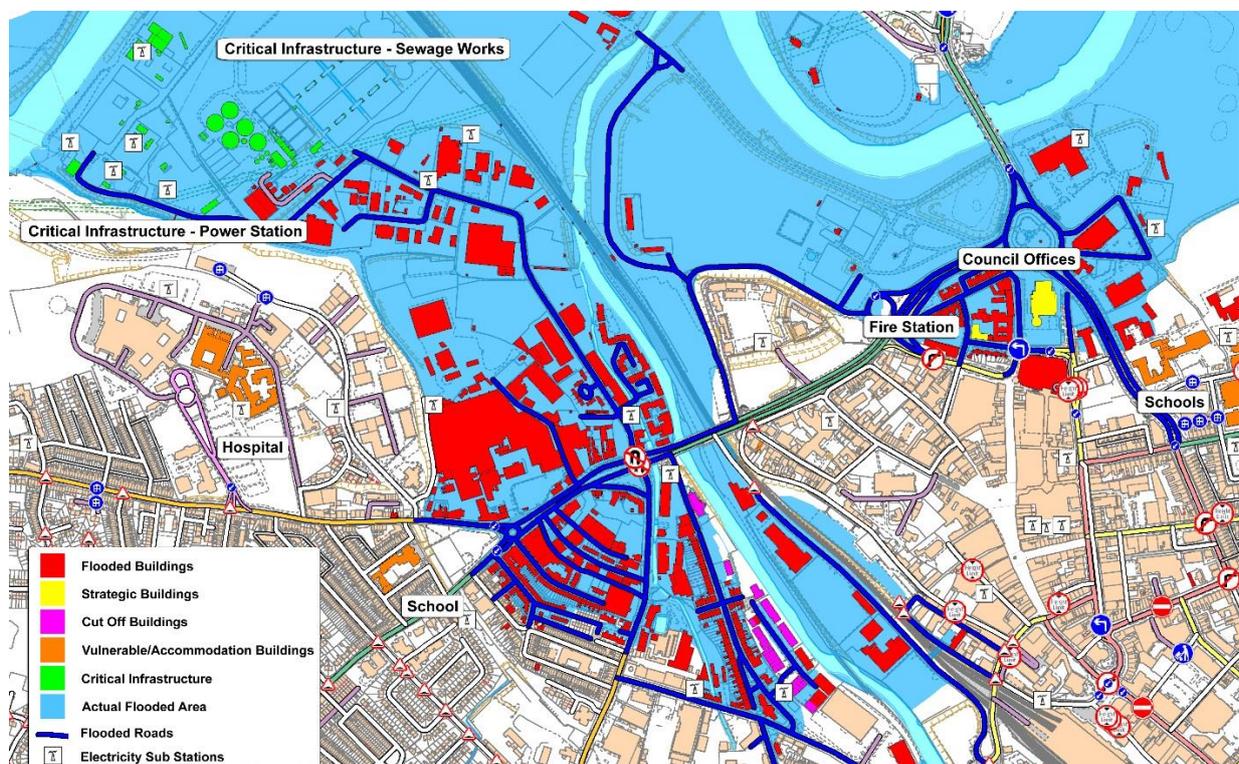

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

It is widely reported that one in six homes in Britain are at risk from flooding; that is, 5.2 million homes are at risk from river and coastal floods, and a further 2.8 million homes from surface flooding. The problem has become more frequent and severe over the last decade with higher levels of winter rainfall, in line with climate change prediction.

As it is impractical to fully protect all properties and assets in all circumstances, the focus must be on mitigation and prioritisation. OS is working with GO-Science and the Environment Agency exploring new ways to collect, publish and manage flood defence data - such as the creation of a national flood defence/asset inventory, and a consistently heightened river networks – as part of the next generation of property-level flood models which would improve both the targeting of resources and the provision of risk-based flood insurance.

Better data is vital to target investment programmes and financial and policy incentives effectively. This should include a comprehensive, maintained dataset of critical infrastructure which can model the interdependencies of services and therefore flood vulnerabilities. Flooding is hyper-geographic in nature; it involves the interplay of numerous physical, environmental and socio-economic factors which cannot be properly modelled without utilising a geographic perspective.

This is illustrated in the example below, illustrating a part of Carlisle during the flood event of 2005. The flooding of roads has left several buildings, shown in purple in the lower central part of the image, isolated from other services. In the same way, the flooding of the sewage works and power station in the top left of the image will have left their own constituencies without key services. These interdependencies should all be modelled as part of the flood protection prioritisation process.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

The National Flood Resilience Review states that one important area for improvement is better management of rainfall in the natural environment by slowing the flow of water from the land into rivers.

Defra's 25-year plan for the environment will aim to achieve these effects by managing whole river catchments intelligently, developing sophisticated modelling to work out what can be done in each part of the catchment to minimise flooding. A 'pioneer' pilot project in Cumbria will test and demonstrate the power of this approach across the different river catchments there. We suggest that funding to landowners for a natural approach to flood risk management could come from a new UK farming policy replacing the Common Agricultural Policy of the EU.

Again, we argue that consistent, maintained reference data at catchment scale is vital for modelling, building and managing natural flood management schemes. For example, OS has collaborated with the Environment Agency to create one of the world's most detailed, heightened water networks showing the flow and precise course of every river, stream, lake, and canal in Great Britain¹⁸.

SOLID WASTE

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

No comment.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

The current disaggregation of manufacturing supply chains and the dispersal of production and consumption have resulted in a net increase in the use of resources. This in turn impacts the cost of goods and services and in addition there is an ecological/environmental impact. Moving towards the implementation of a more comprehensive circular economy could facilitate a reversal of this consumption trend. Work by the Ellen MacArthur Foundation¹⁹ has identified that in advanced economies such as ours there remain opportunities to further advance the implementation of a circular economy. The report suggests that this model could result in additional GDP growth, the creation of thousands of jobs, a reduction in a nation's carbon footprint, and a reduction of up to 50% in the consumption of some material resources.

CONCLUSIONS

In your response to consultation submissions for the NIA process and methodology, you state: ‘The Commission recognises the importance of place and will continue to look at its work through a “place lens”’. Geography acts as the golden thread that enables disparate information to be connected and cross-sector dependencies to be modelled.

Through several examples in our response we make the case for using – and investing in – data to support the realisation of desired outcomes. We illustrate how a single view of the truth, enabled by a common geographic referencing framework, can enable cross-sector infrastructure collaboration and better decision making. At the strategic level, a geographic approach is effective at aggregating information to provide regional and national infrastructure perspectives.

CONTACT INFORMATION

We would be pleased to support you with any aspect of the National Infrastructure Assessment. Please contact [name redacted], [job title redacted], Ordnance Survey.

Email: [email address redacted]

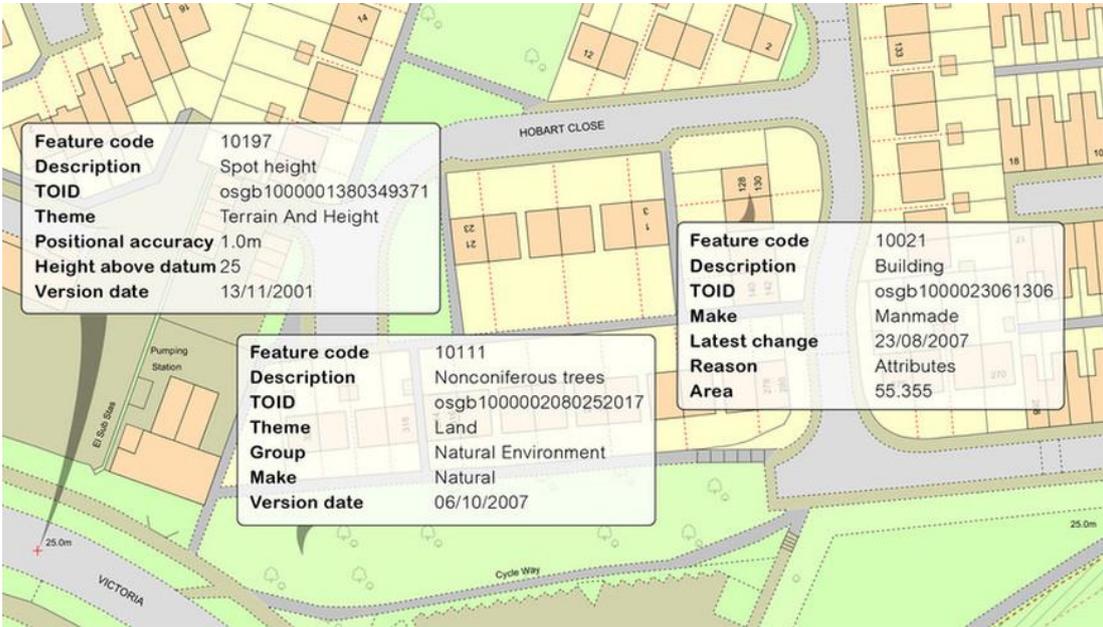

Tel: [telephone number redacted]

ANNEXE: LOCATION REFERENCING DATA

Ordnance Survey information is considered by infrastructure owners to be key to efficient location referencing. This Annexe briefly sets out some core elements of the information which is relied upon by all utility and infrastructure providers, encompassing:

- Topography – mapped real-world objects, enabling assets and events to be analysed in terms of proximity, adjacency and context
- Highways – enabling the referencing of linear assets such as cables, pipes and ducts
- Addresses – representing service end points of linear assets

Topography: we maintain the highly detailed ‘master map’ of Great Britain which provides the context and underpinning data for infrastructure and asset planning and management. The figure below illustrates some of the data attributes which underlie each surveyed object.

The detailed database that powers this output is continuously maintained, with around 10,000 updates registered every day across Great Britain. It is regarded as a core tool for all aspects of asset management, and moreover provides a referencing framework to share information through the unique identifier – the TOID – which is maintained for each mapped object.

Highways: Ordnance Survey is creating a new-generation highways dataset which will consist of the high quality and richly attributed data submitted by local authorities through the National Street Gazetteer (NSG) combined with Ordnance Survey’s widely used authoritative and fully maintained geographic roads data, creating a definitive highways network for England and Wales.

The figure below illustrates the information maintained by road element.

The dataset includes a Unique Street Reference Number (USRN) for each section of road. This identifier is already used as the mandated mechanism to notify the undertaking of street works. The USRN is further used to provide a link between addresses and streets.

Addressing: Through a partnership between Ordnance Survey and the Local Government Association, we maintain and provide the definitive national address database. Each address record is identified by a Unique Property Reference Number (UPRN), has a precise geographic location and a set of attributes relating to functional classification, lifecycle status and alternative address variants.

The figure below illustrates how this can be used to map non-residential address functions.

Access to a consistent and maintained address dataset is vital to manage and share information which links both business and personal customers and properties.

Address changes are built in to the data management and publication process, and are of particular relevance to cross-sector investment projects. The figure below illustrates how the UPRN is allocated and managed throughout a property lifecycle.

The TOID, the USRN and UPRN represent important foundations for data sharing and interoperability. As unique and persistent identifiers, they unambiguously reference geographic entities (such as water bodies and pavements) and addressable properties (for instance homes, businesses and civic functions) in an open way.

‘Sustainable Transport in Growing Non-Metropolitan City Regions’

[name redacted] [position redacted];

[position redacted], School of Built Environment, Oxford Brookes University

[email address redacted]

February 2017

Introduction

This submission is concerned with the scale and nature of the transport challenge faced by growing non-metropolitan city regions and the manner in which it is responded to. Reference is made to important changes currently taking place in local governance giving greater emphasis to strategic issues at the city region scale which should contribute to the Commission’s objectives for identifying and delivering high value infrastructure over the longer term. Attention is drawn to the particular opportunities offered by such a regime to deriving greater benefit from the local rail network whose present form in these areas typically reflects decisions made in the context of their very different economic geography half a century ago.

The general arguments are illustrated by reference to the circumstances of the Oxford area. My credentials for commenting on this and associated research evidence were supplied in my submission to the NIC on its Cambridge-Oxford Corridor Study in August 2016.

Although this submission is written from a transport perspective it is axiomatic that any investment strategy in an area should maximise the opportunities for synergy with land use development and especially with provision for projected housing requirements. In this respect the approach advocated here can be aligned with, and is supportive of, the proposals contained in the separate submission by Dr Nicholas Falk, Director of URBED.

The ‘urban transport problem’ and the demand-management response

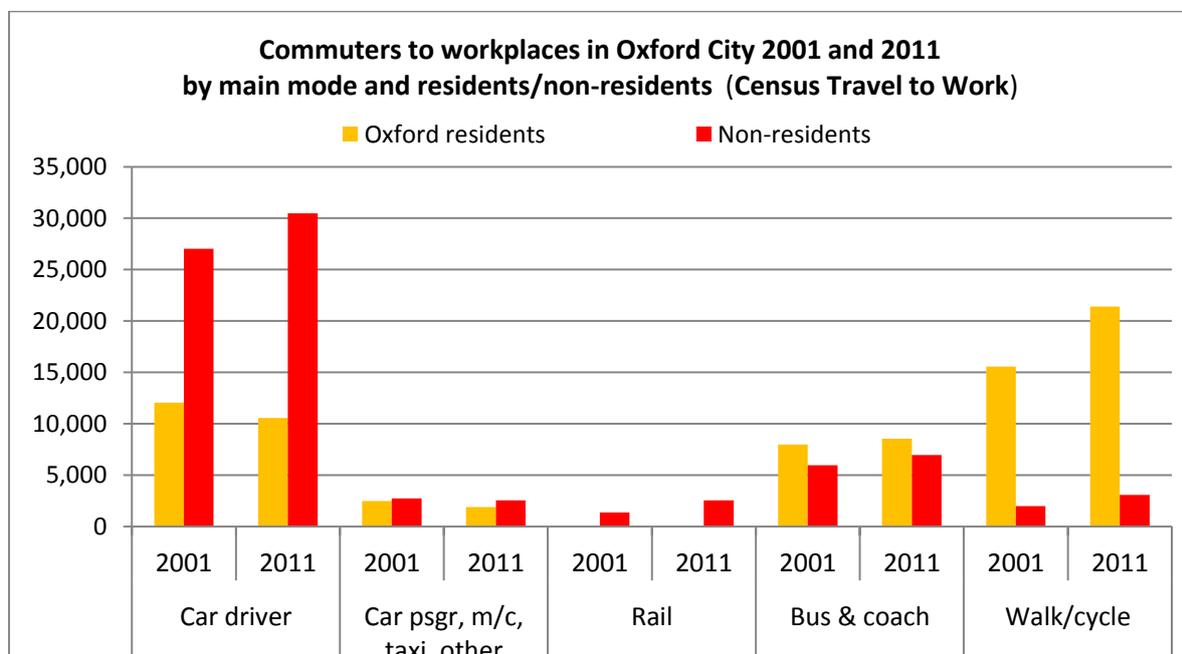

The urban transport problem has traditionally been viewed as one affecting cities and historic towns where the growing demand for car travel (as a product of increased car ownership) has had to be reconciled with the impracticability and/or undesirability of large scale investment to increase the capacity of the highway network, particularly in the vicinity of central areas. Typically a mix of demand management measures has been introduced accompanied by investments to improve the opportunities for travel by modes other than the private car¹.

Oxford was one of the first freestanding cities to adopt such a strategy (in the 1970s). A key feature was the control of on and off-street public parking space in the city centre (extended outwards subsequently) coupled with the provision of several ‘park and ride’ car parks at the city periphery and associated dedicated bus services to the centre. These were designed to intercept motorists travelling from the city’s wider hinterland of smaller towns and villages, most of whom had limited opportunities for using modes other than the car for their journey. Similar bus-based schemes have

since been introduced in many other freestanding cities, including Bath, Cambridge and York. (It is interesting to contrast these bus-based schemes with the ‘park and ride’ role of railway stations serving travellers to London and metropolitan cities where the interception typically takes place at a much earlier point in the journey),

In the intervening decades the distinction between the transport regimes prevailing in and surrounding the non-metropolitan cities has assumed greater significance on account of changes in population distribution. In Oxford’s case the city’s population increased by just 5,000 between 1981 and 2001 (to 135,000) whilst the population of the rest of the county increased by 60,000 (to 471,000). This changed distribution can be attributed to local planning policy (favouring development in the ‘country towns’) combined with the general trend of increasing car ownership and investment in the inter-urban road network which together prompted residential dispersal. By contrast car ownership in the city remains low (at 0.42 cars per adult in 2011 compared with an average of 0.70 in the county’s other towns) and is increasing only very slowly. Jobs remain disproportionately concentrated in the city and this underlines the dormitory or quasi-suburban nature of much of the development that has taken place in recent decades in the outlying towns.

Given these features it is perhaps unsurprising that a majority of people commuting to workplaces in the city now come from places outside it. More significant in terms of its implications for transport management is the fact that these ‘in-commuters’ have much longer journeys on average and are much more likely to travel as car drivers. In the context of planned increases in homes and jobs in the county (of around a third during the period 2011 to 2031 alone) this implies greatly increased pressure not only on transport facilities within the city but on the highway network of Central Oxfordshire outside it.

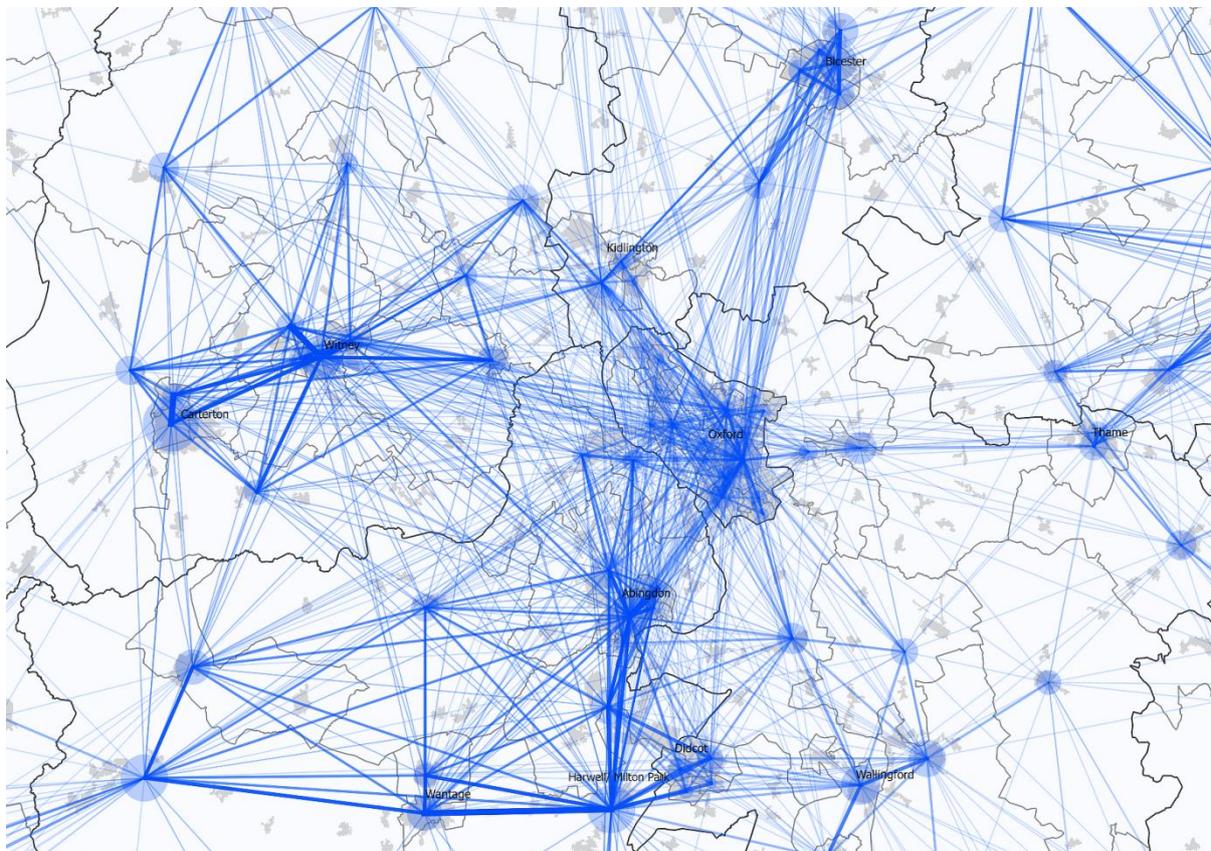

As far as movement into the city is concerned the County Council has responded by proposing major enhancement of the established strategy². This includes nearly doubling the number of park and ride spaces and relocating most of the present P&R car parks further from the city periphery in order to intercept motorists before they contribute to congestion approaching and crossing the city’s Ring

Road. This is combined with proposed investment on the corridors into and within the city to create 'rapid transit' standards of movement for the main bus services. Additional restraint measures in the form of congestion charging within the city, a workplace parking levy and further restriction points for general traffic are also being considered.

There are a number of difficulties associated with this strategy

- Achieving 'rapid' standards of movement for buses on otherwise congested roads is either expensive (if provided in the form of dedicated or prioritised lanes) or politically problematic (if congestion is to be addressed by some form of road user charging, or additional route closures within the city)
- In terms of access to the city centre accommodating the bulk of additional future trips by bus is not problem-free, given the volume of passenger boardings and the rival claims on available street space for pedestrians, public realm improvements etc . (In Oxford's case it has already been mooted that tunnelling under the historic centre will need to be considered in the longer term).
- The Park and Ride system does nothing to counter the growth in traffic on roads outside the city. Over time the car-based movements generated *between* outlying towns (as opposed to movements between them and the core city) form an increasing proportion of the total and are not subject to any of its demand management measures. [See the diagram below of car driver commuting flows in Central Oxfordshire).

Scale 1cm : 2.5km approx. This diagram is generated from 2011 Census Travel to Work data and shows car driver commuters between Medium Super Output Areas in Central Oxfordshire (see reference3) Four sizes of (two-way) flow are shown: 25-100 persons, 100-250, 250-500 and over 500

Inter-action with the strategic road network

Given the trends described above it can be seen how purpose-built strategic roads, originally designed to bypass a provincial city or town have had their role serving longer distance freight and passenger movements undermined by the growth of local traffic within the wider city region. In the case of Central Oxfordshire this is particularly evident on the dual-carriageway A34 trunk road which forms a north-south spine between Bicester, Oxford and Harwell (and also functions as the western arc of the Oxford Ring Road).

One response to this, if conditions are severe enough, is to propose an entirely new route for longer-distance traffic. (In the case of the A34 this is currently being investigated by Highways England as part of its Expressway study for the Oxford-Cambridge corridor). Whilst generating benefits for longer-distance journeys such a scheme is likely to have several adverse consequences. In addition to its very high capital cost and direct environmental impact these include the effects of substantial additional traffic induced by both the new strategic road and by the release of capacity on the existing one. There is no likelihood of car mileage being reduced within the city region as a whole and on most of its main roads traffic conditions will get worse (compounded by the effects of population growth).

In Oxfordshire's case, given that most of its public transport services between towns are bus operated, this prospect directly conflicts with the County Council's aspiration to increase the use of such services as one means of containing future traffic demand. It is in this context that opportunities for greater use of local rail services deserve to be explored as a more effective means of achieving modal shift, reducing overall growth in traffic and lessening demand on strategic roads and their potential investment requirement

Planning at the city region scale – recognising and forging inter-relationships

From the forgoing discussion it is clear that there are critical links between elements of the transport system that in non-metropolitan areas are commonly viewed at separate spatial scales (viz the core city, the outer parts of a city region, and major inter-urban corridors) and in terms of separate modes. Because of their functional interaction policies and investment programmes for all of these deserve to be conceived and appraised as one. In addition strategic decisions on transport and development need to be brought together. This is so that available investment for transport can be deployed to greatest benefit and that the travel outcomes from new developments contribute to rather than reduce overall operating efficiency.

It is unfortunate that at a time of unusually large increases in population and Government emphasis on promoting economic growth the mechanisms for delivering these seemingly uncontroversial objectives should have been subject to serious rupture. In non-metropolitan areas the abandonment of statutory strategic planning in 2011 and the assertion of 'localism' chimed with longstanding cultural and political antipathies between 'town' and 'country'. In Oxfordshire it led initially to protracted and disconnected exercises by the individual (district) planning authorities to fulfil their Government-imposed obligation of identifying developable land in their Local Plans sufficient to meet their 'objectively assessed housing needs' over the next 15 years. Significantly

the County Council's Local Transport Plan (LTP4) followed a separate timetable of preparation such that, general principles apart, the Council's input to Local Plans was and remains constrained to a series of passive observations on individual development site options. In such a situation urban form and functioning is in effect ratcheted forward on an incremental 'business as usual' basis which is entirely at odds with the scale and nature of population and economic change facing the city region.

The responsive position of Oxfordshire County Council as transport authority has continued during the latest phase of planning authorities' Local Plan work in which the four district councils surrounding Oxford City have agreed to accommodate an additional 15,000 new homes to fulfil the needs of the city but which it is not practicable to provide within the city boundaries⁴. In itself this collaborative action can be seen as a somewhat belated response to the 'duty to cooperate' legislated for in 2011 (at the time when regional strategies were abandoned). However it has also been facilitated by the Government's efforts to promote cross-authority working more generally through the Local Growth Deals programme. This has prompted the establishment of an Oxfordshire Growth Board Joint Committee comprising representatives from the six local councils (county plus five districts) together with non-voting participation by the Oxfordshire Local Enterprise Partnership and other key stakeholders. The emphasis on strategic issues in the activities of the Board is an important development within what might otherwise have been a continuation of more parochial and fractious exchanges amongst and between individual authorities.

Green Belt Review and Local Rail Opportunities

Green Belts have been designated around only a small number of metropolitan cities (Oxford being one) but where they exist they have had a profound influence on the pattern of urban growth in the city region. In Oxford's case the designation is the prime reason for the past prioritisation of new development in the 'country towns' referred to earlier (ie as an alternative to outward growth of the core city).

Although there is much antipathy amongst the general public to possible loss of Green Belt land the NPPF does provide for this 'in exceptional circumstances⁵'. The Oxfordshire Growth Board has taken the view that such an argument might be sustained in relation of the housing needs of Oxford City. As part of its collaborative work programme it has therefore commissioned an assessment of land parcels presently within the Green Belt surrounding Oxford which might be released from their current designation. This is an unusual and highly controversial departure from long-standing practice.

In theory, if the principle of Green Belt revision were accepted (and not all the Oxfordshire councils currently do) then the way could be open for a more fundamental review of the spatial strategy for the city region a few years hence. (The bulk of the allocations for the current planning round which lie beyond the Green Belt have already been determined). A much more efficient pattern of development and transport outcomes could be secured - ie less per capita distance and lower car driver share - if there were concentrations of new development close to the city served by 'transit' lines of some kind to which the land value uplift would make a financial contribution (as proposed by URBED⁶).

However it is not necessary to adopt URBED's prescription in full to recognise that there could be opportunities to deliver 'transit' in the vicinity of non-metropolitan cities by exploiting existing rail infrastructure more fully⁷. The scope for such action will vary from place to place but is essentially a combination of the 'inheritance' from past rationalisation of the railway network coupled with current and potential future patterns of development (housing and employment).

Following the recommendations of the Beeching Report in the 1960s many rural branch lines were closed in their entirety. On other routes smaller stations were typically closed and stopping services withdrawn although track and inter-urban services were retained. This retained infrastructure represents a resource which may be capable of more intensive use to serve the much greater volume of internal movement which now characterises non-metropolitan city regions. (An outline of possibilities in Central Oxfordshire is set out here in an annex). Notwithstanding relatively short journey distances and time penalties incurred travelling to and from stations the speed and reliability of rail renders it attractive to motorists otherwise faced with congested roads. The appeal of rail services can also be enhanced by integration and marketing within the wider public transport network⁸.

A longer-term infrastructure strategy for the city region

Under the current statutory planning system, being locally led and confined to a 15 year time horizon, it is almost inconceivable that a pattern of development linked to new or enhanced transport networks could be secured or even contemplated. Some overarching opportunity to inject consideration of potentially transformational investments is needed. Such an opportunity might arise in the event of a longer term infrastructure strategy being prepared for the city region.

The Oxfordshire Growth Board has recently agreed to the preparation of such a strategy with a horizon year of 2040, (ie a decade beyond the Local Plans currently being worked on by the district planning authorities). It is designed in part to overcome the present limitations of fragmented and 'responsive' infrastructure planning:

“ Currently Infrastructure Delivery Plans are developed alongside Local Plans to ensure that, as far as possible, decisions on forward planning are taking account of the infrastructure needs of the area. However this tends to be a **derived product**: the growth options are identified through land availability assessments, and through sustainability appraisal alongside deliverability and viability testing preferred sites emerge. Only then is the infrastructure needed to support these sites identified and tested. We need to do more to look at our infrastructure supply and demand as an opportunity to inform growth in terms of its location, scale and type and to seek to maximise the benefit and minimise the strain on infrastructure provision.

The Infrastructure Strategy is not a statutory policy document but is aimed at shaping and influencing key documents such as Local Plans and service providers' investment strategies”.⁹

The preparation of such a strategy can be regarded as a positive development and, in principle creates the opportunity for more efficient and effective investment programmes being assembled across the city region. However it has to be noted that such an outcome is not assured.

Interventions which straddle local authority boundaries (as with the Central Oxfordshire rail proposal) are bound to result in an uneven distribution of transport and development benefits locally (and no doubt some disbenefits). This may result in resistance to a genuine area-wide strategy by individual councils and lead to the programme consisting of an aggregation of more local, 'incremental' schemes instead. This possibility could be lessened – though not eliminated – by changed governance arrangements in the form of either a Combined Authority or single Unitary authority. Proposals for both of these options are currently being worked on in Oxfordshire at the present time.

The non-statutory nature of an infrastructure strategy would be another potential impediment to securing a satisfactory area-wide outcome. The local autonomy represented by statutory development planning at district council level - having been secured in 2011 - is jealously guarded (and would remain in the event of a Combined Authority being established). An alignment of local interests in development location (especially as perceived by residents) with more abstract 'technocratic' interests in efficient infrastructure networks is not impossible. But there could be resistance to both the principle and practice of longer term infrastructure strategies if it was thought that local discretion over development location through the Local Plan process was being compromised or pre-empted.

Conclusion

Having regard to the transport questions (Q13-15) posed in the Commission's call for evidence....

In the particular circumstances of growing non-metropolitan city regions there is likely to be increasing divergence in per capita travel volumes and car driver mode shares as between residents of the core city and elsewhere.

In the core city more stringent demand management regimes will be needed to contain individual motorised travel, but as far as city residents are concerned this will be facilitated by the improved availability of shared and collective modes which will tend to suppress individual car ownership and use.

In the wider city region where car use is already high there is the prospect of worsening traffic conditions arising primarily from large increases in population (notwithstanding continuing slow falls in trip rates). In the absence of any overarching regime managing the use of roadspace these conditions will be exacerbated by the additional traffic induced by any major investment in the strategic road network.

This deterioration could be lessened by

- a) radically reviewing the settlement pattern which forms the basis of local development planning, achieving a rebalance in favour of locations close to the core city (lessening average trip lengths) along routes well-served by modes other than the car (reducing the car driver mode share), together lowering average per capita car mileage.

- b) exploiting opportunities for greater use of the rail network for journeys within the city region to the core city and other local centres of employment, linking service improvements and station investments with the siting of new or expanded areas of development .

To achieve these benefits and cost-effective investments overall is dependent on governance and public funding arrangements fostering an integrated approach to the generation and assessment of strategic options for transport and development across city regions.

ANNEX : LOCAL RAIL OPPORTUNITIES IN CENTRAL OXFORDSHIRE

This note outlines the case for making better use of rail infrastructure to serve local travel needs in Central Oxfordshire. There are particular features of the Oxford situation which make this proposition particularly attractive at the present time. However the basic characteristics of the network and services in the Oxford area have similarities with several other freestanding English cities where the suggested approach might be replicated. These common features are described briefly first before exploring the Oxford example further.

General background

The rationalisation of the passenger rail network which took place in the 1960s was predicated on the assumption that the main market in which rail could continue to offer an attractive alternative to the private car and public road services was for journeys between larger towns and cities. Accordingly branch lines to smaller towns and other lines through lightly populated rural areas were generally closed whilst stopping services and intermediate stations on those inter-urban lines which were retained were mostly withdrawn.

An exception to this general pattern was made in the case of London suburban services and many local passenger services in the provincial conurbations (metropolitan areas). Here it was recognised that it might not be practicable to accommodate future travel demands by relying solely on road-based modes, particularly as far as access to city centres was concerned. In the metropolitan areas Passenger Transport Executives were established to develop and promote what were often run-down local rail services as part of the planning and management of transport within the conurbation as a whole.

Outside the conurbations the pattern of travel has changed very considerably over the last 50 years. Increases in private car ownership have enabled people to live and work across much larger areas. Smaller, formerly more self-contained country towns within the hinterland of the main cities have become favoured residential locations whilst employment and main services have tended to concentrate in and around the core city. The result is typically a tidal set of flows within a 'city-region' centring on the principal city but with increasingly important set of predominantly car – based flows between secondary centres, including locations on the periphery of the main urban area. Problems of traffic congestion are no longer confined to the city centre but occur throughout the wider region, often on routes whose principal function is to serve longer-distance movements.

As a general proposition therefore it is becoming necessary in planning terms to view these shire city regions as modern day conurbations. Although, unlike their industrial predecessors, the built up areas are set against a mainly rural backdrop the contemporary scale and pattern of travel flows requires a managed, multi-modal approach to be adopted of the kind formerly confined to urban centres if efficient and sustainable conditions are to be delivered. Where they exist, opportunities for making greater use of the rail network deserve to be capitalised upon as part of this approach. This is partly because rail can often offer an objectively higher standard of speed and reliability than other modes but also because there is clear evidence of car-owners being willing to transfer to rail for all or part of their journey and thus lessen demands on the road network.

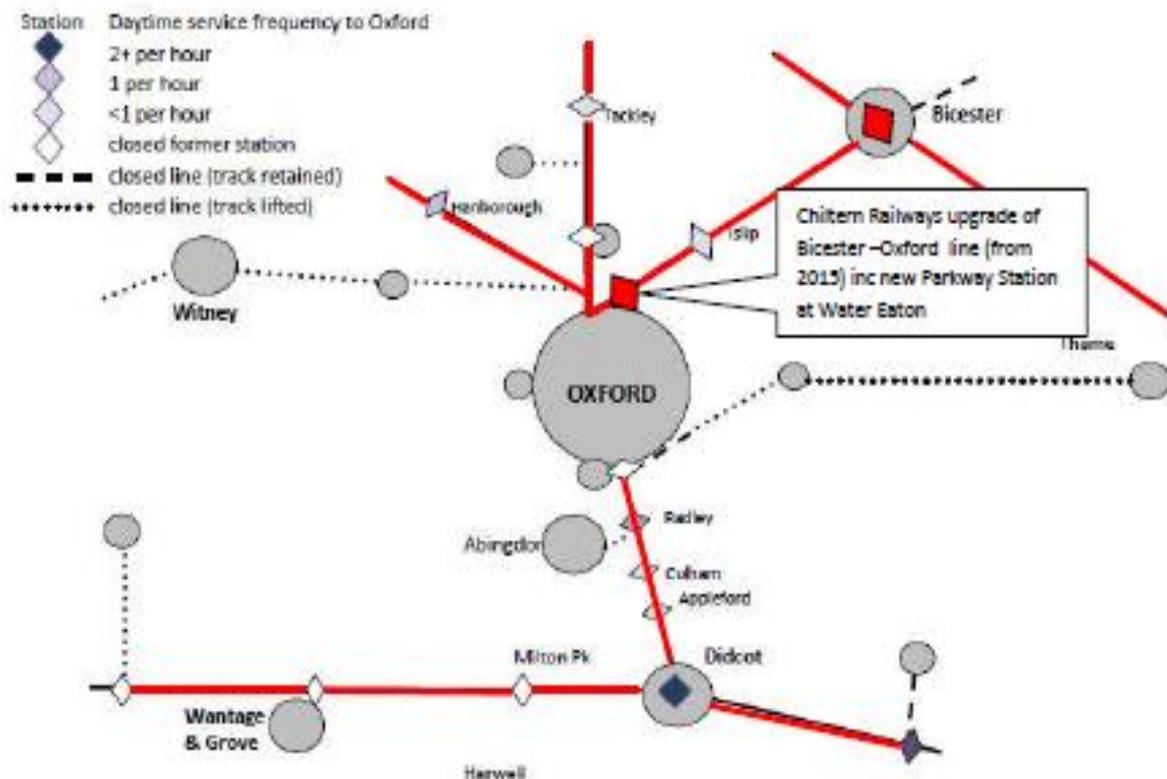

The Oxford situation (see diagram below)

The rationalisation of the rail network in the Oxford area resulted in

- The closure of lines from Oxford to Witney/Fairford and Thame/(High Wycombe), although with a single track freight spur retained on the latter to serve the car works at Cowley
- The withdrawal of passenger services from Oxford to Bicester/(Bletchley) although a limited passenger service was reintroduced over the retained freight line to Bicester from the 1980s
- The closure of branches to Woodstock and Abingdon
- The closure of intermediate stations and local services between Didcot and Swindon
- The closure of Kidlington station, although with other intermediate stations on the line to Banbury and associated stopping service retained

The present pattern of local services in the Oxford area consists of

- An infrequent stopping service from Banbury (supplementing a half-hourly Cross-Country inter-urban service between Birmingham and Reading)
- A half-hourly service from Bicester via a new station at Water Eaton (Oxford Parkway) recently opened by Chiltern Railways as part of their investment in a second 'main-line' service between Oxford and London
- A half-hourly stopping service from Reading via Didcot calling (with varying, lesser frequency) at the intermediate stations of Appleford, Culham and Radley
- An hourly service from Moreton in Marsh calling at Kingham, Charlbury and Hanborough normally originating from Worcester/Hereford and continuing as one of the GWR's fast Oxford–London Paddington services

Opportunities for developing local rail services in Central Oxfordshire

There are two main opportunities for developing local rail services in Central Oxfordshire based on the use of existing rail lines and serving existing land uses. These are

- i) The Cowley branch around the southern edge of Oxford City
- ii) Stopping services on the line between Didcot through Oxford to North Kidlington (Oxford Airport) – the so-called ‘Spine-line’

Services on these lines would complement the local function of the new Chiltern service between Bicester and Oxford.

It is particularly fortuitous that these opportunities are located within the so-called ‘Knowledge Spine’ – the north-south corridor from Bicester through Oxford to Harwell which has been identified by the Oxfordshire Local Economic Partnership as offering the best prospects for economic growth and where investment is being concentrated. Further enhancements could therefore be introduced in future linked to land use developments in the area, several of which are already being canvassed through the Local Plan process. (A summary of possible stations on the Spine-line is listed at the end of this note).

In the diagram overleaf the local rail services are shown linked at interchange points with the bus rapid transit routes into Oxford City proposed by Oxfordshire County Council in their 2016 Local Transport Plan. Together they could form a branded ‘Metro’ network for Central Oxfordshire.

i) The Cowley Branch

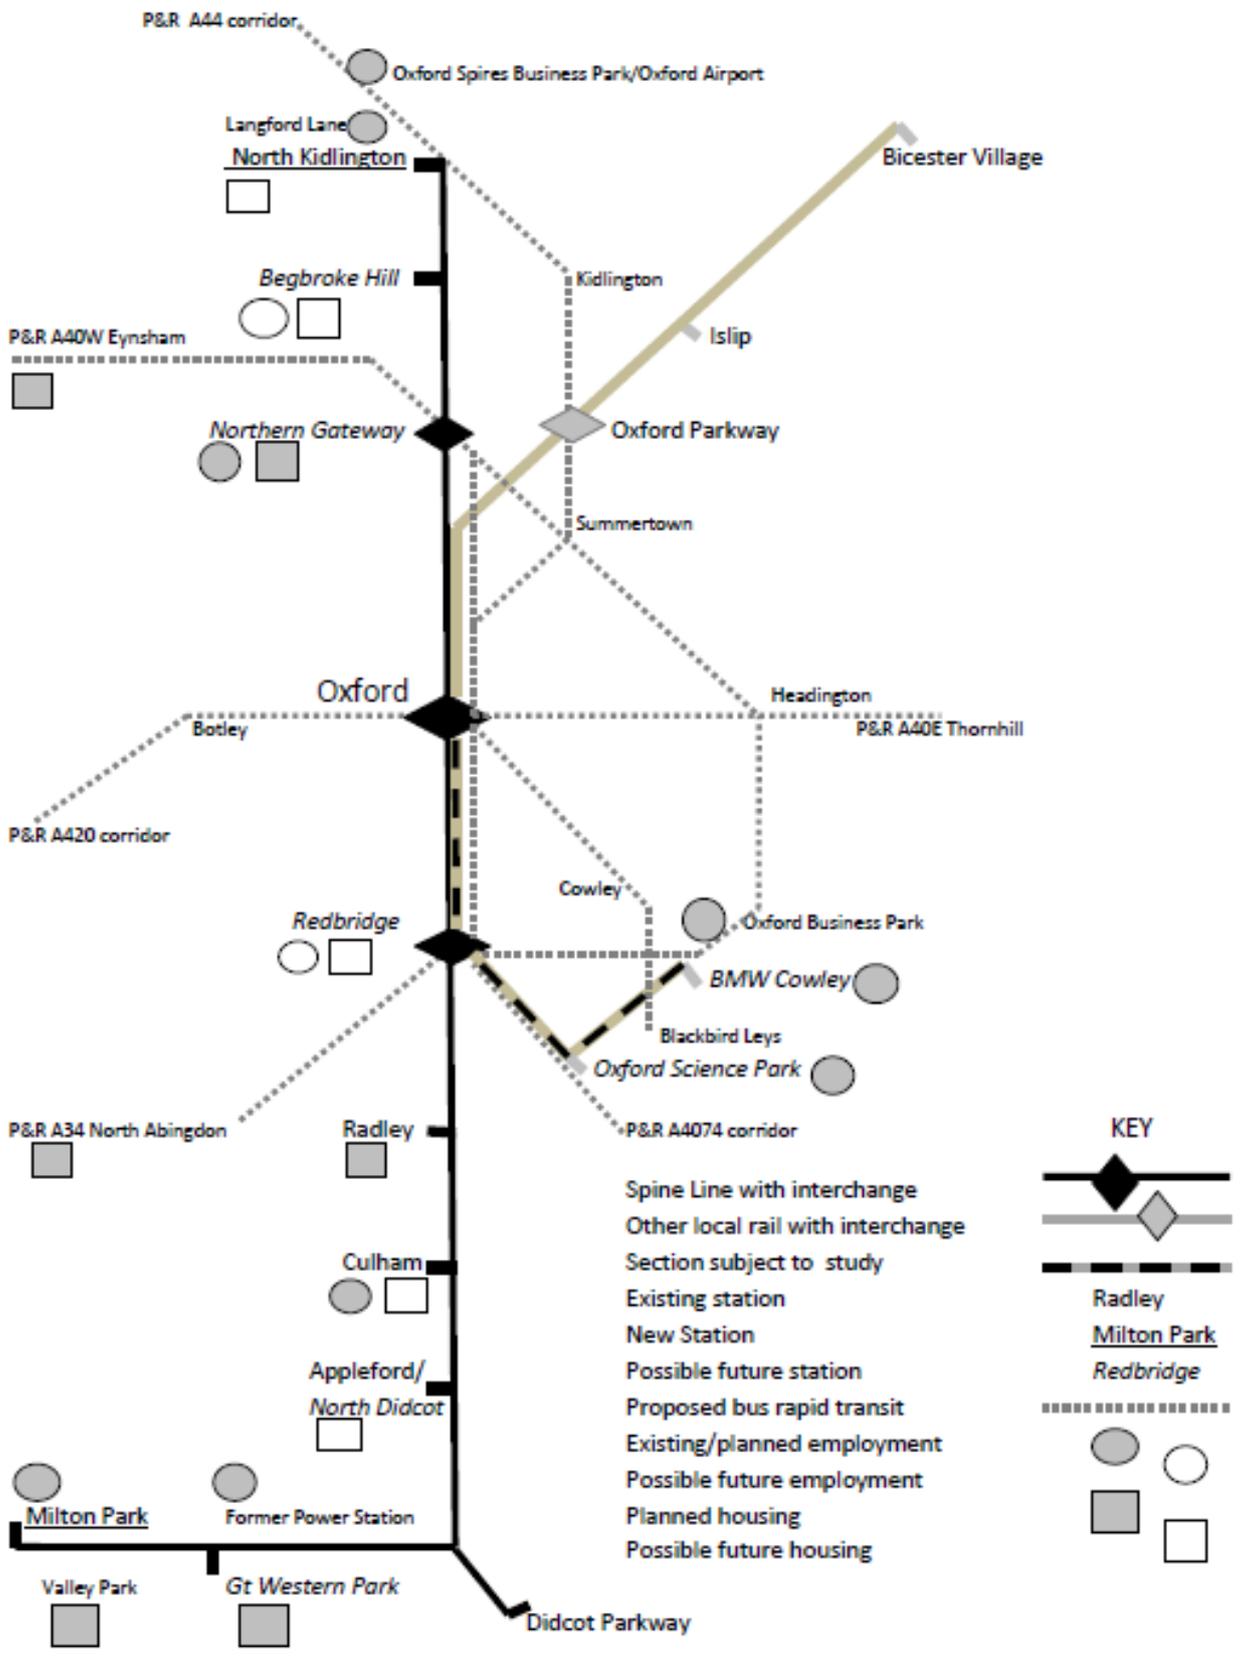

The Chiltern Railways service from London Marylebone via Bicester Village and Oxford Parkway currently terminates at newly-built terminal platforms on the north side of Oxford Station.

Chiltern has already publicised its aspiration to extend these trains southwards through Oxford Station and over the Cowley freight branch. (A demonstration train was operated in 2014.) The extension would include two new stations at Littlemore and BMW Cowley serving the main employment centres of Oxford Science Park and Oxford Business Park respectively and thus provide fast, direct access not only from the city centre but across the city from Bicester and Oxford Parkway (South Kidlington). The new stations would also offer a much quicker means of travel inbound to Oxford City Centre from the residential areas of Blackbird Leys and Littlemore/Minchery Farm. Additional patronage might be generated in future through further development of the employment areas and by the addition of new housing around the southern edge of the city, although the latter (being Green Belt) is not currently favoured by the local planning authority (South Oxfordshire DC).

The present timetabling of Chiltern services involves a half hour layover of trains in the terminal platforms at Oxford Station. In principle therefore extension of services to Cowley (about an 8-10 minute journey) would seem practicable without the use of additional train sets and with only single platforms at the two stations.

Inspection of the present timetables of the main passenger services through Oxford Station (ie the half-hourly Cross-Country and GWR fast London services) suggests that, using the existing single through platforms the Chiltern trains could be extended south to/from Kennington Junction (where

'TOWARDS AN OXFORD METRO': Swift-Rail and Bus Rapid Transit

the Cowley branch diverges) on their existing timetable pattern (ie retaining arrival and departure times at Oxford to/from London Marylebone). In practice however there may be some conflict with present paths for freight trains and generally with the 'crossovers' for northbound trains at Kennington Junction (ie from Cowley) and at Oxford North junction (where the line to Bicester diverges eastwards).

Detailed investigation would therefore be needed to determine whether in fact any such conflicts could be resolved by minor adjustments to timings or whether the extension to Cowley would have to await planned future investment in increasing capacity at Oxford Station (by adding second through platforms) and over the line southwards to Kennington.

ii) the Spine-line

The postponement of electrification between Didcot and Oxford (announced towards the end of 2016) means that the current stopping services from London Paddington and Reading to Oxford (soon to be operated by electric units) will need to be severed at Didcot with the service between Didcot and Oxford continuing to be operated by diesel units.

This separation of the 'Oxford local service' creates opportunities in two respects:

- 1) It allows the possibility of extending the stopping service to provide direct links northwards across Oxford City (otherwise impossible if electric units were introduced from Didcot to Oxford).
- 2) It allows trains to Didcot not necessarily to terminate there (nor continue east towards Reading as at present) but rather to reverse and travel west to serve the major employment and new residential areas immediately west of the town

Because stopping services are already operating over the Didcot-Oxford section and utilising the through platforms at Oxford it is possible to consider their development in a way which does not place any additional demands on track or station capacity (unlike the Chiltern extension to Cowley).

The basic Spine-line proposal is for the half-hourly stopping service north of Didcot to be reconfigured to operate between new (single platform) stations at Milton Park and North Kidlington (Langford Lane/Oxford Airport) on either side of the city. Both are adjacent to existing major employment areas (offering much-improved accessibility 'outbound' from Oxford) and are also well placed relative to A-roads to serve as 'parkway' stations inbound. Milton Park would also serve directly the planned major residential area of Valley Park (west of Didcot, south of the main railway line) whilst North Kidlington would serve existing residential areas in the northern part of Kidlington plus possible future development around its northern fringe.

In operational terms the Spine-line service west of Didcot could utilise the existing freight tracks (on the north side of the main GWR line) plus spurs into the former ordnance depot at Milton Park and/or the (now demolished) former coal-fired power station. A minimum of track renewal/reconfiguration and new signalling should therefore be required. Pedestrian access would be needed from the south side of the railway (ie the future Valley Park), plus probably serving a car park off the A4130 also.

North of Oxford the existing track layout on the line to Banbury is sufficient as far as Kidlington where a new 'siding' and single platform would need to be constructed on the western side of the present line immediately north of the A4260 road bridge, plus a cross-over and associated signalling for return in the southbound direction. Road access (over the canal) would be needed from the adjacent A4260/Langford Lane junction.

The estimated running time between the two new termini plus all existing intermediate stops is 33 minutes. This would require three train units to run a half-hourly service. This is one more than the two likely to be required to provide a replacement solely for the present Didcot-Oxford service

Summary list of existing and (in brackets) possible future Spine-line stations, south to north

Milton Park - new parkway station serving existing employment area to the north and future Valley Park residential area to the south;

(Great Western Park) – future station linked with proposed redevelopment of Didcot Power Station site and Great Western Park residential area (to south) currently under development

Didcot Parkway

Appleford – possible future relocation of present station approx 1km to the south associated with northern extension of main residential area of Didcot

Culham – improved frequency; park and ride facility; future expansion of employment area; possible major residential development in vicinity of station

Radley – planned expansion of village

(Redbridge) - Park and Ride /interchange with bus transit serving outer South Oxford (cf Oxford Parkway to north of city); some opportunity for development in vicinity

Oxford

(Northern Gateway) – possible new station off A40 to serve planned employment development and residential N Oxford; also interchange with bus transit routes

(Begbroke Hill) – possible new station to serve University research campus, prospective major future residential area west of Kidlington and existing central Kidlington

North Kidlington – new parkway station serving Langford Lane employment area, Oxford Spires Business Park and Oxford Airport; also northern residential part of Kidlington

Oxford Brookes University (2) response to National Infrastructure Assessment call for evidence. [Name redacted].

NIA call for evidence February 2017

School of the Built Environment

Oxford Brookes University

I comment here in relation to some of the cross cutting issues. It would be possible to say a great deal under several of the sectoral headings, but I am sure that experts in those fields will be giving a good foundation for work in each case: there is I would say far more recent and effective work to draw on for each sector.

I only make comments on a few of the cross cutting issue questions, in part because they overlap to a great degree. All the questions on funding, financing, maintenance, competition or collaboration are parts of the challenge of the overall approach taken to the provision of infrastructure in the UK. Naturally that approach can be divided up into facets, but how strategy, investment and regulation are carried out all intersect with each other. The UK has in my view a largely broken model for doing many of the things that need to be done. This is critical because it means that it is not only a matter of the NIA pointing out desirable paths. These are likely to be unimplementable unless major changes are made to the whole infrastructure provisioning system. Luckily the NIC has a chance to state a view on improved provision approaches, which the National Infrastructure Plans only addressed extremely gingerly.

Much of the following may appear to be more assertive than evidence based or “scientific”. There are wide swathes of academic work lying at its base. Much that would be more or less directly relevant would be from the fields of political economy and spatial planning, spread over decades, and with large international components, but to reference in this way is inappropriate for present purposes.

Question 1

I will take the opportunity here to discuss some options I see for the Oxford city region, within its wider context. This will I hope lay down some idea of the very big challenges the NIA ought to present to business as usual thinking. Such challenges are only thinkable (if they are) because of the long time frame of the NIA.

Oxfordshire needs a new housing system and a new transportation system (this is far more important than such inter-regional investments as the suggested Expressway or even than East West Rail, as many of us have argued). These are needed to make daily local life more tolerable. At the moment the sub-region is failing to function on numerous levels. It can be argued that only the national linkings (to London and the north) and the international linkings

(to several relatively easily accessed airports and St Pancras) work well. But these are not what determine the quality of life of the majority of Oxfordshire residents.

The change of the transportation system needs a restructuring of the funding and management of present systems. These are now managed in a completely disintegrated way by a range of national and local bodies and companies, none effectively accountable for the outcomes (compare Transport for London for some greater degree of accountable integration). Major new investment and revenue funding is needed to make a functioning region, as has been made clear in valuable work for the Local Transport Plan (LTP4). None of this may appear to be inside the remit of the NIA, but that remit does include national investment in road and rail etc, and the opportunity cost of that investment is clearly related to investment in localities all over England. The very good question put at one of the NIA events, on how much money should be spent on national or on local schemes, needs answering in a sophisticated way. But one part of the answer should I think be to trace the implications of genuinely transformative plans like LTP4 (and that is only a start) being implemented across England. If that is *only* possible by cutting other schemes like Cross Rail 2 or some of the big national transport investment (roads, rail), then at least the choices become clearer.

The new transport system would need to include several of the ingredients which have been discussed in the area over decades, now made potentially more viable by rising population and activity in the sub-region: light rail transit, restored railway lines, restructured bus systems with priority infrastructure, cycle ways built in or sometimes retrofitted. Dozens of European sub-regions have equipped themselves with these infrastructures over the last 30 years. Naturally that has depended on funding and political will, absent here. But if people are asked what they want, that will be a big part of the answer. It will be problematic if the answer when solutions are presented, is that the current system cannot deliver and therefore nothing can be done.

The new housing system for Oxfordshire needs national change and governance change. It may be doubted from initial reading whether the 2017 Housing White Paper will give the lead for such change, but in due course measures will be needed to reduce the continuing escalation of housing costs in areas like Oxfordshire. Control of rents and stopping house purchase price inflation are key parts of that, as well as ensuring new building of permanently usable social housing in the right places (near the improved transport systems of the area). Yet again this is not core NIA territory, but the links will be made in every English locality between the housing dimensions and the infrastructure included in the NIA impacting on that locality, so the connections need to be made in due course, whether by the NIC or by someone else, in a subsequent or parallel step. Perhaps the NIA should call for the making of new strategic plans for sub-regions like Oxfordshire (needed across much of non metropolitan England) to overcome the dramatically ineffective and inefficient present model of five weak Local Plans, most poorly implemented.

So I (like I suspect many people looking at their own localities) would give strong support for local and regionally oriented infrastructure, and for putting the emphasis on working on long term transitions in such infrastructure systems, tied in with overall livelihood. In my case, being interested in national infrastructure, I also argue the case for considerable if selective investment at that level, but within a (for once) clear set of priorities - I would put low carbon and equitable access at the top. That would support for example big investment in rail

including HS2, but making sure that that fits with lower levels investments and meets the low carbon and socially fair criteria (which HS2 may risk not doing, if ticket prices are high). Motorway investment on the other hand may meet socially fair criteria but cannot be low carbon. Similar assessments can be made relatively easily for energy and other big infrastructure systems.

Question 2

I limit comments to a perspective on freight. This has long been regarded as the forgotten and even-less-planned-for transport sector. Whilst the DfT has done interesting work on some of the issues over recent years, this has consistently failed to lead to really full investigation of the core issues of planning and effective implementation. As a result the prospects for any real modal shifts (largely road to rail) in the UK are as dire now as 10, 20 or 30 years ago. This is a major example of governmental policy failure. Given the long term view of the NIA, this is a real chance to change the direction of travel, by suggesting some radical new approaches.

One area I have been particularly interested in is the planning of strategic rail freight interchanges (SRFIs). This is an area where policy has existed, but where the vagaries of the 2008/2011 Acts system (ineffective NPSs in particular) mean that the decisions being taken in this field, regarded by some as critical in moving to a genuine rail based UK freight system, are scattergun and quite unlikely to lead to an efficient system. Poor planning decisions have already been seen such as the approval of a massive warehousing scheme, with some rail access, near Castle Donington in the East Midlands in 2016 (the decision was against Examining Inspector advice, which in turn was constrained by problematic NPS and other government guidance). More problematic decisions on a wave of schemes proposed in the “golden triangle” in the English Midlands are to be expected in the coming years, given the realisation in the logistics industry that such huge warehousing schemes can now be advanced through the 2008 Planning Act regime by the inclusion of rail access, which in the majority of cases appears to be likely to be little used (all schemes are near motorway or strategic road junctions and in reality depend very largely on road access).

A thorough review of the approach of current policy is needed. The situation is crying out for proper strategic spatial planning that can tie up the allocation of such large sites with major transport investment (invariably publicly funded). Without such geographical awareness, the present free for all will result in enormous investment during the next decade, making any modal shift even less likely into the mid and late twenty first century, locking the freight system of the UK even more into its contemporary unsustainable high carbon path. This is as always a mix of regulatory (planning) and investment issues. Only a strong national long term strategy for freight can bring together these two sides, so harnessing industry forces effectively, as against leaving the field to speculative warehousing sectors to control the investment. Such a national strategy can incorporate work done at regional level (such as by Transport for the North and Midlands Connect), but such work is not a substitute for such national leadership. The NIA should lay out the case for a long term national freight strategy.

I would add that a “gateways” approach (drawing on Eddington thinking) is valuable, in pulling together modes and geographies, but it needs to be carried out with an understanding of the particularities of freight. Those mean that freight terminals or warehousing and logistics systems spread around the UK are as critical as the ports or airports that some may

see as the incarnation of gateways. The whole system is “competitive” if it is efficient in social, economic and environmental terms.

Questions 3 and 10

My comments here are to a degree related to the submission of the Common Futures Network, which argues quite correctly for a national spatial strategy for England. My analysis and suggestions however come at the options from a somewhat different angle. I would argue for a radical restructuring of the whole infrastructure planning and provision system at all levels, and that a move to at least *thinking* in national spatial terms must act as one of the route finders and intelligence mechanisms for such a restructuring.

Such restructuring is needed both to choose the right projects (a massive potential gain from the right sort of NIA) and to cut the costs to *society* (the current system is massively wasteful, with schemes being far above costs in many other countries, the result of a largely ill engineered infrastructure provisioning system). Spending less, on the right projects, would be a valuable achievement.

It is not easy to even sketch out what such a new infrastructure provisioning system would look like. The NIC may well express themselves quite happy with the present system, imagining that it can be steered in whatever direction the NIA points. But many observers, from differing political and theoretical starting points, have argued that the whole arrangement of the UK system is problematic – one could mention the work of Dieter Helm on regulation and funding of infrastructure, over a long period, or specialists in the energy and transport fields (Catherine Mitchell at Exeter University, Phil Goodwin ex UWE now UCL, as examples).

Schematically we can divide the infrastructure systems up as being at top (all England or UK), middle (regions and city regions within them) and lowest (town, locality, project) levels. These are densely and fully related to each other, meaning that whilst it is quite understandable that the first NIA will concentrate its fire (we understand) on the top level, this will leave very great problems of actually making any difference, if the other levels are not addressed and then the issues tackled. This is especially obvious when the housing issues are examined (as is becoming clear in the middle level study on Cambridge – Milton Keynes – Oxford). I make some comments on each level here, but the diagonal impacts are critical, one of the several sound reasons supporting the case for a national spatial strategy.

The **top level** is no doubt the one which is going to be easiest to find good evidence for now, given the outputs of the big research programmes, even though even there the challenges are great, in terms of making coherent long term proposals. Part of these challenges is the need to completely re-examine and then overhaul the regulatory and funding regimes across big infrastructure. It will be one thing laying out a path for a sector (such as energy, making recommendations on generation, transport and so on), but quite another working out how such a path can be implemented. Study of the German and French energy transitions is instructive in this regard (there is a mass of website material giving some commentary on this, for example at <https://energytransition.org/>; more considered academic assessment is

only just beginning to emerge). In Germany a very clear route map (the sort of thing one might hope would eventually emerge from the NIA) exists, but the navigation of implementation through a federal state minefield (a problem England at least does not have) and a highly liberalised system (shared by England) is showing how route finding and implementation play into each other in real practice. In France different problems of implementation are beginning to become evident, in a still more centralised and less liberalised state than Germany, but overall the instruments are potentially easier to use there. But in each case the design of appropriate regulatory and funding regimes is proving critical to advancing on the paths chosen. It is difficult to imagine that anything like the mixed energy regime in the UK (OFGEM, energy NPSs and so on) could be remotely fit for purpose for moving along any but the least ambitious path that might emerge from the NIA. Similar analysis could be carried out for each of the other sectors (and has already appeared nicely in some of the early NIC work, such as recently on the structuring of 5G).

The “**middle**” level of infrastructure systems at regional or city region or county level is one that has been hardly thought about since around 2010, although new work by Transport for the North and elsewhere is beginning to change this. This makes any progress on thinking about long term urbanisation especially for housing very difficult. Work for the National Housing and Planning Advice Unit just before its abolition suggested the identification of housing market areas to be a major structuring element of future strategic planning (DCLG 2010). This was not followed up, and the planning system (working with a weakened forward planning tool in the shape of low level Local Plans) has struggled to give any shape to the shaping of real life localities (with travel to work areas far wider than the Local Plan making authorities). The current attempt to explore the possibility of “infrastructure led strategic planning” in Cambridge – Milton Keynes – Oxford project is extremely interesting, but in the absence of effective strategic planning in this part of England is likely to also struggle to find a way forward which will ensure that proposals stick over the many years needed. All this pushes the case for a radically new model to steer investment across sectors (NIC type infrastructure, but also housing and other social infrastructure). Some reinvention of accountable strategic planning is needed, and it is very hard to imagine what this might be if it does not consist of democratically elected bodies spanning many current local authority areas, in other words some new sorts of elected regional bodies. This is of course anathema to many, but I think it is worth stressing that setting paths at this level over the long term needed is almost inconceivably difficult without a new governing mechanism on these lines. These new bodies should have funding power, delegated over reasonable periods by central government, so that they can work with the private sector who will share much of the investment challenge.

The **lowest level** is that addressed in the planning fields largely by the funding mechanisms of planning obligations (Section 106 agreements) and the Community Infrastructure Levy (CIL) processes. Neither now work well (I have not fully taken in the recent CIL review, but it does not look as if fundamental flaws have been tackled), and the NIC, even if this may seem well outside its field, could usefully give an outsider view on these failures, as the non-functioning at this level impacts powerfully on the credibility of any proposals at the middle level just discussed. No authority or other local actors (such as LEPs) can currently make any genuine promises about the infrastructure that local communities may be able to expect, when the framework for such funding has such a broken model. This is a powerful incentive

to the ever increasing loss of trust in the local authorities trying to steer local change. The problems with these instruments have been highlighted often in recent years (the work for the Lyons commission in 2014 is one source), and governmental failure to deal with these problems infects all forward planning for local level infrastructure especially, in England. One solution would undoubtedly be a move to far more public investment (however frightening this may appear to the Treasury in particular). A system like that in the Netherlands could then be set up, whereby the government meets twice a year with local authorities to track investment progress in key projects, in a two way checking process called the MIRT (Zonneveld and Spaans 2014 give some idea of this instrument). This might begin to restore some credibility to forward planning, as well as give both central government and local authorities a sense of shared ownership of projects. The current planning of so called “devolution” mechanisms (combined authorities and so on) may in some parts of England be able to play some role in this, but in many regions there is no sign that this initiative will have helpful effects. A fresh start is needed to examine real local infrastructure needs and create an effective long term mechanism for meeting them.

Beyond this discussion in terms of levels, the following would be necessary related parts of a package to set up a new infrastructure provisioning system.

- The long term reordering of regulation is needed, setting the fresh objective for all infrastructure regulatory bodies of prioritising efficiency and long term sustainability (not as at present liberalisation and the promotion of competition). The goals of planning decision making should be similarly reordered, to make the same objectives central to the real working of the town and country planning regime (NPPF and NPPG), and to the new set of NPSs.
- Change in the management of land is needed, away from a system based on financial speculation, to one based on societal goals. At present, as numerous expert commentators have explained over many years, it is impossible to make a well functioning housing system (especially new production), at reasonable cost, with the present approach to land. If an objective is to make a more efficient infrastructure provisioning system (less concentrated on massively expensive big projects), this land issue has to be resolved. Again, this is not in the core remit of the NIC, but its resolution is integral to any realistic implementation of its recommendations, and especially if there is any linking set up with housing development.

The case for full exploration of really different options

I fear that the NIA may be pressed into considering quite narrowly differing options, at the final stages of its work in particular. This would be a vital opportunity missed. From my perspective, the radical green option is the one essential to the achievement of low carbon and sustainable livelihoods, and I think it is very important that this path is fully explored, not just within each sector (most obviously by demand reduction and / or different tracks in energy and transport), but in an across-the-board fashion. I realise that none of the NIC commissioners identify with this position, and so there may not be much push to give it real weight, given shortage of time and resources. It intersects very strongly with the call for a national spatial strategy, or at least national spatial analytical thinking, because all such green transitioning has to happen in real spaces, locally, regionally and nationally, and coming from

local bases of opinion. Such bases are far from majorities at present, but the lesser influence in the UK than in parts of Europe (and particular parts of North America) may be due in part to the absence of any governmental initiatives with serious interest in such across-the-board change and transitioning. Surely the NIA could be one of the first to promote such a serious discussion, leading (it might be hoped) to a continued interest in such long term oriented radical trend breaks in societal functioning. This could avoid the real risk of being confronted with at best a couple of pretty much business as usual pathways (with of course small percentage differences on a range of issues), when the public consultation takes place in mid 2017.

I would note that I am very sceptical that the control of the Committee on Climate Change (and the 2008 Act) will be adequate in setting the sustainability of the paths analysed. The London airports case does not give confidence that the control worked there (certainly the Davies Commission was strongly constrained by its brief, which it is to be hoped is not the case for the NIC, in this respect). This is one ground for hoping that a strongly sustainable option (as above) can be incorporated into the development of the NIA, rather than largely relying on CCC advice, very valuable though I am sure that will be in many respects.

National Infrastructure Assessment: Call for Evidence

Response of the Oxfordshire Growth Board

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

Oxfordshire has the fastest growing economy outside of London and contributes £21.9bn to the nation's Gross Value Added (GVA) output. Over the period 2011-31 the County is forecast to grow significantly with 100,000 new homes required to support demographic growth and the planned expansion of Oxfordshire's economy that will deliver an additional 85,600 jobs.

Oxfordshire's delivery trajectory against these two targets is mixed. Recent job creation has been higher than forecast but housing growth has fallen significantly short of the Oxfordshire SHMA (Strategic Housing Market Area) target for the last five years with only some 15,000 homes completed, with an uneven distribution of the delivery across the County: the significant jobs growth is both adding to pressure on infrastructure and highlighting the need for advances in the provision of affordable housing. This pressure is noted in the NIC Interim Report on the Oxford to Cambridge corridor which concluded that although the fundamentals of Oxfordshire's economy are strong, connectivity and communication across and beyond the county together with a lack of affordable housing are major factors holding back growth and productivity.

Many of Oxfordshire's growth opportunities stem from a high-tech knowledge economy focused primarily but not exclusively along the Oxfordshire 'Knowledge Spine' which connects the strategic growth areas at Bicester, Oxford and Science Vale (Didcot and two EZs - Enterprise Zones), together with the science parks at Begbroke, Culham and Harwell. Much of this knowledge economy centres on the University of Oxford, which recently topped the global rankings for higher education institutes and is one of the UK's most significant drivers of innovation. A number of the University's research sites as well as those of national/international scientific facilities and high-tech businesses that together form a dynamic eco-system are located at the science parks within the knowledge corridor, a number of which have significant capacity for growth.

High quality transport infrastructure is needed to keep key employment growth locations well connected with each other and with the wider regional and national economy. High quality infrastructure is a critical aspect of international competitiveness and Oxfordshire recognises the need to improve our infrastructure to improve productivity and successfully face the challenge of Brexit. It is also needed to connect homes to jobs at a local level, recognising that housing delivery is driven by economic growth. Oxfordshire's roads are already heavily congested, with the A34 in particular operating beyond its capacity, with significant impacts on the health of the city economy. Long term sustainable growth in Oxfordshire will require an effective mobility system that provides both additional capacity for and alternatives to the private car, including rail and Rapid Transit services.

Investment is also needed in:

- communications infrastructure, for example to complete county-wide superfast broadband and 4G telecommunications coverage and to provide further improvements (e.g. 5G) as future technology leads to demands for higher speeds in both residential and commercial premises
- utilities infrastructure to, guarantee adequate water supply long term, provide flood protection to Oxford, and to reinforce the electricity grid to accommodate renewable energy projects and supply electricity to new development when needed

To bring all this together in a composite picture of Oxfordshire's needs and opportunities, the Oxfordshire Growth Board has commissioned consultants to produce an Oxfordshire Infrastructure Strategy (OXIS) to identify and prioritise the strategic infrastructure to support

housing and jobs growth in the County to 2040 and beyond. The completed strategy report is expected in June 2017.

Appendix 1 sets out a list of the highest value national and local infrastructure investments needed to deliver the required housing and jobs growth by 2031 and to support longer term growth based on the draft findings from the draft OxIS report. It includes national, regional and local schemes for which full funding has yet to be identified.

The Oxfordshire Growth Board, alongside the County Council as transport authority are founder members of the England's Economic Heartland (EEH) Strategic Alliance, currently focused on working collaboratively with all District, Unitary and County Councils to improve the efficiency and effectiveness of infrastructure planning across the Oxford to Cambridge growth corridor. Significantly upgrading and enhancing the strategic rail and road network, including the provision of the following missing road and rail links in the national transport network would improve competitiveness of Oxfordshire, the sub-regional Heartland corridor and the UK. Priorities are

- Completion of the East West rail to connect Oxford (and Reading), via Bicester and Milton Keynes to Cambridge and onwards to Felixstowe/Norwich/Ipswich.
- Oxford-Cambridge Expressway to provide improved links between the economic powerhouses of Oxford and the Oxfordshire knowledge spine area, Milton Keynes and Cambridge and elsewhere within England's Economic Heartland.
- Four tracking of the rail network between Didcot and Oxford to increase capacity to cater for growing passenger travel and for freight movements from Southampton port.
- Capacity improvements to the A34 to improve the highway link between the south coast deep water ports - Oxfordshire – the M40/Midlands and to deal with congestion and journey time reliability issues on the strategic network within Oxfordshire as set out in the DfT/Highways England Route Based Strategies.

The Growth Board estimates that there is a £1.7bn gap in Oxfordshire between planned infrastructure investment across all sectors and the actual amount needed to support the scale of predicted growth up to 2030, taking account of potential funding sources. This not a complete picture however, and in our work in preparing the OxIS to 2040 and beyond we will be identifying additional infrastructure needs to support growth in that period.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Oxfordshire occupies a strategic position on the national highway and rail networks, with Oxford now recognised as a major hub. It is at the centre of the rail network for rail passengers in terms of east-west connectivity and the Strategic Freight Network (SFN) for container traffic between the port of Southampton and the Midlands, North West and Scotland operates through Oxford and Didcot.

Network Rail expect that by 2019 available rail capacity through Oxford will be full with significant enhancements and upgrades required, although these are not anticipated to be undertaken until post 2024. Great Western electrification to Oxford has also been postponed until at least 2024. However, as passenger and freight demand continue to grow, and new connectivity opportunities arise (for example connections to growth centres at Swindon, Bristol and the west), capacity issues will be exacerbated and will have a more significant impact on UK's and Oxfordshire's competitiveness unless planned major rail upgrades can be brought forward, particularly on the critical Didcot-Oxford section of the network.

There is also a need for on-going engagement with Government and Heathrow Airport in respect of proposals to expand airport capacity, focusing on the importance of improving strategic connectivity to/from the airport to the wider South East, particularly by rail. The planned Heathrow western rail link to Reading services should be extended to Didcot and (probably when electrified) on to Oxford.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

We currently estimate a £1.7bn gap between planned infrastructure investment in Oxfordshire and the actual amount needed to support the scale of predicted growth up to 2030. Looking forward, there is a need for a strategic infrastructure/spatial planning approach to planning places to live and work to avoid development triggering a need for additional strategic infrastructure items which cannot be funded. The Growth Board have recognised that and have approved the development of a countywide Spatial plan to provide a holistic picture of growth across Oxfordshire.

The development of this Spatial Plan will allow development to be planned where it can take advantage of and help sustain existing and planned infrastructure, ensuring future communities are attractive and thriving places – particularly on/around main public transport corridors and hubs. We believe that the close working arrangements that exist between Councils and other public bodies in Oxfordshire, together with the development of the Joint Spatial Plan provide the right basis for planning coherently for Oxfordshire. This approach will provide confidence to the NIC that the Western side of the corridor has the right tool to grasp the challenge identified in the Interim Report on the corridor, as well as to integrate with other strategic opportunities that emerge beyond the County boundary.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

There is a great deal of academic work currently being undertaken to better understand the opportunities that demand management offers across the range of infrastructures, recognising that they are disparate in nature and have vastly different physical and psychological drivers/motivating influences.

For example, focusing on energy use, BEIS suggest that the UK “could be saving 196TWh in 2020, equivalent to 22 power stations through, socially cost-effective investment in energy efficiency”. All four scenarios set out in the UK 2011 Carbon Plan to achieve the 2050 carbon targets imply a per capita demand reduction of between 31% and 54% relative to 2007. This is ambitious but achievable if properly managed and funded.

We believe that there are similarly significant impacts achievable across the transport and wider infrastructure network: The Growth Board are working to support the development of an intelligent mobility platform that will allow us to better understand the impact of transport pricing on choice of travel mode, applying learning from behavioural economics. Broadly, the challenge will be developing a robust business case for investment to deliver network improvements that can capture positive externalities (improvement in air quality, health outcomes and noise pollution for example).

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The quality of infrastructure profoundly affects both economic growth and productivity and people’s quality of life. Whilst provision of new infrastructure to unlock growth is vital, the quality of existing strategic infrastructure also needs to be maintained to support existing and new businesses and communities.

A good transport network is vital to supporting economic and housing growth. It is essential that new and existing strategic transport assets together provide for the efficient mass movement of people and goods, including the ‘last mile’ of the journey. Programmes for maintaining the condition of roads and highway related assets, including drainage, should prioritise growth corridors in which there are already planned investments with the potential

for rapid transit services and high pedestrian and cycle usage or where there are safety issues. Incremental repair may be a short term solution but may prove more costly over time.

At 2014 it was estimated that to bring all roads within Oxfordshire alone up to a good state of repair would cost £165m and then an on-going year on year investment of approximately £20m per year to maintain that condition level. It is important that the responsibility for maintaining assets is devolved to the local level where there will be opportunities to spot any advantages from asset rationalisation and for economies of scale through combining construction of new infrastructure schemes with maintenance of other assets.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

The opportunities fall in many ways;

- Use of Central Government and other buying organisations frameworks open for collaborative use.
- Combining of spend by local District and County Councils
- Use of open tendering to local SMEs
- Use of 'Construction line' and other pre-qualified suppliers
- Strategic Planning of Contracts
- Local Forums to develop competition and explain to companies how tenders are released
- Development of strategic alliances with sector experts
- Greater use of innovation partnership procurement

Cross-boundary collaboration through the EEH and other partnerships offers opportunities to align activities and share knowledge/experience across teams to improve planning and delivery of infrastructure.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

We highlighted earlier the ambition of the Growth Board to develop an overarching strategic infrastructure vision for Oxfordshire and believe that future infrastructure funding should be tied to the development of such cohesive and inclusive strategies. The Growth Board supports, through the process of devolution, the defrayment of nationally held funds to locally accountable partnerships to deliver against the publicly stated priorities of the strategic vision.

For example, Oxfordshire's devolution bid sets out our ambition to establish a strategic infrastructure fund. The structure assumes a combination of business rate retention, stamp duty land tax and potential business rate levy to create an investment fund. The presumption is that the income streams will support borrowing and enable early delivery of infrastructure. We have also taken a strategic approach to the use of EZ Business rates, enabling advanced borrowing to pump prime development. We have already committed over £40m of borrowing against EZ1 and are currently reviewing the potential of EZ2.

Strategic partnerships, such as the EEH Strategic Alliance, are developing overarching transport strategies that will include the concept of the Major Road Network – a combination of Highways England's Strategic Road network and the more significant local transport authority-owned roads. There may be a case for the ring-fenced Road Fund Tax to be made available to such partnerships for investment in the Major Road Network rather than just being restricted to Highways England's network.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

At a strategic level, there are a number of projects where clear Government and partnership commitments are in place, but without the guarantee of (full) funding or different options for finance – examples include the East West Rail Western Section, which is partially funded, and the A34 interchange at Lodge Hill, which currently has no specific funding allocation but is required to support delivery of 1,000 homes. These are both pieces of critical infrastructure for which a finance solution needs to be sought to prevent barriers to growth arising.

At a more local level, developments may stall where developers are unwilling to provide a bond to ensure key pieces of infrastructure such as schools can be provided in the event that a developer defaults on payment of agreed contributions. It would be beneficial to have a Government agency acting as guarantor for significant deferred contributions to which applicants/developers could go to enable them to provide appropriate security for prompt payment of such contributions. Developers can be reluctant to progress with a development if they consider the cost of a bond prohibitive.

Oxfordshire has benefitted from front funding of affordable housing in Didcot by the HCA which provided the headroom for a developer to progress key infrastructure at Great Western Park in Didcot, thus advancing the development of the site. The Growth Board also supports this approach.

As part of its development of an Oxfordshire Infrastructure Strategy the Growth Board has commissioned a study of the grid capacity in Oxfordshire from SSE. This has highlighted that the current regulatory framework is based on a reactive approach to connecting new development to the electricity grid and does not provide for the electricity suppliers to invest in the supply network e.g. in new sub-stations, in anticipation of planned growth. This lack of forward planning results in capacity in the existing network reducing as developments come forward to the extent that even relatively small developments are asked to pay for significant investment to achieve a step change in capacity - this is reflected in the costs of that investment and can become a barrier to bringing forward development, as shown by the challenges faced at Bicester in ensuring the grid capacity supports Cherwell's ambitious growth programme for the town.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Councils recognise that they are operating in an increasing global supply chain – can we deliver on our responsibilities in this context? Supply chain management and security (pertaining to raw materials needed to provide infrastructure growth) energy security and housing for example, are fundamental to the delivery of a thriving and successful economy and place.

To mitigate, local government can/could take an active role in developing business models (PPPs etc.) that secure service delivery; particularly where market failure arises. There are various examples of LAs undertaking development work in these areas e.g. Leeds City Council are developing and purchasing corporate housing projects and Bristol CC / Nottingham CC are moving into the ESCO (Energy Savings Company) space. If this is a revenue generation opportunity or building resilience it is difficult to ascertain but this type of project may prove to be examples of strong triple bottom line business ventures.

As well as understanding new approaches, Councils need to focus on specific mitigation exercises in a variety of areas such as:

- Cyber security – the partners to the Growth Board are as part of Smart Oxford are working with OII (Oxford Internet Institute) and the Oxford Cyber Security Cluster to develop an Infrastructure Threat Map. This will be required as our infrastructure becomes smart due to the proliferation of Internet of Things (IOT). Consequently threat levels will grow.

- Improving working practices to remove information silos – mapping interdependency – Smart City working helps with this. Cities need help to develop capability by leading and facilitating collaboration with industry, academia and citizens; deploying solutions requires collaboration between different actors/stakeholders and information silos. Local government is ideally placed to support these relationships. Coordinated by OxLEP, partners in OCC Innovation and Research team together with Oxford City Council have been at the centre of this type of activity for the past three years, breaking down the silos and realising the opportunities, and working closely with partners to enable this across both the County and wider region. Collaborative working is essential to coordinating the delivery of significant infrastructure to support planned housing and jobs growth in Garden Towns at Didcot and Bicester, and Cotswold Garden Village north of Eynsham.
- Better Procurement –
 - Increased corporate governance and scrutiny of the supply chain. Globalisation impacts the ability to purchase raw materials: steel price impacts delivery of East-West Rail for example.
 - Interoperability of data management
 - Insuring ISO accreditation (quality management system that can be integrated into any business. It is focused on ensuring the business delivers a consistent level of quality to its customers by having well defined and regularly reviewed processes and procedures)
- Resilient architecture –flexibility and interoperability must be designed in to our built environment to allow cities to be truly smart.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

We would support close collaborative working between authorities/LEPs with appropriate governance arrangements to undertake strategic infrastructure planning; for example;

- Confirm the EEH Alliance of authorities as a sub-national transport body (STB) to help enable strategic infrastructure planning and delivery for such priorities as East-West Rail and the Oxford-Cambridge corridor.
- At a County level, in Oxfordshire this is achieved through the Oxfordshire Growth Board where the OXIS will identify and prioritise strategic infrastructure through developing a Joint Spatial Plan for the County as a whole that is also aligned with those developed for neighbouring authorities so as to ensure joined approaches to key infrastructure are addressed.
- At a local level, strategic infrastructure should continue to be addressed in up to date district focused infrastructure delivery plans that are published alongside Annual Monitoring Reports and reflected in CIL 123 lists.

Removing the restriction on pooling of s106 contributions would remove a major barrier to the timely delivery of strategic infrastructure schemes required to support growth in a locality with several development sites. Current legislation has curtailed, and unless corrected will continue to curtail the ability of councils to seek various “pooled contributions” to address, in particular, the *cumulative* impact of developments. This is an issue where five s106 agreements are insufficient to cover the funding of infrastructure serving a wider area which means that not all schemes contribute to mitigating the impacts they create and there is a funding shortfall.

There may be difficulties in deciding which five developments would best provide funding for an item of infrastructure; a Council may hold off seeking contributions from a significant number of schemes that might otherwise pay in anticipation of contributions being obtained

from larger developments in the future. Changes in ownership or multiple applications on sites over time can erode the level of mitigation. Delays to one of five sites coming forward may result in secured s106 contributions from the others having to be repaid.

Examples in Oxfordshire:

- It is not possible to collect adequate contributions to mitigate the cumulative impact of development on key transport junctions and corridors in towns with significant growth spread across many sites e.g. at Banbury where allocated growth of 7,000 residential units spread across 16 allocations/planning applications renders it impossible to collect contributions from each site toward improvements to the Hennef Way strategic corridor (link between the town and the M40) as to do so would fall foul of the pooling rules;
- Large strategic sites involving multiple landowners and developers are commonly split into multiple planning application areas, each with their own S.106 agreement. As S.106 contributions to infrastructure needed to mitigate the whole strategic site can only be collected from five sites, smaller sites typically avoid paying contributions for site wide infrastructure, leaving a funding gap. For example, North West Bicester Eco-Town - this will be a mixed use development including 6,000 homes and creating at least 4,600 new jobs. The site is split into seven individual application sites, each of which is at a different stage of delivery.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Development of new infrastructure can impact on the environment including through the loss and fragmentation of habitats, pressure from traffic and people, reduced air quality, noise and visual intrusion. Implementation of new and upgraded infrastructure should follow the environmental mitigation hierarchy: avoid – minimise - restore – compensate for adverse environmental effects. However, well designed new infrastructure can offer opportunities for protecting and enhancing the environment for example the proposed A34 interchange improvements at Lodge Hill would have a beneficial impact on Air Quality in Abingdon through re-routing of town centre traffic.

To achieve this infrastructure design teams should seek views on environmental opportunities in the target area at the earliest stage of project planning and, ensure that budgets include environmental aspects from the outset. East West Rail and the Oxford Flood Alleviation Channel are two local examples of a proactive approach to this. It is important that the costs of maintaining environmental features in the long-term are included as an integral part of the budget settlement for infrastructure maintenance.

New linear transport infrastructure – roads and rail lines – can act as a barrier to movement of wildlife; measures such as provision of wildlife bridges and tunnels/ under or across new infrastructure can help to maintain some habitat connectivity. Road and rail side verges offer the opportunity to provide trees and plant-rich areas to encourage wildlife but will need management to maintain quality. Water management features can provide valuable new habitat. Where new infrastructure is required in urban areas there are often significant opportunities to create environmental improvements that improve peoples' well-being including trees and vegetation to reduce pollution, provide screening, shade and complement recreational facilities such as cycle tracks, exercise routes and parks.

Significant infrastructure schemes should be designed with the environment in mind both in terms of reducing landscape and visual impact and in providing net gains in bio-diversity. The Oxford Flood Alleviation Scheme for example will be a four mile relief channel to divert flood waters away from Oxford; it will create new wildlife habitats and natural watercourses, providing new recreational amenity as well as enhancing the environment. Similarly the design of new reservoirs can provide for enhancements to the natural environment surrounding the reservoir as well new water habitat.

A quality environment is important to economic growth, development, health and well-being. The Oxfordshire LEP has published the Oxfordshire Strategic Environmental Economic Investment Plan (SEEIP) which sits under the Strategic Economic Plan. The plan provides direction on how investment in Oxfordshire's environment will be delivered with a view to both making the county a better place to live and do business and to generating new environmental products and services with wealth creation and export potential. In doing so it is recognising large protected landscapes and features as strategic green infrastructure in their own right and looks to improve connectivity and accessibility to and through these areas to help offset the impact of new growth and to improve public health and maintain quality of life.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Some form of cost-benefit analysis, or more widely value for money judgement, is inevitable, either consciously or unconsciously, whenever there is a demand which outstrips the resources available to service it. Once this is accepted then the important issue is to develop the best assessment of the costs and benefits that is available, providing that the effort involved in this analysis is proportionate to the overall investment in the improvement being assessed.

The cost benefit analysis of a project such as a major transport investment is always likely to be a highly complex set of calculations and the reporting of the results of such an analysis will always be likely to seem to be a "black box" from which answers are handed down, as if from high. It is possible that this impression could be reduced to some extent by the development of a standard format for reporting the input assumptions and output results of the assessment. It would not be sensible to attempt to reduce the breadth of the factors included in an analysis in order that the route through which those findings have been arrived at is more easily understood.

The presence of cost benefit analysis in the decision making process is only likely to be fully accepted if it is clear that it is only one of the many factors which is being taken into account. What is needed to be credible, tractable and transparent is therefore not cost benefit analysis but the wider context in which infrastructure investment decisions are made and of which cost benefit analysis should only play a part.

We will be working with Professor Jim Hall to offer Oxfordshire and the EEH area as real world application of the Mistral project that is being undertaken to step change how infrastructure investment decisions are made through better whole system analytics, testing and analysing cost-benefits of strategically significant infrastructure. This will help Government and NIC to better understand return on infrastructure investment, but also assist the EEH area in understanding its own relative priorities intra and inter-regionally.

We will also be working with the Transport and Future City Catapults to develop mobility and city planning tools that are also in development, that enable better decision making in terms of investment, opportunities identification and management of the "place". Imperative to these tools are that they avoid the black box approach through more user centric interaction portals that allow non-professionals/experts to utilise.

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

In the short to medium term, trends indicate further population shift towards more densely populated urban environments. Centres of employment become more concentrated, population growth increases demand on networks. In localities such as Oxford where there are physical, geographical and other constraints for example Green Belt designation, land values increase as demand grows, creating a wider sub- and peri-urban commuter belt that generates further transit network pressures.

In the medium to long term horizon, new, innovative products and systems will create a very different environment for mobility, with new ways of travelling and more efficient use of time, vehicles and space. More intelligent, data-driven transport systems that better integrate with personal and business mobility needs are widely expected to emerge. Connectivity and exponential improvements in virtual reality and Digital Image processing will all have almost unimaginable impacts on the way citizens consume travel services for work and leisure.

Vehicle ownership models will undergo a seismic shift. It's very likely that a child born in the UK in 2017 will never take a driving test – they simply will not need to. In Oxfordshire, Growth Board partners have developed the Science Transit Strategy to address some of these key issues – it aims to;

- Embrace new technologies and data innovation to unlock intelligent mobility, presenting information to all users to allow them to make truly informed choices about the way they travel;
- Accelerate local growth through innovative R&D, providing opportunities for forward-looking business and research organisations and their highly skilled workforces to test and bring new products and technology to market;
- Improve connectivity between places where people live, work and spend their leisure time, ensuring all aspects of the door-to-door journey are fast, reliable, seamless and affordable;
- Integrate transport and land-use planning to improve non-car-based mobility, creating an environment where sustainable travel is the simplest and obvious choice; and
- Deepen public and private sector partnership delivery for the mobility of people and goods, harnessing the respective skills of the different partners to fund, develop and implement new and improved transport systems.

By 2050 wearable mobile devices e.g. Google watches/goggles/glasses will be the norm; self-driving vehicles, smart machines, seamless automatically translated meetings, and biochips will all affect the future of business/leisure and tourist travel management. Big technology game changes for 2050 to include:

- **Wearables, Augmented Reality and The Internet of Things (IoT)** Augmented reality, many wearables and IoT are already available and all around us, and are already making travellers' lives easier and helping travel managers to offer an enhanced level of service.
- **Smart Advisors:** Smart advisors are another technology that is already becoming an almost everyday reality. As the technology advances and becomes more prevalent, these smart machines may become a good friend to the travel manager. Travel itinerary management could be bolstered by helpful smart advisors in transport hubs, providing useful and perfectly up to date information to travellers and answering their enquiries, saving time for the travel manager.
- **Autonomous Vehicles:** We can expect to see the first commercial autonomous vehicles in around 5-10 years, these will revolutionise travel.

These are just a few of the most exciting emerging technologies that are bound to have an effect on the state of travel and the wider world as a whole. Perhaps the most exciting thing will be those technologies and changes that aren't yet foreseen.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Oxfordshire has benefitted from a number of key investments over the past 5-10 years, with more planned by Network Rail and Highways England. Given the scale of currently planned growth the development of strategic rail corridors and hubs- as shown in diagram 1 Oxfordshire Growth & Infrastructure map – gives examples in Oxfordshire along key growth corridors, including;

- The strategic East West Rail network linking Oxford and Cambridge, and extending beyond to link major centres of growth including Milton Keynes, Swindon and Bristol;
- The ‘core’ rail network through Oxford – connecting Didcot, Oxford and Bicester (the Oxfordshire “Knowledge Spine”) with new opportunities for integrated jobs and housing development at locations such as Culham;
- Development of new rail opportunities, e.g. the Cowley line, serving significant jobs and housing growth around Oxford’s “Eastern Arc” and to connect economic and housing growth with travelling in /out of urban area.
- Mass rapid transit – moving large numbers of people into/through Oxford with three major lines proposed connecting new/expanding growth settlements, a ‘ring’ of new ‘outer’ Park & Ride sites and key employment centres in central and eastern Oxford.

We would also highlight the development/upgrade of the Strategic and Major Road network – in Oxfordshire the key corridors include the M40/A34, A40 and A420 (this links this area to the west and critically links Oxfordshire and Swindon growth areas, as well as the strategic links south to the M4 and Southampton port). Investment in the Oxford to Cambridge “Expressway” will be instrumental in providing the additional connectivity required to support growth and jobs on these corridors, supplementing the existing north-south axis. Of particular importance will be ensuring that targeted investment is made so that the “last mile” is covered as well as strategic links, and that highway and public transport solutions are considered together.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

In Oxfordshire mass Rapid Transit services linked to remote Park and Ride will provide fast and frequent links from key multi-land use and multi-modal hubs in rural areas, intercepting car journeys and decreasing congestion on strategic roads into urban areas – see diagram 2 Oxfordshire Illustrative Transit Network. This approach is becoming ever more significant to managing the growth of the economy of Oxford City.

Development located around rail stations can take advantage of planned/potential capacity in rail services to urban areas. For example, Culham in Science Vale, Oxfordshire offers the potential for significant employment and housing growth as part of a Science City based around an improved rail station offering links to Oxford, Milton Keynes and Cambridge via East West Rail, north to Birmingham and south to Didcot, with links to London, Swindon and Bristol.

16. What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

Enabled by technological advancement, data aggregation and the development of key strategic partnerships with transport providers, researchers and data aggregators, MaaS (Mobility as a Service) can help address our Intelligent Mobility goals, supporting the vision set out in the Science Transit Strategy. There is a clear role for local government in shaping and developing MaaS provision.

An average family in the UK spends circa £300 PCM on personal transport. As vehicle ownership models change less personal capital will be spent on ownership and maintenance of a vehicle (servicing /insurance). Transport network efficiencies will be gained through

improved data collection/management and automation of transport services. This suggests that there will be significant capacity in personal transport budgets. Business models are currently under development to exploit this; a key opportunity for MaaS providers to attract customers is to remove the pain points that travellers face during their journeys. This, more often than not, means delays due to congestion. Dynamic pricing in terms of access to transit and routes could incentivise off-peak travel reducing congestion, delays and travel times.

Congestion charge is potentially a key thought for AV, there is a realistic potential of AV driving around to avoid parking fees in places like Oxford where we discourage vehicles from city centres, through high parking fees, causing added congestion. We are working in collaboration with leading AV companies, like Oxbtoca and Research in ORI to explore potential utilisation of technology, such as real-time geo fenced insurance systems that may allow a simple yet dynamic local added charge to encourage AV use and connected vehicles in an efficient way that works for all city users.

There are few examples of profitable MaaS-style business models, operating at scale. For instance, early mobility experiments in Helsinki have not achieved desired financial results despite their popularity. The MaaS concept is still relatively new to consumers and the market is still in early stages of development stage, some degree of experimentation (and failure of business models) can be expected.

Incumbent transport providers and car manufacturers are beginning to understand that this transition could be shaped by them – public and shared ownership modes of transport may become more widely utilised than the privately owned vehicle in the medium to long term. *These trends are hard to predict as are the supporting business models.* We would therefore suggest Government will need to pump prime this and other demand management technologies and innovation testing.

We are actively looking at a MaaS trial in Oxfordshire that utilises many of existing and emerging partners in transport services, payment platforms and journey platforms to deliver a MaaS offer that would look to be delivered on the basis of an evolving business model, possibly in a joint venture approach. This is still at an early stage but we feel Oxford has more key elements for success than most fully deregulated Cities. In terms of support for this, the initial feeling is that MaaS could be supported via a kick start type mechanism that helps to build a custom base to get to an operating model where, some added administration expenses are reduced, to a sustainable level. As a proportion to N. Users.

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

On the basis that the huge investment required is never going to be commercially viable for the supply market to fund as is, a strategic decision is required as to whether government should step in to directly fund deployment of affordable full fibre infrastructure and to what extent, or if taxation breaks are used to incentivise, or if the UK accepts that affordable fibre penetration will never be achievable into semi-rural and rural geographies. The same consideration applies to enhancing 5G mobile coverage.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

The existing BDUK superfast broadband programme (funded by DCMS, Oxfordshire County Council with contributions from a number of District Councils to extend local coverage) will deliver the infrastructure required to meet current needs, and likely sufficient for the next 5-10 years, to 95% - 97% of the population. Even with enhancements to the existing Openreach copper based access network, it is envisaged that the huge step-change

investment required for end-to-end affordable fibre will never be met under current market conditions.

Distinguishing/categorising digital communications as a utility or not does not help clarify the position. A better analogy is seeing digital communication as Infrastructure, in which case the funding problem is akin to why it is not viable to provide mainline train services to every small community. In the near future it could be argued that digital infrastructure will exceed any other infrastructure in terms of strategic importance for economic growth in the UK.

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Effective decarbonisation of heat remains a barrier to meeting long term national Carbon Reduction Targets. The opportunity of heat networks is well recognised but proving their potential remains very slow. In Oxfordshire, two studies are taking place funded by the Heat Network Delivery Unit in Bicester and Oxford. Continuing the funding of local feasibility will be a key mechanism for supporting delivery.

There is a need for a strategic infrastructure/spatial planning approach that considers 'heat' as a service; networking and collocating heat availability /production with clusters of growth over time. A "heat master planning" approach with investment taken on the basis of cumulative long term development plans will help address the barrier of investment costs seen on single developments.

This approach to considering heat requires a time scale of planning and investment beyond that of most local plans and fits the approach taken in Oxis. There is scope for planning on a larger scale in line with EEH. The future scale of heat demand from dwellings / industry is a major risk factor in the investment decision around heat networks. For this reason clear long term signals from central government on programmes and ambitions for domestic retrofit, standards in new build and carbon regimes for industry will be necessary to support business cases.

Cherwell DC has supported the development of advanced sustainable housing at NW Bicester with delivery undertaken by A2Dominion. Cherwell and its delivery partners have shown what can be delivered as a viable commercial development at a high standard, with a final product that is also selling well to the public on the open market.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Significant generation from distributed renewable energy sources, combined with local storage and demand management through smart grids creates local markets that price/respond effectively for available commodity. A review is needed of the support regime for renewables which has been prematurely removed and is hampering renewable delivery in Oxfordshire. The review should encompass whole system costs in terms e.g. supporting storage on the viability of the renewable sector. There also needs to be greater collaboration, innovation and forward planning between the Distribution Network Operators (DNO), Local Authorities and local users /generators. Grid constraints in Oxfordshire are already reducing scale, delaying and preventing renewable investments.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The majority of ultra-low emission cars and vans on sale today or coming to market within the next few years are plug-in electric vehicles. "Plug-in vehicle" is used as a generic term to describe Battery Electric Vehicles (BEV), Plug-in Hybrid Electric Vehicles (PHEV) and Extended-Range Electric Vehicles (E-REV) The Government's aspiration is that by 2050 almost every car and van in the UK fleet will be an ULEV (Ultra Low Emission Vehicle) as the number of plug-in vehicles on our roads increases, so will the demand for electricity.

Whilst not a concern until plug-in electric vehicle uptake reaches large numbers, the increase in the demand for electricity from the large-scale adoption of plug-in vehicles will impact the electricity network through changes in patterns of daily electricity demand as well as increases in peak demand. However, increases in peak demand may be more limited because evidence suggests people predominantly charge plug-in vehicles at work or at home at night.

The increase in electricity demand from EVs on local infrastructure will require upgrades to be carried out on the distribution network. There is the possibility that a small number of EVs vehicles charging simultaneously could overload the distribution network at a local level. More work is required to deliver a greater understanding / monitoring at local grid level.

If a large number of plug-in electric vehicles are connected to the grid, the DNO (Distribution Network Operators) could manage charge profile to help balance the network. This improves network efficiency and allows the demand from plug-in electric vehicles to be shifted.

DSR (Demand Side Response): EV's can be used to store energy so in the event of a shortfall in the supply of energy to the network; DNO/Grid Balancing Services / could draw power from large numbers of plug-in electric vehicles simultaneously, re balancing the grid. In the event of a power cut an EV's stored energy could be used to supply power to a home or other local buildings. There's some interesting work being done looking at the interplay between micro-renewables (domestic PV) domestic battery storage and EV battery's which could eventually result in reduced network demand as EV drivers consume more of their home-generated power.

Production of hydrogen as a transport fuel could offer balancing services for the electricity network. Hydrogen can be created through water electrolysis which uses electricity to split water into its constituent hydrogen and oxygen molecules. Electrolysers can respond very quickly to demands to turn on or off and are therefore also very useful for DSR (Demand Side Reduction) and utilisation of intermittent Renewable generation capacity. Electrolysed hydrogen created in this way can be stored, used as a transport fuel or added to the national gas grid.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Accuracy of demand forecasts: Water demand forecasts should take full account of the scale of housing and employment growth being planned for in current adopted *and emerging* local plans and ideally should look at growth significantly beyond local plan timeframes as meeting demand will require significant investment in large water resources which have a long planning and delivery timescale. Underestimation of growth in demand will result in sub-optimal supply solutions.

Where water deficits are forecast water companies should first seek to reduce water leakage and implement measures to reduce water use by encouraging changes in customer behaviour e.g. through pressure management, installation of water meters and introduction of tariffs.

Strategic water assets need to be managed over a wide area and require significant investment. Within the Thames Water area meeting the growing demand for water from London will require expensive solutions elsewhere in the Thames catchment area; a water deficit is also forecast in the SW-OX (Swindon- Oxford) area by 2020. New resources to meet demand throughout the Thames Water area require long term planning to ensure economies of scale. Preferred solutions will have long lead in times, including taking proposals through the Water Resource Management Plan submission process and through the planning system via the NIC process.

Options being considered for meeting London's demands are costly and include raw water transfer via pipeline from other water areas e.g. River Severn and a new strategic reservoir within Oxfordshire in the Abingdon area. If investment is to tie in with planning timescales, it would be useful if water company Asset Management Plans (AMP) for water investment schemes could have longer time periods– the AMPs prepared by Thames Water currently cover 5 year periods.

Developers of new housing in areas of water stress can contribute to water use reduction by designing in measures to reduce water use and water wastage for example grey water recycling, provision of water efficient domestic appliances and bathroom fittings and the provision of water butts to collect rainwater.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

In the Thames Water area much of the waste water treatment infrastructure dates to Victorian times and is in need of investment in major refurbishment to maintain services long into the future and ensure processes meet industry standards. Timely provision of wastewater infrastructure is an issue. In Oxfordshire the majority of waste water treatment plants are nearing capacity and will require upgrades to cope with demands from projected population growth. Capacity issues across the water treatment network result in the discharge of excessively nutrient rich water to Oxfordshire's watercourses which reduce the ecological value below the Water Framework Directive target standards.

Developers can requisition infrastructure in order for it to be delivered earlier than planned for the overall network to prevent their scheme from stalling but such up-front costs could impact on development viability.

Water companies should be required to comment on all planning applications in relation to sewerage capacity. In doing so, they should take a holistic view of proposed development across each Local Planning Authority area to provide an accurate view; this can be difficult where an up to date local plan setting out the spatial strategy for growth has yet to be put in place.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Management of water supply in areas of water stress may require consideration of options for importing water from catchment areas which have excess water resources. This requires collaboration between two commercial water companies who are answerable to shareholders. A whole catchment approach could require working across local planning authority boundaries on managing wastewater and flooding. Wastewater discharge from new development to local watercourses could increase flooding in downstream communities which may be in an adjoining local planning authority area. There would need to be close cross boundary working to identify and secure funding of appropriate mitigation measures.

Water - environment issues are being addressed through a number of multi-agency Catchment Partnerships across Oxfordshire.

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

We should aim to be flood neutral even if does require additional flood storage or a decrease in the proposed developments. Schemes that protect locations facing significant economic risk from flooding should be prioritised. For example the major floods in Oxfordshire in 2014 resulted in loss of business and disruption to transport as well as personal cost to people and their homes - the cost to the Oxfordshire economy was estimated to be £50m per week. The proposed Oxford Flood Alleviation Scheme will protect Oxford and enable it to maintain its key role in the regional and national economy as a centre for business, research and

learning, retail and tourism. Construction of the first stage of the scheme is scheduled for 2018, subject to full funding being confirmed – it rates very highly nationally and locally but is still short of implementation with a deficit in funding that could and should be secured as a national priority.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Natural methods of flood management are cheaper on materials, but may be more costly on land use. They have the potential for positive environmental effects in terms of habitat creation but also negative impacts in terms of landscape and visual effects and impacts on adjacent farmland if not planned and implemented with care. Natural Flood Management interventions can also improve water quality. The Evenlode Catchment partnership in Oxfordshire has recently started a pioneering project on the use of natural flood management techniques in partnership with the Environment Agency, landowners, local councils and communities. Natural Flood Management will not be the best solution in all areas and should be informed by the hydrological characteristics of the catchment.

New connected technologies can support community based responses to flood risk, an example of this is the Oxford Flood Network river level monitoring system.

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Government should make it a priority to publish their long term strategy for solid waste. A clear direction for waste, resources and the environment, encompassing circular economy principles, would then set the context for financial and regulatory incentives and provide local authorities and businesses with the certainty to develop services and invest in infrastructure.

Since 2007 Oxfordshire has completed a step change in the way we manage household waste; we have introduced food waste recycling from every house, collect residual waste fortnightly, and have procured residual waste treatment so that less than 5% of our waste is sent to landfill. The LATS (Landfill Allowance Trading Scheme) and landfill tax were effective drivers for this change and have resulted in Oxfordshire having one of the highest recycling rates in the country.

To continue this success, national strategy should set stretching targets applying to not only to household waste, but also to commercial and industrial waste. These should encompass reduction and reuse as well as recycling in order to drive waste up the hierarchy. Financial and regulatory drivers should continue to encourage the management of waste at the top of the hierarchy with landfill disposal as the most expensive option.

Extended Producer Responsibility (EPR) should be an integral part of the strategy placing emphasis on front of pipe solutions. Products and packaging should be designed to be durable, easily repaired and reused, and when at the end of use, materials should be able to be easily segregated for recycling. Quality of materials should be incentivised over quantity, for example, higher payments for WEEE (Waste Electrical and Electronic Equipment) that is operational as opposed to one price for all WEEE regardless of quality. New materials will create new waste streams (e.g.: batteries, permanent magnet materials) and viable markets and suitable flows of producer responsibility funds will ensure that it is advantageous to collect, transport and process more unusual/smaller volumes of materials rather than disposing of them.

Waste should be managed on a sub-regional basis in accordance with the hierarchy. The current system creates silo thinking, with one stakeholder group focusing on increasing recycling rather than reducing waste overall. Streamlining this system would enable financial and environmental efficiencies to be realised.

Greater consistency in collection systems for households and businesses, in particular offices that produce recyclables and waste similar to that produced by households, should be encouraged. This will create consistent volumes and quality of materials giving the market more confidence to invest in secondary materials and associated infrastructure, helping to create employment. In addition, collecting the same core set of materials will mean fewer collection and sorting systems as well as a common container system, potentially leading to cheaper procurement of standardised assets.

Assistance should be given to Local Authorities to standardise collection systems enabling local and national communications campaigns (such as those carried out by WRAP) to work to even greater effect, driving up participation, increasing recycling rates and reducing contamination.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

The circular economy should not be considered as a 'waste' issue. It requires a fundamental shift in how we think about goods and products and should be embedded into each area of the economy. The circular economy model provides environmental and economic advantages and works most effectively when materials are able to be managed without becoming waste, or are managed by the manufacturer. Extended Producer Responsibility should be used to ensure product design and use focus on durability, repair and reuse. At the end of life preventing them from entering the local authority waste stream (though repair or distributor take-back) will save public money.

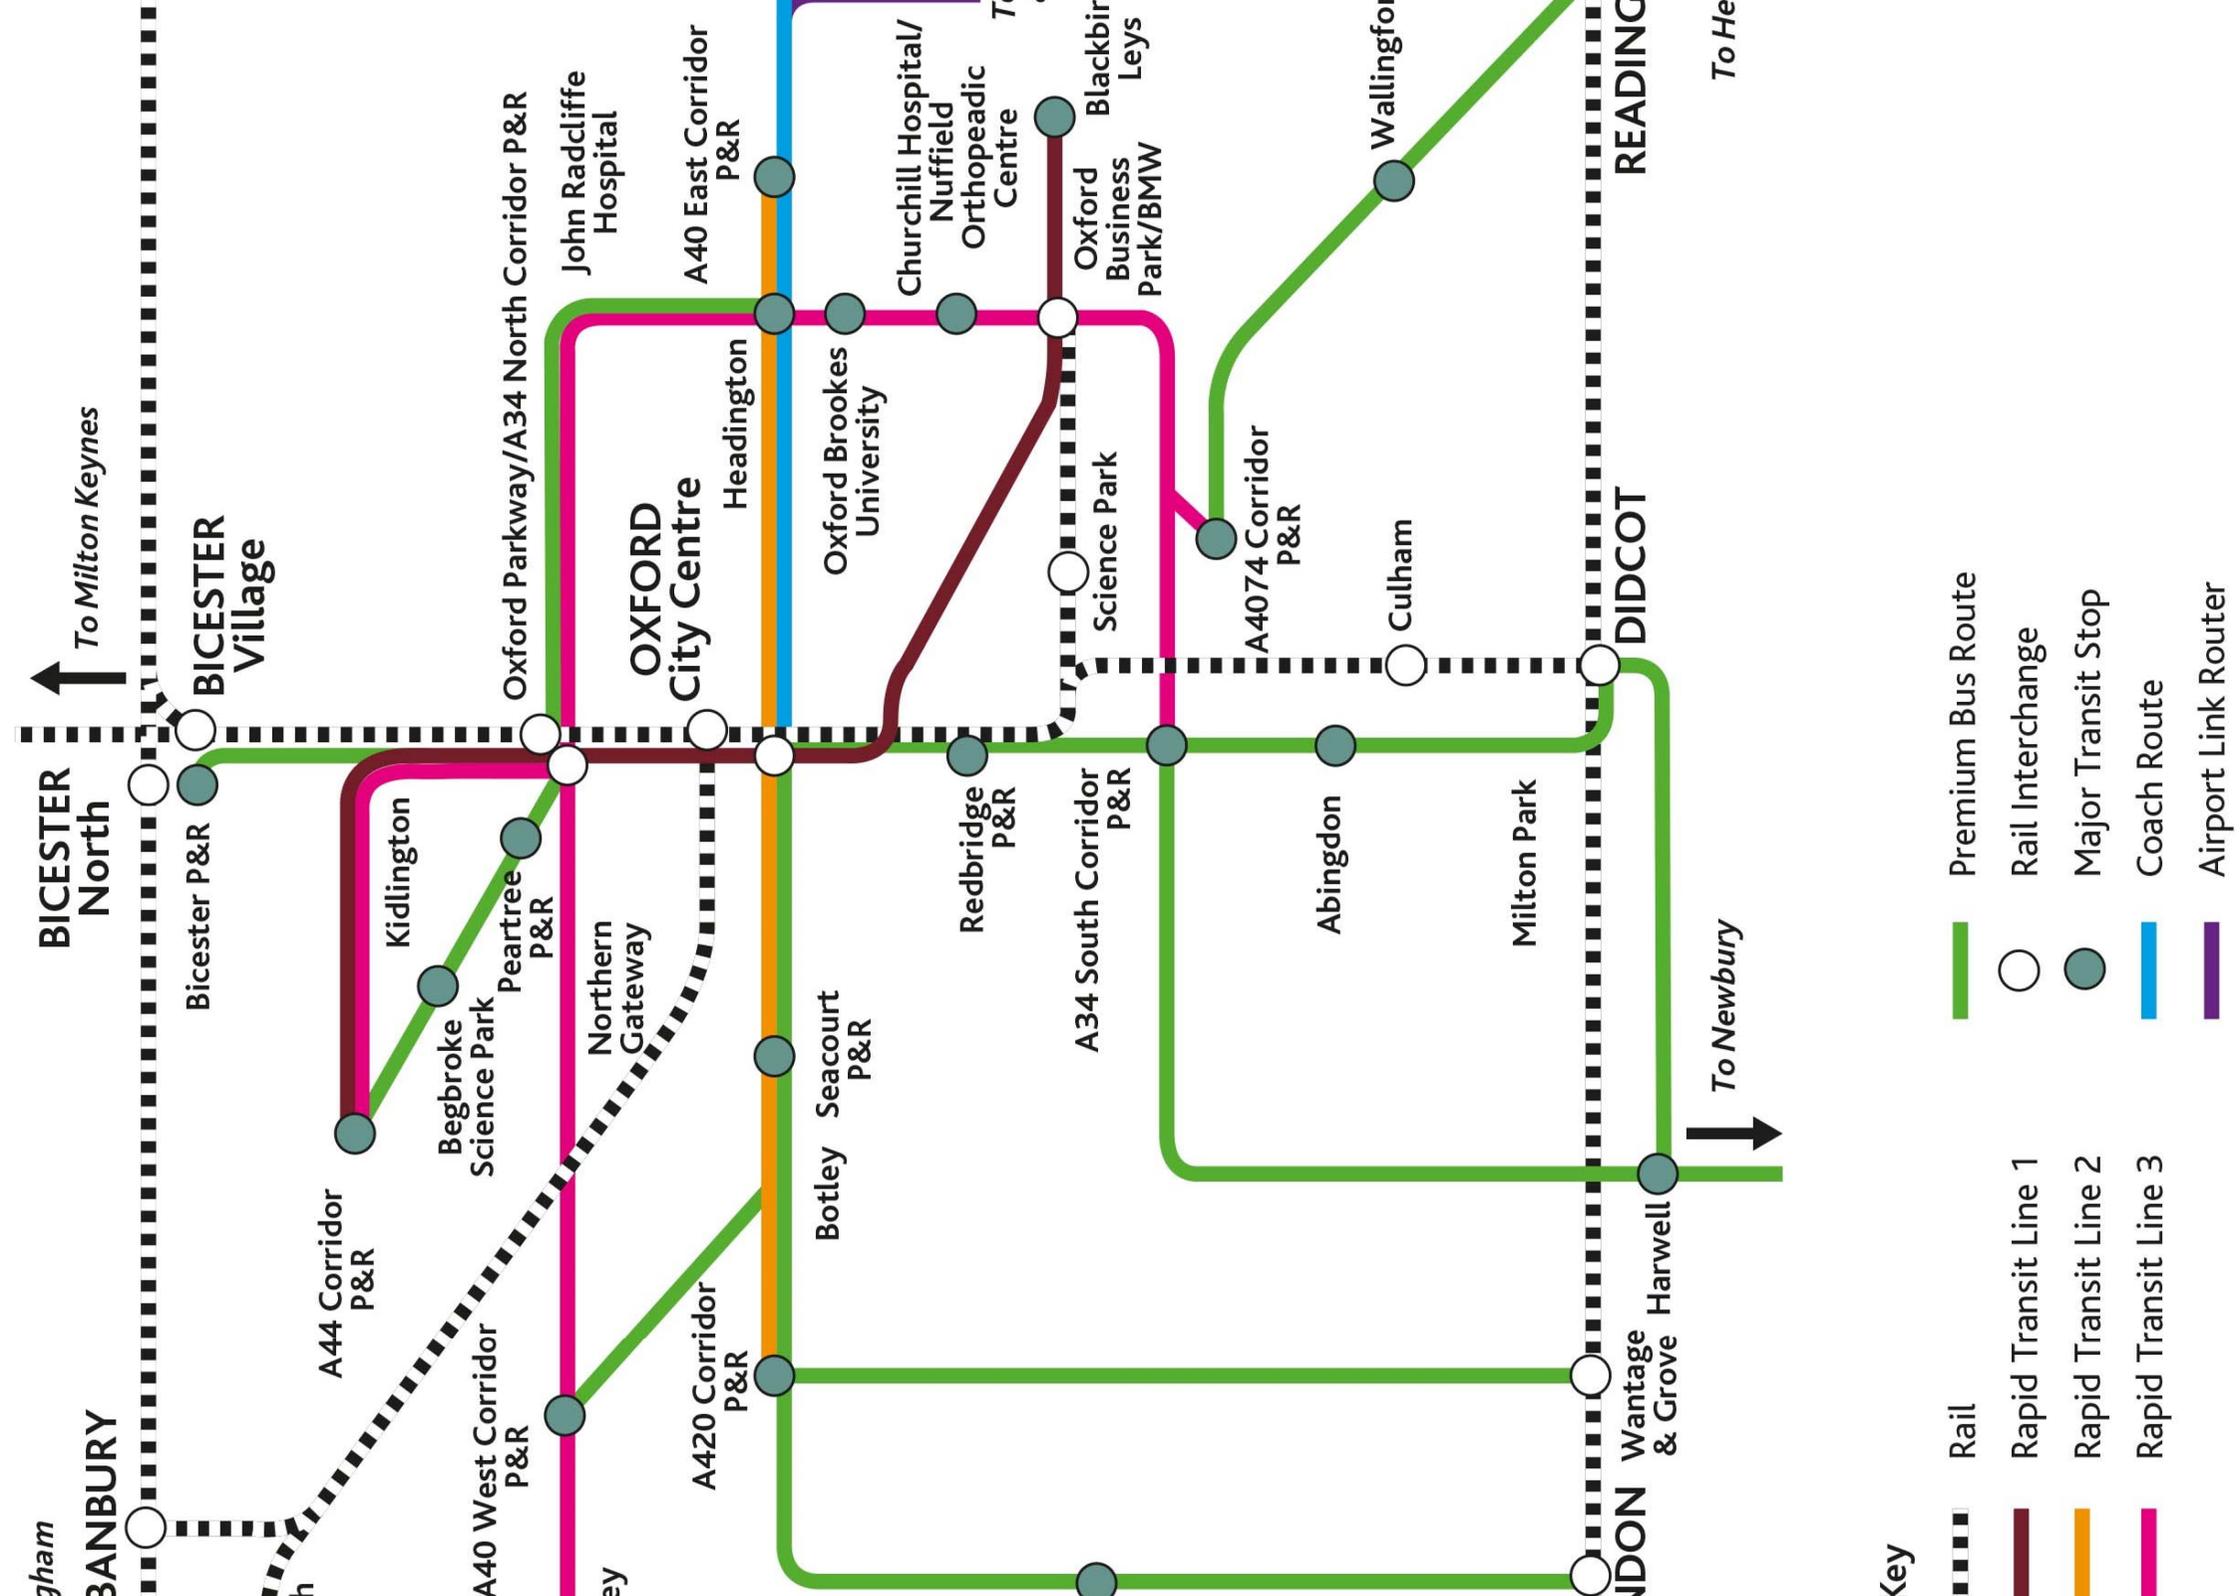

Waste arising's growth tracks Gross Domestic Product (GDP). In times of prosperity, people buy more, undertake renovation projects and therefore dispose of more waste. A circular economy would ensure that the materials are able to be reused or recycled and create jobs but behaviour change and attitudes are vitally important to break the cycle, limit the appetite for 'new stuff', and increase the mainstream acceptance of reuse.

Reuse and repair activities are increasingly being accepted as playing a vital part in addressing social challenges related to poverty and creating paid and volunteer employment as well as training opportunities. Far more capacity is required, however as the industry matures it is important not to lose the valuable social outcomes currently being achieved. Strengthening the social value act could assist this, however it is likely to increase costs (as outcomes will also increase) and this contradicts the current pressure on public services to reduce expenditure.

OXFORDSHIRE HIGHEST VALUE INFRASTRUCTURE PROJECTS: NEEDED TO UNLOCK 100,000 HOMES AND 86,000 JOBS BY 2031 AND CONTINUED GROWTH TO 2050

1. Introduction

The Peninsula Rail Task Force (PRTF) welcomes the opportunity to respond to the National Infrastructure Commission (NIC) call for evidence for its national infrastructure assessment. PRTF also welcomes the strategic overview that the commission intends to apply across the whole of the United Kingdom.

The PRTF published its 20 year blueprint for rail in the South West¹ in November 2016, as a result of a government request to identify what was needed for the region. The PRTF has spent the last 14 months working with the rail industry and the Department for Transport examining and identifying the potential options available to improve resilience, journey times and capacity on our railways to/from and within the South West. This report has identified that improvements to the South West rail infrastructure have the opportunity to contribute to UK plc through potential transport benefits of £1.8bn and wider economic benefits of £7.2bn.

We have suffered from severe weather incidents over the last few years that have highlighted the poor resilience of our rail infrastructure, culminating in the events of flooding across the Somerset levels and the collapse of the cliffs and the seawall at Dawlish, closing large sections of our strategic rail network for several months. Businesses lost confidence, operational costs escalated: an estimated loss of £1.2bn² impacted the economy in Devon and Cornwall for period the Dawlish line was closed.

Network Rail warns that a line closure of between 2 and 7 days every 6 months and significant weeks of, closure to the mainline at Dawlish will occur every 25 years today rising to every 4 years by 2065,³ if no decisive action is taken to address the problems. In addition, we suffer from significant levels of service disruption as a result of trains being used that cannot operate past the seawall at times of high winds and waves, further reducing reliability.

The ability to use diversionary routes east of Exeter is limited due to capacity constraints and has a major impact on established local services when London Paddington services are diverted via this route. Travelling west, once you pass Exeter there is no diversionary route available, with a single mainline to Penzance at an average speed of 60mph. It is acknowledged that potential exists to reopen the route between Exeter and Plymouth via Okehampton and create an additional route to that via Dawlish, however if this is a true alternative it would need to be of sufficient speed and capacity to meet the needs of the region, which would include direct access at Exeter and Plymouth to remove the need to change ends and the subsequent time penalties. In addition, there is also the option to provide an additional direct route between Exeter and Newton Abbot that provides an alternative to the seawall route.

The Exeter to Waterloo line is currently underutilised, but it is key to local transport and growth plans around Exeter and serves as an important second strategic link between the peninsula and London. It is constrained by long, single track sections which limit both the number and speed of trains, not just in the peninsula but also in neighbouring authorities of Dorset and Wiltshire.

The connection to Bristol and the Midlands is a critical artery to support regional connectivity, housing growth and the development of key infrastructure, e.g. Hinkley C.

¹ Within this response the reference to the South West applies to the Peninsula, incorporating, Cornwall, Devon, Plymouth, Torbay and Somerset

² Holding the Line? Report for the Devon Maritime Forum (2015)

³ Severe closure of 1 week or more Network rail

The South West is a peninsula, has an overall population of 2.2 million with an equally significant economy of £4.2bn GVA, but is characterised by dispersed communities. As GVA drops 6% for every 100 miles from London⁴, the further down the peninsula the greater the challenges become. Ensuring shorter journey times, with more opportunities to connect at a local, regional and national level is critical.

Transport spending in the South West peninsula has been an average of £35, per head, compared with an average of £97 per head across the UK and it is plain to see that we are trailing behind other areas in investment, a situation that will only get worse as a result of current and planned rail infrastructure projects like; HS2 and Crossrail.

Our trains are some of the oldest in the UK, with an average age of 32 years old and currently unable to meet the regulatory requirements from 2020.

Rail growth over the last 21 years has reached 128%, and continues to grow. It is clear that both network and train capacity will not be sufficient in the future.

In a society that values the ability to work and communicate on the move, the ability to use Wi-Fi and mobile phones whilst travelling across the rail network is at best patchy and at worst unusable.

Our response to this call for evidence is focused around the rail infrastructure requirements of the South West to achieve the benefits identified above.

2. Resilience

The South West peninsula is served by a single mainline west of Exeter and during 2014 was cut off from the rest of the UK through flooding on the Somerset levels, the collapse of the seawall at Dawlish and the landslip between Dawlish and Teignmouth. It is estimated that these events cost the South West peninsula's economy over £1.2bn. This is a known problem having occurred many times since the line was opened in May 1846, the first of these occasions being in October of the same year as opening.⁵ The spectacular failure of the sea wall at Dawlish followed significant disruption in 2012 through flooding at Cowley Bridge outside Exeter, that washed the railway away resulting in 15 days closure, a similar closure in 2014, and this was repeated in November 2016.

The peninsula geography creates over dependency on the reliability of these single rail routes – and limits connectivity. For example, over 100,000 people in north Cornwall and north west Devon effectively have no access to the rail network.

This line is likely to see greater disruption in the future due to the changes predicted to sea levels in the future. Research carried out by Dr David Dawson, Leeds University, predicts that by 2040 the line will be affected by sea levels by up to 40 days a year and by 2060 up to 63 days a year (Fig 1&2), which will cost the rail industry in excess of £15m by 2060.

⁴ PRTF Productivity and Wider Economic Impact Study April (2015)

⁵ Dawson et al 2015- Summary of findings from a long-term study of the Dawlish mainline, southwest UK

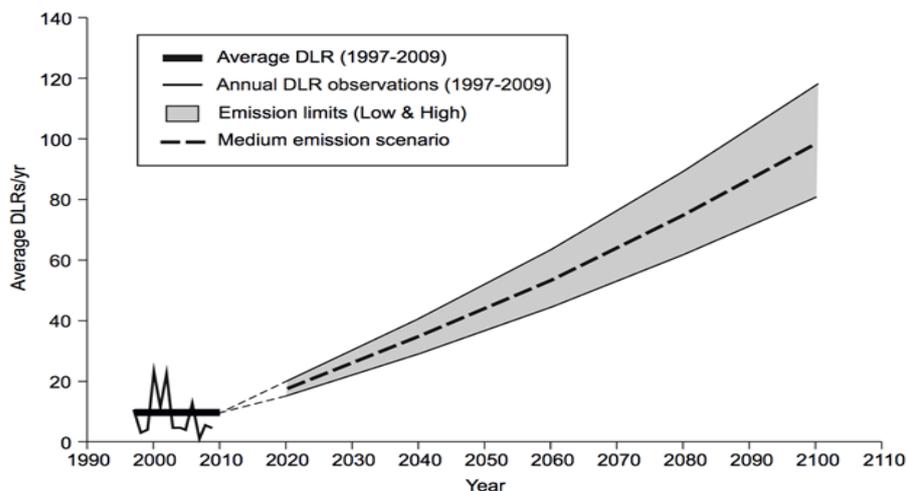

Fig 1: Projections of average number of days with line restrictions (DLRs) at Dawlish as a result of extrapolation empirical trends of sea-level rise and overtopping

Year	Sea-level rise (cm)*	Average days with line restrictions	Increase in DLRs (%)	Annual restriction (%)
1997-2009	-	9.6	-	3
High Emissions				
2020	6.8	19	99	5
2040	22.0	40	320	11
2060	39.3	63	571	17
2080	58.9	90	856	25
2100	80.6	120	1170	33
H++ Scenario				
-	190	269	2732	74

Fig 2: Predicted sea-level rise and estimated days with line restrictions for the 21st century.

The resilience of the rail lines into and out of the South West peninsula cannot just be delivered by Network Rail in isolation and requires a multi-agency approach to deal with the long term problems to drive sustainable improvements based on climate change.

The main rail line to the South West peninsula must be a resilient and reliable connection, protecting our economy, coast and communities with a resilient sea wall and stable cliffs. This does not just mean the seawall and cliffs infrastructure, but also providing an operationally robust service.

Equally other routes that serve the region should be made resilient to prevent further disruption across the Somerset levels and through Cowley Bridge, along with suitable and sufficient resilience along the diversionary route between Exeter and Castle Cary (via Yeovil) to allow London services to operate on a regular timetable when diverted, without compromising local connectivity.

The flooding events on the Somerset levels were identified by the Rail Industry to have cost in the region of £5.15m for the winter of 2011/12 based on Schedule 8 delay compensation payments. In addition, over £3m was spent on remedial works. The direct costs to NR of the 2013/14 events were estimated at £4m of immediate repairs and £13m in compensation costs.

It was estimated that the direct cost of disruption to the Somerset economy was in the region of £92m and the indirect impact, as measured by GVA, was approximately £13m. Of this

between £13m and £21m was attributed to the direct effects of disruption to the railway network. Approximately 22% of the direct impacts of the flooding of the Somerset Levels and Moors were due to the effect on the rail network

A great deal of work has been undertaken since the flooding of 2012 and the subsequent flooding in 2013/14. The works which have been undertaken by the Somerset Rivers Authority and the Environment Agency across the Somerset Levels and Moors should have reduced the impact of such an event on the railway and reduce the duration of major disruption in the future.

2.1. The PRTF has identified a number of key infrastructure schemes that need to be taken forward to deliver the resilience of the rail line to the South West; these include:

- Resilience of the seawall at Dawlish
- Resilience of the cliffs between Teignmouth and Newton Abbot
- Flood resilience works at Cowley Bridge, Hele and Bradninch and on the Somerset levels
- Trains capable of operating along the seawall during times of high tide
- Suitable and sufficient diversionary routes that are able to allow a suitable alternative service to be operated

3. Journey time

The need to reduce journey times to and from London and other key regional cities like Bristol is critical to the economy of the South West peninsula, and as research demonstrates for every 100 minutes journey time from London productivity decreases by 6%.⁶

Investing in journey time improvements will open up opportunities for the South West peninsula to improve connectivity and productivity, improve our contribution to the UK economy and unlock growth. Improved journey times and increased connectivity improves access to education, housing, employment, leisure opportunities and increases social inclusion, all vital to any thriving economy. More frequent connections to London, Bristol and the Midlands will boost productivity. Vital international connections via Heathrow, Manchester, Bristol, Southampton and Gatwick airports will make business more competitive. Improved access to Heathrow through the Western rail link is welcome.

Our average speed to and from London is only 69mph compared to 90mph on the East and West Coast mainlines and over 50% of our businesses rated faster journey times as a top priority.⁷

It should also be recognised that the South West peninsula is far behind other parts of the UK in relation to journey times and earliest arrivals from London, as demonstrated in figure 3;

⁶ PRTF Productivity and Wider Economic Impact Study April (2015)

⁷ PRTF business survey June 2016

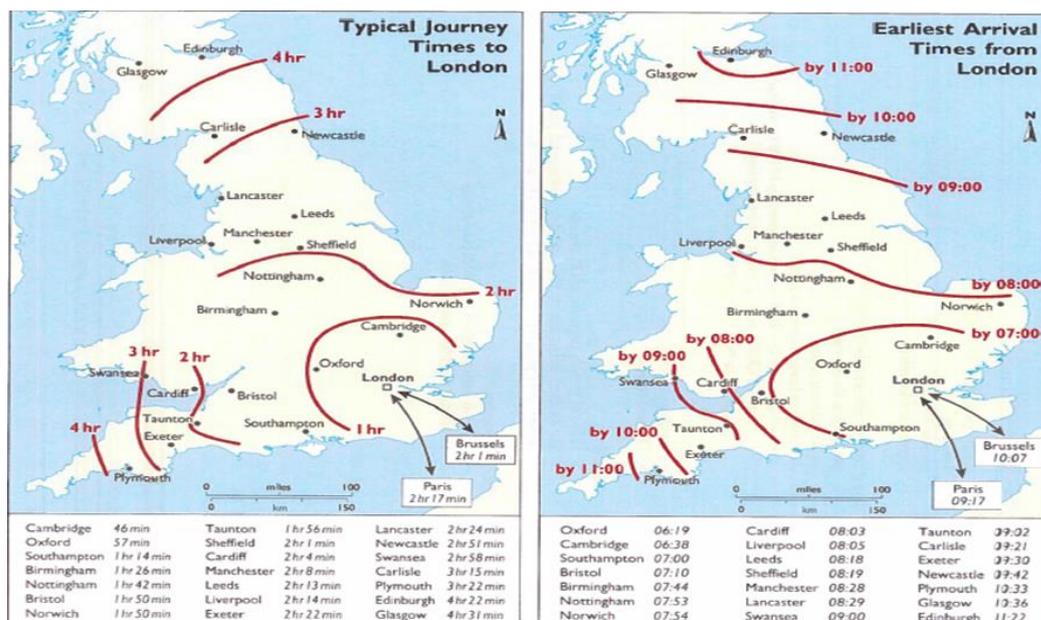

Fig 3. Typical journey times and earliest arrivals across the UK

Access to the rail network is a key element of success for a distributed economy like the South West with many small towns and businesses. Local train services provide access to the inter-city network in addition to linking towns with the major economic centres including Plymouth, Exeter and Bristol. In 2014/15 there were 25m journeys to and from the South West peninsula by rail, a rise of 4.2% over 2013/14, and many of which were to locations other than London.⁸

Through better connectivity and faster journeys there is opportunity and the environment to enable a modal shift to rail, relieving congestion on our roads and improving efficiency and certainty for business. This modal shift also reduces pollution, improves air quality and is an opportunity to maximise the efficient use of the UK's assets. Improving connectivity between urban and rural parts of the South West peninsula also opens up scope for growth with broader travel to work areas, increased tourism opportunities and improved community links.

3.1.

The PRTF identified a number of key schemes that need to be taken forward to deliver the journey time improvements of the rail line to the South West; these include:

- Increased frequency of long distance trains
- Electrification to Bedwyn and line speed improvements between Newbury and Westbury
- A number of line speed improvement schemes between Reading and Newton Abbot delivering 14 minutes journey time saving by 2029
- Further line speed improvements between Reading and Penzance that will deliver a further 19 minutes journey time improvements

⁸ Regional Rail Usage (passenger Journeys) 2014-15 Annual Statistical Release January 2016

4. Capacity and Comfort

Research has shown that the Devon and Cornwall mainline has seen a 128% growth in passenger journeys over the last 21 years with comparable levels of passenger journey growth as other mainlines in the UK, without the level of investment enjoyed by those other lines. It can therefore be surmised that a significant level of untapped demand could be released if investment and improvements are forthcoming to this region. The graph in Figure 4 below demonstrates the increase in passenger journeys.

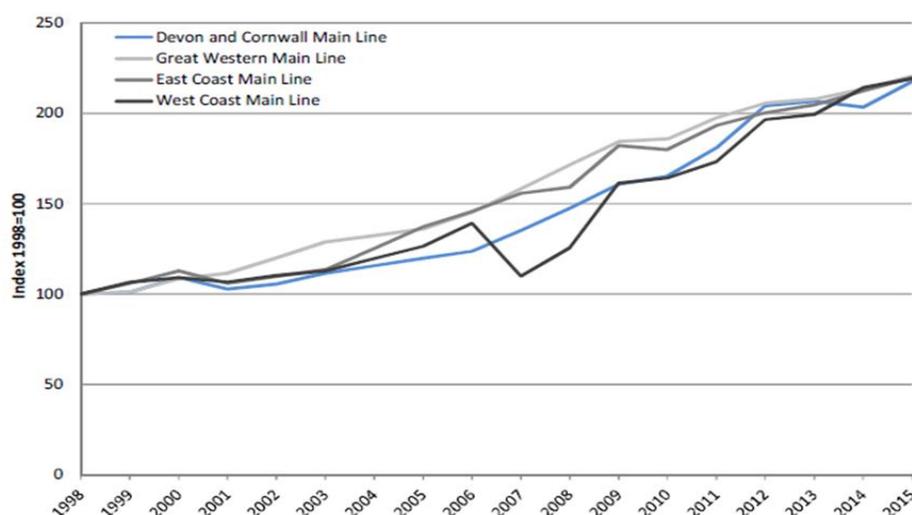

Fig 4; Indexed number of passenger journeys on various mainlines in comparison to the Devon and Cornwall Main Line⁹

Growth within the region has consistently outstripped industry forecasts, with average growth of 5.7% over the last 7 years, compared with the growth rates being used by Network Rail for planning capacity of between 2% and 3.2%¹⁰. This anomaly means that capacity will not be planned and delivered early enough to meet predicted demand. An example of this variation for 2014-15 saw passenger numbers rise by 8% within Devon and 13.1% to Torbay.¹¹ Our previous study into the growth being seen in the South West peninsula identified that industry forecasts for growth in 2019 were exceeded in 2012.¹²

The rail traveller of today expects to be able to access mobile and Wi-Fi services as the norm, with the expectation that it will be available wherever we travel. This is key for business in being able to make travel productive, for leisure and tourism to have access to online or streaming media during travel and for people within the peninsula to carry on with their daily lives.

We recognise that the Government is rolling out free Wi-Fi through the franchise process, but that is only half of the picture. There is no clear single party responsible for delivery of wi-fi and mobile connectivity on the railway system, leading to varied and sporadic implementation. Having the equipment on trains makes no difference if users cannot access or rely the service as a result of the poor mobile phone signal strength in areas that the rail lines pass through, a national rail standard on wi-fi and connectivity would help in establishing the minimum service that should be delivered. This is a particular problem in rural areas such as Wiltshire, Somerset, Devon and Cornwall where topography creates an additional challenge alongside a sparse population. Voice and data signals are affected.

⁹ Dawlish Additional Line study PRTF 2016

¹⁰ Great Western RUS (2010), across Cornwall between 2013 and 2043 in the Western Route Study (2015)

¹¹ Regional rail usage ORR 2014-2015

¹² Spine Report PRTF 2013

Free Wi-Fi on trains is ranked as the 4th highest priority for business in the top ten national priorities for passenger improvements¹³

The benefits of electrification have long been recognised on the railways, probably more so in Europe than in the UK, which include, greater acceleration and faster journey times, lower train failure rates, improved efficiency and reduced noise pollution amongst others. Cornwall County Council and Plymouth City Council commissioned a further study in 2012, refreshed in 2013 on the benefits of electrification to the region which identified that at least £1bn would be saved in operational expenditure over 60 years through electrification in the South West. The introduction of bi mode trains also provides the opportunity to undertake small areas of electrification where there will be a significant benefit to capacity and speed i.e. the Devon Banks.

4.1.

The PRTF identified a number of key schemes that need to be taken forward to deliver the capacity and comfort of the rail line to the South West; these include:

- Improved WI-FI and mobile connectivity, with a clear identification of who is responsible in leading on wi-fi and mobile connectivity along the rail routes
- New line between Exeter and Newton Abbot to increase capacity and allow operation when the route via Dawlish is closed.
- Reopening of the rail route between Plymouth and Exeter via Okehampton
- A series of improvements along the line between Exeter and Plymouth to improve journey times
- Sections of electrification to improve the performance of new bi-mode trains
- Additional infrastructure between the Exeter to Waterloo line to increase capacity

5. Conclusions

There is a widespread consensus across the industry, government and political leadership that the South West peninsula has suffered from under-investment in the railway network, with a resultant loss of quality, reliability and contribution to the peninsula economy.

Much evidence already exists on the contribution to the economy that a reliable and resilient network with quality services and better connectivity will bring. It would be prudent at the very least for investment decisions to be taken in that overall economic context. We have set this out in our 20 year plan which was delivered to Government in November 2016.

The PRTF published its 20 year plan 'Closing the gap' in November 2016, setting out the improvements being sought for the South west peninsula. The 20 year plan outlines these improvements in three phases to 2019, to 2029 and then 2030+, which follow the 3 point plan.

Immediate Priorities to 2019:

- **Invest £284m in resilience**, including commencing the securing of the main rail line through Dawlish and Teignmouth
- **Completion** of committed flood relief schemes
- **Introduce trains** capable of operating along the seawall in all weathers

¹³ Transport Focus Rail Priorities for improvement 2014

- **Invest £2.5m** in GRIP 3 options for the diversionary route East of Exeter
- **Invest £22m** in GRIP 3 options for reducing journey times
- **Increase frequency** to 2 direct trains an hour from Plymouth to London in the new franchise, reducing journey times by up to 10 minutes, whilst at least maintaining existing services
- **Work with the rail industry** to maximise the benefits of the new trains from Dec 2018 and **invest £25m** to make our journeys more productive through on board travelling office, media and mobile/Wi-Fi connectivity.

Medium Term Priorities to 2029:

- **Invest £301m** to complete Dawlish seawall and cliffs resilience, the diversionary route between Exeter and Castle Cary and estuary flood protection
- **Invest £1.5bn** to reduce journey times by up to 14 minutes to Penzance, through infrastructure improvements, partial electrification and franchise renewals
- **Invest £150m** reducing journey times and increasing core capacity on the Exeter – Waterloo line
- **Invest £358m** to improve capacity and comfort through new rolling stock, infrastructure enhancements and phased opening of the Northern Route
- Increase frequency to 2 trains an hour west of Exeter to Bristol and the Midlands

Much has also been made of the heroic efforts of the rail industry to restore services at Dawlish in 2014, however we would like to see a more proactive approach to maintaining infrastructure and development of improvement schemes before failure rather than as a result of. We recognise that this may involve more than one entity and this is where we see a benefit for the route having a strategic infrastructure plan, that maps out and funds a clear progression in upgrades and long term improvements. Key to achieving this is the DfT acknowledging that the infrastructure benefits will deliver real term economic and customer benefits and undertaking the actual work. Commitments have been made, yet remain unfulfilled so we are keen to see deliver.

The PRTF has undertaken a review into the needs and options available to improve the rail service to the South West. It is clear that there is a need for strategically important rail corridors to be considered as a complete entity rather than a series of individual areas or events to ensure that the strategic benefits are realised. The current arrangements where Network Rail considers future capacity, the DfT sets service levels and the operators look to reward stakeholders, appears to miss the point of strategic infrastructure to meet and service the customer and the economic needs of the areas that they serve.

Clearly the ability of Network Rail to undertake a route improvement has been called into question through current difficulties with key projects. The PRTF would like to see the rail route to the South West identified as strategic infrastructure and the options to build a resilient, faster railway explored through different delivery mechanisms, i.e. design & build contracts, where private business takes some risk and deadlines are maintained.

This should include the use of small scale electrification schemes that allow the benefits of new bi mode trains to be realised.

Finally, the South West suffers from only one main line west of Exeter. Moreover, this situation is compounded as although limited diversionary routes are available they have been downgraded to such an extent they are unable to function effectively. In the event of their use, other services are affected, reducing their own capacity or extending the journey time to

unacceptable lengths. We would like to see diversionary routes upgraded to allow a full service to be operated effectively as needs dictate, allowing business and customer to continue to rely on the provision of services.

Pension Insurance Corporation plc (“PIC”) does not regard any of the information in this document as confidential.

About PIC

- 1) PIC is a specialist insurer providing pension insurance buyouts and buy-ins (bulk annuities) to the trustees and sponsors of UK defined benefit (“DB”) pension schemes. At 30 June 2016, PIC had £18.4 billion in assets under management and had insured more than 130,000 pension scheme members.
- 2) With non-callable pension obligations that stretch out decades into the future, we are the natural home for investments that provide secure long-dated cash-flows, such as infrastructure. As such we are enthusiastic about the establishment of the NIC and their consultation programme which seeks to address a real opportunity to repair the broken pipeline of infrastructure projects.
- 3) From a standing start five years ago we have built an internal team which has developed considerable experience and an exceptional track record in sourcing and investing directly into infrastructure debt. We therefore have relevant experience should help be required to develop in-house expertise at other institutional investors and specifically within pension funds.
- 4) We believe that we are now playing a role of real importance to the UK economy by filling the hole that has been left by the withdrawal of the banks from this space. We have invested about 30% of our portfolio in infrastructure debt and have plans to increase the total amount as our portfolio develops. Our portfolio has grown by more than £10 billion over the past three years. We operate in a rapidly expanding sector and expect to have considerably more assets to deploy in infrastructure over the coming years.

- 5) Amongst other innovative direct investments we have completed in the past 18 months, we have invested £100 million in debt secured on the Thames Tideway Tunnel; £75 million in debt issued by Virgin Atlantic Airways, secured on its portfolio of landing slots at Heathrow, the first time this type of transaction has been completed; and £70 million in debt ultimately issued by the Church of England Pensions Board.
- 6) Previous investments in this area by us include the first listed European solar bond, as well as social housing, hospitals, schools and student accommodation. Our business moves capital efficiently through the economy, from generally sub-scale defined benefit pension funds and into infrastructure investments which support jobs and growth. Our scale and expertise allow us to do this more effectively than the majority of pension funds.
- 7) Our pension fund clients include the Pensions and Lifetime Savings Association (PLSA), the Institute and Faculty of Actuaries, the London Stock Exchange, Alliance Boots, Total, EMI, Cadbury, Honda, and the public sector, including DEFRA.
- 8) PIC is authorised by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and Prudential Regulation Authority (FRN 454345).

Introduction

- 9) PIC welcomes the establishment of the NIC and the opportunity to respond to the call for evidence on the National Infrastructure Assessment.
- 10) The UK has an unprecedented need for infrastructure renewal, a government that appears to have recognised the weaknesses of the existing system and investors with pools of capital seeking good quality investments.
- 11) Investment in infrastructure by insurance companies plays an important, and socially useful, role in the development of the UK's economy. Yet the process for procuring infrastructure is difficult and uncertain. Institutional investors require several factors to be able to invest consistently and significantly in infrastructure debt. These factors are:
 - a. The development of a “whole system approach”, which reflects the long-term nature of infrastructure projects and avoids shorter-term political factors affecting the decision making process.
 - b. A predictable deal flow. This would help pension funds and other institutional investors justify building up teams and developing expertise. This creates a virtuous circle of knowledge and confidence, helping more deals to close, lowering costs for borrowers and helping to grow the economy.
 - c. The better alignment of infrastructure investment requirements with the regulatory systems governing institutional investors, such as Solvency II. It is important to make sure that in areas of focus, such as waste and digital, investment risk is managed more sympathetically, perhaps through the creation of investment grade debt structures which work for insurance companies.

- d. The (re-)focussing of (semi) state actors, such as the European Investment Bank, away from opportunities which would naturally attract private sector capital and towards opening up further opportunities by using their balance sheets.
- e. More stability in the planning process.
- f. Making investment more attractive.
- g. Using Public Private Partnerships.
- h. Governance and decision making.

12) PIC would be delighted to help the National Infrastructure Commission with any further work on this topic.

Responses to specific questions set by the Commission

Question 8: Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets? *Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.*

Making investment more attractive

- 13) In principle, infrastructure projects are attractive assets for private investors. They typically offer relatively high and stable returns and can provide a welcome hedge against inflation. Their allure has only increased as long-term interest rates plumb new depths. Pension funds and insurers seeking to match long-term liabilities are perfectly placed to take on the illiquidity of these assets as the cash flows generated from them match liabilities and provide a measure of outperformance.
- 14) The feeling among private investors remains that there is a lack of suitable projects. Infrastructure development in the UK has focussed on a small number of large scale (and high risk) “trophy” projects, as opposed to a larger number of smaller deals. There is also a need for more ready-to-finance opportunities where there is no requirement for investors to involve themselves in the earlier, riskier stages of infrastructure development. Insurers are restricted on their investments due to Solvency II (paragraph 21 onwards), whilst pension funds do not have the necessary in-house expertise to properly assess the risks. We believe this situation can be radically transformed.
- 15) Balancing this lack of expertise in the short term, and encouraging more insurance company involvement in these types of projects, means that the government needs to shoulder more of the early stage risk. Large scale or trophy ventures are typically subject to bidding criteria uncertainties, idiosyncratic contracts, delays in the award of projects and financial approvals, and, reflecting their complexity and technological richness, significant construction risks, as well as the vagaries of the political process. For institutional investors the overwhelming conclusion is that they are not worth the time and effort to understand at this point, let alone invest in.

16) We believe a key objective of the NIC should be to build and then maintain a healthier ongoing dialogue between infrastructure planners and the UK funding markets. In our view there has been a strained relationship in the past, which is now improving. As institutional investors become an increasingly important part of the financing equation, there is a real opportunity now for a more collaborative approach. This would not distort markets, rather it would enable markets to operate more freely.

Predictability of deal flow

17) Compounding the obstacles to investment by institutional investors, outlined in paragraph 15, there have simply not been enough suitable projects to invest in.

18) An unpredictable flow of potential investments means that institutional investors are less likely to invest in building the necessary expertise to allow them to assess risk accurately. The resulting unfamiliarity with risk leads to a safety-first mentality, lowering interest in this area even where suitable opportunities are available. Amongst other issues, this can mean a less competitive tendering process and greater taxpayer expense.

19) It is clear that a lack of follow through on a programme approach to procurement has been frustrating for all parties, including funders. This suggests there is a desire to resolve it and we believe that it is possible to do so.

20) These uncertainties are best exemplified by the ongoing debates around Heathrow, HS2 and Hinkley Point. However, the point is systemic and does not relate just to these projects in isolation. From an investor's perspective, this uncertainty increases risk. And this risk, from a project provider's point of view, increases costs.

Alignment of investment requirements with the regulatory requirements of institutional investors, in particular addressing the limitations imposed by Solvency II

21) The regulatory system for all European insurers, Solvency II, places strict capital requirements on investments that are not based on investment grade (or equivalent) rated debt. This makes it challenging for insurers to invest in some sectors and many forms of infrastructure finance, such as infrastructure equity. A whole-system approach would better align the nation's infrastructure investment needs with the investment requirements of insurance companies under Solvency II.

22) We recognise that this may fall outside the remit of the NIC, but in the interests of joined up government we repeat here the relevant points we recently submitted to the Treasury Select Committee on Solvency II's impact on infrastructure investment.

- 23) A review of the specific rules applied for Matching Adjustment¹ eligibility and the capital treatment of different asset classes could increase the supply of capital to some important areas of the economy. For example, the ability to invest in whole infrastructure projects (not just the debt), or indeed to invest in the equity of key infrastructure projects is precluded by Solvency II, due to the significant capital requirements that currently apply to such investments.
- 24) If the government is to meet its ambitious infrastructure targets with the help of UK institutional investors then the Matching Adjustment and capital rules current in force need to be refined.
- 25) In terms of the Matching Adjustment, we would like to see more pragmatism with respect to the rules around callability and “make-whole” requirements and the need to match in annual cash flow buckets. As an example, we would like to see greater leeway in the longer dated cash flow matching requirements (say beyond 40 years) than is applied to shorter dated cash flows, specifically to be less well matched than shorter term cash flows.
- 26) We see a number of situations where banks wish to sell their PFI / housing association / utility loans as they are no longer capital efficient for the bank to hold. These loans often have very low margins, so offer pre-payment protection implicitly as the funding cost is so low the borrower is not incentivised to repay. However, they do not have explicit “make-whole” clauses so are not eligible for inclusion in the Matching Adjustment Fund under Solvency II. Annuity portfolios are effectively prevented from buying these assets due to the strict rules under Solvency II.
- 27) Similarly, we see a number of project finance / infrastructure transactions which have cash sweeping mechanisms whereby if the project outperforms, excess cash is used to pay down debt. This improves the quality of the asset (due to the deleveraging), but the cash sweep mechanism creates difficulties with Matching Adjustment Fund eligibility because repayment is at par.
- 28) Prior to Solvency II, pre-payment protection in the form of “make-whole” clauses was typically a given for institutional transactions. However, as it is now mandatory for insurers to have pre-payment protection (whereas pension funds and banks don’t need to have it), the insurance industry is at a competitive disadvantage in the lending market, and borrowers can use this as a negotiating tool, in a way they couldn’t before.

¹ What is the Matching Adjustment? Life insurance companies hold technical provisions to ensure they have sufficient funds available to pay their technical liabilities when they fall due. The technical provisions comprise the Best Estimate Liabilities (BEL) and the Risk Margin. The BEL is calculated as the discounted value of the expected future liability cash flows. The default position is to discount the liabilities using a risk-free rate, but companies with highly predictable cash flows, such as pension annuities, can apply to increase this rate using a Matching Adjustment which reflects the risk-adjusted yield on the assets backing the liabilities. The cash flows of the liabilities and the backing assets must be very closely matched in order for the company to be eligible to apply the Matching Adjustment. PIC fully supports the use of the Matching Adjustment for the valuation of long-term, guaranteed insurance liabilities. However, our view is that Matching Adjustment is too restrictive in specifying the characteristics that the assets must display in order to be allowed to be included in the Matching Adjustment calculation.

- 29) A more pragmatic approach to callability / pre-payment protection would therefore be welcomed, whilst appreciating that stability of cash flows is an important requirement for liability matching. It is worth noting that the Solvency I regime had a well understood approach to callable bonds, where cash flows were taken into account on a “call to worst” basis.
- 30) As it stands, it will be a challenge for the NIC to stimulate interest from institutional investors in some sectors of focus, including waste and digital connectivity, which have typically had lower levels of institutional investment because they are perceived to carry higher levels of risk; because there is a perception that returns are poor; and because there is no track record of successful investments. The NIC should look to the levers it has, including subsidies and government guarantees to incentivise this.
- 31) Of the sectors in focus, only transport and energy are currently aligned to the needs of investors under Solvency II. Without further insight into specific risk treatment, it is difficult to see how the NIC will stimulate interest from institutional investors because most of the sectors of focus have historically transferred too much risk to the private sector.
- 32) As the NIC progresses in its work and draws up a National Infrastructure Plan it is important to consider the requirements of insurers under Solvency II in determining how the projects are to be funded. This is particularly the case in the stated areas of focus in this consultation document.
- 33) Judicious use of the government’s guarantee scheme, or leveraging the European Investment Bank’s balance sheet to lower risk in this area, would help ensure that investment by insurance companies flowed into the sectors of the NIC’s focus.

Using Public Private Partnerships

- 34) In the UK, which was something of a global pioneer in the area of Public Private Partnerships (PPPs), these schemes have been bracketed under the term Private Finance Initiative (PFI). The PFI contributed considerably to infrastructure spending over the 15 years leading up to the financial crisis. More than 700 such partnerships were assembled, with a capital value of more than £50bn. This included almost 100 hospital schemes, more than 100 education projects, and around 40 transportation projects and initiatives in areas as diverse as defence and culture. Overall, they were associated with some 12% of total annual capital expenditure over the latter part of that period.
- 35) However, the PFI has been a major casualty of changing political priorities, as well as the banks’ more conservative attitudes to lending, an attitude that has been further encouraged by the losses some banks have made on these projects. Smaller PFI projects in particular were highly dependent on bank finance. The PFI was dealt a further blow by the collapse of the monoline insurers that had hitherto conducted much of the project risk evaluation spadework and lent their stamp of approval as well as their credit enhancement to the bonds issued to finance larger projects.
- 36) Moreover, the more cost-conscious post-financial crisis period saw a growing focus on whether these initiatives were offering sufficient value for money for taxpayers. The net result

is that PFI activities have tapered off decidedly since 2008. The current government has tried to address some of these issues with its PF2 programme, but this effort has yet to reach critical mass.

- 37) We believe that giving new life to PFI should be a central focus of the NIC's efforts to attract institutional investment.
- 38) Under PFI an industry was established around the deal flow, which, whilst having its downsides, was efficient and allowed, in theory, for the taxpayer to obtain better value, because there was lower risk and less uncertainty.
- 39) Today, we seem to have the opposite, where hardly anything is predictable and therefore investors and their advisors can't plan for it. Furthermore, the unpredictability extends beyond the initial planning stages and has become an issue in deciding whether a project can go ahead even quite close to breaking ground, as well as in the financing structure.
- 40) This unpredictability may well be a feature that is hard to remove for the larger end projects, or where they are particularly innovative or complicated. But what we saw under the previous Chancellor was a neglect of the smaller scale infrastructure pipeline, which we believe should be a focus of the new National Infrastructure Plan.
- 41) As regards the largest, most complex, projects, the experience, both in the UK and other advanced economies, is that many of these, such as airports and major railway routes, need a (government) sponsor, even though the bulk of the financing may come ultimately from existing public markets. Government cannot avoid planning, delivering and, to some extent, partially financing projects, at least in their early stages.
- 42) For smaller projects, such as individual hospitals, schools, or renewable energy plants the government is also important, albeit for somewhat different reasons. Historically, equity for a small infrastructure project, such as a PFI deal, came from the sponsor and potentially the constructor, with the debt component supplied largely by the banks. But with the banks now deleveraging, this financing component is in short supply, even though the potential equity providers are still present.
- 43) Hence, to encourage pension funds and insurance companies to invest there is a burgeoning need for government to involve itself in:
 - Managing the procurement process so as to ensure that the debt is delivered to (non-bank) investors in a suitable form, and with feasible timelines in respect of pricing and delivery of funds.
 - Developing risk transfer systems, such as guarantees and stand-by lines of credit.
 - Incorporating into the overall financing assessment the setting of tariffs and user charges for which it is responsible, whether directly or indirectly.

Question 10: What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Stability of the planning process

- 44) From an investor's perspective much time and effort, and therefore expense, is required to do due diligence on each and every project. In practice, investors will have to live with the risks inherent in these investments for decades, with limited opportunity to sell. Moreover, they depend on the cash flows to match pension payments, so have to go to considerable trouble to make sure that the deal works. The uncertainties inherent in the planning system can therefore rule out investments in some types of projects at a very early stage.
- 45) A lower level of interest from institutional investors means that the project developers would have to offer a higher yield to make the project more attractive, ultimately costing the taxpayer more.
- 46) However, there are well-managed and well-run processes which can serve as model projects. For example, PIC recently invested £100 million in debt secured on the Thames Tideway Tunnel, the 25 kilometre tunnel underneath the River Thames in London. This was an innovative investment which required much hard work before the deal was signed. The key aspects of the transaction were:
- The £100m size of the transaction was split across four tranches.
 - A long deferral period (4-5 years), providing certainty of funding cost for the borrower, but reducing cost of carry, with an unusual feature of no funding drawn on day one to help match the cash flow needs of the construction works.
 - A unique inflation linkage, whereby this is the first transaction with inflation linkage with such a long deferral period.
 - The maturity profile has been sculpted to match PIC's long-dated liabilities, a feature which also benefits the borrower as they require long-dated funding.
- 47) We feel that this excellently run project serves as a model of best practice for the following reasons:
- It was a well-managed procurement process.
 - Good co-ordination across different government departments and between government and Thames Water.
 - Rigorous evaluation process reduced bidders down to a very small number, with an emphasis on quality rather quantity, helping to guarantee funding.
 - Smart use of government financial support, which was complex but did not require overall government guarantee. This:
 - i. Was more efficient for government finances.
 - ii. Enabled investors (prepared to commit to the credit work) to obtain a higher return.
 - It was a resource efficient process for investors as the financing competition was based on a firm proposal:
 - i. Certainty of financing provided by initial commitments from banks.

- ii. Institutional debt competition was more efficient as it was not split between different bidding groups.
- iii. The higher certainty of outcome incentivised institutions to commit resources.

Governance and decision making

48) In terms of governance, a stable and accessible long term programme of infrastructure investment will need to be:

- Co-ordinated across different departments and levels of government.
- Devoid of policy reversal and prevarication over key decisions.
- Supported by regulatory stability (especially in relatively regulation heavy sectors such as energy and utilities).
- Cognisant of the ability of construction firms to supply the necessary resources to do the job.

National Infrastructure Assessment – Call for Evidence Response of PIANC UK

Introduction

PIANC UK is the UK Section of the Permanent International Association of Navigational Conferences (PIANC), a worldwide body with a membership in most major maritime nations.

PIANC is the forum where professionals around the world join forces to provide expert advice on cost-effective, reliable and sustainable infrastructures to facilitate the growth of waterborne transport. Established in 1885, PIANC continues to be the leading partner for government and private sector in the design, development and maintenance of ports, waterways and coastal areas.

As a non-political and non-profit organisation, PIANC brings together the best international experts on technical, economic and environmental issues pertaining to waterborne transport infrastructure. Members include national governments and public authorities, corporations and interested individuals.

This document presents PIANC UK's response to the National Infrastructure Assessment Call for Evidence issued by the National Infrastructure Commission in October 2016.

PIANC UK's approach to the Call for Evidence

PIANC UK is of the opinion that port infrastructure and, to a lesser extent, inland waterway infrastructure plays an absolutely essential role in the economic activity and future development of the United Kingdom. It also enables the internal connections between the various land masses forming the British Isles. While the provision of port infrastructure by the public and private sectors aims to meet the demand for transport, decisions taken by these bodies not only have a major impact on the towns and cities in which the infrastructure is located but also influence choices by shippers and travellers that, in turn, have huge impacts outside the immediate vicinity of the ports and, indeed, nationally.

In the planning, design construction and operation of port and inland waterway infrastructure PIANC UK is strongly of the opinion that a balance of economic, societal and environmental factors must be adopted. PIANC operates, internationally, through four main Commissions that address respectively Ports, Inland Waterways, Recreational Navigation and Environmental Issues. It is disappointing that the issue of sustainability is not specifically referenced in the Call for Evidence; in the Call for Evidence the term 'sustainable' is linked only to the term 'growth'. PIANC UK is of the opinion that the Commission should clarify whether it is referring to growth that takes into consideration the three aspects of sustainability or whether it is concerned with recommending measures that ensure that growth itself is sustained.

National Infrastructure Assessment – Response to Call for Evidence

In response to the National Infrastructure Assessment Call for Evidence, PIANC UK has chosen to respond to the issues raised by the Commission by means of a statement that presents four main themes and identifies a number of principles that it believes should be adopted. These principles are referenced to the Commission's questions, as indicated.

Transport of Goods

For transport of goods via the UK's ports and waterways the following principles would maximise the long term benefits of investment in infrastructure:

- An infrastructure planning system linked to demographics and land use. Q2, Q10
- Specific planning for the movement of goods at national, regional and local level. Q2, Q10
- A national strategy for goods distribution recognising major import and export ports, locations of production and consumption, and the location for distribution centres. An objective of this strategy would be to develop efficient links between these points - which may not match established patterns of freight and passenger transport, e.g. routes for cargo from Dover to locations like Purfleet, Daventry etc., or Southampton to the West Midlands. It is important the underlying assessment is based on an accurate understanding of true cargo origins/destinations in the UK and overseas, as the routes used today may not be the shortest but reflect present limitations in infrastructure capacity or quality. Q2, Q10
- Designated locations in and/or around major cities and conurbations for distribution functions, with good access to strategic road network, rail and waterways. At these locations goods could be transferred from larger to smaller vehicles for inner-city distribution, or for reverse flows such as waste, consolidated into larger shipments and into greener modes such as barges or trains. These locations could be decided at a local (city or county) level. Q14
- A balance of competition and sustainability that recognises the importance of port choice for shippers and shipping lines in fostering competitive and resilient supply chains, e.g. no failure at a single point should obstruct major supply chain routes such as cross-channel traffic via the Dover Straits. Q9, Q11
- Government funding support for ports and logistics initiatives that reduce emissions per tonne-mile by re-shaping supply chains to more energy efficient models e.g. allowing use of larger vessels, greater parcel sizes, transfer from road to rail, faster more efficient cargo handling systems, new more efficient warehousing, etc to encourage faster adoption of more energy efficient methods. Q11
- Long term planning that facilitates mode shift when volumes become so large a change of mode is justified, e.g. anticipating provision of rail freight links to ports that currently handle containers and RoRo or bulk without a rail link, rather than assuming all future growth can or should be accommodated by roads. This would have knock-on implications for rail network planning far beyond the port in question to ensure train paths can be provided with adequate gauge clearance. Q11

National Infrastructure Assessment – Response to Call for Evidence

- Rail improvements in terms of debottlenecking freight linkages across the UK, improving route availability for freight, as well as port connections themselves. Q2, Q3, Q11
- Planning of ports and roads that anticipates driverless technologies, e.g. to facilitate a seamless flow for a container from quayside to inland distribution centre, via road, without a human driver. This technology has the potential to change supply chains significantly as the most time sensitive element (in cost terms) for some lorry movements is the driver. Without a driver slower but lower impact routes may become viable for shippers, e.g. taking trucks on ro-ro ferries to ports further inland such as Tilbury. Q13

Transport of Passengers

The following principles should be considered:

- Removal of road bottlenecks around ports – particularly ports located within towns - and increased journey time reliability. Q2, Q3
- Safeguarding of sites close to urban centres and passenger transport hubs for use by ferry or river services, to avoid the situation whereby viable ferry terminal locations become further and further away from centres of population and transport links, therefore less accessible and ferry services less viable. Q2, Q3
- Requiring full integration, in terms of timetabling and ticketing, between public transport services (on rail & road) and shipping services. Q2, Q3

LNG Fuelling

The UK needs to encourage and anticipate LNG fuelling of vessels, partly driven by the Emissions Control Area requirements, through incentives and the creation of availability at key locations. This would have the benefit of reducing emissions within port areas as well as positioning the UK to play a major role in supplying LNG fuel for passing Channel traffic. The Thames, Mersey, Humber, Severn and the South Coast are key locations to capture passing trade. Q13

Network Resilience

Considerable emphasis has been placed in recent years on ensuring that transport networks are resilient in times of disruption from weather, maintenance works, security activity, terrorist incidents, etc. However in the transport field in the last 50 years, almost all developments have resulted in the reverse being the case. The flows of goods and passengers have tended to concentrate on fewer routes with larger flows. As a result resilience has been removed and when disruption occurs the incidents are far more severe, partly because of the concentration of the flows and partly because of the lack of alternatives.

National Infrastructure Assessment – Response to Call for Evidence

Resilience can only be ensured by providing immediately available capacity on alternative routes or transport modes. With the private sector, or the public sector on commercial terms, required to fund an increasing proportion of transport infrastructure, immediately available alternative capacity will not be built. PIANC UK is of the opinion that, if resilience is to be provided and can be justified by means of a cost benefit analysis, it will inevitably fall into the category of capacity that can be funded but cannot be financed. The level of provision of port infrastructure in many European countries is far more generous, and more cost-effectively financed, than in the UK and, as a result, lack of resilience is a far smaller issue. PIANC UK encourages the Commission to investigate means of evaluating the economic, societal and environmental benefits of the provision of resilience in the transport system and to develop methods to justify and finance its provision. Without such an approach, resilience will remain a major problem which will result in the UK not appearing to be “open for business” and place it at a major disadvantage to our European neighbours. Non-market measures have to be taken in the electricity supply industry to ensure system resilience; the same should apply in the transport market. Q8, Q9.

February 2017

We very much welcome the Commission's criteria to collect evidence over a long time horizon. The short termism that has driven many national investment programmes has resulted in prioritisation led by pragmatism, not big ambitions. If we genuinely want to transform the country's economy in a fair and balanced way, we need to be prepared to set ambitious goals, and to recognise the relationship with investment in other enabling factors such as skills, housing and services. All of these factors need to be properly planned, sequenced, integrated and funded to deliver a more prosperous and sustainable national economy. The City council and its partners are already delivering against an ambitious growth agenda and look forward to your support in addressing the strategic infrastructure challenges we've highlighted.

Yours Sincerely

(job title redacted)

Enc: National Infrastructure Commission Call for evidence

NATIONAL INFRASTRUCTURE COMMISSION

Call for evidence

10 February 2017

Context

Plymouth is one of the largest cities on the south coast and the 15th largest city in England with a population of approximately 262,700, an economic output of £5.2 billion, 108,000 jobs and a further 100,000 people in its travel to work area. Plymouth is the most significant economic centre in the south west peninsula and the largest urban area in the Heart of the South West (HotSW) Local Enterprise Partnership, making it a key location for growth. However, considered part of the far south west, the city is located 230 miles from London with the average train journey times of 3 hours 15 minutes and a route that is subject to low levels of reliability and resilience. Our nearest core city is Bristol, located 120 miles, or 2 hours away.

The HotSW partnership area is united by a common ambition to raise productivity levels. Our area has suffered from historically poor levels of productivity, with productivity in the HotSW currently below 80% of the UK average (measured on a GVA per capita basis). A key economic priority for Plymouth, the Heart of the South West and our partners is to address and improve this productivity performance. As part of our approach to this we aim to facilitate innovation and growth in our key opportunity business sectors such as marine and advanced engineering which represent the city's main areas of specialisation.

One of the biggest challenges facing the city is our peripherality and connectivity with the rest of the UK and beyond. This situation has been exacerbated over decades by longstanding chronic underinvestment in our physical infrastructure, an overreliance on a few key routes (road and rail) leading to issues around capacity and resilience, and the lack of an agreed, long term, sequenced and integrated strategic investment plan.

We recognise that Plymouth cannot be seen in isolation and the city's growth is mutually dependent on the wider infrastructure provision across the south west peninsula. The city is therefore not only working across the HotSW partnership to tackle the issues of productivity and connectivity (through the Peninsula Rail Task Force) but is also working across local authority areas to develop a joint local plan setting out an integrated approach to how we plan for new homes, jobs and services across local authority boundaries.

Plymouth City Council, South Hams District Council and West Devon Borough Council are preparing a Joint Local Plan (JLP) for Plymouth and South West Devon through to 2034. The vision is to create a highly successful sub-region whose people and businesses benefit greatly from having a major city and network of high quality market towns and sustainable rural settlements, set within beautiful countryside and natural environments.

An Infrastructure Needs Assessment has been undertaken in support of the JLP which identifies over 400 projects across Plymouth and South West Devon at an estimated total cost in excess of £1.5 billion. The Assessment will inform decisions on plans, programmes and priorities and demonstrate to funding bodies and investors that the local authorities have a clear understanding of the areas infrastructure needs through to 2034. It provides an assessment of the funding required to achieve the aspirations for the Plan Area and identifies any gaps in funding provision.

For the Plymouth Housing Market Area the assessed need for new homes, jobs and services will require substantial investment in infrastructure. Current assessments make provision for at least 26,700 new dwellings and over 300,000 sq.m of employment floor space, providing for over 13,000 jobs. The population of the JLP area is predicted to grow by around 35,000 by 2034.

We hope that the Commission will consider the wider implications of infrastructure provision across the JLP area and HotSW Peninsula through its assessment process. This level of development and population growth requires significant investment in infrastructure at both a local and peninsula level.

Plymouth has significant opportunities to compete in global markets but our current infrastructure provision and connectivity challenges represent a major barrier to our future transformation. We believe that the National Infrastructure Commission, through a weighted assessment process, can take a more regional approach to rebalancing infrastructure investment and unlock areas such as ours to turn around decades of low productivity and poor connectivity.

Cross-cutting issues:

I. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

High value investment programmes supporting growth in Plymouth (and the Joint Local Plan area for Plymouth and South West Devon and wider Heart of the South West) include:

- **The 20 year blueprint for rail in the South West**

We need to increase connectivity and capacity together with improvements to rail network resilience to help meet Plymouth and the South West's challenging growth agenda and unlock our potential. This submission supports that of the Peninsula Rail Task Force (PRTF) to the Commission.

The only major rail transport corridor of the far south west runs through Plymouth (from Exeter into Cornwall). Plymouth needs a resilient railway that has fast journey times with sufficient capacity and connectivity to and from Plymouth from the south east (London) and the rest of the UK. The city supports the collaborative efforts of The Peninsula Rail Task Force and the priorities for investment set out in the recent report 'Closing the gap: The South West Peninsula strategic rail blueprint'.

- A resilient network which is not susceptible to regular disruption due to adverse weather;
- Faster journey times to London, the South East, the Midlands and the North; and
- Greater train capacity and facilities to enable travel time to be used productively.

A key aspect of this is digital signalling and the city has already engaged with the private sector to work together on developing this capability within the region and how we could bring economic or social gain as a result of product development, intellectual property rights or skills.

The PRTF's blueprint proposes a long-term programme of investment in rail links between London and the south west which would unlock a host of benefits, generating an additional £7.2bn of GVA and £1.8bn of transport benefits through improving rail journey times to Paddington from Penzance by 26 mins, and similarly benefits of £677m from improving the journey time from

Exeter to Waterloo by 30 minutes¹. The blueprint also suggests productivity benefits from simple improvements such as high quality, uninterrupted Wi-Fi connectivity enabling productive use of the travel time and tackling the lack of resilience in the south west transport networks which are increasingly vulnerable to extreme weather events.

The events in Dawlish and Teignmouth in 2014 highlighted that our rail network is highly vulnerable to impacts of extreme weather events and that urgent action is required to address resilience and improve the connectivity to London and other major cities to unlock business potential. It was estimated that these events cost the South West peninsula's economy over £1.2bn. In 2016/17 we have seen further closure at Cowley Bridge due to flooding and the loss of cross country services at Dawlish when high tides and strong winds are forecast which is becoming a frequent event. Further background is available at <https://peninsularailtaskforce.co.uk/closing-the-gap-the-south-west-peninsula-strategic-rail-blueprint/>

- **Plymouth Railway Station**

Plymouth is the busiest station in Heart of the South West LEP and third busiest in the South West after Bristol Temple Meads and Bath Spa, yet it is the only station in the region that has not undergone major redevelopment or is included in a plan for major redevelopment, since the 1960s. At present the station presents a poor impression for rail passengers arriving in Plymouth and the station needs a major overhaul. There is a need to improve the passenger experience and provide a new gateway for passengers arriving and leaving the station.

Furthermore South West Peninsula passenger numbers have rocketed by 128 per cent in the last 21 years, twice the national average and still growing. Research has shown that compared to other mainlines in Great Britain, demand on the Devon and Cornwall main line has grown at a similar pace since 1998, despite the volume of investment in upgrades and new services being lower than on many other routes. Assuming demand continues to grow at the same rate as recorded until 2015 (5.7%), demand will reach the 2043 level predicted by Network Rail by 2031, when comparing with the conservative Office for Rail and Road growth rate² www.Peninsularailtaskforce.co.uk. Rail is the most important public transport mode for longer distance trips to and from Plymouth.

The comprehensive redevelopment of the existing station and surrounding area involves the landowners Plymouth City Council and Network Rail working in collaboration with Great Western Railway (the franchise holder) and Plymouth University. There is also strong support from Cabinet Office / LGA through the One Public Estate Programme (OPE). The first phase will lever in circa £40m to £50m in private sector investment and is dependent on £5.5 million funding (including a bid under Growth Deal 3) for the construction of a new multi storey car park and demolition of the existing car park. This will enable the creation of several development sites which will attract inward investment in to the station area and funding for the improved public realm and accessibility. The initial phases of development will need to be completed by 2020 in advance of the Mayflower 400th anniversary celebrations where Plymouth and the south west will be on show internationally.

The planned redevelopment will lead to the creation of over 920 jobs. It will transform the station into a state-of-the-art, visitor-friendly facility, able to address current and future demand and providing high-quality business and retail accommodation as well as an 11,000m² academic faculty

¹ Economic Impact of Rail Network Improvements

² Dawlish Additional Line assessment Feb 2016

for the University of Plymouth which will need to be operational in advance of the 2020 academic year.

- **Road connectivity**

Plymouth is a designated port on the Trans-European Network, an international ferry terminal, home to Europe's largest naval base and a regional hub for fuel at Cattedown port; however the City of Plymouth is located 40 miles away from the M5, our nearest motorway. We would ask that the M5 is extended to include Plymouth. The A38 through Plymouth to Exeter (M5) is one of only two major road corridors down the spine of the Peninsula (the other being the A30). In the meantime upgrades to improve journey time reliability on the A38 are vital to the city and wider peninsula.

The Joint Local Plan (JLP) authorities have an ambitious programme of highway improvements but key to the realisation of growth is the role of the A38, Plymouth's main strategic road link, (managed by Highways England). To ensure that goods and services can be delivered efficiently and reliably, the A38 must provide a high quality and resilient connection to the M5/M4 corridor. Effective operation and maintenance coupled with modernisation of the A38 is crucial to the growth of the city and the JLP therefore seeks a commitment that government will ensure that the A38 is fit for the purpose of delivering growth in the city and will develop the A38 into an 'Expressway' between Plymouth and Exeter. The JLP also seeks a commitment to major improvements of the intersections of the city and the A38: including the junctions at Deep Lane, Marsh Mills, Forder Valley, Manadon and St. Budeaux.

The A38 through Plymouth to Exeter (M5) is one of only two major road corridors down the spine of the Peninsula (the other being the A30). Upgrades to improve journey time reliability are vital to the city and wider peninsula. Five strategic transport infrastructure projects along the A38 Corridor are of particular critical importance to the successful delivery of the growth ambitions for Plymouth and South West Devon. These are:

1. Deep Lane junction
2. Marsh Mills roundabout
3. Forder Valley interchange
4. Manadon roundabout
5. St Budeaux by-pass

Funding for road improvements at strategic pinch points requires far greater funding than simply improving junctions. These infrastructure improvements will not only support the growth of Plymouth and its role as the major regional city in the south west peninsula but improve the Plymouth section of the A38 corridor into and out of Cornwall and support the strategic connectivity of the Naval Base.

The inclusion of Plymouth on the Department for Transport's Strategic National Corridors would also be welcomed in order to keep pace with the economic and population growth in the city and across the south west. Plymouth is the largest city in England with no direct road or rail connections on the network of Strategic National Corridors and is a designated port on the Trans-European Network with strategic commercial links to Spain and France, criteria that should be considered when national corridors are designated. The lack of connection to the Strategic National Corridors inhibits our plans for growth and for investor and developer interest.

We also acknowledge that infrastructure improvements in other parts of the UK can unlock growth and connect Plymouth and South West Devon to wider markets as well as improving traffic flow into the south west. This includes improving journey time reliability on the A38/M5/M4 corridors and on the second corridor to London and the south east via the A303/A358/A30

corridor are also vital. The wider economic impact of improving the A303 corridor is £41.7bn over 60 years³.

- **Protecting and strengthening Her Majesty's Naval Base (HMNB) Devonport and Dockyard's strategic role**

Devonport Naval Base is the largest Naval Base in Western Europe currently home to the Type 23 frigates and the primary UK location for deep maintenance of surface ships and submarines including base-porting options for the Type 26 and Type 31 frigates. HMNB Devonport is of vital importance to the UK's defence capability and is important to our overall marine offer. It has world class infrastructure and a highly skilled workforce. It directly supports 8.4% of Plymouth's total Full Time Equivalent (FTE) employment and 11.8% of its Gross Value Added (GVA). When direct impacts are included, this rises to 10.7% of FTE employment and 14% of GVA.

The Dockyard and Naval Base encompasses facilities for highly specialised engineering work including the refuelling and defueling of nuclear submarines. With significant government investment to upgrade these facilities it is vital that the right infrastructure is put in place in the city to accompany this future growth. This includes motorway links and improving the road junction capacity around the Dockyard and Naval Base at Camels Head, the A3064 Wolseley Road and St Budeaux Bypass to accommodate the increased use of this section of the road network. This should also be accompanied by the right skills supported by a national skills plan, please see our response to question 9.

- **Protecting port infrastructure and activities**

Plymouth's waterfront is home to the Royal Navy, strategic defence facilities in the navy dockyard and at Ernesettle, commercial ports in the Cattewater, international ferry terminal at Millbay, a large fishing fleet in Sutton Harbour as well as various marinas and other marine-related uses. Supporting the expansion of port activities in Plymouth with modernised and accessible port infrastructure, and safeguarding the existing port infrastructure including the mineral wharves and fishing industry is critical. The fishing industry brings over £12m in GVA to Plymouth each year, and accounts for around 15% of the entire English fishing fleet by FTEs-supported. Furthermore, in order to support the priority marine employment sector, protecting sites with deep water berths is key.

- **Flood and water management**

The 60 miles of Plymouth's waterfront (accounting for inlets), consisting of the land and the adjacent waters, is arguably the city's most valuable asset and is central to its identity as Britain's Ocean City and vision to become 'one of Europe's most vibrant waterfront cities'. It is essential that government acknowledges the ongoing infrastructure costs and requirements to maintain this unique asset, for example Plymouth Hoe and Foreshore, Mount Batten landing point and Plymouth breakwater (owned by the MOD). With climate change and increasing prevalence of stormy conditions these assets will require repair and ongoing maintenance. The Environment Agency flood zones are based on still water measurements rather than factoring in more extreme and increasingly prevalent stormy conditions. Work is underway to address this failing, the impact of which will be to add further to the infrastructure costs required to support development in the coastal zone and so reduce the viability of development.

Furthermore, drainage in the city centre and waterfront growth area is hampering development. Combined sewers are increasingly at risk of flooding due to extreme rainfall events. Plans to increase residential density in the city centre will require new surface water sewer infrastructure

³ A303 Prospectus and Wider Economic Impact 2013

to release capacity in the foul sewers. The scale of investment is likely to be more than can be supported by new development, and it should be forward funded so that there is a functional network in place for new development to connect to.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Plymouth's ports provide an opportunity for the city to maximise its export potential and contribute to the UK's international competitiveness, in particular Plymouth ports are of national significance for landing and exporting fish. The fishing industry brings over £12m in GVA to Plymouth each year, accounts for around 15% of the entire English fishing fleet by FTEs-supported and is the largest English port by volume of landings. Despite its growing importance nationally, and as a hub for marketing fish from across the south west peninsula, the last major investment in the city's fishing port facilities was 1992 and a major upgrade is required to improve productivity, regulatory compliance and to remain competitive. The fish quay is in a central location in historic Sutton Harbour and redevelopment would have wider regeneration benefits.

Protecting key access routes and where appropriate safeguarding existing land and infrastructure is important. This includes the need to support demand-driven investment in road-rail-port interchanges in order to optimise the economic value to the city of its port and help meet demand for storage and distribution of freight. The facilities at Millbay Docks used by Brittany Ferries for cross channel ferries and international cruise liners has major potential to be developed further as a gateway (as set out in the Plymouth and South West Devon Joint Local Plan). However for these assets to be fully exploited, investment is required to connect different modes to the national road and rail networks.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Recent experiences developing the new community of Sherford highlight that front-loading infrastructure funding is fundamental to the success of new communities and the pace of housing development. In order to 'de-risk' sites for developers Government commitment and support for upfront infrastructure funding is vital if it wants to deliver housing on the scale it has set out in recent announcements.

Plymouth supports an integrated approach to investment in infrastructure as outlined in the Heart of the South West's Prospectus for Productivity which looks to establish an Infrastructure Commission for the HotSW area. Complementing the National Infrastructure Commission the HotSW body would bring together local partners to formulate a HotSW Strategic Infrastructure Plan. As part of this Plan partners could explore more flexible funding models that would enable infrastructure to be designed, planned and targeted at agreed areas of growth as set out in Local Plans; for Plymouth and South West Devon this is clearly set out in the Joint Local Plan. In order to facilitate this Government would need to allow local areas to control investment for example they would need to lift pooling restrictions for those areas that wish to enter into new arrangements for the use of CIL, Section 106 and other capital investments.

The identification of the infrastructure requirements for the JLP are set out in an Infrastructure Needs Assessment which will inform decisions on plans, programmes and priorities for the areas infrastructure needs through to 2034. It provides an assessment of the funding required to achieve the aspirations for the Plan Area, and any gaps in funding provision, and hence will also support the

review of the Community Infrastructure Levy for Plymouth and decisions over the use of Section 106 agreements.

4. What is the maximum potential for demand management, recognising behaviour constraints and rebound effects?

There is considerable potential for demand management on the highway network. With one or two exceptions outside London there is currently unrestrained access to the network resulting in significant congestion at peak time. Examples may include smart ticketing. Improvements to the way we interrogate data and links to the 'big data' and 'smart cities' agendas could improve demand management and influence behavioural change.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

This is a very real issue for Plymouth and the wider peninsula. Whilst improving access to Plymouth and the peninsula through new or upgraded assets is key the maintenance of our existing assets, given the size of our road network in comparison to the rest of the UK places a disproportionately large burden on local authorities. The use of cost-benefit analysis and ensuring there is a strong business case in place are critical when making investment decisions and local expertise should be used to assess whether it is a more efficient use of funding to repair and maintain infrastructure or to replace it with modern infrastructure.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Improvement in the way procurement is undertaken for significant infrastructure projects could be made by government making available a national template on which local areas could draw to drive economies of scale through the procurement process and reduce complexity.

7. What changes in funding policy could improve the efficiency with which infrastructure funding services are delivered?

The current policy of 'funding competition' to allocate large tranches of resources to local highways and transport projects is extremely time consuming and costly to local authorities. Authorities are developing schemes 'at risk' until capital funding is secured and risk the sunk costs reverting to (scarce) revenue pressures if bids are unsuccessful. Making funding available for feasibility studies to develop well thought through projects would be welcomed.

The Industrial Strategy sets out a commitment to drive growth across the whole country and signals its intention to use infrastructure investment to address productivity weaknesses across the country and imbalances between areas. Investment in infrastructure should take account of the economic potential of Plymouth and its contribution to the wider south west peninsula. There is a risk that investment in rail and the Strategic Road Network is only prioritised in areas where it already provides for business productivity. Highways England, through Route Strategies will determine investment priorities for RIS2. The problem will be that those investment decisions will be based on where problems are most severe and where action is the greatest. This approach tends towards investment being prioritised at areas that are already heavily invested in and perpetuates the peripheralisation of the regions such as the south west. A National Infrastructure Assessment weighted to addressing the regional disparities would be greatly welcomed.

One of the key barriers is the siloed nature of funding pots and inflexibility and fragmentation of the current funding regime. The government's current approach to infrastructure spending disadvantages regions such as the south west and therefore Plymouth. This perpetuates years of underfunding in Plymouth and the wider area and the city's ability to transform. An example of this can be shown in the Autumn Statement announcements for Growth Deal 3. The Government will award £1.8 billion to Local Enterprise Partnerships (LEPs) across England. £556 million of this will go to the North of England, £392 million to LEPs in the Midlands, £151 million to the East of England, £492 million to London and the South East and £191 million to the South West. Clearly only a proportion of this will come to the HotSW LEP and subsequently even less for Plymouth.

Plymouth would support a Single Investment Framework for the HotSW area which would bring together public and private investment into a fund that would deliver on the priorities for the area and bring significant efficiencies. Infrastructure investment needs to be planned over the long term such as a 20 to 50 year period not on 5 to 10 years in order for it to be truly strategic.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

No response provided.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

One crucial factor relates to the skills shortages and distortions in the market created by the demand for specialised skills in competing areas. Particular examples relate to the requirement for construction skills which are already in high demand and short supply, and with the imminent significant potential for Hinkley C to draw labour from other areas. Similarly, with the need for specialist nuclear skills at Hinkley, and a growing requirement at the naval base in Devonport for refuelling of nuclear submarines and the Royal Navy's overall maintenance programme.

The risks around skills shortages need to be better understood and planned for at a national level. We would welcome a national skills plan that accompanies the infrastructure plan but with the ability to contribute to it from local and regional intelligence sources. This will aid our planning process, ensuring that resources are located in accordance to need and in turn contribute effectively to the aims and objectives of the UK Industrial Strategy.

We are addressing skills shortages in construction and the built environment through our Building Plymouth Programme and evidence from this points to not only skills shortages but also the need for a responsive skills infrastructure with the ability to flex funding and it them fit for purpose as well as have the ability to deliver localised training products from local centres instead of having to rely on centres elsewhere which are costly to employers. We know there is demand here from our work to date and it is increasing.

As a city we have recognised the importance and contribution that STEM skills makes to our sub region as well as recognising current STEM skills shortages; our STEM strategy is based on growing, keeping and attracting STEM talent. Our Regional STEM Centre of Excellence provides part of our infrastructure from a combined funding package that has enabled this, but as we anticipate an increase in demand for these skills from cross cutting sectors, then this capacity will need to increase as part of our skills infrastructure.

We therefore support the government's Industrial Strategy and in this instance key areas of STEM, Maths, English and Digitalisation of the workforce. We would also like to work with government on the development of an Institute of Technology.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

A challenge for the city is the difference in land values across the country and therefore the contribution to infrastructure from developers. The whole viability assessment process is not currently fit for purpose. Local authorities are ill-equipped to challenge developers' claims that delivery of infrastructure is not viable. These issues cause significant difficulty in securing sufficient funding to deliver the infrastructure required, meaning development impact is often not appropriately mitigated. To avoid this, the planning system needs to be better equipped to either control or capture land value uplift. In Plymouth our approach to challenging the viability assessments of developers has led to increases in both S106 financial contributions and affordable housing but the ability to fund the necessary infrastructure remains a significant issue.

Furthermore, Regulation 60 of the Community Infrastructure Levy (CIL) Regulations makes provision for a percentage of CIL receipts to be used to pay borrowing costs. Currently however the percentage of CIL that can be used to pay back loans, as prescribed within the Regulations, is set at zero. There is also provision for the Secretary of State to change this and allow repayments, specifying the percentage that could be applied.

Often, and particularly in Plymouth's case, infrastructure needs to be provided up front, to enable growth, and before the benefits of that growth have been secured. Not being able to apply CIL funds in this way could be an impediment to growth. We therefore request that the Secretary of State issues a direction that allows a percentage to be used to make repayments on loans.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Plymouth and the wider HotSW is the ideal location to trail blaze natural capital-led productivity growth. It is rich in natural capital, spectacular coastline, and substantial land area within National Parks/Areas of Outstanding Natural Beauty.

The area is reliant on abundant natural assets and the ecosystem services that derive from them to power economic growth. Our coastline, moorlands and countryside attract more domestic tourists than any other UK region. Employment in sectors that depend directly on natural capital, such as agriculture and fisheries, is proportionately higher than any other UK area. However, in contrast, there is also more potential for increasing economic benefits from natural capital than in any other region.

For this reason, we need the National Infrastructure Commission to support areas such as Plymouth and the wider HotSW to develop local strategies that can deliver sustainable infrastructure projects that protect and enhance the natural environment but help deliver on our productivity objectives. Many of the digital industries for example cite natural and cultural capital as pre-requisites before making investment and locational decisions: the quality of the south west's natural capital is a significant draw and part of its essential character.

We should also recognise the ability of the natural environment to offer natural solutions to some of our biggest infrastructure challenges, such as flood management. The natural environment offers the potential for significant benefits at relatively small levels of investment.

In addition, there is no routine allocation of infrastructure for bus networks or walking and cycling networks as part of sustainable transport schemes. There is some flexibility for Local Authorities to use existing capital grants however this can be limited. We would therefore suggest that specific funding should become part of routine national funding allocations for these networks.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

We would like to see public realm improvements for transport schemes acknowledged as core benefits by the DfT and included in the WebTAG guidance for Business Cost Ratio (BCR) calculations. A good example of this would be public realm improvements at Plymouth Railway Station creating an enhanced experience for commuters and visitors alike, as cited in the response to question 1.

Transport

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Our travel studies already demonstrate our networks have limited capacity and demand continues to grow. Commuting patterns are such that overall 71% of the working population of the Heart of the South West LEP live and work within the area. Plymouth sees a +4,700 gain from inward migration of commuters. The support for Broadband and rail improvements could help to influence more sustainable travel and work patterns and reduce problems at peak periods.

Government should enable the market to come up with technology solutions and then form appropriate frameworks for managing new technologies as they mature. A flexible and agile approach is needed to enable rapid response to change as it will be impossible to predict what the technologies and impacts will be. It makes sense to plan ahead in relatively short periods (15-20 years) so that sensible investments can be made for the medium term allowing change to happen in the longer term. It is clear that autonomous vehicles and smart cities technologies will have a radical impact over a relatively short time period.

14. What are the highest value transport investments to allow people and freight to get into, out of and round major urban areas?

As set out in question 1 our rail, road and port infrastructure are the highest value transport investments linked to movement of people and freight. We acknowledge that further work could be done locally in partnership with bus/rail/ferry operators to deliver a more joined up transport system across all modes of transport at key locations within the Plymouth Travel to Work Area.

Smart technologies will become an increasingly important area of investment to facilitate efficient movement into and around urban areas. As new technologies mature and vehicles become increasingly autonomous it could be possible to re-allocate more of the road-space and parking space and dedicate it to other modes.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

There are just two main road routes from London into HotSW: the M4/M5 and the A30/ A303, of which much is a single carriageway trunk road. Both routes are prone to disruption due to road accidents, adverse weather and congestion, making travel times unpredictable and unreliable. An obvious solution to the risk of dependency on the M5/M4, would be to make the A30/A303 a dual carriageway from beginning to end, a project that many consider vital. Partners are also working to deliver series of improvements on the A30/A303 corridor and to address a series of Pinch Points across the LEP area.

Future investment on the Strategic Road Network is fundamental to achieving the ambitions of the Plymouth and South West Devon Joint Local Plan. Plymouth does not currently host an airport and rail connections are vulnerable to disruption and breakdown and suffer increasingly due to severe weather events. Strategic connectivity from Plymouth to the wider economy is a significant issue for Plymouth and the wider HotSW LEP alike. Plymouth is reliant on a single rail line and a single trunk road (A38) for connectivity with the rest of the UK. Plymouth's ambition to grow its population from 262,700 to 300,000 by 2034 will need to be supported by the proportionate level of investment in transport infrastructure.

As stated in the response to question 1, of particular significance in the Plymouth and South West Devon Joint Local Plan area are junctions on the A38 at Deep Lane, Manadon, Marsh Mills, Forder Valley and St Budeaux by-pass. Peak time congestion at these junctions is impacting on Plymouth and South Hams' ability to deliver significant numbers of new homes

Authorities in the south west welcome the opportunity to engage in this consultation and would like it to be recognised that they want to work with Highways England and Network Rail in developing the evidence base and development of schemes for RIS2 and CP6 respectively.

16. What opportunities does 'mobility of service' create for road user charging? How would this affect road usage?

No response provided.

Digital Communications

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

A Full Fibre infrastructure network providing symmetrical and ultrafast connectivity across the country is currently acknowledged as the way forward for fixed Broadband infrastructure. Existing programmes achieved significant uplift in the numbers of premises receiving SF broadband (24 mbps) in a relatively short time, largely by utilising and upgrading existing infrastructure. However a number of these premises will have to be revisited to achieve Next Generation Access (NGA) (30 mbps) speeds. Dated copper networks are being superseded by fibre technology and are unlikely to merit significant or long term maintenance investment. Investment needs to be made as soon as possible as demand increases rapidly and feeds economic growth.

Government should encourage commercial providers to provide this infrastructure. However gap funded or public/ private collaborations should be considered for areas which are not yet commercially viable. Particularly those where the public sector is funded to deliver increases in

uptake and exploitation by business and householders in order to make capital investment more attractive to the private sector.

Continual technical developments should mean that most areas will become commercially viable. This is illustrated by the recent Connecting Devon and Somerset (CDS) experience. In December 2016, CDS awarded 4 contracts for the delivery of NGA Full Fibre services on a gap funded basis. NGA broadband infrastructure requires high levels of investment which are secured by very long term returns of around 20 years. This may point to a different investment model using equity investment. CDS recent experience suggested a good appetite in the market for investment in NGA networks with significant private investment being made. Providers are currently using state aid as a barrier to hold back full fibre networks in urban areas by using their commercially planned areas to block development while in practice not investing.

It is also important to add that with the increase in use and adoption of new technologies come increased risks of cybercrime. While not part of our physical infrastructure, cyber security and safeguarding citizen's sensitive and personal information is just as vital in terms of our virtual infrastructure.

18. Is the existing digital communications regime going to deliver what is needed when it is needed in the areas that require it if digital connectivity is becoming a utility? If not how can we facilitate this?

No. The roll out of comprehensive full fibre networks does not match the timeline for development of alternative solutions.

Fixed connectivity

In addition to testing markets and taking a gap funding/ public/private collaboration approach the following should be considered;

- Pump prime poorly connected business parks/zones.
- Promoting effective competition and seeking to achieve a more balanced market rather than continued market dominance by a single provider.
- Pump-priming more remote communities and business parks or co-investment models using public funds.
- Availability of long term low cost finance whether by loan or equity investment.
- Use of "interim" solutions pending a Full Fibre solution.

Mobile Connectivity

National targets mask under delivery in rural areas. It is anticipated that there will be a shortfall of between 6-10 % indoor 4G mobile coverage in Devon and Somerset and a shortfall of around 1 % outdoor coverage for the area. These are significant shortfalls when compared to the national targets.

Mobile coverage around key rail links should be seen as a priority. The lack of clarity over ownership and responsibility for delivery of WI-FI and mobile phone signals along our rail routes appears to create a situation where no one body is responsible. This leads to the current situation where much of the route from Penzance to London does not have connectivity to WI-FI and mobile phone signals. The current obligation to put Wi-Fi on the main train lines linking the south west with London has been complied with only to be let down by the lack of the mobile infrastructure along the routes.

We would advise;

- more consultation (not imposing large lattice masts on communities where smaller less obtrusive masts would be appropriate);
- being flexible - inconsistencies in mapping between operators needs to be considered; and
- reflecting the costs that the market can sustain when compared to annual revenues

Other ways in which mobile infrastructure might be facilitated include;

- amendments to planning and permitted development rights for small cell sites;
- business rate relief for small masts; and
- offer some form of subsidy for more costly connectivity pending a universal Full Fibre network.

Energy

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Please refer to response provided under question 20.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Plymouth has an ambition to reduce citywide carbon emissions by 50% by 2031 on a 2005 baseline. The evidence behind this target

http://web.plymouth.gov.uk/plymouth_co2_2013_report.pdf is based on an assumed roll out of various demand reduction, energy efficiency, smart and low/zero carbon generation technologies. These assumptions are based around the government trajectories established in national Carbon Budgets. A number of these rely on interventions that Plymouth would like to flag as national infrastructure requirements:

Energy Efficient Housing - Plymouth would like to highlight the role increased domestic energy efficiency can make in meeting the NICs objectives. As well as helping to reduce the cost to energy consumers of the transition to a low carbon economy, this approach can also simultaneously improve the quality of life for those living in the UK, particular the most vulnerable. Recognising energy efficient housing as a national infrastructure priority is widely recognised as an significant opportunity to drive new jobs and economic growth (1 million homes per year need to be energy retrofitted to meet Government CO2 targets), whilst at the same time (i) avoiding the societal costs associated with the morbidity that cold homes prompt, (ii) reducing the cost of investment in new power generation, and (iii) decreasing the need for (and cost) of network reinforcement.

(<http://www.ukgbc.org/sites/default/files/A%20housing%20stock%20fit%20for%20the%20future%20-%20Making%20home%20energy%20efficiency%20a%20national%20infrastructure%20priority.pdf>)

Smart Flexible Power Distribution networks: Plymouth calls the NIC to ensure the city and the south west gets the proactive approach to anticipatory grid investment required to support the future growth of distributed generation. Network constraints continue to limit the growth of distributed low carbon and renewable technologies across Plymouth and the wider HotSW LEP area. RegenSW's study <https://www.regensw.co.uk/distributed-generation-and-demand-study-technology-growth-scenarios-to-2030> considered four technology growth scenarios and even the lowest growth option shows distributed generation will continue to grow placing further demands

on the electricity network. The forecast growth in electric vehicles, storage and heat pumps that will be required to meet national carbon budgets and Plymouth's local targets compound this infrastructure need.

Heat Networks - Plymouth recognises through its Local Plan and infrastructure needs assessment the strategic role district heat infrastructure can play in its required energy transition. Plymouth calls on the NIC to secure further investment initiatives such as that being promoted by BEIS Heat Network Development Unit and associated Heat Network Investment Programme. The NIC should also seek to learn from emerging thinking from projects such as Heatnet <http://www.nweurope.eu/projects/project-search/heatnet-transition-strategies-for-delivering-low-carbon-district-heat/>. Plymouth has developed this project and is seeking to explore potential for 4th generation district heating to bring 'smarter' more integrated approaches to energy efficiency and heat supply technologies.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Please refer to response provided under question 20.

Water and wastewater (drainage and sewerage)

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Water supply and demand are not thought to be an issue in the city. However, much of Plymouth's drainage consists of combined sewers, taking surface water as well as foul sewage. The impacts of more extreme rainfall events (heavier rainfall, and more frequently) place increasing pressure on the sewer network, increasing risks of flooding and increasing operational costs. New development provides the opportunity to design separate surface water drainage, but in large parts of the city development sites are isolated from strategic surface water drains. Studies have identified where these are required but there is no adequate funding mechanism to address this particular infrastructure need: Environment Agency budgets are linked to flooding of homes; South West Water funding to amelioration of specific sewer flooding incidents. Whilst all parties recognise the problem, funding the strategic solutions necessary to respond to the impacts of climate change are nonetheless very challenging.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Close working between the Environment Agency, South West Water, Highways Agency and local planning authority / lead flood authority is important. The JLP policies will ensure embedding the issue in the planning process and have to be informed by water companies and housing/development projections.

In Plymouth City Centre and Waterfront growth area, strategic surface water drainage infrastructure needs to be forward funded. This will enable more effective use of s106 agreements and planning consents conditions and obligations to secure on-site SUDs (sustainable urban drainage systems) and connections to a functional drainage network.

Elsewhere in the city new strategic surface water drainage routes have been identified which will require significant public investment for which there is no clear funding mechanism. The availability of dedicated capital funds at appropriate times will enable other public and private funds to be

levered in to upgrade drainage infrastructure to meet the dual challenges posed by climate change and a growing city.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Partnership working and appropriate funding is critical to the success of a whole catchment approach particularly given that this includes areas outside the city boundaries.

Flood risk management

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

As identified in the response to question 1 under flood and water management, our ports and coastal areas are vital to our identity and economy. Protecting and maintaining them in the face of climate change and increasingly prevalent adverse weather conditions is critical. Unfortunately grant determination often requires maintenance and repair to be undertaken on a 'like for like' basis when in fact it is improvements that add resilience to these assets that are required. We would like grant determination to allow for more flexibility to make these improvements. In addition a more proactive approach to planning for future flood and storm events is required. Supporting the MOD to make sure that the naval base and wider port infrastructure is maintained and upgraded to reflect climate change risks should also be provided for at a national level.

Furthermore in terms of addressing Plymouth's challenges around productivity, ensuring that our port, road and rail networks are resilient to flooding is vital. As previously stated in question 1 the events in Dawlish and Teignmouth in 2014 highlighted that our rail network is highly vulnerable to impacts of extreme weather events and estimating that this cost the South West peninsula's economy over £1.2bn. Finally, the resilience of the Torpoint ferry is important to servicing the travel to work area as is Brittany Ferries to our visitor economy and transport of goods to and from European markets. If flood events and storm events prevent either from docking this will in turn impact on the local economy.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

In densely developed urban environments making space for SUDS (sustainable urban drainage systems) is challenging, and their delivery through planning problematic (problems including aforementioned challenges regarding development viability assessments). The public realm affords an opportunity to achieve multiple benefits, which the Council is exploring through a pilot project, but these are unlikely to be cost-neutral solutions for the public sector. Funds are needed to develop strategic solutions in areas with identified problems.

Solid Waste

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Plymouth City Council as part of the South West Devon Waste Partnership has procured 25-year residual waste treatment solution incorporating a high efficiency combined heat and power Energy from Waste (EfW) facility that effectively treats the city's municipal residual waste and meets the city's landfill diversion objectives with less than 2% of the city's waste being sent to landfill.

Under a commercial arrangement, this EfW meets all the power and heating needs of HM Naval Base Devonport and also supplies surplus electricity to the national grid. However, the facility is performing above expectation in terms of efficiency and has surplus heat which could be used for a local district heating scheme to local housing if government grant funding support can be secured towards the capital infrastructure to make such a long-term sustainable green energy scheme viable.

The city's recycling rate has been on a plateau around 33% since 2007/8. A modernisation programme of waste and street services is currently being undertaken with a key aim to stimulate recycling activity, anticipated to gain around 5% increase in recycling.

If higher recycling rates are to be achieved new material markets for reuse and recycling need to be gained but this is not currently financially viable in the current market conditions coupled with increasing pressure on the authority's budget.

Local authority funding support is needed to explore and gain new material markets for reuse and recycling and to deliver continuing comprehensive waste minimisation and recycling educational and community engagement programmes to stimulate the cultural change in attitude and behaviour towards waste needed to achieve higher recycling rates.

A review of the Landfill Tax Scheme is an avenue which could provide funding support through a central fund open to all local authorities or others such as social enterprise, community groups or partnerships to apply rather than the fund being specific to a locality and the landfill operator.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social be)?

Product design is a key limiting factor; in general it is not cost-effective for reprocessors to prepare household goods and appliances, in particular Waste Electronic and Electrical Goods, for reuse and resale. In addition, many products cannot be readily recycled due to the design or type of materials used, i.e. 'black' plastic food trays the colour presents difficulties for recycling or goods that are difficult to disassemble to obtain the components for recycling, i.e. mattresses are difficult to strip to obtain the metal springs.

The eco-design of products is central to achieving a circular economy through the design and use of materials in manufacture that increase product life, facilitate the reuse of goods and enable maximum benefits to be derived from the product components at the end of the product life.

This could be facilitated by increased producer responsibility measures to improve eco-design which are likely to increase design and production costs but could be outweighed from the benefits of increased life and performance of the products leading to improved and increased longevity of natural resource use and in turn leading to a reduction in the environmental impact associated with the utilisation of resources and manufacturing and inevitably a reduction in waste and the related financial costs. Increased employment opportunities could arise from the preparation and resale of goods for reuse and increased recycling of goods.

Funding support for the development of the circular economy is needed to facilitate the growth in reuse and recycling reprocessors and the creation of increased sustainable markets for secondary material use. Funding streams that support the third sector and provide employment and training opportunities particularly for those experiencing difficulties in finding work confer many benefits although funding for this type of activity has become limited. A review of the Waste Electronic

and Electrical Equipment Producer compliance scheme is one such area in which funding opportunities could be created.

Date: 10th February 2017

Dear Sir or Madam,

RE: National Infrastructure Assessment Call for Evidence

Portsmouth City Council welcomes the establishment of the National Infrastructure Commission, and the opportunity to shape the advice to be provided to government on major long-term infrastructure challenges. We are pleased to note that the objectives of the Commission include supporting sustainable economic growth across all regions of the UK, improving competitiveness and improving the quality of life for people.

Portsmouth is a densely populated city that is nonetheless growing in terms of population and economy, despite the physical constraints presented by its geography and the international significance of its environment. It lies in the most urbanised area of southern England and plays an important role both in generating and accommodating economic growth. Both offer - natural infrastructure of international significance.

The city hosts assets of national strategic importance including its sheltered **deep-water** frontage. The Port of Portsmouth comprises Portsmouth International Port and HM Naval Base; neither have a railhead so road connectivity is paramount.

Portsmouth International Port (PIP) is the UK's second largest cross-channel ferry port. It provides an international gateway for over 2 million passengers and up to 1 million cars and freight vehicles to France, Spain and the Channel Islands - 80% of goods consumed on the Channel Islands are exported through Portsmouth. It is the main port in the UK for deep-sea fruit and vegetable imports, with 70% of the bananas consumed in the UK arriving through the Port.

PIP supports 805 direct and 1,595 indirect jobs. It provides an injection of £38.7m into the greater Portsmouth economy and drives an additional £71.3m indirect income. This is set to increase as the Port seeks to increase small to medium-sized cruise calls,

Continued.../

complementing the large cruise facilities offered at Southampton. A recent study carried out by Strategic Transport Solutions identified that the current level of cruise calls to Portsmouth generates £2m income to the city. However, the majority of calls are tourist calls, meaning that connectivity by road between the Port and the city is of strategic importance.

Adjacent to the International Port, HM Naval Base is at the heart of the Solent sub-regional defence cluster which provides 20,000 jobs across the sub-region and contributes over £1.6bn GVA of output. Portsmouth is the base port for half the Royal Navy surface fleet and this drives a strong maritime services sector including integrated ship support, complex software engineering and advanced manufacturing solutions. Associated local businesses include BAE, Babcock, Lockheed Martin, Northrop Grumman, Qinetiq, Serco Denholm Ltd, Vector Aerospace and the Centre for Maritime Intelligent Systems.

The Base will welcome the first of two new QE Class Aircraft Carriers this year. Portsmouth will be their base port, the largest and most complex warships in the history of the Royal Navy. The ships themselves are significant strategic and national assets. They will require around 2,000 crew and associated support personnel with links into the local economy and wider supply chains. Multiplier effects mean that with every £1m spent by the base £0.75m of additional spend is generated locally; and every 100 jobs support up to 66 jobs elsewhere.

Taken together, the Port of Portsmouth's assets provide the anchor for the Solent's global marine and maritime sector, contributing 20.5% of sub-regional GVA, 5% of private sector jobs and 7% of manufacturing in the area. However, as the **National Policy Statement for Ports** makes clear, Government policy is to enable port development to cater for long-term forecast growth in volume of imports and exports by sea, enabling a competitive and efficient port industry capable of meeting the needs of importers and exporters. This means that there is a compelling need for substantial additional port capacity over the next 20 to 30 years, and a clear imperative for the transport infrastructure necessary to support increased capacity. Equally, supporting nationally important strategic defence assets will require reliable and upgraded infrastructure (most notably in relation to transport and energy). The QE Carrier arrivals will certainly create demand on infrastructure and draw on a pool of skilled labour across a national market, meaning that good connectivity is essential.

Base-porting the QE Class Carriers in the city creates an immediate requirement around **energy** supplies. The new high voltage substation at Portsmouth Naval Base will support the energy requirements of the ships whilst in port. Each ship will host an independent distribution network capable of managing equivalent energy to power 5,500 family homes. It is as yet unknown if the upgrade to the energy supply will be sufficient to provide for the occasions (up to ¼ of the year) when both Carriers will be in Port at the same time.

Investment in the Strategic Road Network (SRN) is critical to support access but it is the end of the journey and entry to the city that takes a disproportionate amount of time, with the same routes used by commuters, business (including freight) and visitors.

Continued.../

In Portsmouth, significant investment in the **Portsmouth City Centre road scheme** is needed from where the M275 enters the city. This would provide a fundamental re-design of the most strategic access route into the City Centre and beyond to the Naval Dockyard. This would strengthen network connectivity both north to the "City Deal" development sites at Tipner and Horsea Island as well as south to Gunwharf (retail and leisure centre), the Historic Dockyard and the Seafront. This strategic route carries just under half (46%) of all inbound traffic at morning peak and will be under additional pressure with the base-porting of the Carriers.

More significantly, the majority of future development set out in the Local Plan to 2026 will be on the western side of Portsmouth with a concentration of that development within the City Centre. The increase in development across the whole City is expected to lead to a 41% increase in inbound traffic at the morning peak, the majority of which would be along this M275 and western corridor.

The **Portsmouth City Centre road scheme** is of the utmost importance to the City. It is essential that traffic flows continue to be efficient and avoid being a drag on the productivity to the existing concentration of City Centre businesses and the Port of Portsmouth interests. Importantly, it is necessary for the Port of Portsmouth to maintain the current (and differentiated) competitive advantage in an increasingly competitive international market in order to secure their future attractiveness for growth. It will secure significant transport benefits and be a catalyst and enabler for the additional housing required and employment growth in a tightly bounded, densely populated City.

Without this critical piece of transformational infrastructure for the City, the productivity and future growth prospects of our Marine and Maritime sector will be jeopardised, the extent of development which can progress in the city will be severely constrained, and Portsmouth's role as a world class venue for sporting and leisure events would be compromised, affecting the growth of the visitor economy.

It is not only road connectivity that is an issue for the city, but **rail connectivity** too. Rail travel to Southampton from Portsmouth is slow (45 - 60 minutes for a 20 mile journey, compared to Nottingham - Derby or Newcastle - Sunderland (both 20 minutes for 15 miles). As a further example, from Portsmouth it can be quicker to get to Gatwick than to Southampton Airport. This results in use of the M27 as the default option, resulting in chronic peak period congestion. Rail access between Portsmouth and London is unacceptably slow (a 75 mile journey takes 96 - 129 minutes, compared to Bristol Parkway to London - 115 miles in 100 minutes). This connectivity challenge is becoming even more pronounced as rail access to London from other towns and cities is enhanced. This is detrimental to efforts to build the identity of the city and the region in wider markets.

Continued.../

Portsmouth's "island city" nature also means that there is particular relevance to **flood defence**. Considerable work has already taken place to improve defences, and the next projected phase is the Southsea flood defences. Portsmouth City Council in conjunction with the Environment Agency need to improve a further 2.8 miles (4.5km) of Southsea's seafront and provide coastal defences to reduce flood risk and avoid circa £1bn of direct damages within the city for the next 100 years.

The project is significantly advanced with outline designs and ongoing consultation identifying leading options for infrastructure improvements. The Outline Business Case has been reviewed by the Environment Agency and Defra and now awaits final approval from HM Treasury. This transformational project will:

- safeguard critical infrastructure serving the wider city and region (sub-stations, gas network, roads, water)
- reduce flood risks to 4,114 existing homes and 704 non-residential properties
- unlock development sites in the coastal zone to enable the delivery of 1,000 new homes (following review of the Portsmouth Plan this could increase by enabling further sites to be released for development)
- improve coastal access and promote linkages along the seafront (including to Southsea Town Centre) and wider city
- deliver an attractive waterfront that increases the city's draw as a safe place to live, work and invest and enable the Seafront to grow as a world class events space
- protect significant heritage assets including Southsea Castle, Southsea Common, Long Curtain Moat and the Kings Bastion.
- safeguard significant nature conservation assets

This work has been identified as 'critical infrastructure' needed to support the development proposed in the Portsmouth Local Plan and future growth in the city. Without this the ability of the city to generate and absorb growth will be restricted. Naturally, the costs are significant - the projected whole life cost is £114.5m, with a construction and risk cost of £87.4m.

Therefore, as well as supporting the responses made by the Solent LEP and the Partnership for Urban South Hampshire, the council strongly proposes that the National Infrastructure Commission focuses on:

- Importance of internationally significant infrastructure, such as deep water ports
- Improved strategic connections from Portsmouth to London, particularly rail
- Improved highway access to strategic bases, including the Port of Portsmouth (International Port and Naval Base)
- Improved energy infrastructure to support immediate needs around Carrier base-porting
- Flood defence to unlock and enable growth.

Continued.../

Additionally, we urge the Commission to consider develop recommendations around the **governance structures** required to prioritise and deliver significant infrastructure projects. There are a number of general issues worthy of consideration. One is the extent to which often out-dated administrative and political boundaries can influence the provision of investment in infrastructure and delivery of economic growth. These can inhibit economic growth - so many of our cities are 'artificially' constrained in their growth by their civic rather than economic boundaries.

Current policy to address some of these matters through provision for Combined Authorities is thus far proving an insufficient remedy. Attempts to achieve a Mayoral Combined Authority for the Solent have been frustrated because it is seen as a threat to the corporate entity of organisations, inhibiting the growth agenda and the provision of an additional £30m per annum for infrastructure from HMT as part of the Solent Devolution Deal agreed with HMT, BIS and DCLG in March 2016.

One final point of particular relevance to Portsmouth is the requirement for a more joined up process of **transferring sites between Government Departments** where Department are 'compensated' for any asset transfers but not necessarily from each other - maybe a Government held central pooled fund to facilitate asset transfers could be considered? In Portsmouth and the surrounding area there are a number of complex strategic sites, particularly defence, where the nature of Government landholdings adds greatly to the challenge of bringing development forward.

I hope that, taken alongside other responses from partners in the region, this provides an outline of key infrastructure issues in the city and region, and where we would wish to see particular focus in the work of the Commission. We believe this City has exceptional assets for our national economy but also that there is more required in terms of support for infrastructure if the full potential is to be unlocked and realised.

I would be very happy to develop any of the issues touched on or to follow up this letter with a meeting.

Yours faithfully,

Leader of the Council

Submission to NIC CfE February 2017: Waste Infrastructure

[name and organisation redacted]

NB: This is an edited version of a forthcoming paper “On a voyage of recovery: a preliminary review of the UK’s resource recovery from waste infrastructure.” The document should be read as a whole, but here, we cross-reference to the relevant sections that address the individual questions in the NIC CfE with regard to waste, or resource recovery from waste (RRfW), infrastructure.

Question	Answer
Cross-cutting issues	
1	The highest value investment would be in establishing an “Office for Resource Stewardship” to replace regulation in the sector by environmentally-focused organisations; changing the perception of the industry from one that is tasked with preventing pollution to one that is tasked with protecting UK resources [see §8 esp. 8.6, 8.9], mandating data collection in the sector to promote the emergence of robust markets for recycled materials [see 8.4, 4.1, 4.3, 4.4] and establish distributed responsibility for materials up and down the supply chain [see 6.1, 8.7].
2	See 8.9, 5.4, 8.10.
3	The relationship between waste infrastructure and housing (i.e. residents) is crucial. Recycling targets and secondary material markets can only be achieved if household collection systems are matched to local RRfW infrastructure and behavioural changes promoting e.g. reuse are encouraged. See 3.2, 5.5, 6.2, 6.3.
4	Demand management in this context means reduced production of waste and in turn reduced consumption of disposable materials, increase reuse and changed design practices to promote refurbishment, dismantling etc. See 1.8, 5.7, 6.1, 6.3, 7.5.
5	Not explicitly addressed
6	See 1.7 – the market is difficult to penetrate in many ways for smaller enterprises. Lack of data makes it difficult to project resource flows and hence assess investment risk and uncertainty in the regulatory landscape associated with Brexit does not help [4.2-3, 5.6, 8.5]
7	See 4.2, 8.6-7.
8	See 4.2 esp. footnote 5, 6.2
9	Some analyses suggest that we can only avoid a capacity gap if the ability to transport waste across the country is retained; this introduces a dependency on transport [3.1-2]. The use of energy from waste is a small percentage of our total energy generation capacity and so the interdependence with the power sector is small. The biggest resilience threat is the current reliance on export of refuse-derived fuels (RDF) to the EU to fill our capacity gap for waste management; if this market is closed off, we may well miss recycling targets [3.3-4; 5.4-5].
10	See recommendations in §8, esp. 8.9.
11	Waste management and RRfW infrastructure contributes on two levels; prevention of pollution of air, land and water by waste; and reduction in consumption of declining primary resources and the carbon emissions associated therewith. An additional benefit is the use of EfW to replace fossil fuels, although this is a double-edged sword as it lock-in a dependence on diverting waste to energy recovery – i.e. destruction – rather than recover of valuable materials. The reuse sector is currently under-exploited in this regard. See 5.1, 5.5, 5.7, 6.1, 6.3. Resource recovery should be given equal status to prevention of pollution; the latter currently dominates policy, regulation and hence behaviours in the sector [8.1]. The RRfW sector will be essential to any future ‘circular economy’ [8.3].
12	One of the projects contained within the NERC RRfW portfolio [see 7.3] addresses exactly this issue. Appended to this submission (Appendix 1) is a brief description of the CVORR project.

Solid waste sector specific questions: these are addressed by the whole of the document but particularly pertinent sections are highlighted below.

27 See 2.2, 4.2, 5.4-6 and the recommendations in §8 esp. 8.2, 8.6-7, 8.9.

28 See 2.2, 4.3-4, §6, 7.5 and the recommendations in §8 esp. 8.3-5, 8.8.

1. Existing infrastructure

1.1: Statistics on the UK's waste and resource recovery infrastructure are scattered, inconsistent and riddled with definitional and coherence issues. This makes it difficult to produce a concise overview of waste infrastructure capability and capacity. Some of the available data from key sources is presented here, but a full reconciliation of all the data is beyond the scope of this document.

1.2: **England:** In England, a total of 6305 sites accepted waste in 2014, managing 187 Mt of waste. These facilities are classified as [DEFRA 2016a]:

Facility type	Number of facilities	Mt managed in 2014
Landfill	338	41.3
Transfer	2383	46.7
Treatment	1896	57.4
Metal recycling	1290	13.6
Incineration	74	8.6
Use of waste	143	2.3
Land disposal	181	17.1

1.3: Some double counting is likely to have taken place as an item of waste may pass through two or more of the facilities listed above. As noted by Vinagavado [2013], "*mixed waste might be accepted by a transfer station, sorted and then be transported to a recycling facility or for final recovery or disposal. For this reason, waste managed is not analogous to waste arisings and no direct comparison can be made*". Comparable figures for the capacity in each category do not appear to be available for England; the 2012 capacity figures are unhelpfully reported under different headings [DEFRA 2015] and the 2014 capacity figures are not reported [DEFRA 2016a]. However, in all categories, there are significantly more sites permitted to take waste (9382 in total) than the number of sites that accepted it in 2014 (by between 32% and 96%), suggesting there is unused capacity in the system. Remaining landfill life based on 2014 inputs varies from 3 years in London to 13 years in the West Midlands¹.

1.4: **UK:** Other reports (DEFRA, 2015) break this capacity down differently for the UK as whole:

Process type	Number of facilities	Capacity Mtpa
Energy recovery	27	2.9
Incineration	87	8.4
Recovery other than energy recovery, including backfilling	3542	n/a
Landfill	594	remaining capacity 633 Mm ³

1

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/470475/Waste_management_2014_England_summary.pdf

Energy generation from biowaste was 7.5 GWh in 2014, split between:

- Landfill gas (5.0)
- Sewage sludge digestion (0.8)
- Animal biomass (0.6) and
- Anaerobic digestion (AD) (1.0; 152 anaerobic digestion sites operate in the UK)

with a further 2.0 GWh contributed by the biodegradable portion of EfW fuel [DEFRA 2016a]. This accounts for 2.5% of UK energy generation. In terms of organics treatment capacity this is given as 6.6 Mtpa, broken down as:

- Composting (5.1 Mtpa)
- Commercial, R&D and on-farm AD (1.3)
- Industrial AD (0.3)

with a further 2.4 Mtpa added by mechanical-biological treatment and 3.5 Mtpa AD co-located with drinks manufacturers.

1.5: Residual waste is the fraction of waste that is not separated for recycling (i.e. what is left over after recyclates are removed from a waste stream). It may derive from household, commercial or industrial sources. The DEFRA Waste Infrastructure Delivery Programme (WIDP) Residual Waste Treatment Infrastructure Project List (IPL) “*lists residual waste treatment facilities/contracts in England [and Wales] that are tracked by WIDP for the purposes of assessing treatment capacity. The list includes both existing and pipeline facilities and is informed by WIDP monitoring of its portfolio of PFI (Private Finance Initiative) and PPP (Public Private Partnerships) projects and public domain information concerning other PPP and merchant facilities.*”² As of 31 March 2016, it lists 96 projects, of which 62 are operational and 34 are either in construction, consented, “post close” or with status TBC.

1.6: The operational facilities have a total capacity of 11.2 Mtpa, with:

Facility type	Number of facilities	Capacity Mtpa
Energy from Waste (EfW)	37	8.3
Biodrying mechanical and biological treatment (BMBT)	20	2.2
Landfill mechanical and biological treatment (LFMBT)	5	0.7

Eunomia (2016) report that the UK’s effective treatment capacity for residual waste is 19.5 Mtpa with 47 incineration facilities, 10 advanced conversion technology plants, 36 mechanical-biological pre-treatment facilities, 19 IED (industrial emissions compliant) biomass and co-firing plants, and 8 cement kilns; this suggests a different definition of operational facilities compared with DEFRA data.

1.7: In economic terms, the waste management sector adds just under 0.5% to UK GVA, split between (2014 figures from DEFRA, 2016a) waste collection (£2.9 billion, Bn), waste treatment and disposal (£1.7Bn) and materials recovery (£1.6Bn). The sector is dominated by the so-called ‘big six’ waste management companies³ who between them have a market share somewhere between 70% and 80%. The sector employs around 140,000 people split between remediation (12k), wholesale of waste and scrap (5k), materials recovery (24k),

² See <https://data.gov.uk/dataset/waste-infrastructure-delivery-programme-widp-residual-waste-treatment-infrastructure-project-li>

³ <http://www.rwmexhibition.com/content/Overview-of-the-UK-Waste-Market>

waste treatment and disposal (40k) and waste collection (58k). There was a 50% increase in the number of employees in the sector between 1993 and 2013 [DEFRA 2015].

1.8: The repair, reuse and leasing sectors – arguably operating higher up the waste hierarchy – added a further £40Bn, over half of which can be attributed to the repair, renting, leasing of motor vehicles plus second-hand car sales [DEFRA 2015]. Analyses of the reuse sector beyond motor vehicles are rare, but in Scotland it is estimated that reuse of furniture, electrical items and textiles accounts for 89000 tonnes of material with a turnover of £244M pa, employing 6000 people. A further 3000 fte volunteers were also engaged, highlighting the anti-poverty and social need agendas that drive many of the actors in the sector, who are often associated with one or more charities. It is estimated by local government organisations that the potential scale of reuse in the UK could be as high as 660 thousand tonnes per annum (ktpa) with a value of nearly £0.5Bn [CIWM 2016].

2. Planned infrastructure

2.1: The WIDP-IPL (see §1.5 above) lists 34 residual waste treatment projects as being in the pipeline in the UK. The planned facilities have a total capacity of 8.5 Mtpa, with:

Facility type	Number of facilities	Capacity Mtpa
Energy from Waste (EfW)	30	7.5
Biodrying mechanical and biological treatment (BMBT)	3	0.6
Landfill mechanical and biological treatment (LFMBT)	1	0.4

The National Infrastructure Plan Pipeline [IPA 2016] highlights 10 of these planned waste projects totalling £0.5Bn:

Surrey County Council	Quest Waste Disposal Project	The infrastructure consists of an anaerobic digestion (AD) plant and a gasification plant to be developed within a new Eco-Park at Charlton Lane, Shepperton.
Cornwall	Waste Management Procurement	This is a 33 year semi integrated project for the provision of all waste services (except collection) and provides infrastructure for materials handling, household waste recycling centres (HWRCs), transfer facilities, energy from waste and landfill.
Derby City Council and Derbyshire County Council	Derbyshire PPP Waste Management Project	The new EfW in South Derby is being developed by Derby City Council and Derbyshire County Councils in partnership with Interserve plc and Shanks Group plc. The Waste processing centre will combine recycling capacity with an advanced gasification plant capable of generating power for up to 14,000 homes in the city.
Gloucestershire County Council	Gloucestershire County Council Waste Management project	The project is an EfW facility with a capacity of 190,000 tonnes per annum, to be constructed at the Authority's Javelin Park site just off the M5 in Gloucestershire, by Urbaser/Balfour Beatty.
Milton Keynes	Milton Keynes Waste Management Project	The EfW which is being designed, built and operated by AmeyCespa on behalf of Milton Keynes Council. The plant will process non-recyclable and non-hazardous household waste using gasification technology. This waste will be converted into a syngas using partial combustion heat to free hydrogen and carbon. This will produce high temperature steam capable of generating 7MW of electricity. It is expected to be completed in 2016

South London Waste Partnership	Waste Management Procurement	The plant forms part of Viridor's 25-year contract with the South London Waste Partnership signed in November 2012. It is expected that the plant could begin treating waste by around 2017.
Herefordshire & Worcestershire	Waste Management Project	Integrated contract for municipal waste management services to be provided over a 25-year period including the construction of an EfW facility.
North Yorkshire & City of York	Waste Management Project	The PPP project is being developed by North Yorkshire County Council and City of York Council alongside sponsors AmeyCespa for the construction of and EfW facility.
Merseyside Recycling & Waste Authority	Waste Management Project	The project has begun construction. It is a 430,000 tonnes per annum Combined Heat & Power (CHP) EfW facility at Teesside supplied from a rail transfer station at Knowsely in Merseyside.
West London Waste Authority	West London Waste Authority	SITA, along with its partners Scottish Widows Investment Partners and the Itochu Corp., will design, finance, build and operate the energy-from-waste facility in Severnside, (South Gloucestershire), which will manage up to 300,000 metric tons of residual municipal waste every year.

2.2: Of these 10 listed projects, while 8 involve EfW, only 2 have any mention of recycling; none mention resource recovery, re-use or reprocessing. The perception that EfW is a more stable revenue stream with predictable capital costs is the most likely explanation. No waste or resource recovery programmes are listed as priority projects; the NIP explicitly states that no further investments are planned as the UK is on track to meet landfill diversion targets. It is difficult to see how the focus on this driver alone can be reconciled with the NIPs stated aim “to have the right infrastructure in place” to achieve its ambition to move towards a circular economy. Waste management is mentioned in the NIP as forming part of the UKCRIC science and infrastructure research investment ⁴ and this will stimulate research into more advanced systems.

3. The capacity gap; or surplus?

3.1: Analyses of the degree to which UK waste management and resource recovery infrastructure are operating at capacity differ. National assessments tend to suggest that the UK has sufficient waste processing capacity for the near future, while analyses that disaggregate facilities (i.e. compare local arisings to local facilities) often suggest that local deficiencies exist. The difference can be reconciled by permitting transport of wastes from areas of under- to over-capacity, but whether these transport arrangements are sustainable, desirable or practical is still a matter for debate.

3.2: The National Needs Assessment [ICE, 2016] states that the UK possesses ‘adequate capacity’ to meet projected trends in waste management. Other national reports provide a deeper analysis, largely focussed on the ability of the sector to achieve 2020 targets to divert biodegradable municipal waste from landfill. They suggest that there is a >95% probability that such targets will be met with an excess capacity of over 2 Mtpa [DEFRA 2013]. However, investigators who took into account the detailed composition of waste streams and local variations in capacity and technology suggest that significant capacity gaps exist at regional level; the agglomeration of the data hides the high probability that there will be insufficient treatment capacity at the regional level, perhaps to the tune of a deficit of around

⁴ <http://www.ukcric.com/>

15 Mtpa. They also suggest that the implications of long-distance haulage of waste have not been taken into account [ICL 2014]. In response, it has been suggested that there is no significant barrier to transporting waste between regions and that the system is “*not sensitive to restrictions in market clearing*” [DEFRA 2014]. Other commentators suggest that the appropriate scale for efficient and commercially viable collection and processing is dependent on the waste stream in question. WEEE reprocessing to capture maximum value and plastics recycling requiring collection of high-quality separated material, is best operated at a regional scale; anaerobic digestion of food waste should be handled at the local authority scale [Benton 2014].

3.3: Other investigators have reported various figures for the capacity gap or surplus. Some commentators suggest that a treatment capacity gap of 5 to 15 Mtpa is likely by 2020 when commercial and industrial waste is taken into account [Vinogradavo 2013]. Others state that the UK currently has a gap between residual waste arisings and treatment capacity of between 6 Mt [Eunomia 2016] and 18 Mt per year [SITA undated] caused by closure of 1500 landfill sites and the slow rate at which new facilities are coming on-line [ESA 2010; ESA undated]. The gap is currently filled by over-reliance on export of RDF. This gap is projected by some to disappear by 2020 and change to a capacity surplus of around 4 Mt per year by 2030, mainly owing to a reduction in waste generation and partly owing to an increase in projected operational capacity [Eunomia 2016]; others suggest a capacity gap of 6 Mt per year will remain in 2025 [SITA 2025]. Many commentators note that projections of future waste arisings and thus capacity requirements are complicated by a lack of data on waste flows, particularly for commercial and industrial wastes and that from the construction sector [e.g. ICE 2016; DEFRA 2013; Vinogradavo 2013].

3.4: Exports of waste as SRF/RDF have grown from effectively zero in 2010 to approach 2 Mtpa. However, the point is made that there is no way of forecasting how future export levels might evolve given the uncertain political, technological and economic situation, with some suggesting that this could decrease significantly in the future. Current EfW capacity in the UK is 5 Mtpa and this is will rise to 12 Mtpa by 2020 considering all projects under construction [GIB 2014].

4. Data and investment

4.1: Several shortcomings in the sector need to be addressed before significant progress can be made. The most often cited is a lack of data. There is no responsibility on many waste producers to report on the quantity or quality of the waste they produce unless it is hazardous or otherwise regulated. Data is particularly scarce in the commercial, industrial and construction/demolition sectors which together account for three times the volume of municipal waste [ICE 2016; DEFRA 2013] not least because this sector is not obligated to track and report waste arisings, in contrast to LAs [Vinagavado 2013]. This problem can be further compounded by changes in the definition of waste. For example, in 2011 the definition of municipal solid waste (MSW) was changed to include waste collected by LAs not from households but similar in composition to household waste and thus the reported proportion of MSW attributable to households dropped from 90% to 50% [ICL 2014] unless due regard is taken for new sub-categories of waste (which it often isn't). Even within the waste treatment supply chain, data is non-standardised. For example, DEFRA [2016] report that: “*Generation and final treatment are at opposite ends of what can be a complex and multiple staged treatment process. Different methodology is used to estimate generation and final treatment figures. Furthermore, final treatment excludes some treatment processes*

identified as predominantly intermediate, which nevertheless may effectively be the final treatment for some waste. As a result, there is no direct reconciliation between generation and final treatment of total waste. Users should also be aware that in most cases it is not possible to estimate the final treatment of waste generated by specific economic activities.”

EU “end of waste” regulations, while useful in promoting recycling, can further complicate the tracking of secondary resource flows; some recycling sectors (e.g. packaging) have well-defined processes for tracking waste and secondary resource flows (e.g. the PRN/PREN system) while other recyclers may be handling a mix of waste and non-waste. Such uncertainty and volatility surrounding waste data makes it very difficult to determine what new resource recovery capacity is likely to be needed in the future using robust mass balance approaches. This impedes coherent policy making which in turn increases the risk to potential investors (public or private) wishing to commission new resource recovery infrastructure [ESA undated].

4.2: Yet it is very clear that such investment is urgently needed. Public-private partnership (PPP) finance agreements for local authority waste processing infrastructure are coming to an end (largely because landfill targets for biodegradable waste have been met and thus the ‘problem’ is seen to have been solved), with around £1.7Bn of further investment required by 2020 of which £0.5Bn has yet to secure finance [GIB 2014]. It has been estimated that an additional £5Bn [ICE 2016] to £25Bn [SITA, undated] investment in infrastructure will be required to achieve a close-to-circular economy; this should now be the focus of governmental support for investment. The almost singular focus on EfW plants treating household waste has left investors “...*sceptical that there is enough waste remaining to justify building new infrastructure*” and this increased risk perception has already led to delays and cancellations [GIB 2014] including withdrawal of PPP investment⁵. This risk is compounded by the perceived difficulties in gaining planning permission for new waste-related infrastructure in the UK owing to ‘NIMBY-ism’ [Ekogen 2011] and the increasingly uncertain regulatory landscape catalysed by the Brexit vote.

4.3: Better data and forecasts on the arisings and quality of residual commercial, industrial and construction/demolition waste will be required to reassure investors that there is a gap in the existing market. A coherent, standardised approach to waste data collection, analysis and forecasting would appear to be the most effective way of reducing the investment risk for new resource recovery facilities [Vinogradovo 2013]. Currently, waste data is only recorded and collated in response to specific regulations; wherever deregulation has occurred (e.g. where end of waste status has been achieved) or activities are not covered by regulation (e.g. prevention and re-use, commercial and industrial wastes, construction and demolition wastes) little if any data is collected. Systems have been proposed that would provide a platform for more comprehensive and coherent data analysis⁶ [Aplin 2016]. Better data and information would help communication between LAs (as collectors rather than users of recyclate) to become less detached from the end markets for recovered material.

4.4: Stimulation of the new markets and investments required that move away from a focus on EfW towards resource recovery and/or reuse, to realise the environmental, economic and social benefits of a circular economy, will require strong, progressive policy instruments. These are likely to be based on aggregated services models, creation of resource

⁵ <http://www.letsrecycle.com/news/latest-news/veolias-herts-efw-pfi-withdrawal-blow/>

⁶ <https://www.edoconline.co.uk/>

management networks and extended producer responsibilities for materials in the supply chain [Viridor, undated; CIWM 2016]. The PRN system, where producers of packaging must effectively purchase packaging recovery capacity from recyclers, was supposed to encourage investment in new infrastructure via collaboration between the two sectors but results have been mixed⁷.

5. Pressures on the system and drivers for change

5.1: General social, economic and political pressures for greater resource conservation, lower environmental impact and increased recycling will change how waste management and resource recovery infrastructure operates and develops in the medium and long term. Combinations of climatic and demographic changes will force an increase in waste arisings. The UK, in common with the rest of Europe, is a significant net importer of many resources, some of which (especially high technology metals) are 100% imported [EEA 2012] and resource recovery will need to play a key role in securing the availability of these materials in the future.

5.2: However, a number of specific drivers can be identified that are having a more immediate effect. Many of these are connected to taxation intended to implement pieces of UK and/or EU legislation, rather than an awareness of the inherent value of recovered resources [ITRC⁸, cited in ICE 2016]. The rise of landfill tax to over £80 per tonne (index linked) makes it now the most expensive of the common disposal options and drives increased reliance on resource recovery systems. There are calls for a tax on incineration of waste to be introduced⁹. Changes in EU legislation (the Revised Waste Framework Directive)¹⁰ are expected to effectively ban all recyclable waste, including paper, metals, glass and biodegradable materials from landfill by 2025 and promote the sorting of construction and demolition waste for at least wood, aggregates, metal, glass and plaster; they will also require 70% of municipal waste and 80% of packaging waste to be recycled or prepared for reuse by 2030 [ICE 2016; GIB 2014]. Waste electric and electronic equipment (WEEE) is also subject to EU regulation, with collection (4 kg per person), recovery (70-80%) and reuse/recycling (50-75%) targets. Other targets exist for e.g. tyres¹¹, end-of-life vehicles¹², and batteries¹³ [EEA 2012].

5.3: Other legislative instruments that will drive the need for an increase in capacity for resource recovery infrastructure include the EU packaging waste directives, Zero-Waste Plans in Scotland¹⁴ and Wales¹⁵ and the Waste Prevention Programme for England¹⁶. Allied with the projection that 15% of the UK's recycling capacity is set to close in this timeframe (reducing recycling rates by 5% and costing around 8000 jobs), some commentators suggest that as a result, waste could cost UK businesses and LAs an extra £300M-500M by 2020 [ESA, undated].

¹⁵ <http://www.wlga.gov.uk/waste>

¹⁶ <https://www.gov.uk/government/publications/waste-prevention-programme-for-england>

5.4: A large proportion of current UK resource recovery capacity is achieved through the export to EU countries of calorific waste – i.e. that which can be burned as fuel in EfW facilities – processed into ‘refuse-derived’ or ‘solid recovered’ fuels (RDF, SRF). Two issues will constrain this route in the future. First, there is a current overcapacity in EfW in continental Europe that drives RDF/SRF production in, and export from, the UK. As EU recovery legislation becomes implemented, this overcapacity will either be filled by local (i.e. continental) RDF/SRF production or decommissioned, decreasing the export opportunities [ICE 2016]. Secondly, the implications of the UK’s decision to leave the EU (“Brexit”) will greatly increase uncertainty around the medium-term viability of such exports [Eunomia 2016], both in terms of a continuing stable regulatory framework and the potentially worsening £/€ exchange rate from a UK perspective

5.5: EfW capacity in the UK is insufficient to absorb this material if it is diverted from export [ESA, undated]. Existing waste management operations in the UK are described as fragmented and inefficient, with huge variations in how waste is presented by businesses and households impeding scale-up of operations. Recycling is currently in decline because commodity prices are depressed, which adds pressure to increasing the quality of recyclates in order that they can compete with virgin materials; yet fiscal austerity for LAs leads to increased contamination [ESA, undated] presumably as collection becomes less specific and/or less well enforced. While commentators present UK EfW as a potential investment opportunity [GIB 2014], there is no specific commitment to promoting EfW as a low-carbon energy source in the NIP [IPA 2016].

5.6: Brexit also generates uncertainty around the UK’s adherence to the current suite of EU legislation surrounding resource recovery (including the Circular Economy Package¹⁷ which further increases the perception of risk surrounding investing in resource recovery infrastructure in the UK.

5.7: The role of resource recovery in reducing carbon emissions is likely to receive increased attention. The carbon emissions associated with the production of the materials that end up in waste in the UK is estimated at over 200 Mt eCO₂ per year i.e. about a third of the total¹⁸; the emissions avoided by the current rate of recycling (i.e. those that would have been associated with the production of the relevant primary resource replaced) are only ~60 Mt eCO₂ per year [DEFRA 2016a]. Direct emissions associated with the sector are comparatively small (~7 Mt eCO₂ per year, mainly associated with methane release from landfill). Hence increases in recycling and recovery rates will be desirable to help balance the UK’s carbon budget.

6. Future system developments

6.1: The evolution of the resource recovery infrastructure will involve changes not only in waste management but also in ‘upstream’ activities – i.e. waste prevention, product specification, design and use – that promote the retention, recovery and reuse of the function provided by products, as well as recycling of the materials or recovery of the energy they contain. The UK recycling sector should be reimagined to include tangible input from manufacturers as well as reprocessors and recyclers. Designing for recyclability, designing

¹⁷ http://ec.europa.eu/environment/circular-economy/index_en.htm

¹⁸

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/496946/2014_Final_Emissions_Statistical_Summary_Infographic.pdf

out waste, eco-packaging and light-weighting to drastically reduce waste volumes¹⁹ will be essential, as waste minimisation offers the greatest 'bang for buck' in reducing waste volumes and their direct (through pollution) and indirect (through reprocessing) impacts on the environment [ICE 2016]. A key driver that would help effect this change is the transfer of responsibility for custodianship of in-use and end-of-life resources from the public sector – where responsibility currently lies via LA obligations for waste management – to supply chains. Extended producer responsibility requires that the producers of products and packaging remain (at least partly) responsible for these materials throughout the lifecycle, obliging them to fund waste collection systems. This would improve incentives to reduce waste through design for recycling as it would reduce direct costs; it would also encourage better recycle and secondary materials markets [ESA, undated] and minimise waste exports [ICE 2016]. It could also help promote reuse, especially if combined with better cross-sector engagement activities and support packages, particularly for the 'micro enterprises' that are prevalent in the sector [CIWM 2016].

6.2: Although such 'upstream' design and behavioural incentives will deliver the most efficient and effective responses in the medium term, waste management by LAs will remain an important activity in the short-term transition phase. By 2020, up to 47 Mt of household waste will be recycled; a 20% increase on current rates and so increases in capacity will be required [GIB2014]. To install the required capacity, especially as new technologies come online, more coherent investment planning will be required and LAs will need to work together to exploit economies of scale. Larger scale investment in energy recovery technologies such as gasification will also require careful collaboration with energy companies (as energy recovery from waste will only ever be a small fraction of total generating capacity) as well as the waste sector to secure reliable supplies of waste material. Financing is severely affected by reliability of supply, and current individual local authority waste contracts cannot be used as financial security [ICE 2016].

6.3: Reuse has been described as the 'neglected child' of the waste hierarchy [CIWM 2016]. While there are established markets for reuse in some areas (motor vehicles, antiques) and guidelines are appearing for the reuse of certain other products (e.g. WEEE PAS141, see footnote²⁰), the potential for exploiting the significant contribution towards a circular economy that reuse could make remains dormant. The reuse sector is dominated by third sector bodies with charitable and social aims, and it is precisely this ability for reuse to simultaneously deliver financial, social and environmental benefits that is the key to its promotion as an important enabler for waste prevention; partnerships between private and third sector organisations regarding reuse can be leveraged via a Corporate Social Responsibility agenda, for example [CIWM 2016]. However, such relationships are currently ad hoc and often driven by key individuals; a stronger policy framework together with fiscal incentives that encourage more coherent investment in reuse will be required to build capacity in the sector [CIWM 2016]. Other recommendations include extending retailer 'take back' schemes, adapting public sector procurement to prioritise reused goods, adopting British Standards for remanufacture in design to promote reparability and using the Green Investment Bank to support innovative products designed for reuse [LGA 2014].

¹⁹ NB: Eco-packaging and light-weighting have to be considered with caution; often eco-packaging such as vegetable-based plastic, and light-weight design can become disengaged from the need to prolong product functionality, durability and manageability by existing waste management/recovery practices, potentially creating more problems than they solve.

²⁰ <http://www.wrap.org.uk/sustainable-electricals/esap/re-use-and-recycling/guides/PAS-141-Guide>

7. Technology developments

7.1: Advances in resource recovery technology will allow a wider range of useful materials to be recovered from waste streams in the future. Naturally, the range of new technologies emerging from academic laboratories and commercial developers evolves daily; here we provide a brief, non-exhaustive summary.

7.2: Commercial technology forecasters have identified a wide range of technologies for waste treatment at varying technology readiness levels²¹ (TRL) [Ricardo 2016]. Those that have a resource recovery component include:

- Various flexible and reconfigurable multi-material recycling facilities that sort residual waste according to a combination of size and density, material sensing technology (mainly based on optical or infra-red sensors) and air separation to recover plastics, paper, cardboard, glass and metals (TRL9)
- Plastics reprocessing using biological enzymes to break down polyethylene terephthalate (PET) into its original monomers, which can then be used to replace traditional petroleum precursors for PET (TRL4)
- Hydro-recovery or composting processes treating absorbent hygiene products (nappies etc.; a mixed material waste that is notoriously difficult to recycle) to recover cellulose fibre for use in e.g. fibreboard, acoustic panelling or biomaterials for land treatment, with recovered plastics sent for secondary reprocessing (TRL8)
- Cryogenic and ultrasonic processes for carpet recycling. Carpets are a pernicious mixed polymer waste stream but new technologies can recover and recycle around 80% of the waste into surface coverings or polypropylene feedstock, with a further 10% being sent to EfW (TRL9)
- Pyrolysis or thermal depolymerisation of wastes to produce charcoal, oil and gas fuels, generally for homogenous organic waste streams such as tyres or wood chips (TRL7) but in some cases for mixed wastes (TRL5). The oils derived can also be used to produce commodity chemicals, replacing virgin petroleum feedstock.
- Micro-AD systems designed for local householders or businesses, producing biogas, liquid fertiliser and solid soil conditioner.

7.3: A great deal of research work on resource recovery systems is also taking place in the academic arena. A complete review of this work is outside the scope of this document, but one major investment is the NERC “Resource Recovery from Waste” programme²². This £7M portfolio of six complementary projects includes:

- Systematic analysis of the suitability of ash and digestate residues from biomass energy generation for use as nutrient providers and conditioners for agricultural soils, in part as replacements for mined nitrogen and phosphorus mineral fertilisers (presented in Chief Government Scientist report From Waste to Resource Productivity, expected publication in 2017)
- Using combinations of low-energy biochemical, dielectric and geochemical processes to refine and concentrate valuable and/or functional materials (including metal sulphides, nano-metallic structures rare earth elements, ‘E-tech’ elements and

²¹ TRL – an estimate of how close the technology is to being widely operational, ranging from 1 – basic science demonstrated in the laboratory, to 9 – technology successfully in operation.

²² <http://www.nerc.ac.uk/research/funded/programmes/waste/>, <https://rffw.org.uk/>

uranium phosphates) from a variety of bulk wastes (refining slags, alkaline mine wastes etc.) either in- and/or ex-situ

- Developing complex value modelling techniques that can assess creation and dissipation of the economic, financial, environmental, social and technological value associated with production systems that currently emit wastes, to highlight upstream interventions in these systems that will prevent the dissipation of value into waste.

Other major research investments that deal with 'upstream' changes to supply systems include: redesigning metal alloys to reduce demand on strategically important elements²³; taking a 'whole systems' approach to the upgrading and reutilisation of unavoidable food supply chain wastes to move towards closed-loop food production²⁴; and developing reliable methods for recycling plastics derived from biological (i.e. non-petroleum) sources by depolymerisation for reprocessing either as new plastics or other value added chemicals²⁵.

7.4: A number of technological opportunities and challenges will arise in the resource recovery space as a result of changes in the mix of materials used in our products and infrastructure. These must be addressed by a combination of design for recovery and development of end-of-life recovery technologies. Chief among these are [KTN 2016]:

- Technologies to recover the valuable and critical materials used in low-carbon energy and transport systems, in particular lithium (used in high-performance batteries in electric vehicles) and rare-earth metals (used in high-strength permanent magnets for electric motors in vehicles and generators in wind turbines)
- Increasing use of composite materials and/or multi-material products (such as insulation-backed construction blocks and sheets)
- Decommissioning of North Sea oil infrastructure and first-generation wind turbines
- Bio-based, bio-inspired and biodegradable packaging materials will require specialist reprocessing (e.g. to capture methane through composting) rather than allowing the false encouragement of 'safe discarding'
- Advances in robotics, automation and sensing/vision technology will allow a wider range of materials to be more efficiently and reliably sorted
- Opportunities and challenges presented by hyper-connectivity i.e. the 'Internet of Things', both in terms of data management and exploitation (opportunity) and the inclusion of WEEE in almost every item of packaging (challenge).

7.5: It is important that such advances in resource recovery technology be considered alongside upstream policy, design and business innovations; they are interdependent. Upstream interventions need to prepare the system such that any downstream wastes are matched to the availability, capacity and evolution of emerging processing technology; technological advances in the waste processing sector must develop mindful of the ability of upstream processes to provide secondary materials of the correct quality and quantity to make them commercially, environmentally and socially viable. Too often new recovery processes are developed with no markets, or interventions are made that rely too heavily on fragile, localised or unproven reprocessing technology. A key aspect of this is skills; the industry has reported that there are skills gaps both within the sector (e.g. insufficient energy

²³ <http://gtr.rcuk.ac.uk/projects?ref=EP%2FL025213%2F1>

²⁴ <http://gtr.rcuk.ac.uk/projects?ref=EP%2FP008771%2F1>

²⁵ <http://gtr.rcuk.ac.uk/projects?ref=EP%2FP016405%2F1>

from waste technicians) and outside it (e.g. a lack of manufacturing and packaging technologists able to make use of secondary materials) [Ekogen 2011].

8. Discussion and Recommendations

8.1: Waste management is a growth industry, with targets being reached and exceeded. For it to continue to grow more infrastructure needs to be put in place. The current focus of infrastructure development is still largely on treatment (i.e. amelioration of the environmental and social impact of waste disposal) rather than on resource recovery (i.e. preserving the value of resources through reuse and recycling).

8.2: Where new, planned and projected infrastructure growth does involve recovery of value, it is almost entirely focussed on energy from waste, as this is seen as the easiest route to financing new waste infrastructure. While this should rightly form part of a balanced resource recovery portfolio, it should not be the whole of it. In a commercial sense, reduced residual waste arisings and the development of more efficient recycling technology and systems will eventually reduce the amount of waste available for EfW systems over time; uncertainty over continued viability of exports further complicates the picture.

8.3: From a resource recovery perspective, overuse of EfW destroys technical value by rendering potentially useful material unrecoverable, and creates an infrastructure system that paradoxically relies on the continued creation of suitable waste, reducing incentives to find reuse and recycling routes. The NIP's aspiration to move towards a circular economy will not be realised without a much greater focus on preventing waste and recovering recyclates, rather than burning them. The proportion of waste that is sent for energy recovery should be a function of its ability to be recycled, not of the ratios between the price of fuel and materials; this is a 'market failure' that needs correcting.

8.4: A recurrent theme in most the publications reviewed here is the deficiency of data on waste flows in terms of quality, availability and consistency. The collection of data is driven solely by the need to achieve targets for recycling broadly-defined fractions of waste, or requirements to account for the correct disposal of hazardous materials. An example of the perverse behaviour driven by this is that the sectors producing the majority of total waste arisings are under no obligation to report on the quantity, quality or destination of this waste. As such, what limited data is collected is not of the required quantity or detail to allow mass flows of materials and their quality (i.e. useful physical properties) to be calculated. Within agencies, data is reported in such a wide variety of formats, typologies and units that calculating the flows of material through our economic systems is impossible; these agencies explicitly admit that it is not even possible to reconcile waste arisings with waste managed using public domain figures.

8.5: This in turn prevents the development of new infrastructure technology; impedes the efficient recycling of useful materials; adds unnecessary risk to investment in infrastructure projects; obscures comparative analysis at local, regional and national scales; and stymies the communication between materials suppliers, product designers and waste managers that will be necessary for the circular economy. Data collection and reporting in the sector should be rationalised, with a first priority of accounting for the value and volume of material flows; the current requirement to demonstrate adherence to health or environmental legislation would follow naturally.

8.6: The role of public investment in the sector should be re-examined. Fiscal support for the industry should be focussed on protecting investments in both the supply chain, from design through to recycling, and the waste infrastructure, that prevent dissipation of material value (technical, environmental and social as well as financial) into waste. This might include providing a buffer against price volatility for recovered materials; supporting markets in recyclates; incentivising design for durability, upgrading, refurbishment and reuse; providing platforms and standards for data collection; and investing in research and development in the sector. The overall aim should be to shepherd in a transition towards the infrastructure required for a circular economy by removing barriers and/or providing support for business models that move away from the linear make-use-dispose consumption of materials. Existing market support such as the PRN system should be better administered to provide a revenue stream with which to develop and install new resource recovery infrastructure, in collaboration with all actors in the supply chain.

8.7: All such support should be based on reinforcing a principle of extended producer responsibility, where the manufacturer of a product explicitly shares responsibility for the life cycle management of the materials from which it is made with materials suppliers, users and waste processors. Public procurement processes also have the ability to send powerful economic and cultural signals; a requirement for the public sector to prioritise the use and reuse of British products made from recycled materials is a possibility in a post-Brexit UK, for example.

8.8: All the above must be reflected in regulation of the resource recovery sector. The most damaging implication of Brexit on resource recovery infrastructure development is simply the uncertainty generated with respect to continued adherence (or otherwise) to the existing suite of EU regulation that currently dominates behaviour in the sector. The Government needs to move quickly to reassure the industry and potential investors that a stable policy and regulatory framework for waste management, recycling, resource recovery and associated activities will be implemented as soon as possible.

8.9: Brexit also offers opportunity for fundamental changes in regulation. Perhaps the most radical change would be to move responsibility for waste management regulation from environmental agencies (which implicitly reinforces the culture that waste management is first and foremost an environmental protection issue) to a new Office for Resource Stewardship. Such an agency would have a specific focus on protecting the national interest by enforcing efficient use of materials, and by extension preventing waste and encouraging reuse and recycling. Targets would be expressed in terms of recovery of value and function, rather than diversion of waste from landfill. Political drivers would include increasing the material security of the UK by reducing reliance on imports; creating both low- and high-skilled jobs in the reuse, recovery and recycling sectors and associated infrastructure provision; developing new recovery technologies for export; and achieving sustainable development goals.

8.10: As the UK embarks on developing a new industrial strategy alongside redefining our trading relationships with the world, it would seem an ideal time to reimagine the resource recovery industry as an engine for sustainable growth at home and a crucible from which we export the science, technology and services required for a global circular economy.

Appendix 1: CVORR

Complex Value Optimisation for Resource Recovery (CVORR) – Phil Purnell, February 2016.

Summary: *We all want to live in a world without waste, where resources are recovered, reused and recycled, not squandered. Sometimes, efforts to achieve this can have unintended consequences. For example, using biomass to replace coal shuts off the recycling route for the ash; mining the metals used in low-carbon technology causes serious pollution in other countries. This happens because we don't have a framework for analysing the system-wide effects of local decisions. The CVORR project will provide this framework. It will track how "complex value" – the combination of economic, social, environmental and technical costs and benefits – is created and destroyed in production systems. It will allow analysts to identify impacts that might occur upstream or downstream of a proposed change in a process. It will allow policy-makers to design regulation that prevents negative impacts occurring, or helps industry generate and distribute the value created by positive impacts. Ultimately, it will help us achieve a circular economy that preserves our resources and environment for future generations.*

One way to preserve our planet's resources and environment is a circular economy that works towards eliminating waste. We must keep products in use as long as possible and make sure that at the end of their useful life, the materials and resources they contain are recovered and reprocessed into new products. We must also make sure that any outputs from industrial processes that are not sold have environmentally harmful or technically useful resources removed before we send them for disposal. In short; we must recover value from waste.

At the moment, society is trying to do this by bolting on a recovery technology to the end of a process and assuming that because we're recovering materials, everything else is OK. For example, we have set targets for recycling of household waste. Yet relatively little of that collected in the UK is turned into new products in the UK. Some of it is burned, which provides energy but destroys the value of the material resource. Still more is exported for reprocessing, often to countries where not all industries meet modern environmental and health & safety standards. Some exported materials including electronic wastes end up being recycled by manual labour, including children working under dirty and hazardous conditions. In such cases, have we really achieved recovery of value from waste, or have we just gained some environmental value at home while destroying social value somewhere else?

Even when we find ways to use wastes, changes in the primary processes that produce them may have knock-on effects. Ash recovered from the chimneys of coal-burning power stations can be 'upcycled' as an ingredient to reduce the carbon footprint of concrete. But as we switch from using biomass and fuel derived from wastes to replace coal, we change the chemistry of the ash – one of its technical values – such that it is no longer suitable for concrete. Because of this, there are now shortages of low-carbon concrete. We've saved carbon in one part of the system, but lost the ability to save it elsewhere and closed off an upcycling route. How do we work out the overall impact of this complex change in value?

Looking at broader system-level impacts is also difficult. Mining of the 'rare earth' metals (mostly in China) needed for low-carbon technologies such as wind turbines and electric vehicles is reported to have serious impacts on local environmental and social value. How do we account for and balance saving carbon in the UK with polluting cities and lakes in China? Analyses using life cycle assessment (LCA) of proposed processes for recovering rare earth metals from wastes don't accurately predict their environmental impact and neglect social, economic and technical value altogether.

We aim to take on this problem by creating a new way of modelling these systems. CVORR will design a framework for analysing how value is created, destroyed and distributed in waste-producing systems. It will treat value as a multi-dimensional concept that includes environmental, technical and social value as well as traditional economic value. Taking a wide view, it will be able to look upstream and downstream of individual processes into the other systems with which they are connected. It will bring together the best aspects from existing analysis techniques – material flow analysis, LCA, value chain analysis and others – into a

flexible, totally transparent and user-focussed toolkit that will help industry, policy-makers and communities make better decisions concerning waste-producing processes.

We expect that CVORR will be operated in two ways. First, it can be used to highlight how changes made in one part of a production system or supply chain might have unintended impacts in other parts of the system, often by swapping one dimension of value (e.g. carbon savings or recycling) for others (e.g. social impacts or the amount and hazard of waste produced). This will help us avoid making well-meaning interventions that actually do more harm than good.

Perhaps more interestingly, it can also be used to highlight how making changes in specific parts of the production system could create increased value for society overall. If we can identify and capture this value, it can then be redistributed to help firms to make the required changes, correcting a market failure. For example, if a producer makes an item of plastic packaging by joining together different plastics, recycling is difficult. If this item could be made out of a single plastic, recycling would be much easier and system value in multiple dimensions could be created (reduced use of raw materials, increased recycling, reduced carbon emissions etc.). But if the producer has to incur costs by e.g. changing machinery, using a little more material, or reducing profit margins, they won't automatically make the change. If CVORR can identify the added value that moving to a single plastic product would create elsewhere in the system, policy makers can set up rules that take this added value and recycle it back to the producer, providing the incentive for change.

In this way, CVORR is as much about creating business opportunities as it is about environmental and social science. It will be a tool to help align the incentives of the actors in a system such that those who most need to act can benefit from the advantages of working towards the circular economy.

Progressive Energy Response to the National Infrastructure Assessment Call For Evidence October 2016

[name redacted] [job title redacted]

[email address redacted]

10 February 2017

1 Background to Progressive Energy

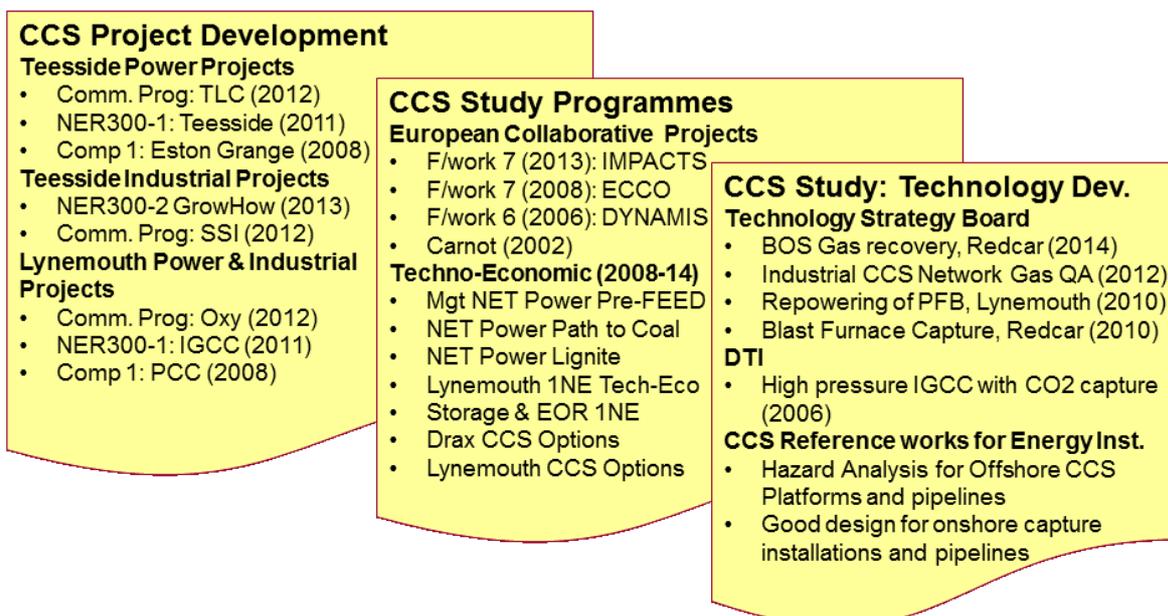

Progressive Energy is an established independent UK clean energy company focusing on deployment of emergent technologies and associated project development and implementation. It has pursued Carbon Capture and Storage since 1998 with an international reputation in the sector in particular associated with capture from industrial processes and activities relating to decarbonised hydrogen production and power production. It also has particular expertise with regard to decarbonisation of heat and transport. It also provides advisory services, in particular providing expert due diligence to a range of investors considering investments in new low carbon technologies. It undertakes advisory work for policymakers and is a founding member and on the industrial advisory board for the EPSRC Supergen Bioenergy Hub. With regard to this scope of this consultation it is most active in the energy and waste fields so is responding to the specific consultation questions relating to these sectors (Q19,Q20, Q21,Q27 and Q28), although we have also commented briefly on Q1, Q2, Q4, Q5, Q7 & Q8.

1.1 PROGRESSIVE ENERGY BACKGROUND RELATING TO CARBON CAPTURE AND STORAGE

Progressive Energy has been at the forefront of CCS development in the UK since 1998. Early work was based on development of a 400MWe coal to hydrogen power plant in south wales with carbon capture. Subsequently it conceived and developed the Eston Grange Project, an 800MWe IGCC with CO₂ Capture of CO₂ based in Teesside, linked to the necessary CO₂ storage and transportation in the North Sea. In 2006 secured investment from Centrica through two subsidiaries, jointly owned by both Progressive and Centrica. In 2009 Centrica relinquished its stake in the project. Progressive Energy subsequently redeveloped it, and this formed the basis for the Teesside Low Carbon Anchor Project. The 400 MW Teesside Low Carbon Project (TLCP) was developed in consortium with GDF Suez, BOC/Linde and Premier Oil. The TLCP was a £2 billion venture that bid into the DECC Carbon Capture and Storage Commercialisation Programme as well as the NER300 process. It was shortlisted down to the final 4 projects, but did not proceed through the latterly cancelled programme.

In parallel to pursuing power related CCS opportunities, Progressive has worked on industrial CCS opportunities, primarily predicated on an intermediary hydrogen vector, including development of patented technology relating to decarbonisation of steelworks. It undertook a significant element of the engineering work with Amec Foster Wheeler in the 2015 Teesside Collective Industrial CCS programme. Latterly it is undertaking work with National Grid Gas distribution regarding the role, opportunity and development pathways for hydrogen infrastructure and CCS as related to industrial users.

An overview of its CCS activities is shown in the figure below, including wider European research it has undertaken.

1.2 PROGRESSIVE ENERGY BACKGROUND RELATING TO LOW CARBON GAS FOR HEAT AND TRANSPORT

Since its inception in 1998, Progressive Energy has always been active in the sector of thermal conversion of solid feedstock to syngas and subsequent upgrading. In 2010 it undertook a feasibility study with CNG services for National Grid, Centrica and the North East Process Industry Cluster (NEPIC) into the production of Bio- Substitute Natural Gas (BioSNG) for heat and transport. BioSNG is biomethane produced by thermal means, as opposed to Anaerobic Digestion. This approach produces the same fungible natural gas fuel, but uses a wide range of feedstocks including residual mixed waste, enabling production of significantly greater quantities of gas in the UK.

Since 2012 it has worked in consortium with National Grid and Advanced Plasma Power to deliver initially a pilot plant funded through BESTF and OFGEM's Network Innovation Competition (NIC). The consortium is now delivering the world's first full-chain, waste-fuelled BioSNG full chain plant, taking residual waste input and producing contracted renewable gas output. This is funded by both Department for Transport (under the Advanced Biofuels Competition) and NIC. This facility will be operational in 2018 and produce 22 Giga-watthours of gas per annum. The facility will deliver gas both to a haulage company with an existing Compressed Natural Gas (CNG) fuelling station, to convert their HGV fleet to renewable gas, and to the local gas grid for heat consumers. Further information about these projects can be found at <http://gogreengas.com/>

Since 2016 Progressive has developed the HyDeploy Project in conjunction with a consortium including National Grid Gas Distribution and Northern Gas Networks. The project will demonstrate that natural gas containing levels of hydrogen beyond those in the GS(M)R specification can be distributed and utilised safely & efficiently for the first time in a section of the UK distribution network. Successful demonstration has the potential to facilitate 29TWh pa of decarbonised heat in the GB, and more by unlocking extensive hydrogen use. This was successfully bid into OFGEM's Network Innovation Competition (NIC) and secured funding in December 2016.

We welcome any opportunity for further discussion on the points raised in this response

CMW February 2017

2 Response to specific Consultation Questions

Cross-cutting issues

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

We believe that development of carbon capture and storage infrastructure (CCS) has the potential to deliver cross cutting value to enable UK growth.

Universally 2050 UK energy system models (based on cost and benefit) show a role for CCS, and often BioCCS to meet our targets. An example is shown below by the ETI.

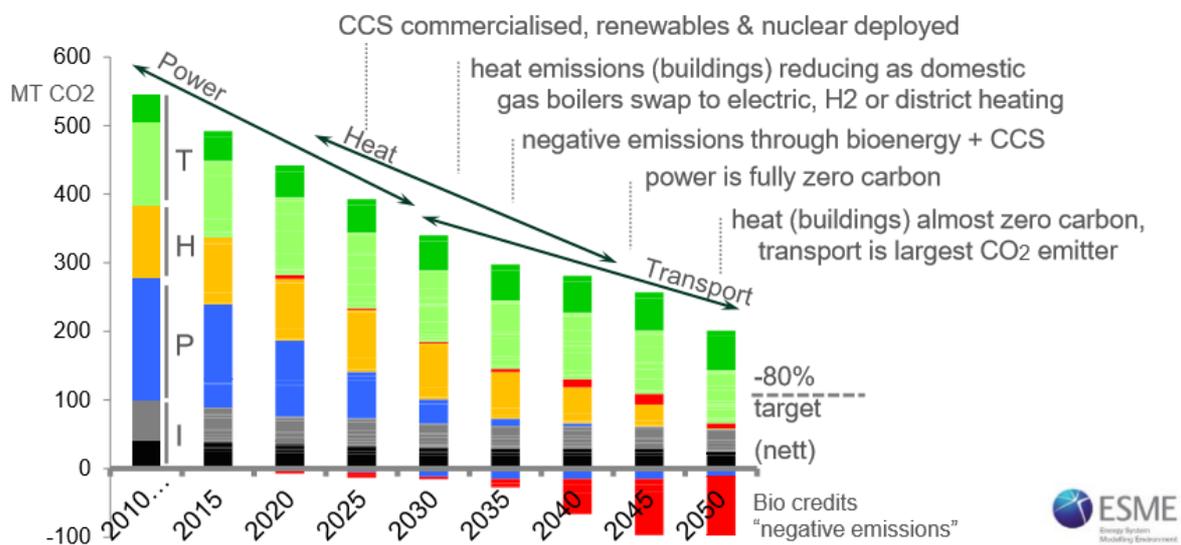

Figure 1 UK Energy system decarbonisation routemap to meet 2050 targets¹

The offshore geology around the UK provides a unique opportunity for CCS which few other countries in Europe or around the world can match. There is extensive, well characterised, deep storage yet in relatively shallow waters.

This not only provides opportunity to provide flexible decarbonisation of our heat and power demands, it allows decarbonisation of industry – particularly those for whom carbon emissions are not just a consequence of energy consumption but of the chemistry of the process, such as fertiliser, chemicals and steel production. In a global low carbon economy, this should provide a huge opportunity for growth in export of low carbon goods, which other countries cannot deliver. To achieve this requires (a) deployment of CO₂ transport and storage infrastructure and (b) a drive to retain our industrial base rather than allowing it to close down (and mistakenly assume that the corresponding reduction in UK stack emissions of CO₂ is benefiting the planet, rather than simply being emitted elsewhere, often with a worse carbon footprint). Given this issue there is an urgency to pursue CCS infrastructure before the opportunity is lost.

¹ Heat and Energy Systems, Dr David Clarke FEng, Chief Executive ETI, Heat Catapult November 2016

Linked to this is the continued use and transformation of our world class gas infrastructure asset which provides a means by which we can distribute decarbonised energy to users

2. How should infrastructure most effectively contribute to the UK's international competitiveness?

The CCS infrastructure opportunity shown above is a good example, building on unique aspects of the country's geological and existing asset base.

3. No Comment

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

We are not able to comment in detail. However, we recognise that energy efficiency should be pursued and is an important element to most energy system models, but that the 'rebound' effect is a real phenomenon. Furthermore, UK population growth, particularly when compared with 1990 levels does represent an additional constraint on demand management.

Therefore, a resilient view of energy infrastructure going forward needs to be realistic about both these factors if we are to meet our 2050 obligations.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

We are not able to comment in detail on this, but this should also consider positive *repurposing* of existing assets such as the gas network to carry low carbon gases.

Like many infrastructural assets, they are the result of decades or a century of development, often built under less constraints (smaller population, less built-up environment, lower planning constraints, different economic environments). The value these assets deliver should not be overlooked (eg their capacity to deliver highly variable energy and their world class interconnectivity). Furthermore, were such assets allowed to decline, this would be a one-way event, so decisions not to continue to use them would not be reversible, so any alternative would have to be absolutely resilient and risk free.

6. No Comment

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered? Note: by "funding", the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

Infrastructural assets are capital intensive and long life. The cost is highly sensitive to the required return on capital. Where assets can be delivered in a regulated rate base environment there is the potential to substantially drive down cost. This does require an appropriate risk allocation between the private and public sector, but given this, there is no shortage of private sector funds. A good example is CCS infrastructure. The issues are well laid out in the Oxburgh report².

This is also relevant to wider energy infrastructure. In the highly liberalised UK market, the focus has been on private sector investment for infrastructure which is of national importance. Not only does this

² http://www.ccsassociation.org/index.php/download_file/view/1043/508/

increase cost, it can introduce misaligned objectives between the needs of the country and shareholders, and the balance sheets of the large energy companies are under stress.

Going forward a more nuanced role for private sector efficiencies within public sector/regulated environment is important with regard to infrastructure.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

CCS is a good example, as shown in the Oxburgh report.

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

We have responded to aspects of this question in detail below, but our key observations are:

- The UK's world class gas infrastructure has a critical role in the delivery of heat, in a way that the electricity system is not well suited.
- Decarbonising this infrastructure delivers cross cutting solutions: low carbon heat for domestic consumers, low carbon energy and feedstock for industrials, low carbon transport as well as enabling low power
- Decarbonisation is likely to take the form of both renewable gas and hydrogen with a progressive roadmap of delivery from biomethane today, through to higher volumes of BioSNG, blended hydrogen, industrial users and potentially roll out of 100% hydrogen.
- This depends on deployment of CCS infrastructure, which also offers the possibility of negative emissions.

In order to deliver this requires:

- Firm and stable, cross-cutting energy policy across heat, transport and electricity
- A recognition of the challenge of delivering low carbon, heat and particularly need to meet customer's needs
- Recognition that the gas infrastructure is a world leading network; this asset should not be discarded but should be developed to deliver low carbon
- Recognition of the importance of and GVA opportunity in decarbonising of industry, rather than simply accepting its closure and 'offshoring'
- Firm CCS policy, recognising the genuine world-leading opportunities the UK has with its offshore geological storage
- A Practical CCS roadmap, recognising the reality of post "CCS-commercialisation programme" world

Timing

- The next RIIO period will drive key decisions on the gas network asset management and direction. Evidence base and policy direction is required before then.
- The perception that we can "wait and buy CCS later" fundamentally misunderstands where the key cost reductions come from CCS – which is from build out of infrastructure and its utilisation, not primarily from incremental technology improvements which can be bought in
- We will not meet our 4th and 5th carbon budget without action now.

The Role for Gas

The UK is committed to a pathway to carbon reductions through the Climate Change Act. On the 30th June 2016 it adopted its ambitious and legally binding fifth carbon budget for the period 2027-2032 as part of this trajectory. Heat contributes a third of the UK’s carbon emissions. The Carbon Plan³ specifically identifies the need for low carbon heat in order to meet these targets. In its July 2016 Progress Report to Parliament⁴ the Committee for Climate Change has highlighted that whilst there has been progress in decarbonising the power sector, there has been ‘almost no progress in the rest of the economy’, citing specifically the slow up take of low carbon heat.

The Carbon Plan identifies that by 2030 there is a requirement for between 83-165TWh of low carbon heat per annum. In 2015 the combined domestic and non-domestic RHI delivered less than 4.5TWh, with an expectation by DECC⁵ in 2016 that by 2020/21 the Renewable Heat Incentive (RHI) could deliver 23.7TWh of renewable heat. Therefore a step change in low carbon heat is required.

Currently gas dominates the UK heat supply curve, with 83% of the UK’s buildings heated by gas, typically using efficient modern gas boilers as shown in Figure 2. Similarly, most industrial heat demands are fuelled by gas. The entire existing gas network asset has over 284,000km of pipelines, delivering over 720TWh per annum to over 23 million customers with 99.99% security of supply⁶.

⁷ Too Hot to Handle? How to decarbonise domestic heating, Policy Exchange, Richard Howard and Zoe Bengherbi, September 2016

Heat demand is highly variable, as can be seen by heat demand curves used by the Gas industry and work by Robert Samson, Imperial as shown in Figures 3 and 4 respectively. The gas network is able to meet peak demand for any 6 minute period over 20 years. The gas system not only sustains peak heat demand but also supports the very large swings in demand within the day through significant storage capacity.

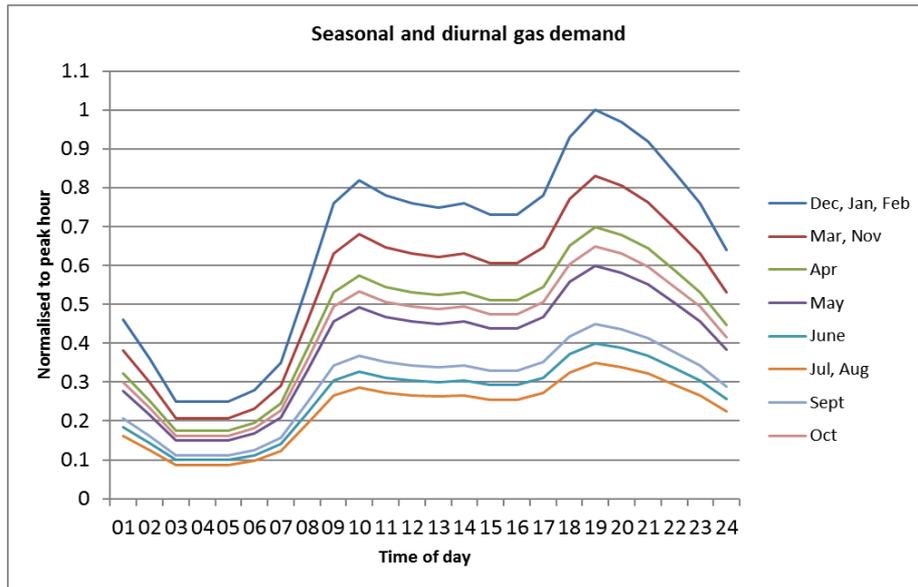

Figure 3: Diurnal gas demand throughout the year

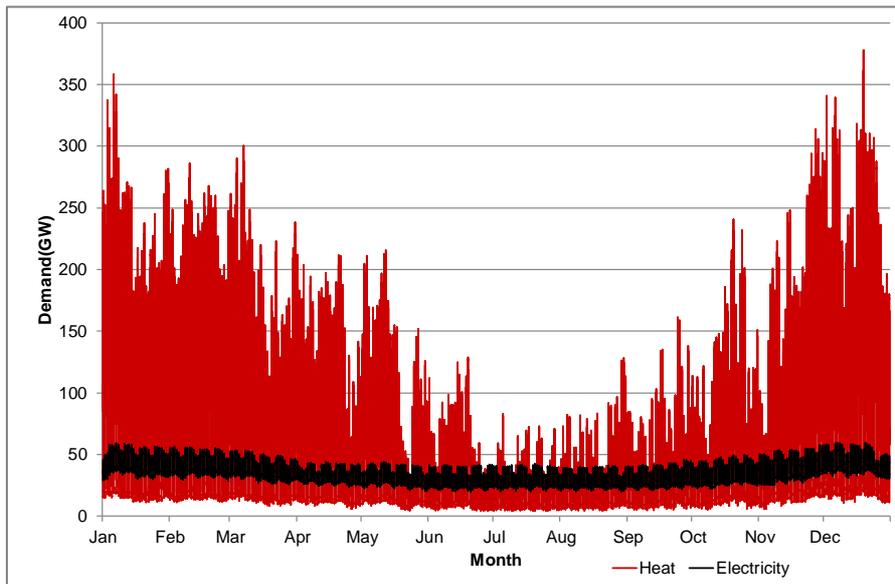

Figure 4 Comparison of half hourly electricity and heat demand variation⁸

⁸ THE IMPACT OF FUTURE HEAT DEMAND PATHWAYS ON THE ECONOMICS OF LOW CARBON HEATING SYSTEMS, Sansom R et al, Imperial College, BIEE – 9TH ACADEMIC CONFERENCE 2012, OXFORD

The peak capacity load on a daily basis is more than five times the lowest day, and the peak capacity hour is more than ten times the lowest hour, which places particular challenges on low carbon solutions for heat.

Alternative means of delivering low carbon heat other than low carbon gas include:

Electrification: Efficient electric heat pumps will make a contribution, but, as recognised in DECC's Heat Strategy⁹, and more recently in its RHI consultation, they require substantial consumer capital outlay and disruption, as well as national infrastructure investment. Consumers are required to change the basis of their heating system in terms of heat source and low temperature heat distribution systems. Furthermore, electricity generation, transmission and distribution network will require additional capacity to handle the additional variable demand for heat.

Biomass Boilers: Biomass installations require substantial capital outlay, are large and cause disruption. In practical use, there is concern that small scale biomass boilers can be inefficient and give rise to air quality issues because of high emissions of particulates¹⁰ and potentially nitrogen oxides.

Heat networks: Heat networks have a role in delivering low carbon heat, but themselves require a low carbon source of heat, new infrastructure and sufficient heat density of the load which constrains their use, and have challenges associated with counterparties to provide the basis for investment.

All of these approaches require that the consumer makes substantial changes to their own heating system. This represents a substantial barrier to adoption of such low carbon heat solutions, as demonstrated in the NIA Funded Bridgend study undertaken by WWU in 2015¹¹, which drew the primary conclusion that *'the majority of domestic consumers (87%) will not change their existing heating provision unless significant financial benefits will be accrued, and only then if they have funding available... If their current system was operating well and providing heat for their homes they would not change their heating systems and spend money unnecessarily.'*

Further, it is difficult to conceive of alternatives to gas for industrial heat applications, so renewable gas is the only realistic decarbonisation option for much of our industrial heat usage.

The gas asset therefore has an important role to play in the cost-effective delivery of heat into the future¹². A key element of this is delivering low carbon gas, as outlined in NGGDs Future of Gas review.

Gas can be decarbonised by:

- (a) using bio- rather than fossil- carbon, i.e biomethane, already increasingly & successfully deployed in the UK, as described below, and;
- (b) removing the carbon entirely by using hydrogen as identified as important by DECC¹³. Two hydrogen scenarios are envisaged; either as a blend in the network feeding existing appliances

¹³ 'The Future of Heating: Meeting the challenge' DECC (March 2013)

with no requirement for changes to equipment or infrastructure, or as a conversion to 100% hydrogen. The former has the potential for roll out in the near future. It offers not only valuable decarbonisation and financial savings across the distribution system with no disruption to consumers, but it also provides a pathway to establishing hydrogen more widely through areas of 100% conversion as proposed by the H21 Leeds CityGate project.

Renewable Gas

The benefits of renewable gas in the energy system, compared to a scenario without it were quantified in the business case for National Grid's 2015 bid for funding from Ofgem's Network Innovation Competition for a Commercial BioSNG Demonstration plant. The benefits were found to be a £0.5 billion per year energy system cost saving in 2030 (for 37 TWh/a of renewable gas) rising to £3.9 billion per year in 2050 (for 100 TWh/a of renewable gas).¹⁴

National Grid has published a series of documents intended to inform this debate, including one on the supply of renewable gas¹⁵. That publication noted that there is a consensus in the industry that UK sources of wastes and residues could generate 80 to 120 TWh/a of renewable gas, and so could meet around one third of future domestic gas demand.

Anaerobic digestion (AD) plants are already producing more than 2TWh/a of biomethane. However, conventional AD can only process some wastes which limits the potential of the technology to around 20TWh according for an SKM Enviros report for DECC¹⁶. In order for biomethane to make a significant contribution to meeting heat demand is it necessary to develop technologies that can process all types of waste.

This is the rationale for the development of Bio Substitute Natural Gas (BioSNG) project: biomethane produced by the thermal conversion of mixed wastes and residues. We have been working with National Grid and Advanced Plasma Power since 2010 on the development and demonstration of this technology. The consortium has constructed a pilot plant that has demonstrate the technical, commercial and environmental feasibility of the technology and commercial plant is now being built in Swindon. This will produce 22GWh/a of gas from local household's residual waste. Further information about these projects can be found at <http://gogreengas.com/>

The new commercial BioSNG plant will commence operations in early 2018, and the intention is for this plant to lead to the development of large scale thermal biomethane production plants later in the decade. National Grid forecasts that by 2025, BioSNG will be a mature technology. At this point, given a favourable policy environment, the adoption of the technology could accelerate such that by 2030 over 50 large scale plants could be in operation, producing 37TWh/a of BioSNG.

In view of the very large potential contribution that renewable gas could make to the decarbonisation of heat, **it is important to prioritise the allocation of waste and biomass resources to the production of renewable gas, and to make the decision to do this in the very near future, before such resources are locked into long term contracts for electricity generation.** There are many other

¹⁴ https://www.ofgem.gov.uk/sites/default/files/docs/national_grid_gas_distribution_-_commercial_biosng_demonstration_plant.pdf (Appendix 2)

¹⁵ <http://www2.nationalgrid.com/UK/Industry-information/Future-of-Energy/Gas/>

¹⁶ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/48166/2711-SKM-enviros-report-rhi.pdf

ways of generating low or zero carbon electricity (e.g. nuclear, wind, or solar) but few readily-accessible alternatives for producing low carbon heat. In addition, the efficiency of energy conversion from waste or biomass to renewable gas (c. 65%) is much higher than the efficiency of electricity generation from waste or biomass (c.25% for conventional incineration plant or 35% for very large ex-coal steam turbine plant).

Hydrogen

BioSNG has the potential to make a significant contribution to heating UK homes and businesses but will not be able to meet all of the UK's demand. It is ultimately limited by the availability of sustainable feedstocks. Heat pumps and heat network will fill some of the gap but in order to fully decarbonise heat it is essential to develop hydrogen production through steam methane reforming combined with carbon capture and sequestration (SMR with CCS).

Hydrogen can be blended into the existing gas grid and is compatible with existing appliances at higher blends than currently permitting under the gas quality regulations. The HyDeploy¹⁷ project will test the impact of increasing the hydrogen blend to 20% by volume for the first time in the UK network. This offers a route to establish low carbon hydrogen production, distribution and use without disruption to the gas consumer.

As discussed elsewhere in this response, low carbon hydrogen also provides a route to decarbonise industry which cannot otherwise be decarbonised. It can provide a low carbon feedstock, and deliver heat, including high grade. Furthermore, it can provide a valuable part of the roadmap towards wider hydrogen adoption. By deploying hydrogen supply to selected industrial plant, it is possible to achieve substantial emissions reduction, establish hydrogen production volumes including CCS, and potentially assist in managing wider network demand fluctuations.

Longer term, it may also be possible to convert complete sections of the gas distribution network to 100% hydrogen, as proposed by the Northern Gas Networks H21 programme¹⁸

Carbon Capture and Storage

In view of the important contribution that hydrogen can play in decarbonising heat that it is important **the Government supports the introduction of infrastructure to enable carbon capture and sequestration** as recommending in the Oxburgh report¹⁹.

Key requirements include a firm CCS policy, recognising the genuine world-leading opportunities the UK has with its offshore geological storage.

Delivery requires a Practical CCS roadmap, recognising the reality of post "CCS-commercialisation programme" world. This involves a staged, incremental, deployment plan rather than the previous ambitious large scale infrastructure approach. This requires a focus on projects with lower initial investment (and so low cost capture, limited CO₂ volume requirements, transport and storage options which are low cost for limited volumes and have growth potential).

¹⁷ https://www.ofgem.gov.uk/system/files/docs/2016/04/ng_ngn_hydeploy_isp.pdf

¹⁸ <http://www.northerngasnetworks.co.uk/wp-content/uploads/2016/07/H21-Report-Interactive-PDF-July-2016.pdf>

¹⁹ http://www.ccsassociation.org/index.php/download_file/view/1043/508/

To make CCS happen Government must:

- Accept storage and cross chain risks
- Be prepared to invest itself
- Work in partnership with industry
- Commit to a believable near term deployment vision

Deeper decarbonisation

There are substantial synergies between BioSNG production and the conversion of the gas network to hydrogen. The technology used to produce BioSNG can be easily adapted to produce hydrogen or to produce a blend of hydrogen and BioSNG. BioSNG facilities can offer the flexibility to adapt to increasing levels of hydrogen as the network evolves. This provides a very cost effective route to hydrogen production, and unlocks early adoption of hydrogen.

The GHG impact of BioSNG improves dramatically when it is combined with carbon sequestration. The BioSNG process creates a stream of relatively pure carbon dioxide that is suitable for sequestration. If infrastructure for storing carbon dioxide is developed the GHG savings of BioSNG increase by more than 50%. If a BioSNG facility using carbon sequestration is converted to biohydrogen production even higher savings are achieved because all of the carbon in the feedstock is captured. The biogenic carbon dioxide captured from the atmosphere in the biomass is sequestered creating genuinely negative carbon emissions.

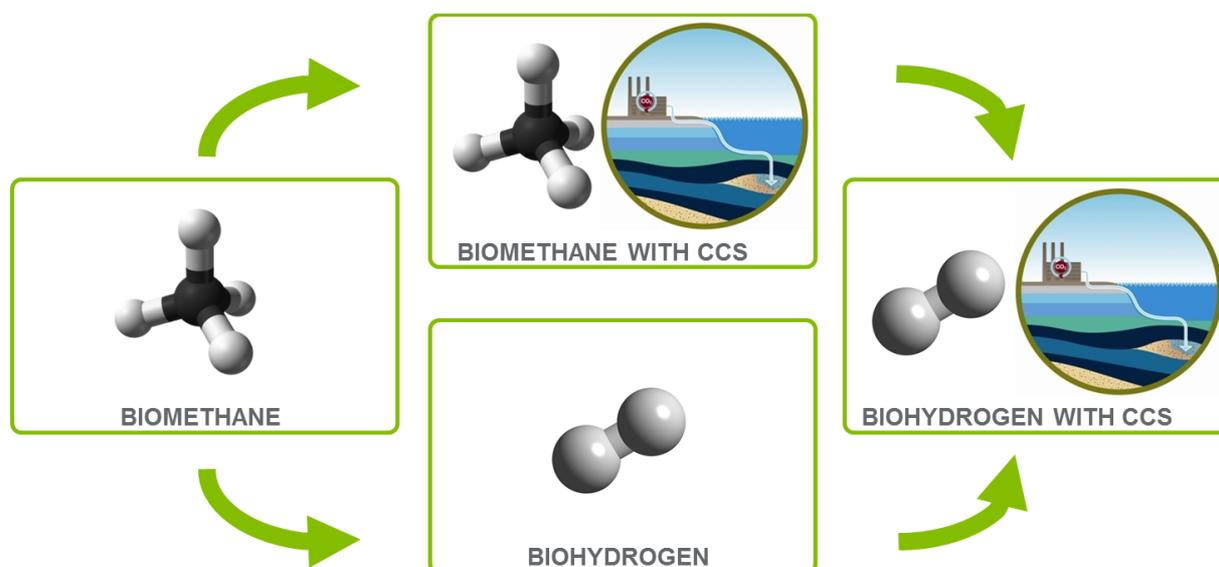

Figure 5 Routes from BioSNG to deeper decarbonisation

Developing technologies with negative carbon emissions is essential in meeting 2050 climate change goals. The negative emissions will offset emissions from hydrogen produced by SMR with CCS and from other sector that are hard to decarbonise such as aviation and farming. The imperative of this is shown very clearly by ETI in their ESME Modelling in Figure 1

The incentives for production of low carbon heat should recognise and support the importance of hydrogen whether it comes from renewable sources or fossil sources combined with CCS technology.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

We believe that such a sector will involve zero carbon renewables such as wind and solar. However, these cannot provide reliable and dispatchable power. Therefore, there is likely to be a role for both nuclear and electricity storage. However, recognising (a) the baseload nature of nuclear and (b) the quantum of the storage phenomena required at a grid scale, there will also be a need for dispatchable fossil fuel with CCS, which can provide the resilient supply required. Both CCC and ETI share this view.

Furthermore, CCS also unlocks opportunity for negative carbon emissions via BioEnergy CCS (BECCS), which cannot be achieved elsewhere. This provides vital offsetting for other aspects of the energy system which cannot be decarbonised.

The ETI show this as being significant. We are of the view that it could certainly play a role in the electricity sector, although from our responses elsewhere, our biomass should probably be focused on the heat sector which is harder to decarbonise than electricity, but it can deliver the same outcome across the energy system – negative emissions. In reality there is likely be element in the electricity sector, for example where a generator is fuelled by negative-carbon hydrogen.

Whilst we understand the role that distributed generation can make, there will always diseconomies of scale in terms of resource utilisation and cost, as well as need for resilience, that means a balanced portfolio that includes centralised as well as decentralised power. We have a world class transmission and distribution network and this asset should continue to be used.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Electrification of passenger vehicles is an important element of decarbonising transport and also addresses air quality concerns especially in cities. This will place increased demand on electricity generation and networks. Given that generation capacity is already under considerable strain and reliant on sweating old assets and new interconnectors, this cannot be ignored. Additional demand in this sector also has cross-cutting implications for assumed electrification of part of the heat sector.

Whilst there is an argument that the inherent storage provided by EVs may assist in balancing the electricity network, the utility of such vehicles to consumers will remain paramount. It is unlikely that there would be universal acceptance of that storage being drained to fulfil network load demands thereby precluding the consumer from making planned journeys.

Charging times are also likely to become a significant issue as the vehicle parc increases. This may be ameliorated by advances in battery technologies but will remain a fundamental limitation. Hydrogen as a low carbon, low emission vector offers the opportunity to address this, with filling times more consistent with existing fossil routes. Development of robust electric drive trains and vehicle platforms provides an excellent foundation for hydrogen vehicles in the future. Combined with the potential transition of the gas network to hydrogen there is an obvious and practical roadmap towards alternative low carbon passenger vehicle infrastructure.

However, whilst continued electrification of passenger vehicles is inevitable, this is not suitable for HGVs where the battery payload and charging times become a major constraint. Renewable gas provides a deployable technology today to replace diesel HGVs, recognising that current biodiesel is not truly fungible with blend limits. This can deliver savings in the current and foreseeable carbon budget periods as well as low noise and address city air quality issues. Furthermore, as with passenger vehicles, a

transition towards gaseous based fuels provides a transition route to hydrogen in the future on a longer-term basis. Air quality and noise are on a par with electric vehicles.

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Financial incentives are extremely important in the short term to develop a sustainable waste to energy industry, but that currently they are not correctly aligned between heat, transport and electricity outputs to produce outcomes that optimise least-cost carbon reduction. Some very specific issues are discussed below across each of those incentive regimes.

In addition to coordination within BEIS and between BEIS and DfT it is also important that there is a joined-up approach between DEFRA (and WRAP) and the energy related departments. The requirement for public health considerations of waste and the recognition of it as an energy resource needs to be appropriately joined up.

As is discussed elsewhere in the consultation, there needs to be careful treatment of the waste hierarchy. Waste avoidance and recycling are undeniably highest priority. In terms of recycling, the primary focus should be on materials with the highest inherent carbon, energy and resource intensity; glass and metals. It is also important to recycle plastics and paper – however only providing that the quality of the recyclates are sufficient to provide good quality products. There is a limit to this downcycling; either by the carbon/energy involved in the upgrading chain, or the genuine lack of utility of the output. It should be recognised that taking the materials down to their fundamental hydrocarbon building blocks as C1 chemistry which can then be rebuilt into new materials or energy vectors is a valid form of molecular recycling. Historically this position has been considered an anathema, and that recycling should be pursued at all costs. It is time for a more nuanced understanding and application of the principles. Currently the energy market values the renewable, biological element of this (with BioSNG being a good example of the pathway and providing the early platform), but over time bio-materials will be valued.

Renewable Heat Incentive (RHI)

The RHI provides support to biomethane produced by AD and gasification technologies such as the BioSNG process. However, support drops off rapidly for facilities producing more than 40GWh/a of gas. This is an appropriate limit for AD, which works best in small facilities designed to use locally available agricultural feedstock, but it is too restrictive for BioSNG, which operates in an urban environment where waste volumes are higher.

DECC launched a consultation on reforms to the RHI in the spring of 2016. We, along with National Grid, the Renewable Energy Association, and range of engineering companies responded to ask for more focussed support for BioSNG with a separate RHI band providing 5.87p/kWh without any limits on scale.

BEIS published their response to the consultation on 14th December 2016. They agreed that BioSNG could increase the supply of green gas but rejected setting up a new band because of lack of evidence on costs and the risk of overcompensation.

Issue

Progressive Energy and its partners in the BioSNG projects are engaging with waste companies to start development of large scale BioSNG plants. The completion of the first commercial plant in 2018 will be followed by facilities around ten times bigger if appropriate support schemes are in place.

However, the failure to amend the RHI to support BioSNG plants is likely to have the following impact:

- A significant delay in deployment of an innovative low carbon heat solution.
- Failure to exploit the R & D into advanced biofuels funding by Progressive Energy, National Grid, APP shareholders and the UK Government.
- Continued landfilling and export of waste and inefficient use of waste to generate electricity with Government support under the Contract for Difference scheme.

Solution

We accept the Government's position and recognises that it is not feasible to introduce a new RHI band for BioSNG. A compromise would be to keep BioSNG within the AD band but to increase the size of the first tier when calculating support. This would be done with the following change to paragraph 21 of the RHI order.

(a) "initial biomethane" means the amount of eligible biomethane measured in megawatt hours which is injected in the 12 month period commencing with, or with the anniversary of, the tariff start date for the original biomethane ("the relevant period") up to 40,000 megawatt hours in the case of biomethane made by anaerobic digestion or pyrolysis and 120,000 megawatt hours in the case of biomethane made by gasification;

This minor increase in the tier would provide sufficient support to enable the development of the first large scale commercial plants.

Renewable Transport Fuel Obligation (RTFO)

The RTFO is a further scheme that has the potential to incentivise waste to renewable fuel plants. The Department for Transport issued a consultation on changes to the RTFO on 29th November 2016.

The key proposals are to:

- Increase the level of renewable fuels from 5% to 10% by 2020 and maintaining it at 10% or above until 2030.
- Introduce a cap on the amount of biofuels produced from crops that can contribute towards the 10% target – the consultation proposes 2%.
- Introduce a new obligation for the supply of development biofuels that are produced from wastes and residues. This will grow to 1.2% (3.8TWh) by 2030. The consultation asks if biomethane should be included in this development category.

In our response we said that:

- The proposed changes are good for decarbonising transport and establishing a biofuels and low carbon transport industry that will create jobs, investment and exports.
- Biomethane is one of the best candidates for decarbonising heavy goods vehicles and buses and should be included in the development target.
- The buy-out price for development fuels should be set at a high level to provide strong incentives for this new technology.

Contracts for Difference (CfD) Scheme to support renewable electricity generation

We have recently responded to BEIS's call for evidence on fuelled and geothermal technologies in the CfD scheme. In summary, we have suggested that so-called Advanced Conversion Technologies (ACTs) should no longer be supported by the CfD scheme but that ACT-based heat and fuels are appropriately supported. This is because the current ACT regime means that some projects are receiving a substantial subsidy for converting waste to electricity at efficiencies (<18%) lower than open market projects which operate with no support. This means that consumers are paying a subsidy for a worse carbon outcome; this is certainly not cost effective decarbonisation.

As noted above, the journey to decarbonise electricity generation has progressed far further, and there are many options available to produce clean electricity. Being mindful of the relative immaturity of the heat and transport sectors on the low carbon journey, and the many options for electricity production, we believe that feedstocks potentially capable of producing low carbon fuels for heat or transport must be carefully managed. Incentivising their use in electricity generation could lock away valuable feedstocks for many years e.g. 15 year waste contracts, or sewage treatment investments.

We suggest that removal of support for ACTs under the CfD regime should be undertaken in a co-ordinated way including enabling support for heat and fuels. This must focus on ensuring the future incentive regime for renewable heat provides the transitional support which was formerly delivered to AD, to allow gasification to deliver early commercial projects prior to being able to operate without support. Similar co-ordination is required with the Department for Transport on the Renewable Transport Fuel Obligation which is also currently under consultation.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

A circular economy delivers effective resource utilisation. As noted previously, simply burning waste to generate electricity misses the opportunity which this bio-rich resource offers. Reforming the waste to a clean syngas, which can be used as a chemical precursor for production of fungible gas, fuels or chemicals, is a perfect form of molecular recycling.

Production of a clean syngas by gasification of waste also facilitates carbon capture using existing proven carbon dioxide separation technologies which have been operating for many decades. Conversion of a solid to a gas or a liquid inevitably leads to excess bio-carbon which is rejected as bio-carbon dioxide. This forms the basis for the use of BioEnergy CCS (BECCS) which is recognised by both the Committee on Climate Change²⁰ and the ETI²¹ as fundamental to meeting our 2050 targets. This approach already delivers captured bio-carbon dioxide today. For example, production of methane from solid biomass leads to around half of the carbon separated as storage-ready carbon dioxide. This is already undertaken at all ~70 AD biomethane plants, some of which capture the carbon dioxide and sell it to industry. It will also be demonstrated at the BioSNG project at Swindon, where 5000 tonnes of carbon dioxide per annum will be sold to industry. In the future, this approach can be extended (simplified), with hydrogen produced as the energy vector with separation of all the carbon for storage.

NATIONAL INFRASTRUCTURE ASSESSMENT – CALL FOR EVIDENCE

Submission from Publica

10 February 2017

1. INTRODUCTION

- 1.1. Publica is a London-based public realm and urban design consultancy, specialising in research, strategy and design for public space, urban design and masterplanning. Since Publica was formed in 2010, every masterplan we have worked on has had a significant infrastructural change as its catalyst. We welcome the opportunity to provide a view on the pressing infrastructure challenges to be highlighted by the National Infrastructure Assessment.
- 1.2. Our response to the call for evidence relates to the 'Cross-cutting issues' and 'Transport' sections of the call for evidence, as these most closely relate to Publica's area of work and expertise.
- 1.3. The material shared is underpinned by our belief that the future lies in compact urban growth, and recognises the importance of density and intensification in the development of high quality urban neighbourhoods. It focuses on the relationship between infrastructure, urbanism and liveable cities, and is based on evidence from Publica's projects in London as well as international case studies.

2. QUESTION 2: HOW SHOULD INFRASTRUCTURE MOST EFFECTIVELY CONTRIBUTE TO THE UK'S INTERNATIONAL COMPETITIVENESS?

- 2.1. Infrastructure has a vital role in supporting cities' efficiency, resilience and their attractiveness to future and current residents as well as investment, both internally and externally.
 - 2.1.1. Infrastructure is an intrinsic part of development across London. The link between infrastructure investment and large scale change and development is visible on a map of Publica's recent projects (see Appendix 1), which have all overlapped with the routes of the Elizabeth Line and the proposed Crossrail 2. Embracing this opportunity is currently led by the private sector's energy and enthusiasm to contribute to the improvement and development of London as a liveable and internationally competitive city.

- 2.2. One of the truly critical factors which supports modern cities and their infrastructure in allowing their populations, economies, and built and natural environments to thrive is strong leadership and vision.
 - 2.2.1. In France, Mayor Anne Hidalgo is leading work to improve the pedestrian experience in Paris's public squares, as well as running a major competition – *Réinventer Paris* – for the private sector to lead in re-positioning Paris as a city of innovation. This has signalled a major shift in how the city is viewed and used; streets are being given back to people, the city is re-establishing its relationship with the river Seine, and, as a result, the urban competitiveness of Paris is on the rise.
 - 2.2.2. In the Brazilian city of Curitiba, three-time Mayor Jaime Lerner provided a visionary leadership needed to deliver truly transformative infrastructure. One of the city's key achievements is its Bus Rapid Transit system. Facing the option of the costly construction of subway lines, Lerner commissioned instead a functional bus network with attractive transit stops, dedicated bus lanes along the city's main arteries, and handicapped access equipment. This ambitious programme succeeded in rendering public transport accessible to all and the BRT system has become a symbol for the city.
- 2.3. A city's international competitiveness is fundamentally tied to the quality of life that it is able to offer to its inhabitants. Offering citizens a clean, green, safe and attractive environment is therefore crucial to cities' prosperity.
 - 2.3.1. The City of London is aware of the pressure on its streets and spaces, and how the area's qualities affect its overall global competitiveness as an international financial and business services hub. Once the domain of private vehicles, the streets of this area are being re-imagined as spaces for pedestrians, cyclists, consolidated servicing, increased spatial efficiency, and enhanced public space in response to rapid intensification and growth. Publica's Bank Area Strategy¹ for the City of London demonstrates this shift in understanding space in the area. It sets out the City's vision for transportation and public realm improvements in the Bank area over the next ten years. A long-term vision planning for future growth is crucial in maintaining the City's status as the world's leading international financial and business centre.
 - 2.3.2. Pollution, in all its forms, is a major issue faced by many cities around the world. The City of London, for example, has some of London's highest levels of pollution due to its central location within the city and also the density of development in the area. In 2015, the City of London appointed Publica to produce a set of site-specific recommendations for public realm enhancements, and general recommendations or principles for public

¹ <http://www.publica.co.uk/projects-bank>

realm design that mitigates the impact of air pollution (see Appendix 2). This is crucial to improving the health and wellbeing of residents, workers and visitors – a central aspect of global competitiveness.

- 2.4. With growing and aging populations, we need to design our infrastructure and developments with capacity to accommodate future growth. To do this we must: make more of what we have work harder (including land, building stock, spaces in between); integrate infrastructure which is sensitive to the specificity of place and its character as well as its pattern of use; and apply long-term thinking to ensure future resilience and sustainability.
3. QUESTION 3a: HOW SHOULD INFRASTRUCTURE BE DESIGNED, PLANNED AND DELIVERED TO CREATE BETTER PLACES TO LIVE AND WORK?
 - 3.1. The first thing to establish in deciding what a new site needs is what already exists in the district and what is missing as the basis for the integration of a new neighbourhood. Publica’s methodology begins with a wider area survey to look carefully at existing spatial, social, and cultural conditions. This informs all aspects of the design process.
 - 3.1.1. In April 2014, Publica was commissioned by the Northbank BID to produce a Public Realm Survey.² The project examined existing public realm conditions within the Northbank area – an area stretching between Trafalgar Square, Covent Garden, the Thames, and Aldwych – and to make recommendations for potential future improvements to the district as a whole, providing a strategic overview to identify key issues and opportunities. This careful survey of existing conditions is necessary to ascertain improvement needs.
 - 3.2. Infrastructure, often considered as a ‘hard’ element that allows a city to function, should be recognised as an integral part of city life and incorporated within it. For example, new infrastructure can provide opportunities for new public amenities and open spaces.
 - 3.2.1. The Westway, in west London, opened in July 1970 as the A40(M). A 3.5-mile elevated dual carriageway section running from Paddington to north Kensington, it was built to relieve congestion at Shepherd’s Bush caused by insufficient capacity on central London’s roads. Its construction also bisected neighbourhoods, changing their character forever. However, the Westway Development Trust was established soon after the completion of the Westway to claim back and develop surrounding land for local community uses. The charity has had a significant impact on the territory underneath the Westway, converting 23 acres of previously vacant land into a thriving sports and amenity zone.

² <http://www.publica.co.uk/northbank>

ground level activity is for the city. Animating the ground plane and creating a sense of civic identity is key in designing infrastructure to create better places to live and work.

- 3.4.1. Hanover Square is a historic London square laid out in 1713, situated between Oxford Street, Regent Street and New Bond Street. The opening of the Bond Street East Elizabeth Line station on the square has been the catalyst for an integrated approach to public space improvement around new infrastructure, which has also offered a chance to restore a once over-looked square in the heart of London's West End. Further detail on the work that Publica has been undertaking to integrate this key new infrastructure within a central urban neighbourhood can be found in the project summary in Appendix 3.
- 3.4.2. In August 2014, Publica was commissioned to develop a detailed Vision for the Northbank and Public Realm Strategy for the district. The Northbank is a district subject to several new development proposals. These include a number of major infrastructural projects, such as the proposed Garden Bridge, the removal of the Aldwych gyratory, TfL's east-west Cycle Superhighway and changes to the riverbank as part of the Thames Tideway Tunnel works. Publica's Vision sought to build upon this context to reinvent the area's identity and maximise its potential by giving consideration to the public realm. Four key themes were used for analysis: mitigating the impact of traffic, upgrading the public realm (including greening, materials, lighting, and decluttering), connecting the public realm (wayfinding strategies, strategic walking routes and connections, and improved crossings), and celebrating public life (cultural programming and supporting an active and vibrant street life).
- 3.5. Infrastructure also has a key role to play in addressing socio-economic inequalities, by improving connectivity within cities and regions, promoting local economic growth, and supporting access to, and provision of, social infrastructure.
 - 3.5.1. In 2004, Mayor Sergio Fajardo implemented a new city plan in Medellín targeted at reducing social inequality by identifying priority areas for intervention, where social and economic issues were more acute. Part of this plan was a cable car transport system (MetroCable) that was a solution to the challenge of isolation and poor connectivity created by the natural topography of the city. It now connects the informal residential areas with the centre of the city; bringing citizens close to economic opportunities, leisure, culture and education. Social amenity is clustered around MetroCable stations, bringing transport and social infrastructure together. This can be seen in the example of the *Parque Biblioteca España*: designed by Giancarlo Mazanti, three black buildings house a public library, which hosts a range of programmes, resources and services for

the local population; the public space formed by the buildings directly connects to the MetroCable station.

4. QUESTION 3b: HOW SHOULD THE INTERACTION BETWEEN INFRASTRUCTURE AND HOUSING BE INCORPORATED INTO THIS?

4.1. Infrastructure and the built environment should support and promote density and diversity to ensure our cities remain liveable and attractive places for people to live and work.

4.1.1. The creation of new transport hubs can unlock new areas for the creation of liveable urban neighbourhoods, which bring work, amenities, and living closer together. Transport developments like HS2, the Elizabeth Line and Crossrail 2 have the capacity to unlock land for denser residential and commercial use, which will in turn create new demands on infrastructure; including water, internet, and electricity as well as increased demand for new and existing transport links.

4.1.2. In London, the development of large sites – potentially a valuable resource for meeting the city’s housing needs – has historically been constrained by a lack of local and transport infrastructure. As a key criterion in determining the levels of density permissible in London, transport infrastructure should thus be considered and designed as a key driver for housing growth.

4.2. Densification, which involves increasing the number of dwellings per hectare through a number of methods including infill, and demolition and rebuild, is currently viewed as having great potential for increasing housing supply, specifically in London. If this represents a crucial opportunity to address persistent housing shortages, the potential of new developments in stretching the local community resources and infrastructure should be carefully assessed.

4.3. The provision of social infrastructure – referring to a wide range of assets and services, including those related to health, education, community, culture, play, recreation and sports, faith and emergency facilities and services – is also central to meeting local needs and contributing to quality of life of residents.

5. QUESTION 11: HOW SHOULD INFRASTRUCTURE MOST EFFECTIVELY CONTRIBUTE TO PROTECTING AND ENHANCING THE NATURAL ENVIRONMENT?

5.1. A sustainable city requires for its operation that natural systems are fully integrated within its physical structure and that their benefits – often referred to as ‘ecosystem services’ – are fully recognised. Green infrastructure – defined as any system in which active biological

organisms participate, ranging from green spaces to green roofs of walls – performs multiple urban functions including transportation, waste removal, temperature control, removal of air pollutants, power generation, stormwater management etc.

- 5.2. Conceptualising cities and their natural systems in more holistic terms, through concepts such as green infrastructure, is crucial in protecting and enhancing the natural environment.

- 5.2.1. The All London Green Grid (ALGG) policy framework, first initiated in 2012, gives a comprehensive overview of London’s natural assets, what it terms green and blue infrastructure. The policy asserts that the city’s green open spaces, woodlands and rivers should be seen alongside what we typically regard as infrastructure, and be managed in a similar long-term strategic vision.

6. QUESTION 13: HOW WILL TRAVEL PATTERNS CHANGE BETWEEN NOW AND 2050? WHAT WILL BE THE IMPACT OF THE ADOPTION OF NEW TECHNOLOGIES?

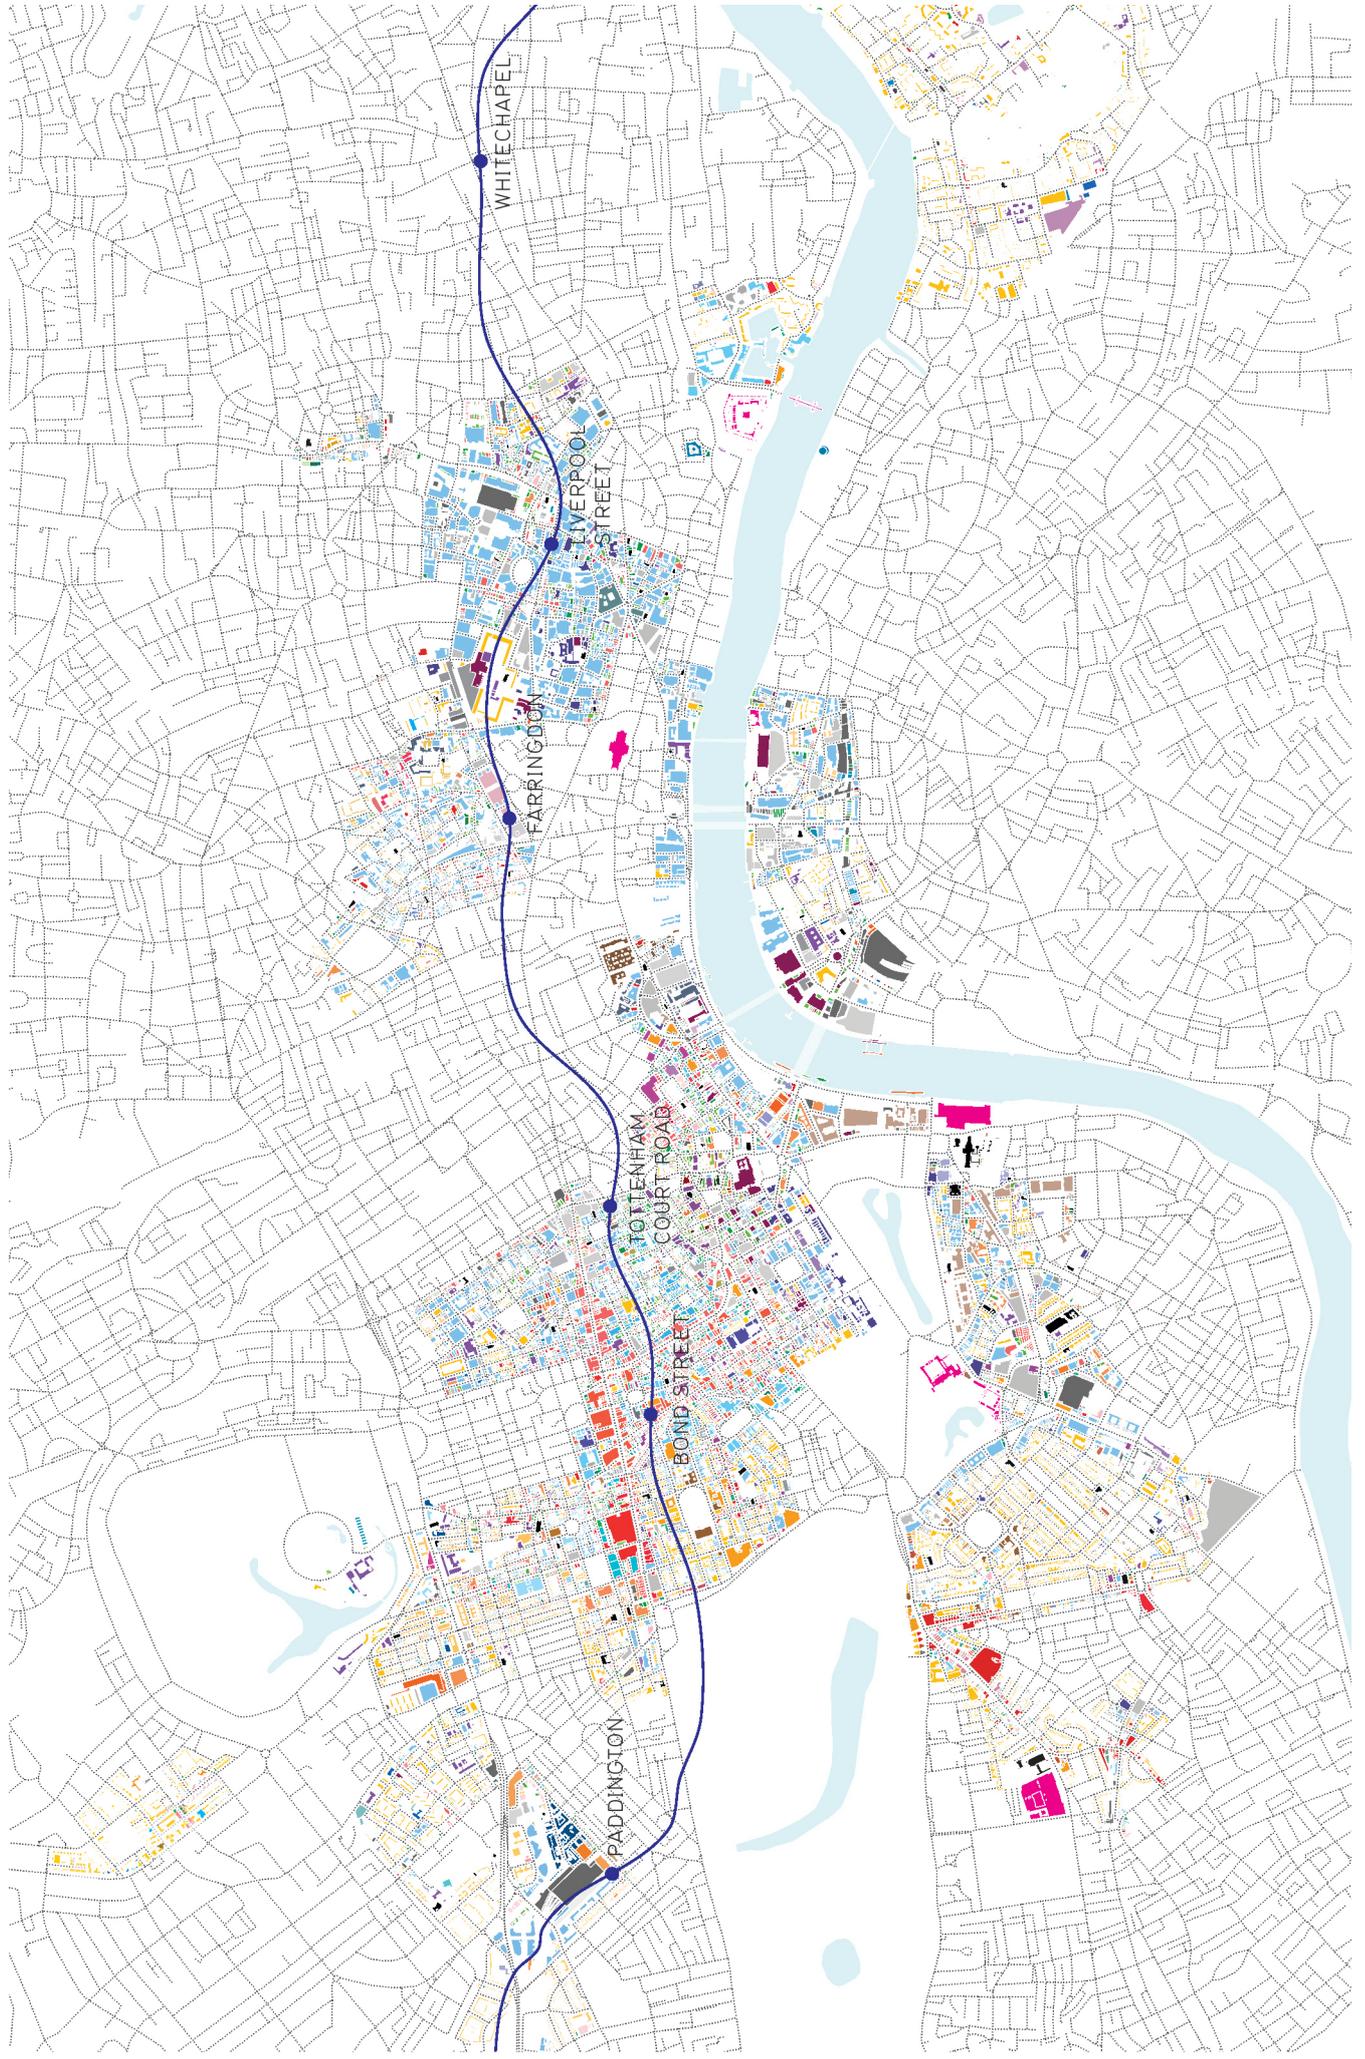

- 6.1. In modern cities, transport and communications technology are becoming increasingly interdependent, with communications being key to the operation and integration of a modern transport network. Transport users expect increasingly up-to-date service information, access to Wi-Fi on the underground network, and the ability to navigate the city using GPS on their mobile phones. This can be an opportunity to reimagine the space of public transport and the public realm as one in which people are increasingly connected. As technology develops, it is important to growth the capacity for connectivity throughout the transport network.
 - 6.2. Active travel is expected to become increasingly important, as cities densify, and seek to reduce their carbon impact. It is therefore important that active travel infrastructure is not just built to respond to current problems, but rather pre-empts future challenges and can be adapted to respond to future unknown problems. For example, a sustainably designed public realm would consider our ageing population, and include regularly placed seating, and crossings that are timed to meet the needs of older pedestrians. The ‘Healthy Streets’ approach developed by TfL and the GLA, and shortly to be launched as a core element of the Mayor of London’s Transport Strategy, provides further detail on this.³
 - 6.3. The growth of the night time economy, an important part of what attracts people to cities, is likely to impact travel patterns and intensify pressures on transport networks. Night time travel will have to be supported by an animated and inclusive public realm, allowing those people who might feel more vulnerable at this time, such as women, to take full advantage of the night time economy.

³ <http://content.tfl.gov.uk/improving-the-health-of-londoners-transport-action-plan.pdf>

6.3.1. Publica has recently developed a vision for Oxford Street, in partnership with economic planner, Volterra, and planning consultants, Gerald Eve. The study looks at the whole Oxford Street district, accommodating diverse projects and drivers for change, including increasing capacity for additional workspace, the provision of new public spaces and amenity and uses to ensure a long-term dynamic future for this economically vital district. One of the principles seeks to diversify uses on Oxford Street, incorporating additional evening services for locals and visitors to support the introduction of the Night Tube and to support the cultural and entertainment uses of neighbouring areas.

APPENDIX 1: PUBLICA'S CURRENT AND RECENT PROJECTS AND THE ELIZABETH LINE

APPENDIX 2: CITY OF LONDON AIR QUALITY STUDY

Executive summary

Air pollution is the introduction into the atmosphere of chemicals, particulates or biological materials that cause discomfort, disease or death, and damage to the natural and built environment. It can exacerbate potentially fatal health conditions, including asthma, heart and lung diseases, other respiratory diseases, and allergies. In the UK it is estimated that air pollution costs the lives of 29,000 people each year; over 4,000 of these are estimated to be of Londoners.

The City of London has some of London's highest levels of pollution, due to its central location within the city and also the density of development in the area. In February 2015, the City of London appointed Publica to prepare a report on opportunities for reducing exposure to air pollution through public realm considerations.

In preparing this report, Publica carried out a literature review, examining best practice in mitigating the impacts of air pollution, as well as relevant EU and UK air pollution policy. The central focus of the study was an analysis of three streets in different parts of the City of London. The analysis of these streets—Beech Street, Liverpool Street and Mansell Street—included: an examination of plans for the surrounding areas; meetings with a small selection of stakeholders; an on-site survey to understand how the streets are currently used; and an assessment of the impact of air pollution on those using the streets.

Publica produced a set of site-specific recommendations for public realm enhancements, and general recommendations or principles for public realm design that mitigates the impact of air pollution (shown on the next page). These recommendations are designed to assist decision-making, as the City of London strives to meet its commitment to improve the health and wellbeing of residents, workers and visitors.

General recommendations for reducing exposure to air pollution through public realm considerations

- Consider all efforts to reduce exposure as accompaniments to committed, borough-wide (and London-wide) actions to reduce emissions.
- Enforce idling bans across the City of London, particularly at known high exposure sites, such as residential areas and schools
- Ensure ongoing monitoring of air quality within the City of London, and explore the possibility of raising the visibility of monitoring stations to increase awareness of the issue.
- Consider developing a coordinated communications strategy, to ensure consistent messaging when engaging with a range of different stakeholders on the subject of air quality.
- Continue to engage with City businesses, supporting their encouragement of employees to walk and cycle to work.
- Consider each specific site and its wider context when looking to implement public realm enhancements and measures to reduce exposure; use TfL's Roads Task Force Street Types and site analysis to understand how to reduce exposure of people when they are stationary as well as when they are moving through the City of London.
- Explore how efforts to reduce exposure can be balanced with a desire to maintain vibrancy at street level.
- Explore promotion of pedestrian priority in high exposure areas, in order to encourage walking and reduce use of vehicles.
- Identify opportunities to enhance the pedestrian environment, in order to encourage pedestrians to use low emissions routes.
- Consider and review the impact on pedestrian flows which the 2018 opening of Crossrail stations across, and in close proximity to, the City of London will have on particular areas.
- Explore how greening efforts (including tree planting and green wall installation) can be used to signify and encourage use of lower emissions pedestrian routes and places for people to sit.
- Explore options for establishing low emission neighbourhoods (LENs) at City of London air pollution hotspots.

APPENDIX 3: HANOVER SQUARE FOR WESTMINSTER CITY COUNCIL

Public realm upgrades to Hanover Square and its environs will create a well-designed public space fit for the arrival of Crossrail, as a new front door to the West End and a true oasis space in the city. This project will provide a step change in the quality of public realm provision in the West End heralding a new approach to the district's historic townscape, its integration with the upgraded transport infrastructure and restoration of an important and beautiful amenity space. The project will provide a high quality setting for a number of significant new buildings, and help to support the promotion of the wider West End as a retail environment, place to do business and area to visit.

The project is currently at early design stage and is planned to be delivered for the opening of the Crossrail station in late 2018, to address the acute need for improvements to the public realm outside Bond Street (East) station. The project is being developed with Westminster City Council, Transport for London, Crossrail, Historic England and with the neighbouring landowners and developers, funded by GHS (GP), represented by Great Portland Estates. Publica is developing materials that will allow stakeholders to adopt a shared vision and concept design and for the East Mayfair Project Board to take forward. Potential additional funding streams and promoters are currently being identified.

The project for the garden square will be fully integrated with the Crossrail public realm works for Tenterden Street and the immediate setting of the station. The relationship with connecting spaces such as Harewood Place, Princes Street, Dering Street, St George's Street and Brook Street will be considered to optimise benefits for the West End.

Expected outcomes and benefits of the project will include:

- Improvements to pedestrian environment; including expanded pedestrian space outside Crossrail station exit
- Accommodation of new pedestrian flows, minimised pinch points and congestion, and accommodation of pedestrian desire lines
- Improvement of the experience of shopping, visiting, working in and commuting into the West End, as well as the arrival experience into this unique area of London
- An improved look and feel of the streetscape; including optimisation of the latent townscape assets, views, landmarks and the unique built heritage, to allow access and enjoyment by all
- A fully restored garden square as a high quality, green and restful oasis space close to Oxford Street, Regent Street and Bond Street
- Better dispersal routes for the increased pedestrian flows and connections through the West End towards Oxford Street, Regent Street and Bond Street from the new station
- Encouragement and facilitation of walking at street level through the West End, to help relieve use of Underground, buses or vehicles for short journeys
- A strengthened north-south walking route through the West End, from Marylebone and Oxford Street into Mayfair on the axis of Cavendish Square to Conduit Street through Hanover Square and St George Street
- Improved cycle facilities, cycle parking close to major transport interchange(s)

- Changes to vehicle access and routes, which will have benefits for local air quality
- Linkages with and support of wider public realm objectives in the West End, such as review of bus operations and an emerging taxi ranks strategy
- Integration with neighbouring public realm projects on Oxford Street West, Cavendish Square, Bond Street, Brook Street, Mayfair traffic management, and the Royal Academy north-south walking route
- Building on recent upgrades in the area, such as Regent Street and Oxford Circus
- Development of designs in collaboration with WCC to ensure long-term management
- Improved image of the West End, its range and quality of spaces, for all local and international visitors, workers, businesses and residents.

Elements of the project will include:

- New natural stone paving and materials
- New pedestrian crossings
- De-cluttering of street spaces through removal of superfluous objects in the public realm,
- A new lighting strategy
- Opportunities for public art and other markers in the area
- New trees, and improvements to existing gardens,
- Improvements to reveal historic vistas, listed buildings, the Pitt statue and the historic cabmen's shelter
- Vehicle access changes, which might encompass timed service access only or bus priority streets in some areas and a new taxi rank.

Mobility • Safety • Economy • Environment

RAC Foundation's Response to the National Infrastructure Commission's Consultation on National Infrastructure Assessment Call for Evidence

February 2017

Introduction

The RAC Foundation is an independent transport policy and research organisation which explores the economic, mobility, safety and environmental issues relating to roads and motoring. The Foundation carries out independent and authoritative research with which it promotes informed debate and advocates policy in the interests of responsible road users.

In August 2016, the Foundation responded¹ to the Commission's earlier consultation on The National Infrastructure Assessment Process and Methodology² and some of the material in this earlier document are relevant to the current consultation – particularly on cross cutting issues that affect road transport. Again the Foundation's response deals mainly with roads as these are the type of infrastructure of greatest significance to the responsible road user, hence in the pages that follow we have focused on the specific transport questions in the Call for Evidence.

On your cross cutting-questions we offer the following observations which we would be happy to discuss further if you wished:

Q 3: How should infrastructure be designed, planned and delivered to create better places to live and work?

With the benefit of hindsight it is at least questionable whether we would have sought to bury so many network services underneath our road carriageways. The resulting streetworks are a particular problem where those utility networks are ageing and in need of frequent repair/maintenance. Looking ahead, we could look to new technology to limit the problems by the use of better, more resilient materials, and by 'keyhole surgery' techniques that minimise the need to break the road surface. There is plenty of material to be found in the DfT about options for improving streetworks management.

¹ RACF 2016.

² NIC May 2016.

Q 3 (part 2): How should the interaction between infrastructure and housing be incorporated into this? How should the interaction between infrastructure and housing be incorporated into this?

This question is absolutely central to the Commission's work, and warrants a questionnaire all of its own. The Government's appetite for new housing development suggests that while brownfield development might be part of the answer, entirely new greenfield (even green-belt) development is possible, with consequent opportunities to get all the infrastructure services and connections, including transport, right from the outset.

Q 4: What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Our submission, below, touches on road pricing. Clearly there are other traffic management options, some of which would have the potential to limit the capacity of road infrastructure required, though probably not the corridors i.e. same route, fewer lanes.

Q 5: How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

For roads, in particular, this is a key issue. Whilst new capacity gets the headlines, the condition of the existing network is a cause for concern. We would urge the Commission to look carefully at the risk to network resilience of inadequate maintenance provision, in particular on the vast majority of roads that fall to local government to maintain (see 'The condition of England's local roads and how they are funded', RAC Foundation, November 2015). This links also to question 12.

Q 12: What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Investment appraisal could also, as a topic, absorb the Commission's time in perpetuity, not least because the accurate forecast of economic benefits and, often environmental, disbenefits over several decades is both hard to calculate and hard to monetise. The answer probably rests in ensuring that cost-benefit calculations are always presented in ranges. The Foundation has offered thinking on the refinement of transport appraisal (see 'Transport Policy, Appraisal and Decision-Making', RAC Foundation May 2015). Not so much a thought about technique, there is a case for improving the economic appraisal of maintenance activity. This clearly needs more work, one avenue of which might be to assess more thoroughly the traffic impact of deteriorating road condition, in terms of pothole claims, then reduced speeds and ultimately impassibility (see 'The Economics of Road Maintenance', RAC Foundation, June 2013).

Questions on Transport

Q1: How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

1.1 Future travel patterns will depend on the size and location of the population, the form and patterns of economic activity, developments in transport technology, the costs of transport fuels, the provision of transport infrastructure and public policies on matters such as transport pricing and environmental regulations. Ranges for some of these factors can be estimated with a reasonable measure of certainty for some years ahead³, whilst others are so uncertain that their future can only be a matter of speculation. Attempting to forecast all of these and how they will interrelate over thirty years ahead with any confidence is beyond the Foundation's (and probably any other organisation's) capability.

1.2 The most thorough attempts to estimate future transport demand for England and Wales have been made by the Department for Transport⁴ and the most recent estimates of road travel demand stretch out to 2040⁵. For planning purposes this is a reasonable horizon in avoiding the huge uncertainties of trying to forecast further ahead yet giving a sufficiently long timespan for major infrastructure decisions to be made taking account of the first 15+ years of their operational lives. However it is important that this horizon is rolled forward every few years to incorporate changes in current circumstance, improvement in forecasting methods and ensure a significant number of projects' early lives are captured in the appraisal process. The Scottish Government has published its own Economic Strategy, and plans for infrastructure investment⁶ but these do not include detailed forecasts like those for England and Wales.

1.3 The DfT forecasts are based on 5 scenarios for England and Wales with trip rates, income elasticities and general economic conditions varying between them. They incorporate the established drivers of travel demand (population, income, car ownership etc.) and also take account of limitations in the capacity of the road system. The forecasts are disaggregated by trips numbers and distance, traffic volumes and congestion, vehicle type, road type, time of day, area type and region.

1.4 The forecast traffic growth between 2020 and 2040 ranges from 10% to 27% with the median (3) forecasts giving an increase of 18%. The greatest growth is forecast to be in LGV traffic with articulated HGVs also growing faster than car traffic. Growth in larger urban settlements and cities is expected to be less than in rural areas. There are also regional differences with the North East and North West expected to see less growth than average and the most growth forecast for the East of England. As would be expected London is

³ Population being perhaps the best example as in NIC 2016d.

⁴ DfT 2012a.

⁵ DfT 2015a.

⁶ Scottish Government 2014a.

forecast to have the lowest road traffic growth but the estimates nevertheless paint a picture of substantial traffic pressures on the Capital's road network.

1.5 Whilst these estimates do not claim to be precise forecasts, they are a useful guide as to how travel demand is likely to develop; given what is known about current travel patterns and their causes and on reasonable expectations of how economic, social and, to a degree, technological conditions will change in future. The range is sufficiently broad to encompass reasonable sensitivity tests for appraisal of infrastructure projects. However, as in our earlier response, we believe that more attention should be paid to social and cultural changes (response⁷ to Q3).

1.4 Much of the technology that will affect our transport system over the coming two or three decades is already available in one form or another. The major uncertainties relate to its rate of adoption, the types of applications it will be used for and the role of public policies promoting, steering or regulating its use. The major changes that currently appear to be in prospect most likely to affect road transport are:

- changes in road vehicle traction systems – more efficient ICEs, hybrids, plug in electric (light) vehicles and, in due course, fuel cell drives;
- increased use of technology in vehicle operations ADASs (Advanced Driving Assistance Systems) and autonomous operations (Connected and Autonomous Vehicles (CAVs));
- improved information systems allowing more sophisticated travel planning, traffic operations and vehicle scheduling; and
- further improvements in general electronic communications which will aid transport operations but also allow more physical transactions to be replaced by electronic transactions.

1.5 It is also possible that we will see a migration toward electronic Pay As You Go (PAYG) charging systems for road use, e.g. for a more sophisticated congestion/emissions charging regime in London.

1.6 The first of these should allow the problems of fossil fuel dependency and road transport emissions (assuming a sympathetic national energy strategy) to be much reduced and, as such they should be positive for road transport. The second presents the greatest unknowns as this type of innovation is still at the 'nursery' stage and in a state of considerable flux. The Foundation believes that there is considerable scope to improve safety and ease the driving task by the use of this family of technologies but that, with present and prospective systems, it would be unwise to assume that there will be widespread use of autonomous vehicles which substantially increases the efficiency of all road use – although this may be possible on motorways and some expressways. A recent study for the DfT has concluded that CAVs could improve the operation of the Strategic

⁷ RACF 2016a.

Road Network and, when they form a substantial proportion of traffic, urban roads - but was not able to adequately represent the interaction of CAVs with cyclists, pedestrians and other non-motorised users and roadside activities⁸.

1.7 The recent emergence of drones has led to speculation that these will become a common means of home deliveries. However the costs, nuisance and safety considerations are likely to limit this to a range of niche markets; as is 'aerial congestion' in urban areas. Past predictions of mail being delivered by parachute in 1921 and the widespread use of personal helicopters in 1951⁹ have not come to pass as a result of insufficient attention to the laws of physics and economics.

1.8 Information on the operations of road and rail transport has been transformed since the turn of the century and most travellers are able to access information on existing travel conditions and, to a lesser extent, how these are expected to change in the near future. Improvements will continue to be made, with more widespread consumer information on parking availability and public transport crowding - and more immediate information on events causing travel disruptions. The challenge in this area is to provide more accurate information on prospective travel conditions further ahead – and to allow for the effects of this on traveller behaviour.

1.9 There is also a public interest issue as to whether travel advice should be used to manipulate travel behaviour (by for example spreading traffic between two or more routes to ease pressure on the preferred route) to moderate congestion. Developments of these technologies has the potential to improve road travel, but their effectiveness will depend on the availability of a range of acceptable travel options. A classic example of this problem is that of congestion on the SW-W quadrant of the M25 where the rerouting options are so poor that even perfect information for road users is unlikely to provide significant real-time improvement to traffic flow.

1.10 Increasingly rich and inexpensive electronic communications have been affecting the way firms conduct their business, people plan their lives and public and private service providers interact with their clients for many years. Whilst these have to potential to substitute electronic communications for some physical movements they also allow more efficient operation of transport systems and widen trading, market and social hinterlands so expanding travel potential. It would be unwise to assume that travel will be largely replaced by electronic transactions, although we might expect the nature (frequency, destination, duration etc) of that travel to change over time¹⁰.

⁸ Atkins 2016a.

⁹ Popular Mechanics 2011a.

¹⁰ Cairns estimated in 2004 that that with realistic levels of take-up, a direct substitution of car trips by van trips for shopping for food and other household items could reduce vehicle-km by 70% or more – clearly an over estimate.

1.11 The concept of ‘telecommuting’ goes back to the early 1970s¹¹ and is probably now not far off achieving maturity as a working practice. Internet shopping is still growing and has reduced shopping trips from home with shopping travel rates in England reducing by 13% between 1995/7 and 2012 compared with a 6½% reduction for other trips¹². To some extent this has been associated with an increase in van deliveries but if shopping travel were to reduce by a further 13% then this would reduce overall travel by 1½% before any compensating increase in van traffic was taken into account.

1.12 Teleconferencing is an established business practice and is used for a limited range of types of transactions however there are a number of good reasons why its impact will be limited unless the functionality of existing systems is significantly increased¹³. Again where it is used it can open up new (and more distant) business alliances which in turn may generate longer physical journeys. It would appear that the use of these technologies will have some limited effect on overall travel demand but more important impacts on patterns and times of travel.

1.13 Electronic Road Pricing is a well-established theoretical concept and its economic rationale clearly spelled out as long ago as 1952¹⁴. The technical and economic merits in the UK context were established as long ago as 1964¹⁵. The economic merits are widely accepted and, with the subsequent developments in Information and Communications Technology (ICT) the practicability is now beyond doubt. General acceptance of the widespread tracking of mobile communication devices might, to some extent, have eliminated concerns about personal location privacy but public and political resistance to its widespread use remains. The potential advantages of PAYG include¹⁶:

- moderation of the use of congested roads producing large economic savings;
- creation of a new and buoyant revenue stream to fund the maintenance, management and development of the road system;
- a reduction in the need for some of the most costly additions to the road system’s capacity; and
- providing a powerful indicator of where additional capacity is needed and how much it is worth paying for.

1.14 If an acceptable scheme for the introduction of PAYG road charging could be devised then the development of the national road infrastructure to meet future needs would be an easier task with funding assured and reduced congestion providing benefits for business and general motorists alike. But the fact, at the time of this evidence-gathering exercise, is that no such scheme has yet been devised – let alone achieved political acceptability – anywhere

in the world, and that has not been for the want of trying. And in thinking about infrastructure needs, even a sophisticated and intrusive scheme that seeks to deter certain trips is likely to be indicative of an infrastructure shortfall, just doing so more accurately than might otherwise be the case. The advance of technology *per se* does not solve all of the practical challenges in bringing this particular piece of economic theory to life.

Q2: What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

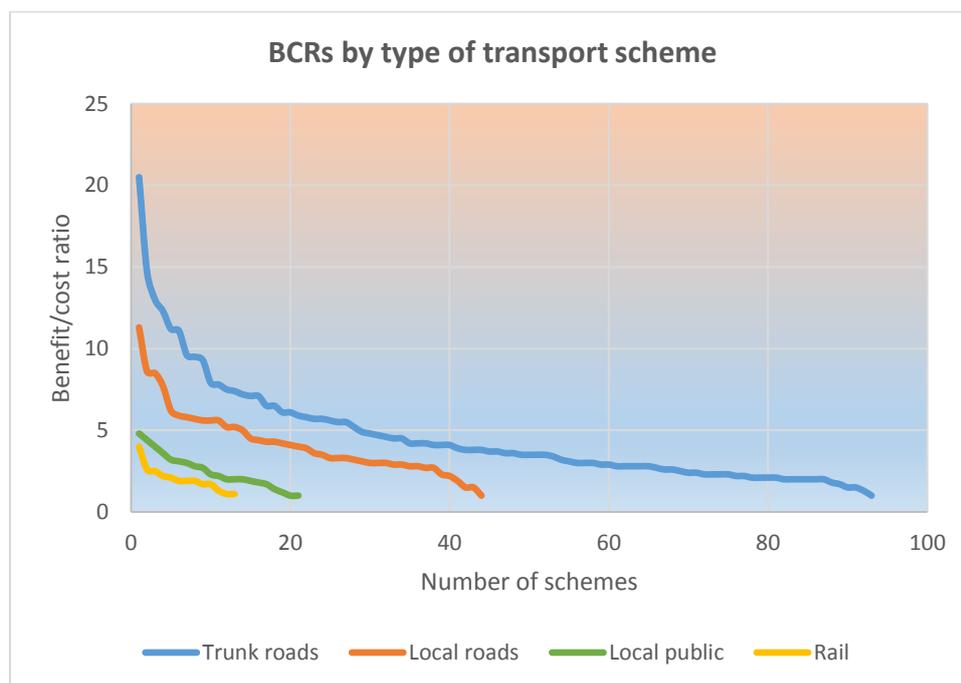

Figure 2.1: NATA¹⁷ B/C Ratios for a Range of Transport Projects by type

Source: Eddington 2016b.

2.1 Comparing the value of transport investments is complicated by the circumstances in which they are made. Thus a new freight railway may make a good deal of sense in linking a port to a major industrial complex but much less so in other situations. One of the most recent studies of the benefits and costs of a wide range of transport investments was carried out as part of the Eddington Study¹⁸. As part of this, evidence was gathered on the findings of appraisals of roundly 170 transport projects and further assessment was carried out on a few others. The distributions of Benefit:Cost ratios from this work for four different types of projects are shown in figure 2.1. These excludes a few projects such as public transport service & fare changes and canal path schemes, which are recreational in nature, as these are not strictly 'transport infrastructure' projects.

2.2 Local road projects appear to give the best value for money using the NATA assessment with an average B/C ratio of 4.71:1 followed by trunk roads at 4.15:1. Local public transport schemes were found to have an average B/C ratio of 2.64:1 and major rail projects 1.9:1. The analysis also classifies schemes by geographic type (inter urban/rural, urban and major city) and, in some cases separated out the freight and business benefits.

2.3 For local roads business benefits were double the (total) costs of the schemes. In the case of trunk roads benefits to business were 90% more than their (total) costs. For major

¹⁷ DfT 2012b.

¹⁸ Eddington 2006a.

rail schemes these benefits amounted to 75% of costs and for local public transport projects half the scheme costs.

2.4 The Eddington study showed that major rail and local public transport schemes were most often designed to facilitate passenger (but not freight) movements in and out of major urban areas with most trunk roads helping inter-urban travel (both passenger and freight). However inter-urban travel also included longer distance movements between major urban area and their hinterlands. Of the trunk roads schemes that helped movement into and out of large urban areas those on the periphery of metropolitan area stood out – particularly the M25 around London.

2.5 We would counsel the Commission to think laterally about its definition of ‘urban areas’. As has already been noted in the Commission’s work, it is impossible to separate thinking about network infrastructure from thinking about housing and household formation. The highest value transport interventions might well prove to be those which link new housing to established commercial/industrial/employment areas in, and around, cities.

Q3: What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

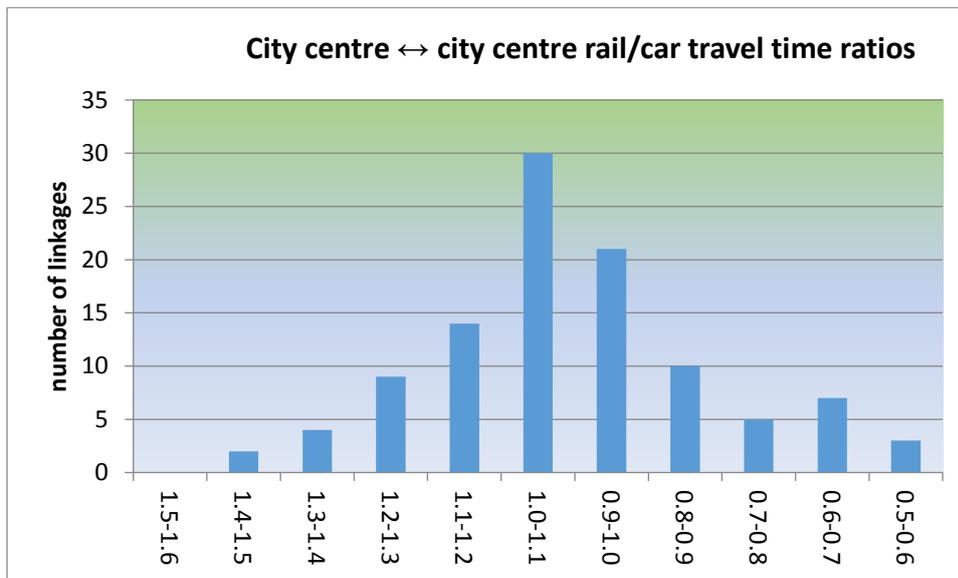

Figure 2.2: Distribution of Rail/Car Travel Times between selected British City Centres

Source: Google 2014a.

3.1 It is useful to clarify the respective travel time (as a major determinant of mode choice) advantages of road and rail – the two main form of domestic transport infrastructure in the UK - for journeys between different types of settlement. Figure 2 shows the ratios travel times by road and rail between the centres of 15 British cities. In 59 cases car travel is faster whilst in 56 cases rail is faster. So for these types of journeys rail times are very competitive with car travel the overall ratio is unity. Between city suburbs (see figure 2.3) however the picture is rather different with 85% of linkages having faster times by car. These are for large cities as there is scarcely any suburb ↔ suburb rail travel in medium sized and smaller urban areas and even some of these will involve bus access to the rail network. The overall average ratio here is 1.32:1.

3.2 Between nearby towns rail will often not be a practicable means of transport as buses and coaches will provide a faster (and cheaper) service. Figure 2.4 shows the distribution of relative public transport/car travel times between towns that are well enough apart for rail to be a reasonable travel option. Some of these journeys will have gone by road based public transport so this is probably a favourable picture of the rail/car ratios. The overall average for these types of journeys is 1.8:1.

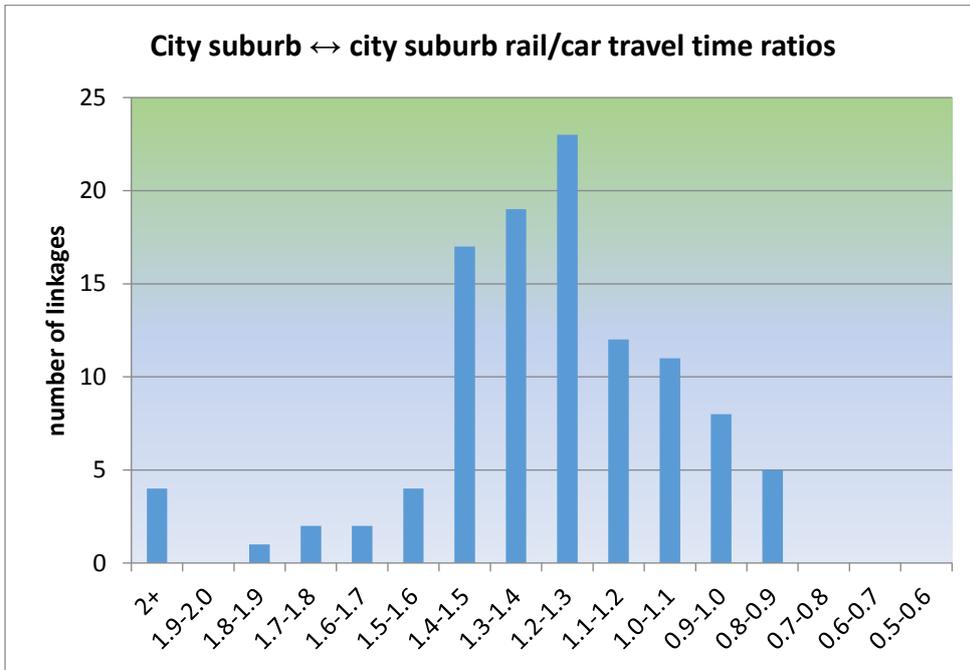

Figure 2.3: Distribution of Rail/Car Travel Times between selected British City Suburbs

Source: Google 2014a.

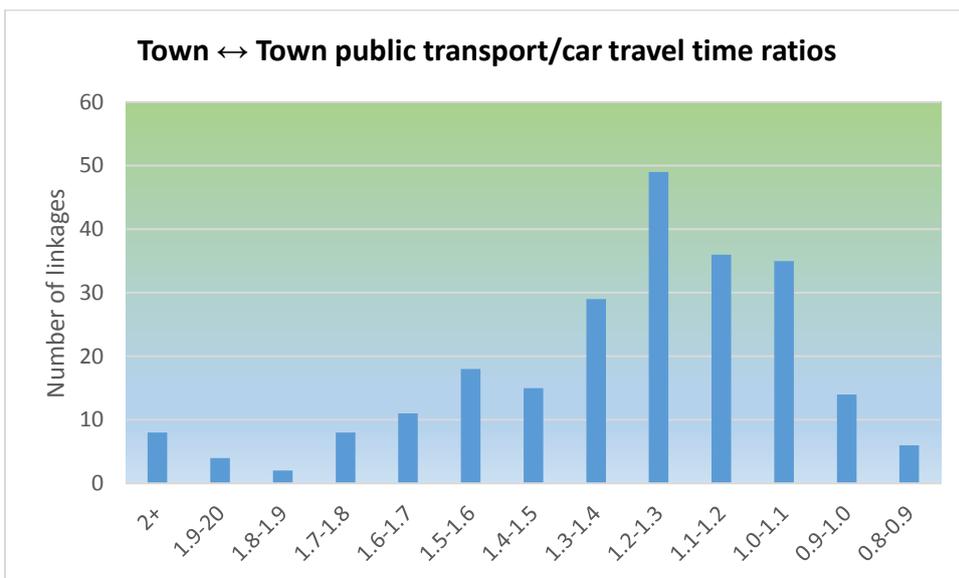

Figure 2.4: Distribution of Rail/Car Travel Times between selected British Towns

Source: Google 2014a.

3.3 Whilst these comparisons are illustrative they clearly indicate that road and serve different travel sectors with rail being strongest in intercity and metropolitan commuter markets and road in a wider range of markets with least potential in central commuting and between the centres of cities.

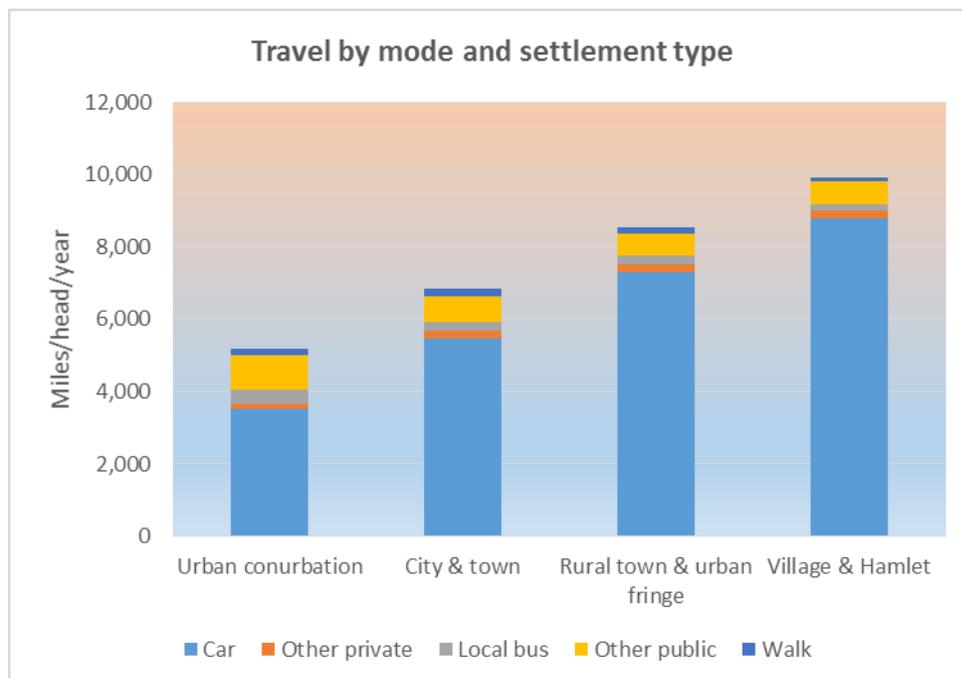

Figure 2.5: Travel by Mode of Transport and Settlement Type – England 2014/15

Source: DfT 2016j.

3.4 Figure 2.6 shows how the use of different forms of transport changes with settlement type. Whilst cars generally are the dominant mode both bus and other public transport modes (including rail) reduce with settlement size. Given that non local bus public transport will be less rail orientated the smaller the settlement (many small towns and villages have limited or no direct rail services) it is fair to conclude that residents free standing towns will make between 350 and 500 miles of rail travel a year compared with 6,000- 8,000 by road transport. This is consistent with the analysis set out in figures 2.2, 2.3 & 2.4. (See also para 2.4 above).

3.5 The geography of the location will play an important part in determining the merits of different types of investment. Towns located at important rail nodes (e.g. Carlisle, Crewe, Derby, Peterborough, Stafford and Wolverhampton) will have a significant use of rail for medium and long distance access whereas others which are not (e.g. Barrow, Ipswich, Leicester, Newquay and Plymouth) less so.

3.6 23m international passenger journeys were by sea in 2015¹⁹ compared with 201m by air²⁰ and 21m via the Channel Tunnel. Air transport is consequently the most important for international passenger movements. Figure 2.5 shows the means of passenger access to the 15 UK's major airports. Seven of these rely almost exclusively on various forms of road transport for passenger access. The London airports rely substantially on rail access; as do those of Birmingham and Manchester. All of these have 'direct' connections between the airport and the city centre which provides convenient access for business personnel and

¹⁹ DfT 2016d.

²⁰ DfT 2016e.

tourists based in the centre and indirectly, via the metropolitan public transport system, to a wider area. Clearly road access is important for all airports (for both passengers and freight) but where corridor flows are sufficiently high or where a low cost linkage allows airport travel to 'piggy back' on other rail services the case for expanding rail access to a wider range of airports should be considered – there being 18 UK airports with throughputs greater than 25m passengers/year²¹.

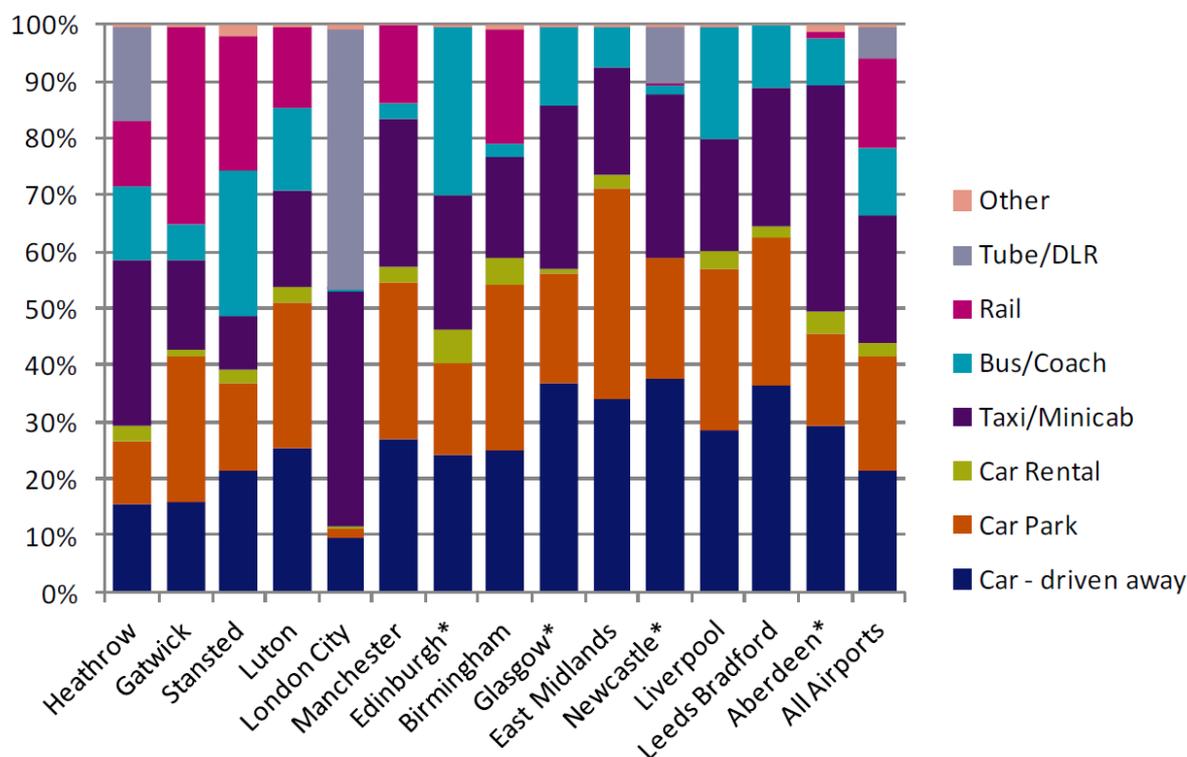

Figure 2.6: Means of Passenger Access to Large UK Airports 2013/14.

Source: CAA 2016a.

3.7 International freight (by weight) is carried mainly (94%) by sea, 5% by Channel Tunnel and the remaining 1% by air (although this is higher value freight)²². Of the channel tunnel freight over 90% is carried by lorries using the Shuttle²³. Overall about three quarters of European international freight is carried by road in the UK²⁴ so road transport is very important for ports access but rail also provides linkages of varying value to eighteen of the UK's 54 sea ports²⁵.

3.8 As a rule free standing towns have no direct rail sidings and only 48 intermodal rail sites²⁶ – mostly at ports and in large industrial complexes rail access to these towns for the carriage of goods will be negligible. Again this points to road improvements as the most

useful way of improving access and connectivity to these towns and, because of their more local hinterland than the large cities and conurbations, these are likely to involve a mixture of trunk and local authority schemes.

Q4: What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

4.1 Road users are presently charged for using public highways through vehicle excise duty and fuel duty. If these were replaced, in whole or in part, by an electronic PAYG system then there would be opportunities for closer integration of payments for road use and other transport services. The most obvious of would be to extend the road charging account to include, vehicle hire, fuel and parking services. In principle this could be extended to other modes of paid for surface transport such as taxi, bus, tram, and rail - and the larger the PAYG (as opposed to ownership) costs element included the less incongruent the charge rates would be so removing the bias of car or season ticket ownership.

4.2 This would allow a mixture of market (e. g. fuel) prices and social (e.g. congestion and pollution) prices to be included in the charges levied to users making, in theory at least, a level playing field for all forms of surface transport. A regime of this kind was advocated by McLean Hazel in a study for the Foundation in 2010²⁷ but so far there have been only limited examples of significant applications. Within the public transport sector the London Oystercard is a good example of paying for a service rather than an individual journey, in offering multi - (public) modal travel on a period and PAYG basis. Within the private transport sector both cycle hire and car club schemes provide a combination of ‘service’ (membership fee) and PAYG (time used) charges so are a form of hybrid conventional/mobility service.

4.3 Examples of public/private mobility services are uncommon, but a long established example is the Annual Travel and Mobility card offered by the Zurich public transport operator²⁸. This allows users to unlimited public transport access to Zurich’s public transport system as well as a fleet of cars both in Zurich and across Switzerland – but does include an hourly charge for occasional – but not full tariff - car users. Where most urban public transport operators extend their tickets to include other services however, there are usually in the form of discounts for entry to tourist attractions or discounted charges at restaurants, served by the public transport network.

4.4 Overcoming the fragmentation of ownership, sponsorship, regulation and pricing of the various modes of transport is a formidable task but a mandatory system of PAYG charging for road use has the potential to greatly ease this is the knotty problems - if revenue allocation can be satisfactorily resolved. This could promote a more efficient use of the main modes of transport, increase consumer choice and provide rational funding for the operation, maintenance and development of transport system.

Rail Delivery Group

Response to consultation:

The National Infrastructure Assessment: Call for Evidence

Date: 10 February 2017

Rail Delivery Group response to consultation: The National Infrastructure Assessment: Call for Evidence

Name: [Name redacted]

Organisation: Rail Delivery Group

Address: 200 Aldersgate Street, London EC1A 4HD

Business representative organisation.

Introduction: The Rail Delivery Group (RDG) was established in May 2011. It brings together Network Rail and passenger and freight train operating companies to lead and enable improvements in the railway. The purpose of the RDG is to enable Network Rail and passenger and freight train operating companies to succeed by delivering better services for their customers. Ultimately this benefits taxpayers and the economy. We aim to meet the needs of:

- Our Members, by enabling them to deliver better outcomes for customers and the country;
- Government and regulators, by developing strategy, informing policy and confronting difficult decisions on choices; and
- Rail and non-rail users, by improving customer experience and building public trust.

For enquiries regarding this consultation response, please contact:

Rail Delivery Group
2nd Floor, 200 Aldersgate Street
London EC1A 4HD

Overview

The Rail Delivery Group (RDG) welcomes the opportunity to contribute to the National Infrastructure Assessment Call for Evidence. The response has been led by the RDG Planning Oversight Group, who's remit is to provide strategic planning information for decision makers, including overseeing the Long-Term Planning Process work at Network Rail.

The key points of the RDG's response are as follows:

- In recent years, Britain has had the fastest growing and safest railway in Europe. Rail journeys have doubled in the last 20 years and are expected to double again by 2040. Over the last decade the industry has also halved the subsidy required per passenger. Today the industry generates sufficient revenue to cover its day to day running costs. This is a remarkable success story.
- This success has delivered much for the country but leaves the industry with significant challenges to deliver the capacity and the level of service customers expect. There are specific parts of the network where the level of performance and crowding has reached unacceptable levels and this must be addressed as a priority.
- The rail industry is already working with its funders and stakeholders to deliver a range of infrastructure investments which will support the growth of the economy at a national, regional and local level. However, these will only just be able to keep pace with expected levels of demand growth.
- The highest value infrastructure investments proposed by the rail industry are those which seek to address the most severe performance and crowding challenges on the network. The capacity of the rail network to carry more passengers and freight services is fundamental to the industry delivering more punctual comfortable journeys, and ultimately supporting and driving a number of socio-economic benefits.
- Through its Long Term Planning Process (LTPP), the rail industry has agreed long term forecasts for passenger and freight demand, and has developed a further 'pipeline' of enhancements to address anticipated capacity bottlenecks.
- Alongside conventional infrastructure solutions, the more widespread use of digital signalling technologies could provide an alternative means of increasing the capacity of the network. These technologies are being developed as part of the industry's extensive modernisation agenda.
- The industry is working to diversify its sources of funding, moving away from a historic reliance on government funding and investigating the potential for greater private financing.

Cross-cutting issues

Q1: What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

The railway plays an essential role supporting sustainable economic growth, by enabling the safe, fast and efficient movement of large volumes of passengers and goods into and between major economic centres, their catchments, and international gateways. The rail network is particularly important to the success of large urban areas, where some of the most productive parts of the economy are based. The huge volumes of commuters carried by the railway drive the economic growth of the nation.

Great Britain has one of the fastest growing railways in Europe and the second most intensively used – passenger journeys have more than doubled since 1996, adding up to over 1.69 billion journeys per year. £30 billion of goods are moved by the freight sector every year, equating to £10.1 billion of added value that the rail sector contributes to the UK economy every year. In addition, the supply chain employs around 120,000 with an estimated annual economic contribution of around £7 billion. However, the significant growth in demand brings both benefits and challenges – the performance of the network has become inadequate in many areas, and passengers experience levels of crowding well beyond acceptable levels.

The rail industry is already working with its funders and stakeholders to deliver a range of infrastructure investments which will support the growth of the economy at a national, regional and local level. Current initiatives such as the 'Northern Powerhouse' are a positive step towards a more polycentric pattern of economic and urban development in Great Britain. It is recognised that a more even pattern of economic development across the country would in itself lead to a more efficient, effective and even utilisation of railway resources over the network.

The Thameslink and Crossrail projects are nearing completion, and both will deliver a significant increase in capacity on services into London, and will dramatically reduce journey times by providing new cross-London journey opportunities. Across the North of England, a more diverse range of services will be able to operate as a result of the Ordsall Chord - a short stretch of line linking the cities of Manchester and Salford scheduled to begin passenger operation in December 2017.

Looking further ahead, government and the National Infrastructure Commission have both expressed their support for four schemes which will transform the rail network:

- HS2, which will provide fast, high capacity services between London, Leeds, Manchester, the East and West Midlands and South Yorkshire. The integration of HS2 with the existing network will also allow for faster direct trains to cities such as Liverpool, Newcastle, Glasgow and Edinburgh; and will increase capacity for freight on the conventional network.
- Crossrail 2, which will transform travel across London and the wider South East, linking destinations to the South West and North East of London with direct train services.
- Northern Powerhouse Rail (also referred to as HS3), the strategic priority for providing significantly better rail links between the key economic centres in the North. The project is aimed at transforming the rail journeys between the key economic centres of Leeds, Manchester, Liverpool, Newcastle, Sheffield and Hull, together with Manchester Airport.
- East West Rail, which will provide improved connectivity by providing new and rehabilitated infrastructure along the corridor between Oxford, Milton Keynes and Cambridge.

Through its LTPP, and ongoing dialogue with funders and stakeholders, the industry has identified a further range of recommendations designed to enhance the capacity and connectivity of the railway. The LTPP consists of a number of different elements, which, when taken together, seek to define the future capability of the rail network over a 30-year horizon¹:

- Market Studies forecast future rail demand, and develop conditional outputs for future rail services. These outputs are based on stakeholders' views of how rail services can support delivery of the industry's strategic goals – covering economic growth, reducing environmental impacts, enhancing quality of life and improving affordability.
- Route Studies develop options for future services and identify options for investment in specific areas of the network. Options are based on the conditional outputs and demand forecasts from the Market Studies, and are assessed against economic appraisal criteria to provide choices for funders.
- Cross-Boundary Analysis considers options for services that run across multiple routes, providing consistent assumptions across Route Studies.
- Network Studies consider network wide issues such as providing capacity for freight, or enhancing the inclusivity of the railway.

Each study or analysis is delivered through a Working Group, including funders and train and freight operators, which will consult wider stakeholders such as local authorities, passengers, freight users and their representatives and Local Enterprise Partnerships as part of their work. A Board oversees the delivery of the work and all studies will be published on Network Rail's website in draft form and subject to consultation for 90 days. The final study will then be established within 60 days of its publication subject to approval from the Office of Rail and Road.

Through its LTPP the industry has identified the scale of the capacity challenge on the network. This shows that:

- The volume of rail passengers into London in the peak hour is three times the combined volume of all other urban centres.
- The level of crowding (expressed as number of passengers to available seats) on services into London today is, on average in the peak hour, a third more severe than on any other parts of the network into major urban centres.
- Nine of the ten busiest stations in the country are in London (Birmingham New Street is the exception). Over the past 20 years, passenger demand at London Waterloo, the country's busiest station in terms of passenger numbers has doubled.

Whilst the committed programme of enhancements will provide a 10% increase in peak seats into central London (relative to current levels), and a 30% increase in overall capacity, this will only broadly be able to keep pace with the expected increase in demand.

These aggregate figures mask significant variation between routes. Standing is common on many inner suburban services, in part reflecting the fact that these trains are designed to carry high volumes of standing passengers over short distances. Of greater concern is standing on outer suburban and long distance services, given the longer journey lengths and resulting need for some passengers to stand for long periods of time. Without further interventions, the Brighton and South West Main Lines are expected to be experiencing severe levels of crowding by 2026, with some passengers having to stand for over 30 minutes. The industry is developing proposals to address the severe capacity challenges it faces on these routes, which should be taken forward as a priority.

Recent work undertaken under the auspices of the LTPP has also identified a number of stations that need congestion relief schemes. A combination of years of under-investment in stations (apart from a select few such as Reading, Birmingham New Street and London King's Cross), as well as significant passenger growth, will lead to many stations being severely overcrowded in the coming years. Priority stations to be addressed in the short term comprise Clapham Junction, London Liverpool Street and London Euston.

Alongside additional physical infrastructure, digital signalling technology can offer a less disruptive approach to increasing the capacity of the network, in turn supporting sustainable economic growth. Other industries, from aviation, to roads, and the London Underground, have already unlocked significant additional capacity through digital control systems. Rail has the opportunity to make use existing technology, similar to systems currently being used on the London Underground, and due to be deployed in the coming months and years on Thameslink, Crossrail and HS2.

The industry's vision for new technologies is set out in the recent Rail Technical Strategy Capability Delivery Plan², which covers 12 Key Capabilities (KCs). One example is KC02: 'Minimal disruption to train services'. This aspires towards 100% availability of assets when needed, which requires investment in a range of technologies and new approaches to infrastructure renewal and maintenance, for example in real time asset intelligence that leads to 'predict and prevent', coupled with a far more modular approach to infrastructure assets that leads to rapid 'swap in, swap out' replacement. Lowering the cost of the infrastructure will also be a significant contributor to long-term sustainable growth and opportunities for connecting communities, particularly on less intensively used parts of the network. KC11: 'Low-cost railway solutions', is focused on this.

Finally, infrastructure investment in a number of key areas will enable the freight sector to realise its potential in serving the British economy and driving down carbon dependency:

- A rail network fit for freight: dedicated investment in a Strategic Freight Network linking key deep sea, short sea and bulk ports with the terminals and railheads serving centres of production, distribution and consumption.
- Railheads and terminals: a network which adequately reflects projected traffic levels and patterns

- Network performance and availability: enhancing the capability of the network to support longer, heavier and faster freight trains.

Beyond these priority investments, the interventions identified by the LTPP form a further 'pipeline' of choices for funders covering the entire network. These are designed to be taken forward on a rolling basis, as and when individual projects reach sufficient design maturity, enabling better alignment with franchising and facilitate a broader range of funding models.

Q2: How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

The government's recent industrial strategy³ identifies upgrading infrastructure as one of its 10 key pillars for driving growth. As the strategy indicates, high quality transport infrastructure can reduce delays, and raise productivity by enabling towns and cities to achieve agglomeration effects, supporting the rebalancing of the economy.

An effective, extensive and reliable rail network can effectively bring cities and their catchments closer together, opening up new markets, improving access to extensive pools of labour, providing new employment opportunities, encouraging the transfer of knowledge and improving the efficiency of supply chains. Rail can support this in four key ways:

- Connectivity – by providing higher frequencies, new direct services, more convenient connections and reduced journey times. Connectivity to other modes; whether air, sea or local modes, is also key.
- Capacity – providing sufficient seats or standing space to allow sufficient numbers of passengers to undertake the journeys they need to make.
- Performance – providing a reasonable level of certainty of journey duration to allow passengers and businesses to plan effectively, avoiding spending unproductive time on disrupted services, or having to allow additional time for their journeys in the anticipation that services could be disrupted. For goods markets especially, competitiveness is extremely sensitive to journey time.

Through its LTPP and ongoing dialogue with funders the rail industry has set out a series of interventions to improve the connectivity, capacity and performance of the network.

Improving access to ports is one of the key priorities for the rail freight strategy. As referenced in the response to Q1, the Strategic Freight Network aims to provide a freight-capable network linking ports with inland terminals close to the main centres of population. The priority investment corridors to improve access to ports comprise:

- Felixstowe / North corridor: the priority freight scheme to establish a direct freight capable route from Felixstowe through the Midlands to the North West avoiding London. This will become the country's high capacity arterial maritime intermodal import/export corridor, enhanced through a programme of interventions to address bottlenecks at Haughley Junction, Soham, Ely, Peterborough, and Leicester.
- Solent / North West corridor: linking the UK's second largest deep sea port to the distribution and manufacturing heartlands of the West Midlands and North West, serving both import maritime intermodal traffic and export automotive traffic. Beyond near term initiatives to optimise train lengths ultimately line of route capacity will become constrained with the interaction of forecast passenger and freight volumes, potentially requiring major interventions such as grade separation at Basingstoke.
- Trans Northern corridor: the work of Transport for the North in developing Northern Powerhouse Rail offers a new northern rail freight opportunity, building on the major port developments in the

Liverpool and Hull and Humber City Regions. It demands identification and development of a freight capable Trans-Pennine corridor serving intermodal and industrial traffic between manufacturing centres and ports, and bulk construction flows serving northern cities.

- Cross-London corridor: enhanced cross-London freight capacity on the North London and Gospel Oak to Barking lines through the development of 'filter lanes' to separate the movement of freight services joining/leaving these orbital London lines from the high frequency passenger service. This would be underpinned by rerouting of non-London destined traffic through the Felixstowe/North Corridor (where this offers a more direct route) and the realisation of a Thameside Nodal Yard complementing that established at Wembley.

Rail links to and from airports and ports can be considered to be gateways to the country. However, the current quality of these links is variable; therefore, more targeted investment to make all airport and port links an equivalent standard is therefore desirable.

The enhancements pipeline includes a number of schemes specifically designed to increase train ridership to airports, including Western Access to Heathrow and enhancements to the passenger circulation facilities at Gatwick Airport station. Responding to the work of the Airport's Commission, the Government has recently agreed that the most appropriate way to increase airport capacity in the South East is through a third runway at Heathrow. In making this decision the Department for Transport (DfT) noted that Heathrow Airport already has good rail and road links, but in future these will be improved by direct access from Heathrow to Crossrail and linked to HS2 at Old Oak Common. Network Rail's report into Southern Access to Heathrow published in April 2016 identified significant economic benefits could be accrued by a link from Heathrow Airport into the existing South West Trains network near Staines. Such a scheme would enable direct services from a wide range of towns in Surrey, Hampshire and South West London to the airport.

Rail infrastructure can most effectively contribute to the UK's competitiveness more directly, through the development of new rail technologies and talent, which could allow the UK to export expertise and skills. The industry has set out a modernisation agenda which will accelerate the adoption of new technologies and working practices, with the aim of strengthening efficiency, enhancing the skills of the workforce and ultimately the quality of the customer experience. The industry intends to use the opportunity of delivering these priorities to realise the wider economic potential of a vibrant, world-class UK-based supply chain by collaborating with the Rail Supply Group to deliver their strategy 'Fast Track to the Future'. Rail investments form a significant part of the potential workload for the UK-based supply chain, and provide the confidence to support investment in skills, equipment and innovation. This investment will support efficient delivery and provide a platform for import substitution and, ultimately, an increase in exports.

Q3: How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The best way to assess and deliver the benefits of better places to live and work is to collaborate effectively with a variety of stakeholders throughout the design, planning and delivery process. Relevant stakeholders include funders, business groups, local authorities, operating companies, and user groups. The rail industry's planning processes already encourage extensive stakeholder involvement: in the Market Studies, future demand and requirements (expressed as 'conditional outputs') of the rail network were built upon stakeholders' views, and thorough review of how rail services can support delivery of the market's strategic goals. In Route Studies, when options are developed for geographically aligned routes they are assessed against the identified market study outputs, funder and stakeholder criteria, and an early assessment of value for money.

Early stage planning and design could arguably be further improved to focus upon 'better places to live and work' through increasing consideration of social value planning and wider benefits in the appraisal of options. Wider benefits such as community improvement, jobs creation, and social value can be difficult to capture in an economically aligned business case. Effective project sponsorship will be key to providing an infrastructure option which delivers the benefits outlined in earlier integration of strategies and planning.

There is also the opportunity to promote rail and the industry as a 'good neighbour' that will introduce new technology and ways of working that, for example, minimise the impacts of infrastructure maintenance on neighbours (noise, vibration) through better design and operation.

It is important that housing and more sustainable transport modes are considered jointly. Ideally, development planning should be integrated with transport planning; ensuring higher densities of development around transport nodes, and the appropriate distribution of employment opportunities. Improving bus or cycle connectivity to existing stations may provide the connectivity to support development as part of a wider transport strategy.

Where contingent developments such as housing are dependent upon infrastructure, early collaboration and integration are key to successful delivery of ultimate benefits. For example, large housing developments can deliver benefits of better living and working if they are situated near a station. However, aspirations for new stations need be considered carefully alongside the market characteristics and long term plans for the corresponding rail corridors. The construction of new stations on congested parts of the network, or where the adding a new stop would disadvantage long distance passengers, can act to contradict other industry objectives such as reducing journey times or increasing capacity.

For the rail sector, the railway station is the key interface where the industry has the opportunity to help create better places to live and work. Its 'Vision for Stations'⁴ sets out nine principles to help achieve this:

- Customer focused
- Intelligent use of technology
- Seamless journey experience
- Reflect local needs and opportunities
- Safe and secure environment
- Entrepreneurial spirit
- Flexible and long-term stewardship
- Shared industry know-how
- Optimised network

The industry recognises the need to support an enhanced role and profile of stations within the communities of Britain through facilitating them as demonstrators of technology, active supporters to local small businesses and community organisations.

The rail industry also recognises the need to engage with other wider policy such as industrial strategy, land use and housing planning to help ensure a closer match between rail demand and capacity. It is committed to encouraging new ways of delivering its plans by engaging with a wider range of partners.

Q4: What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

As discussed in the response to Q1, demand for rail infrastructure services has increased consistently in recent years, and is set to continue under any forecast scenario. Where demand is expected to outstrip capacity, the LTPP works to identify options to address the resulting gap. Notwithstanding required infrastructure enhancements of varying scales, in a capital and capacity constrained environment, demand management can provide additional tools to alleviate or redistribute some demand for the benefit of increased efficient use of an existing network.

The rail industry has practised demand management through pricing for many years, and customers are familiar with the concept of saving money by avoiding the busiest times. The more widespread adoption of online ticket retailing has been instrumental in supporting this trend, and as technology evolves customers will be able to buy tickets in an increasing number of different ways.

The growth of smart ticketing offers considerable potential at being able to tailor this in a way that is easy for consumers to use and understand. In particular, there is considerable potential to use smart pricing in the context of the traditional season ticket market to further encourage the existing trend towards working from home for at least part of the working week. This will also offer companies the potential to provide part-time and shift workers with season tickets that reflect how they work.

At the moment, traditional season ticket products do not provide mechanisms to credit non-use and can therefore encourage travel to work at the margins where the incentive of 'saving' a day's trip might otherwise tip the balance towards staying at home.

However, the contribution which smart ticketing can make towards managing demand should not be overestimated. For example, research carried out in 2007, 2012 and 2014 from three separate sources placed a considerable question mark over the ability of pricing and smart ticketing alone to tackle the periods of most intense demand. For commuting such as into central London, this is typically the period between 08:00 and 08:45 Monday to Friday, where there are many services that are at absolute capacity. Studies into the kind of price differentials that might be required to shift people away from this peak established that there was an extreme inelasticity for this period, meaning that price differentials would need to be at politically untenable levels to achieve any meaningful shift in travel patterns.

Fare regulation has not changed for 20 years, and the existing peak fare structure sits within a very crowded product structure which has evolved in a very short term tactical way and is subject to multiple layers of regulation. This complexity, and the risk of there being customers which stand to lose from overhauling fares regulation, has meant that the political will to undertake such a review has not been forthcoming. However, this is set to change, as it was recently announced that passengers on trains between London and Sheffield or Scotland will be among the first to benefit from an overhaul of rail fare regulations as part of the tests agreed between train companies and the government. Due to start in May 2017, the trials to simplify the complex rail fares system will mean:

- **A route will be overhauled** to reflect what is actually on offer, ending the existing situation where changes to train services in many cases only allow fares to be added to the system rather than older, less relevant routes which customers do not use being removed from the fares system to make it clearer;
- **A best value end-to-end 'through fare'** will be offered for test journeys where customers change trains, by offering one price combining the cheapest fare for each leg of the journey. Current rules require operators to set and maintain a through price even where there are cheaper deals;
- **Easier journey planning** by showing customers the best price in each direction on selected routes, allowing customers to mix and match the best fare – like airline bookings.

This requires changes to regulated return fares dating back to the 1980s that can't be sold easily online, giving customers much more clarity and simplicity.

A ten-point plan and design guidelines for ticket machines include getting rid of jargon, informing customers when a machine will start to sell cheaper off-peak tickets and making clear what types of tickets machines do and do not sell. All the improvements to ticket machines will be in place by the end of 2017, several by the summer.

On an infrastructure level, day-to-day demand spikes and recovery from incidents can be managed through improved traffic management technologies and performance strategies. For example, one element of the Digital Railway programme is deployment of a traffic management system which could assist signallers and operators to more efficiently manage increased levels of train service on the infrastructure.

Q5: How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Any activity on assets should be directed to support statutory and customer requirements. In the case of infrastructure, this normally means delivering safe, reliable assets that have capacity and functionality when the customer requires them. A balance needs to be struck between ensuring that the established capability of existing infrastructure is retained (where still required to meet customer needs), and investment to offer new and improved capabilities (providing expanded services to existing and new customers).

Network Rail's capital expenditure is typically disaggregated between maintenance, renewals and enhancements:

- Maintenance activity involves keeping the existing assets in a fit-for-purpose state, without requiring significant replacement of the asset
- Renewals occur on a periodic basis and involve the replacement of the asset with a modern equivalent capable of delivering a comparable output.
- Enhancements entail the replacement of an existing asset, or supplementing the existing infrastructure with new assets, to deliver an enhanced level of output – primarily accommodating an increased level of traffic.

Whilst the precise level of maintenance and renewals activity will be dependent on a range of factors, some level of activity will always be required, even if the assets are not used on a regular basis. However, investment in a range of technologies and new approaches to infrastructure renewal and maintenance offers the opportunity to deliver improved maintenance techniques and procedures that will in turn deliver asset renewal more efficiently/quickly, and with less disruption to services, than is possible today.

In contrast, enhancements are discretionary in nature, and are developed and implemented where circumstances require. As discussed previously, the rail industry's LTPP is the primary route by which these drivers are identified – with the Market Studies identifying likely changes in demand, and the Route Studies identifying the interventions required to support this. Whilst maintenance and renewals activity are effectively covered by income from passengers, enhancements require government investment, and consequently decisions around which enhancements to progress are made by the industry's funders – under current arrangements principally the DfT and Transport Scotland.

Q6: What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

When the rail sector was privatised in the 1990s, responsibility was split between managing the infrastructure and operating train services. Whilst there was a strong justification for this division, at the same time this has generated some inefficiency and misaligned incentives, which have prompted several external reviews.

The sector is responding to these reviews in a number of ways, most importantly through accelerating the process of Network Rail devolution, which encourages greater collaboration between the infrastructure provider and passenger and freight operators. Network Rail further recognises the benefits of collaborating with train operators in an increasing number of 'railway alliances'. These can be undertaken through a number of models, such as the joint management of ScotRail and Network Rail Scotland, with ultimate aim of providing enhanced service and value to users and funders.

In the renewal and enhancement of rail infrastructure, Network Rail additionally welcomes competition and collaboration. Indeed, most railway renewals and enhancements are already provisioned through market competition.

Increased collaboration with the supply chain through Early Contractor Involvement is now widely recognised to be essential in helping to keep costs down. The 'Staffordshire Alliance' of Atkins, Laing O'Rourke, Network Rail and VolkerRail is successfully delivering infrastructure to address a historic bottleneck on the West Coast Main Line in the Stafford Area, and the Digital Railway Programme is aiming to maximise supplier buy-in

from an early stage to drive down costs and ensure alignment of supplier capability with the emerging needs of a railway which adopts digital signalling on a more widespread basis.

Q7: What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Funding is the commitment of ultimate payment mechanisms to pay for the revenue requirement of the infrastructure provider. The funders will be parties recognising benefits arising from railway enhancements, but without the infrastructure provider taking on a capital repayment liability.

Currently the rail industry derives its funding from taxpayers, users and third parties. Government policy for a number of years has been to shift the burden of funding from the taxpayer towards users, and this trend is expected to continue. Accompanying changes to channel more government funding through train operators, rather than through payment of a direct grant to Network Rail, are designed to encourage greater efficiency through a stronger focus on users. Third party investment primarily takes the form of rental payments for property, or contributions from the beneficiaries of enhancement schemes.

Securing financial contributions from the beneficiaries of enhancement schemes is a means to ensure that the industry is able to monetise the value it creates for third parties, as opposed to this value being lost. The Shaw Report challenged Network Rail to 'explore new ways of paying for the growth in passengers and freight on the railway' and identifies that the private sector also has a part to play in supplementing available railway funding, particularly for enhancement projects, for example from property developers, local businesses, airports, freight terminals, train operating companies as well as from other parts of the public sector (for example local authorities and Passenger Transport Executives) and publicly funded bodies (for example Local Enterprise Partnerships or Growth Deals).

Whilst securing of such funding is not new to the business, the future incremental non-government funding requirement for infrastructure schemes will be a higher scale and will need to focus on some key priorities. To pursue these opportunities, Network Rail will need to:

- Integrate its processes for strategic planning and prioritisation of projects (which also involves the DfT) with its seeking of funding commitments for example prioritising projects supported by third party funding. This is a change to long-established public-sector and railway industry practice which ranks projects primarily by a cost-benefit analysis including non-financial and socio-economic elements.
- Develop a pipeline and gear up for project preparation and procurement.
- Put in place additional internal commercial capability to seek and manage funding commitments at earlier stages of project development.

Funding plans are being developed to capture non-DfT incremental funding, the value of which will be dependent on a wide range of variables and subject to caveats and assumptions around certainty, phasing and availability of ring fenced and other government funding.

Recognising that third party funding requires significant lead times to reach commitment, enabling work is already under way to support mobilisation of the required route-led capability by spring 2017. This includes the development of funding and governance guidelines and high level local funding strategies, sharing of proven practice, organisation proposals including a route business development role to lead this activity and consideration of commercial tools, resource and governance requirements across the business. Network Rail is also engaging more widely across the industry for support to unlock funding locally, and is supporting the RDG's Alternative Finance and Project Delivery workstream.

Additionally, the structure and geographies in which funding is provided can have secondary efficiency impacts on a variety of factors, such as flexibility of long-term planning and supply chain confidence. Network Rail is moving its enhancements model towards a progressive funding situation built around stage gate joint governance, which aims to resolve some of the inefficiencies created by the existing five-yearly control period structure.

Q8: Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Financing involves the provision of capital by private sector investors and lenders in the expectation of a repayment of capital and/or, a financial return on capital.

In general, the cost of private sector finance will typically be higher than the public sector cost of capital faced by Network Rail. Therefore, the use of private sector capital will create incremental value for money if the efficiency and performance gains, innovation and the risk transferred outweigh the extra cost of finance (the differential is at historic lows), transaction costs and any incremental interface costs. Projects which cannot be structured to separate adequately risks to the project's promoters from risks to be borne by Network Rail are likely to be delivered more effectively through Network Rail's standard procurement processes. In addition, there is a minimum size of project for private sector financing to make commercial sense and the scale of some projects will be relatively small.

Supported by Cambridge Economic Policy Associates (CEPA), the RDG's Alternative Finance and Project Delivery workstream has undertaken a two-phase project to consider:

- The obstacles faced by investors interested in rail and the opportunity for private delivery and/or finance to play a greater role; and
- How the obstacles might best be addressed in order to take advantage of the opportunities identified.

The project identified clear opportunities for the sector, but also found some key obstacles which together mean that projects can be funded but not financed:

- Significant change requires whole industry support.
- It is not clear what the industry is being asked to achieve, beyond an aspiration to attract private finance.
- Projects have a lack of certainty throughout their development, which investors dislike.
- Many current projects are unsuitable to attract private finance / delivery and would need to be rethought to be able to do so.
- There is a lack of clarity and transparency which has a strong negative impact, particularly if the industry fails to speak with one voice.
- Level of interaction between projects adds complexity to seemingly simple schemes.
- There is complexity which can be perceived as the industry not having a 'can do' attitude, particularly in terms of timescales and processes.
- The industry may not currently have the required skill set and the private sector needs to have confidence in the industry's capabilities.

The report made the following key recommendations to improve financing in the rail industry:

- There should be a clear and transparent process for seeking private involvement.
- An appropriate detailed and independent approach to value for money analysis is required. Value for money is predicated on effective transfer of risk to the party best placed to manage it.
- Costs to investors should be minimised, and project timescales should be short as practicable.

- A sustainable pipeline of PPP projects (including for the longer term) should be developed and published. The aim should be for a pilot programme of 5-6 projects.
- ORR should review its accessibility to investors and ensure that regulation facilitates alternative approaches, without undermining the principles of the existing track access regime. Project promoters will potentially bear risk on the outputs of the assets they deliver, but not on wider system outputs (which they could not effectively control and to attempt to transfer this risk to them would be poor value for money). The exception to these assumptions might be a concession under which a whole region of network is to be recapitalised by the private sector which takes over as a network owner and operator.
- Projects to be structured appropriately (standardised where possible, e.g. contract form, risk share, etc.). It will be necessary to structure availability or usage payments to the project deliverers based on the availability and performance of their assets. Many schemes may not be fully self-funding, meaning that DfT and other funders may need to consider how it allocates its long-term support to privately financed assets, including some projects which may have some element of other funding as well as generating project income.
- Institutional capacity in the industry needs to be developed and relationships built directly with the private sector.

There is currently a strong availability of funds looking to invest in infrastructure, part of an ongoing and upward trend of greater allocation of long term investment into infrastructure assets. The evidence suggests that there would be a strong take up for a pipeline of appropriately structured deals which could either offer a self-generating revenue stream for investors and/or which provide opportunities for efficiency and innovation; provided the identified obstacles can be addressed.

Delivery credibility should be supported by the introduction of the 'Integrated Assurance' improvements but will also be dependent upon DfT funding continuity to enable committed projects to be taken to conclusion. In addition, to increase Network Rail's attractiveness to third-party investors, it is important to address the size of Network Rail's existing debt and to develop a future funding approach that is more sustainable.

Q9: How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

There are a variety of interdependencies which arise between infrastructure sectors – some of which have been identified by the National Infrastructure Commission for investigation, which can provide uncertain and varied risks to service provision. For example, a key interdependence for rail is with the energy sector. An increasing degree of electrification of the rail network can bring a number of economic and environmental benefits, but requires a robust and reliable energy supply network.

Increased collaboration and visibility between sectors, alongside effective integration of resilience in planning, asset management, and operations, can help identify and mitigate these risks. For example, the rail sector working with key stakeholders such as Highways England, National Grid, MI5, and the Environment Agency could allow for information sharing and the development of strategies cognisant with identified interdependencies and risks in areas as diverse as climate change, environmental management, energy policy, and security incidents etc.

Long-term consideration for interdependence and resilience could be built into planning through engagement between contingent system operators, regulators, government organisations and stakeholders in different sectors. Collaborative working with other transport operators can produce resilient operational strategies where interdependent risks arise. For example, a failure of a transport mode – such as a major road incident – may significantly increase pressure upon rail transport along a geographically similar route.

Another way of ensuring resilience is to be less reliant by managing the energy mix differently through, for example, increasing the proportion of energy recovered through regenerative braking, energy generation

and storage technologies, self-powered (battery) trains, etc. This is covered by KC05 'Optimum energy use' in the RTS Capability Delivery Plan.

Climate change poses challenges for the resilience of infrastructures and their interdependencies. For example, better drainage and the management of flood events collectively will help manage impacts across sectors.

Q10: What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The planning processes of Network Rail's Enhancement Programme 2014-2019 were recently the subject of a review by Dame Colette Bowe. One recommendation made by the Bowe Report, when issued in November 2015⁵, was for the DfT and Network Rail to reset the formal framework for enhancements planning, implementation and oversight. The issues highlighted, and processes put in place, could provide lessons learnt for wider how infrastructure planning and governance is conducted with a variety of funders.

In response to the report's recommendations, both the DfT and Network Rail issued a Memorandum of Understanding⁶ to jointly commit to new working practices and governance. The Enhancement Improvement Programme has been established to address major structural issues in the industry around the planning and delivery of enhancements.

Additional governance has been put in place to assist in the timely and efficient delivery of works, and to recognise that projects and programmes in early development are highly immature. Network Rail now aims to develop a pipeline of projects to be put through a series of joint decision points, so that funding is committed progressively and the value for money of delivered outputs is tested at key points in development. Funding should only be committed to progress to the subsequent joint decision point, to ensure clarity of cost and outcome expectations. Through this process, it is envisioned that at each stage planning faces discipline to investigate an increasing clarity of scope, outputs, outcomes, and benefits, as well as decreasing risk to funding and timely delivery.

Alongside these improvements to the planning and delivery of rail enhancements, the planning system could arguably be further improved in a number of areas. Continued review of processes and planning strategies on a variety of levels is required to ensure that supporting processes are effective, and that infrastructure developments have line of sight to national, regional, and local goals. For example, the Transport and Works Act could be reviewed to reflect experiences of major programmes. Similarly, if timelines of delivery for contingent projects and programmes are not aligned, then it can lead to frustration of stakeholders and delays to benefits. Collaborative working and transparency through such processes can provide opportunities of continuous improvement and likelihood of efficient delivery on time.

Q11: How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Existing rail infrastructure can frequently offer a habitat for a range of wildlife. However, difficulty arises when the primary use of this land, safe railway operation, potentially limits or comes into conflict with these environmental benefits. As such, proper planning and an understanding of estate and ecological management are required to provide both transport and environmental benefits. Gathering environmental data in partnership with organisations outside of the rail industry, and contributing to national datasets by enabling access to experts to catalogue habitats and species on railway land, provides a better understanding of the rail estate and information on affected species.

Major investment projects are often required to enhance natural environments and some are involved in the biodiversity 'net gain' trials. Collaboration is key to effectively deliver environmental benefits, including within; data collection and analysis, access, use of natural resources, use of personnel and knowledge sharing.

The industry has agreed a series of Rail Sustainable Development Principles⁷, and recognises the need to embed these in all its activities.

At the national level, government policy will be critical to meeting to ensuring sustainable outcomes. It is vital that the correct incentives are in place to make the best decisions for the whole railway and for the long term.

Ensuring better alignment between operator and infrastructure manager and between operational and capital costs will be fundamental to delivering sustainable long-term benefits for customers and taxpayers; environment and society. Greater consistency in sustainability performance and collaboration across devolved routes and investment projects needs to be ensured – there is still significant variation in how routes and train operators collaborate on issues including noise, non-traction energy and asset renewals.

Although whole life costs are considered, environmental and social benefits are often the first to be cut when project costs come under pressure, leading to higher operational costs. It is vital to ensure that opportunities for greater operational efficiency are not so easily lost to ‘value engineering’ projects. This balance between capital and operational costs will be critical in ensuring a more sustainable railway.

Q12: What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Business cases for transport investments are typically supported with cost benefit analyses which follow the guidance set out in the HM Treasury Green Book⁸ and DfT Transport Appraisal Guidance (WebTAG)⁹. These use welfare benefits (for example, the value of savings in travel time) as key measures of the benefits of transport investments. However, maximising welfare benefits is not always the sole or even main objective of decision-makers. For example, economic growth, rebalancing the economy and deficit reduction represent different objectives; and the investments that would be most effective at achieving these are not necessarily the same as those that would maximise a traditional welfare-based Benefit / Cost Ratio. It is important that business cases consider the extent to which the investments are likely to achieve the desired objectives, even if this is difficult to quantify precisely, rather than the extent to which they meet objectives which are easier to measure but are not the primary goal of decision makers.

It is also important that cost-benefit analyses consider the full range of costs and benefits from a given scheme. This includes using whole-life cost estimates, and assessing schemes at an overall programme or strategic level. Transport investments are increasingly being planned as part of wider development strategies that include multiple investments in transport, housing and other infrastructure, as well as non-infrastructure investments such as in skills and training. Consequently, assessing the transport investment in isolation will not give a fair assessment of the overall strategy. As referenced in the response to Q3, wider benefits such as community improvement, jobs creation, and social value can be difficult to capture in an economically aligned business case.

Although there are a number of ways in which transport cost-benefit techniques could be improved, it is important that decision makers do not place too much emphasis on a single quantitative output – numbers like the benefit-cost ratio should be one of the key things that inform a business case and thus decision-making, but not the only one. There are few, if any, major investments for which cost-benefit analysis is likely to accurately quantify, let alone value, all the relevant considerations. Ironically, appraisal guidance itself often recognises this, stressing the importance of qualitative considerations in the overall decision. In practice, however, an arguably disproportionate amount of effort is sometimes put into the quantitative cost-benefit analysis.

Transport

Q13: How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Growth in rail travel markets, or indeed any mode, is dependent on a number of changing factors and trends: macro-economics such as employment and economic activity, land use, micro-economics such as travel costs and competition, demographics of population and age, consumer tastes and perceptions, and the supply of travel opportunities such as modal generalised journey times can all affect travel pattern changes.

As part of the LTPP, Network Rail facilitated the production of four Market Studies to estimate how demand is expected to change over the subsequent 30 years in rail’s four key markets: long distance, London and South East, regional urban and freight. The passenger Market Studies concluded that the number of rail journeys would double over broadly the next 25 years. This growth is expected to be driven by a combination of economic and population growth, and deep rooted structural trends in the market which have supported

growth over the last two decades. These trends include re-urbanisation and growth of the 'knowledge-based' economy in large towns and cities. A positive shift in rail's competitive position against car travel has also contributed to growth, although in rail's largest markets (most obviously the commuter market into central London) travelling by car rarely offers a practical alternative. The strength of these underpinning structural trends were particularly evident during the economic downturn of 2008-9 when the passenger market continued to grow throughout despite a 6 per cent fall in economic output (although a change in ticket purchasing patterns did place greater pressure on passenger revenue growth during this period).

Whilst the economic impact of the decision to leave the European Union is uncertain, the medium to longer term drivers of rail growth remain fundamentally robust. As a result, it is difficult to construct plausible scenarios in which rail passenger demand growth stagnates, particularly in markets where rail is fundamentally aligned to the direction of economic development – commuting into large cities, high speed travel between urban areas, and providing connections to international gateways.

Based on the Office for Budget Responsibility's (OBR's) most recent forecast for the UK economy it is anticipated that the rail passenger market in England and Wales (measured in terms of passenger kilometres travelled) will grow by 13 per cent between 2015-16 and 2023-24, with a range around this central forecast of between 8 per cent and 18 per cent reflecting the OBR's range for GDP growth over the period to 2021. This forecast reflects 'external' drivers of rail passenger demand only (for example, anticipated economic and population growth), and is based upon an assumption that rail fares will increase by no more than the Retail Price Index (RPI) measure of inflation during the term of the current parliament.

In addition to this 'external' growth, once completed the committed components of the Railway Upgrade Plan could generate up to 9 billion more rail passenger kilometres per year by the end of CP6 - an increase of up to 15 per cent on today's total - even before major schemes such as HS2 and Crossrail 2 are taken into account. Further growth can also be expected as the result of operator initiatives delivered through the franchising process. As a result, committed improvements to the railway are expected to make a substantial contribution to demand and revenue growth over the next Control Period, potentially doubling the level of growth delivered by 'external' factors only.

Changes in energy generation policy and the simultaneous impact of a globalised steel manufacturing market have prompted a period of rapid structural change in rail freight's commodity base. This structural shift entails the loss of traditional commodities such as coal for the electricity supply industry and reductions in steel rail industry raw material / finished product traffic.

However, whilst volumes of coal for energy generation have reduced significantly, demand for rail freight is expected to grow strongly across a range of other commodity sectors: intermodal, construction, automotive and express freight and urban logistics. A new geography of rail freight demand is emerging, an increasing density southward from a line between the Humber and the Mersey increasingly focused on sectors with a fiercely competitive road haul alternative.

Adopting new technologies that can significantly reduce the cost of the delivery of railway services to customers will open up new market opportunities and present new options for connecting people with jobs, family and friends. Taking a radically different approach to the design, build and operation of the railway network will open up opportunities for less intensively used parts of the network, bringing the many benefits of rail to more people.

Major new technologies of note emerging in the UK rail sector include those which enhance national and regional infrastructure capability (such as High Speed Rail and Digital Railway signalling), and those which enhance transport service provision (such as 'Smart Ticketing' and digital communications technologies). The former should build upon rail's established economic benefits with technologies providing opportunities of enhanced inter-regional connectivity, increased capacity on congested routes, and better operational performance. The latter may allow for increased user experience and productivity, as passengers can prospectively integrate journey planning, efficiently purchase travel, and work on the move with high-speed internet connectivity.

Technologies of note emerging in other sectors include the possible development of new transport modes, such as Autonomous Vehicles (AVs) along road networks. If technology develops to maturity where AVs can operate safely at high speed in a coordinated manner, it could arguably provide large benefits and advantages to road transport. However, rail may still maintain an advantage with the efficiency it transports

large volumes of passengers. Indeed, AVs could be regarded less as a competitive threat, but as a complimentary means to plan for – for example, station planning and development could integrate AVs as an additional transport mode in a customer's journey.

Should AVs become viable modes that compete with mass transit, then decisions will have to be made as to whether their rollout is purely market led, or whether regulation and a level of accompanying infrastructure is to be invested in at a city, regional or national level. Where there are finite resources, there will be opportunity cost impacts from deciding to invest in infrastructure and systems for AVs, instead of the already established modes. This may slow down the forecast rate of growth of these modes, including rail.

Assuming some form of regulation and supporting infrastructure for AVs is granted, then the impact it has on changing patterns of rail demand travel will be critically dependent on the eventual form it takes. Careful long-term forward planning and in-depth consideration is required to ensure that infrastructure and systems to support AVs act to complement sunk and planned infrastructure investments in other modes.

The industry continues to assess the prospects for further growth under a range of scenarios. Most recently the RDG commissioned a study that addresses the question of how resilient rail demand is to a broad range of future 'shocks' to the economy¹⁰. The Commission is invited to discuss this work with RDG.

Q14: What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Rail's key strengths are in transporting large volumes of passengers, both for long distances between major cities, and for short distances within large urban areas. Many of the largest urban areas in England and Wales are already served by dense urban rail networks; all of which have experienced significant growth in passenger demand in recent years.

As highlighted in the response to Q1, following the completion of the schemes currently committed or underway, the next priority for the rail industry will be to support the delivery of the priority schemes identified by its funders and the National Infrastructure Commission. The schemes which fall within the remit of this question comprise Crossrail 2 and Northern Powerhouse Rail.

The next category of schemes is those which the industry has identified as priorities in light of the severe capacity challenges they seek to address. All of these interventions will support travel into, out of and around London; comprising upgrades to the Brighton and South West Main Lines, and interventions to address passenger crowding at Clapham Junction, London Euston and London Liverpool Street stations.

The next highest value investments are the projects set out in the enhancements to improve access to major urban areas. Examples include:

- Greater London: potential increased capacity of up to 27 trains per hour delivered by Great Eastern Main Line Upgrade Programme through train headway reductions.
- Northern city regions: transformation in the North of England to be delivered by the Northern Powerhouse Rail Programme (specific schemes and outputs to be developed).
- West Midlands: various interventions to accommodate passenger growth on services into Birmingham as part of the Midlands Rail Hub.
- Leicester: increased capacity to accommodate passenger and freight growth through Leicester delivered by Midland Main Line Programme.

In addition to enhancements, removing 'barriers' between transport modes through – for example – improved interchange, addressing ticketing and more personalised information will support the greater mobility of people and goods. New technology will support greater mobility and the true 'door to door' experience. Key Capability 3 'Efficient passenger flow through stations and trains' and Key Capability 9 'Personalised customer experience' in the CDP and the RDG Customer Experience activities address these areas. Additionally, the end point of having intelligent and autonomous trains is to deliver far greater flexibility and

far more journey opportunities that will support greater movement in and around urban areas and connect seamlessly with other mobility services.

Q15: What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

The key arteries for long distance rail travel in Great Britain comprise the following:

- East Coast Main Line: London Kings Cross to Leeds, York, Newcastle and Edinburgh.
- Great Western Main Line: London Paddington to Reading, Oxford, Bristol, Cardiff, Swansea and Plymouth.
- Midland Main Line: London St Pancras to Leicester, Nottingham, Derby and Sheffield.
- West Coast Main Line: London Euston to Birmingham, Manchester, Liverpool, Preston and Glasgow.

HS2 represents a significant expansion in capacity and connectivity from London to the Midlands and the north, with Phase 1 between London, Birmingham and Handsacre (near Lichfield) to be opened in 2026. Without HS2, the West Coast Main Line will be unable to meet the demands placed on it by passengers, freight or the economy. By 2033 HS2 services are expected to be running on Phase 2 between London, the Midlands, North West, Yorkshire and North East. Ultimately HS2 will offer transformational levels of connectivity between destinations currently served by the East Coast, West Coast and Midland Main Lines; and will provide links to international gateways at Birmingham and Manchester airports, and Heathrow via an interchange at Old Oak Common. For the East and West Coast Main Lines, the highest value investment comprise the various schemes included in the enhancements pipeline to provide additional capacity to support existing and post-HS2 traffic patterns. Examples include the East Coast Main Line Power Supply Upgrade project, and capacity improvements at Newcastle station.

Northern Powerhouse Rail aims to transform rail connectivity between the main economic centres of the North by offering faster and more frequent journeys. It will deliver enhanced east-west rail links with significantly reduced journey times and higher frequencies by developing a network comprised of new routes in some corridors, and significant upgrades in others. HS2 will be an integral part of Northern Powerhouse Rail, and Northern Powerhouse Rail and HS2 will together deliver the vision of city to city links, both east-west and north-south. Northern Powerhouse Rail will also be an integral part of the wider rail network and needs to be planned as such from the outset. Northern Powerhouse Rail stations will be integrated with local services with smart ticketing across the network.

The Great Western Main Line is currently undergoing an extensive upgrade which will deliver electric trains and increased train frequencies, and further enhancements in the future will build on this programme of work. Towards the west end of the route, the highest value investment will be to address the resilience of the coastal section from Exeter to Newton Abbot through Dawlish and Teignmouth. The Exeter to Newton Abbot Resilience Programme is being developed by Network Rail to achieve this.

In recent years the reopening of previously closed rail lines has transformed connectivity and brought significant new traffic to the railway. A particularly successful recent example has been the Borders Railway, which has linked Edinburgh and the Scottish Borders by rail for the first time since the closure of the 'Waverley Line' in 1969. Opportunities exist to support similar schemes elsewhere on the network.

Investing in the technologies that will enable the closer running of trains and far greater flexibility in delivering services will directly support connecting people and goods outside of a single urban area.

Q16: What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Although not strictly related to road user charging, Mobility As A Service (MAAS) offers further opportunities for people to access rail by providing people with far greater flexibility and choice as to how they use rail services. For example, through purchasing packages of travel as opposed to the more traditional season tickets and not having to purchase individual and different tickets for different modes.

National Infrastructure Assessment – Call for Evidence

Response from Rail Freight Group

February 2017

Rail Freight Group (RFG) is pleased to respond to the National Infrastructure Commission's Call for Evidence on the National Infrastructure Assessment. No part of this response is confidential.

RFG is the representative body for rail freight in the UK. We have around 120 member companies who are active in all areas of the rail freight sector, including train operators, end customers, ports, terminals, developers, equipment and rolling stock suppliers and support services. Our aim is to increase the amount of goods moved by rail.

In responding to this call for evidence we have focussed on the cross cutting and transport questions. Other areas of infrastructure development are however relevant for the rail freight sector – for example, we are involved in the construction phase of some new energy projects, and move fuel for power generation. Decisions on other infrastructure can therefore create business opportunities for the rail freight sector. Conversely, unclear policy direction in such sectors can hinder business planning and detract from investment. A coherent approach to infrastructure planning is therefore welcome.

General Comments

The movement of freight by all modes is critical to the effective functioning of the UK economy. This relates to imported and exported goods via the UK's ports (including Channel Tunnel) and domestic distribution of materials. With a renewed focus on post Brexit trade, the effective functioning of freight links will be more important than ever – if the UK cannot compete on transport costs and on 'time to market' it will impede our ability to grow exports.

Despite its importance, the movement of freight can often be overlooked in discussions on transport infrastructure. The recently published Government Green Paper on industrial strategy does not reference freight at all, and mentions logistics only once. Flagship policies, such as HS2, have no compelling case for freight as central to their development, and public policy is often negative towards both road and rail freight. City centre transport policy is a particularly acute example of this.

The competitive, private sector operation of freight transport on publically owned infrastructure compounds this position. Freight operators are low margin business, with efficiency gains competed away in pricing to customers. This is good for customers, and the economy, but tends to mean that the financial contribution of freight operators to network costs is limited. Although comparative data is not available, both road and rail freight fail to cover their full costs to some extent. This includes both infrastructure costs and social costs (particularly for road freight). Given the current focus on how transport infrastructure should be funded, the

inability of freight transport to pay more without passing costs onto customers is a key factor.

Presently rail freight has around 10% of the UK surface transport market overall, but has (for example) around 25% of imported containers, and around 40% of construction aggregate supplies into London and the South East. This means that increasing the ability to operate more rail services can make a significant impact on road traffic volumes on key routes.

Specific Questions – Cross Cutting Issues

Q1 For rail freight, schemes which improve the capacity of the rail network, and enhance the efficiency of rail freight are most likely to deliver value for the UK. Although there are local bottlenecks, most often interventions will be necessary on the trunk route network between conurbations, and between ports and inland destinations. Current priorities include;

- Transpennine corridor to enable freight to operate alongside enhanced passenger services;
- Enhanced capacity from Port of Felixstowe, including the route via Ely, and from Southampton and around London;
- Capacity for all users on the northern section of the West Coast Main Line after the start of HS2 services to Scotland
- Measures to improve the efficiency of rail freight services on the network, including incremental gauge enhancement, removal of speed restrictions, enhanced timetabling and so on.

Q2 Rail freight already plays a significant role in the inland distribution of port traffic, and a smaller role in through services of international freight via the Channel Tunnel. The cost and efficiency of such links is important in ensuring that UK trade can prosper. Supply chain failures will influence trade decisions particularly when other economies are investing to ensure their goods have effective routes to market. In a post Brexit economy this is likely to be even more important. As such, we believe that investment in links to international gateways remains critically important.

Q3 Decisions on housing and infrastructure must be cognisant of the needs of freight and other industrial activity. This is particularly acute for the road freight sector that must have full urban penetrations for (e.g.) shop deliveries, whilst for rail freight; it means that the planning framework must support rail deliveries into urban terminals. Presently, we are finding that rail activities are hampered by inappropriate adjacent development which can lead to operating constraints – for example, night time planning conditions at terminals which conflict with the available capacity on the rail network which is set to avoid peak times. We also see land sites lost to rail, or planning rejected particularly for construction use – meaning that house building materials cannot be rail served. Warehousing on rail connected sites is desirable, but the inability to get planning consent frustrates many developers.

We believe there must be clearer and stronger planning guidance which balances industrial and housing use, protects existing facilities and helps promote a use of rail.

Recognition of the ongoing need for industrial land, and for the distribution of goods, must be a stronger consideration in urban planning.

Q4 Such effects are less common in freight transport than passenger. However, constraints on movement – for example, peak time bans – will have consequent impacts on the efficiency and hence cost of freight deliveries, which should be factored in to decision making. A move towards road pricing could be helpful for rail freight if it was targeted effectively – however the inherently different charging frameworks for road and rail makes it difficult to fully understand the impacts.

Q5 We believe there is a place for both. Rail infrastructure must be maintained in a fit condition for freight.

Q6 The currently ongoing Hansford Review aims to assess the role of third parties in developing Network Rail's infrastructure. We believe that there may be merit in considering alternative delivery models in certain circumstances. For small freight schemes, our members have expressed frustration with the cost and timescales associated with Network Rail projects, which can be an impediment to their plans.

Q7 As outlined above, the competitive model for freight distribution means that the ability of freight operators to pay an increased charge for infrastructure is difficult. For rail, an increase in cost tends to result in modal shift to road, with associated dis-benefits. We have distinctly different cost models between modes, and the transparency of information for rail is greater than for road, which makes comparisons difficult. We consider that;

- There must be proper cross modal consideration of infrastructure funding and charges
- Decisions which increase (overall) the cost of freight transport must take explicit account of the impacts on customers and the wider economy
- Government should be explicit in its support of the transport infrastructure for freight and provide a long term stable framework which supports third party investment in equipment and terminals.

Q9 Building resilience into rail infrastructure is a key priority which includes establishing a network of diversionary routes between key hubs. Stability in Government policy to infrastructure over the long term also helps to ensure effective investment – for example, changes in Government support for biomass generation created uncertainty in the rail freight sector.

Digital technology represents a large opportunity for the rail sector, which is arguably lagging in this area, and the interface of these areas should be a priority.

Q10 As outlined above, there needs to be a greater emphasis on planning for industrial and distribution land use alongside housing priorities, including on adjacent development. The Planning Act 2008 reforms have helped provide certainty for some larger rail freight developments, but others are still frustrated by extended timescales, and a lack of specialist knowledge within planning departments e.g. on minerals planning.

Q11 Rail freight has environmental advantages over road freight and should be a core part of transport policy. Government should also clarify its future position on rail electrification to inform future traction investments, and also consider how the long term reliance on diesel can be reduced, given air quality concerns.

Q13 For freight transport, the overall volume moved will rely on a significant extent to UK economic performance, and the balance of import / export and domestic trade. Assuming no seismic shift, we would expect to see a continued emphasis on port trade, including to the major deep sea ports in the south east and the smaller ports in the north which are more likely to be dominated by feeder services. For domestic movements, the balance of retail and e-commerce will be an important factor.

Q14 For rail freight, there are three principle markets. For bulk materials such as construction materials and waste suitable urban terminals with suitable rail access can help minimise road trips and should be protected. For retail deliveries, rail linked warehousing and consolidation on the edge of urban centres can make end road delivery more efficient. Although undeveloped, use of rail stations for retail deliveries is also growing in interest, and can exploit passenger trains for niche deliveries including e-commerce and biomedical products.

Q15 Unlocking capacity and improving the efficiency of freight movements is the priority, as outlined above.

RESPONSE TO THE NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE

Background to the Railway Industry Association

The Railway Industry Association (RIA) is the recognised Trade Association for UK-based suppliers of equipment and services to the world-wide industry. It has around 200 member companies, active across the whole range of railway supply, both infrastructure and rolling stock. That range is exceptionally diverse and includes many skills and resources which were previously part of the national railway undertaking but which now operate commercially in the private sector.

RIA members represent the greater part of the UK railway supply industry by turnover. Most large firms are members, as well as a wide range of smaller companies.

Relationship with the Rail Supply Group and the Rail Delivery Group

RIA is key supporter (and co-funder with DfT) of, and delivery partner for, the Rail Supply Group which is the sector leadership council which has an underpinning industry sector strategy entitled “Fast Track to the Future”.

As a member of the RDG Planning Oversight Group (POG), representing the supply chain, RIA has been party to the development of the Rail Delivery Group (RDG) response. We strongly endorse that response which we would like to supplement with the following supply chain specific comments.

Supply Chain Specifics

It is essential that investment in infrastructure is focussed on supporting sustainable economic growth. In addition to the points that the RDG response makes about the important contribution the rail industry makes to economic growth we would highlight the additional contribution of a strong UK based supply chain.

Employing over 120,000 people and with an estimated annual economic contribution of around £7bn the UK supply chain makes a key contribution to the wider economic benefits realised by investment in railway infrastructure.

However the UK has not always successfully maximised the benefit for the UK economy. Given the £80bn pipeline of domestic rail projects there is a great opportunity to strengthen the domestic supply chain, reduce imports and create a platform for export growth.

Rather than repeat the RDG response we set out below some key considerations which, if addressed, would help the UK rail supply chain deliver infrastructure even more efficiently.

Pipeline Visibility/ Stability

To support supply chain investment in people, plant, process and innovation to drive productivity and competitive advantage it is vital that there is visibility of a stable workload pipeline. As we have stressed in our responses to various rail industry consultations (Bowe, Hendy, Shaw and the initial ORR PR18 consultation), this is critical if suppliers are to invest in the resources and kit required to deliver the required volumes of work. And the corollary is that spiky demand profiles drive up costs. We have previously submitted evidence to the Commons Transport select Committee and to the McNulty review that demand volatility adds between 10-30% to the cost of products affected.

And whilst the move from an annual funding round to the current 5 year Control Period funding blocks for Network Rail is hugely welcome, there is still an issue around demand hiatus towards the end of a Control Period and the start of the next – with the attendant implications for supply chain mobilisation and efficiency. Consideration of a rolling 5-year programme might help smooth this volatility.

Whole-Life Costing

We would encourage major infrastructure programmes to focus more on whole-life costs rather than initial up-front cost as a way of achieving longer term savings and reducing potential exposure to increased operational and maintenance costs.

Greater Use of Output Specifications

The greater use of output specifications rather than input specifications is another area of potential efficiency. The former allows much greater scope for innovation on behalf of suppliers in order to either speed up process, reduce costs or both. It is accepted that the use of output specifications comes a responsibility on the supply chain to warrant that their products will meet them.

The Thameslink Programme, for example, was ambitious in adopting and contracting on an 'output specification' of 24 trains per hour when the perceived wisdom was that this was high risk. The difference here was that 24 tph was the output needed for the business case to work and therefore there was a 'grand challenge' which had to be achieved and focus was applied to delivering this output whilst mitigating the risk.

Consistent use of procurement and contracting best practice

There are clear lessons from a number of recent rail projects which can be applied elsewhere when the situation is appropriate.

The Staffordshire Alliance is an excellent example of success being delivered through aligned objectives and incentives. This challenging multi-disciplinary project was contracted with a target cost lower than estimated cost and all parties including the client were subject to pain/gain share. This created an environment where all parties collaborated and innovated to deliver to time and target cost.

Early Contractor Involvement (ECI) also has a major role to play, typically bringing in contractor construction and integration expertise before the design and programme are finalised. ECI was successfully used on Thameslink Civils projects and was recently used on the Digital Railway Programme where it identified a potential 30% cost reduction subject to a collaboration between client and supply chain throughout the life-cycle.

For all types of projects, including the less complex projects there is a strong argument that delivery will be improved and costs reduced by a mature long term collaborative and trusting relationship with suppliers.

Stimulating innovation

The public sector has been dominant in rail industry procurement and often adopts a risk-averse approach favouring proven technology over innovation. It is common for 'proven technology' to be an explicit sponsor requirement. It therefore can be difficult for suppliers to prove new technology and obtain UK reference cases to support exports.

However these challenges are not insuperable. Public procurement bodies can choose to set ambitious output requirements, such as the Thameslink example cited above, to achieve their business case and thus drive the innovation that will both improve the outcomes for the customer and help the UK supply chain develop new world leading products and services.

It is often the case that the technology to achieve a particular outcome is available but may not have been proven in the required application or simply has not been used in the UK. For public funders there may be a good case to de-risk the most ambitious new technology off line and in advance of the need on the main programme. This can be supported by the 'Innovation Partnership' arrangements included in the EU Public Contracts Directive (2014). This provides a mechanism to allow the selection of the partner(s) to develop solutions where products are not yet available to deliver the required outputs. This could, for example, be a route to de-risking the collaborative development of ETCS Level 3 for the Digital Railway Programme.

Conclusion

We realise this is only a snapshot of a number of key issues and we would be delighted to talk these through in more detail if that would help.

Rees Jeffreys Road Fund

A Major Road Network for England

A Rees Jeffreys Road Fund Study

David Quarmby
Phil Carey
October 2016

The **Rees Jeffreys Road Fund** has, since its inception in 1950, provided support for education and research in all forms of transport. It helps to fund projects that improve safety, the roadside environment and rest facilities for motorists and other road users. The Fund has nine Trustees, all with considerable transport experience. This study has been overseen by a Steering Group drawn from the Trustees, comprising David Bayliss, Stephen Glaister and David Tarrant, and chaired by David Hutchinson. For further information, please see www.reesjeffreys.co.uk

The study has been led by David Quarmby, with Phil Carey as co-author. The study administrator was Frances Leong.

David Quarmby CBE has had a long career in policy, planning, management, operations and research, mostly in transport, with 38 years' board-level experience in government, public agencies and the private sector. For the past 18 years he has had an extensive portfolio of chairman and board appointments in transport, railways and tourism, and in transport research and consultancy. David was Chairman of the RAC Foundation to 2013, a member of the **London Mayor's Roads Task Force**, and an Adviser to the Airports Commission. He led the **Government Review of Winter Resilience of England's Transport Systems** in 2010 and was a member of the A12 Commission in 2008. Prior to 1996 he was a main board director and joint Managing Director of Sainsbury's; up to 1984 he was a board member and Managing Director (Buses), London Transport after a period as Head of Research and then Chief Planning Officer.

Phil Carey has been working as an independent consultant specialising in roads strategy challenges since leaving the Department for Transport (DfT) in 2011. He is the Road User Policy Advisor to **Transport Focus**, which now has the role of statutory consumer representative for users of the Strategic Road Network in England; he is also Vice-Chair of the **Transport Associates' Network**. In a series of Deputy Director roles in DfT and elsewhere in the Civil Service, he led projects ranging from the Transport Strategy Review for the Cabinet Office in 2001-02 and the Ports Policy Review in 2006-7, through to the road pricing research programme in 2007-9, and the cross-cutting transport security and contingencies team after that.

This study report should be read in conjunction with the series of Supporting Documents, listed at Appendix A, and available at www.futureroadsengland.org and at www.reesjeffreys.co.uk/transport-reports, where the Report Summary may also be found.

Executive Summary

1: A Major Road Network that is more than Highways England's SRN

Roads are vital to the economy and for mobility to support quality of life. Roads account for 89% of all personal travel – by car, bus, coach, cycles and motorbike – and 86% of all inland freight movement.

England's economy – nationally and regionally – needs a designated, coherent network of major roads with good connectivity and geographical coverage. We conclude that the 4,200 mile Strategic Road Network (SRN) of motorways and trunk roads run by Highways England – important though they are, carrying a third of the nation's traffic – is not sufficient for this. With a major increase in investment now lined up, we must focus too on the more important local authority

'A' roads, which also play a crucial role in meeting the needs of business at both national and regional level.

We have identified another 3,800 miles of 'strategic' local authority-controlled 'A' roads – also heavily trafficked, especially with commercial transport, providing essential connectivity by filling the gaps in the SRN. Together, these constitute an 8,000 mile **Major Road Network (MRN)**, carrying 43% of England's traffic on 4% of its roads.

See page 14 for a map of the MRN.

2: A consistent approach to planning, management and funding of the network

The whole MRN needs to be planned, managed and funded in a consistent

way – to fulfill its potential in supporting economic growth, through providing the effective service that users need. Consistency does not mean uniformity, though: we recognise three different tiers of road within this MRN, reflecting the diversity of the network.

We are not proposing any changes in the existing split of responsibilities between Highways England and local authorities – this is to avoid unnecessary upheaval, and to retain local accountability for the local authority roads on the MRN.

A high degree of collaboration between Highways England and the relevant local highway authorities (LHAs) would be needed for planning and managing the MRN in each area. The current momentum of devolution in England could facilitate this, with new sub-

national transport bodies, combined authorities and Local Enterprise Partnerships (LEPs) able to inject a strategic view of need in their region.

With connectivity underpinning the MRN, this network should help 'join the dots' of spatial planning and economic development at a regional level. Achieving this alignment can be elusive, where various institutions with differing jurisdictions hold the respective responsibilities. LEPs have an increasingly important role in facilitating this process of integrating land use and economic growth plans. Meanwhile, clear spatial planning policies are essential to head off any adverse development pressures generated by otherwise beneficial transport improvements.

Roads are crucial, but can only perform well if managed as the core infrastructure in an overall transport strategy, to support economic growth and improve the quality of life and mobility. This must recognise the wide range of transport modes which use roads, as well as the role of rail, and embrace a willingness to consider options for demand management to contain road traffic congestion over the longer term.

The funding challenge

Government is already committed to substantial and rising investment in Highways England's SRN, to underpin the growth agenda, and in the face of traffic levels already at their highest to date, and expected to climb further. A £15 billion programme of improvement and renewal is in train over the six years to 2020/21.

But the problem is the gulf between this funding for the SRN (and the planning regime which supports it) and the unsatisfactory arrangements still in place for the 98% of roads that are run by over 150 LHAs – this includes nearly half the MRN as we have defined it. They face declining revenue support and a patchwork of capital funding pots. There's a pressing need to avoid focusing the roads investment programme too narrowly. The local authority sections of the MRN deserve a better deal.

Any new funding arrangement should enable prioritisation of need and value for money irrespective of administrative boundaries, and should provide stability, certainty and continuity of funding over a reasonable planning period. An opportunity may come with the

prospective National Road Fund (NRF), due to start in 2020 and fed by Vehicle Excise Duty receipts in England, from users of all roads. This is expected to fund the SRN. Now is the time for government to consider whether local authority Major Roads should also be eligible for contributions from a new NRF.

3: The Major Road Network must be fit for purpose

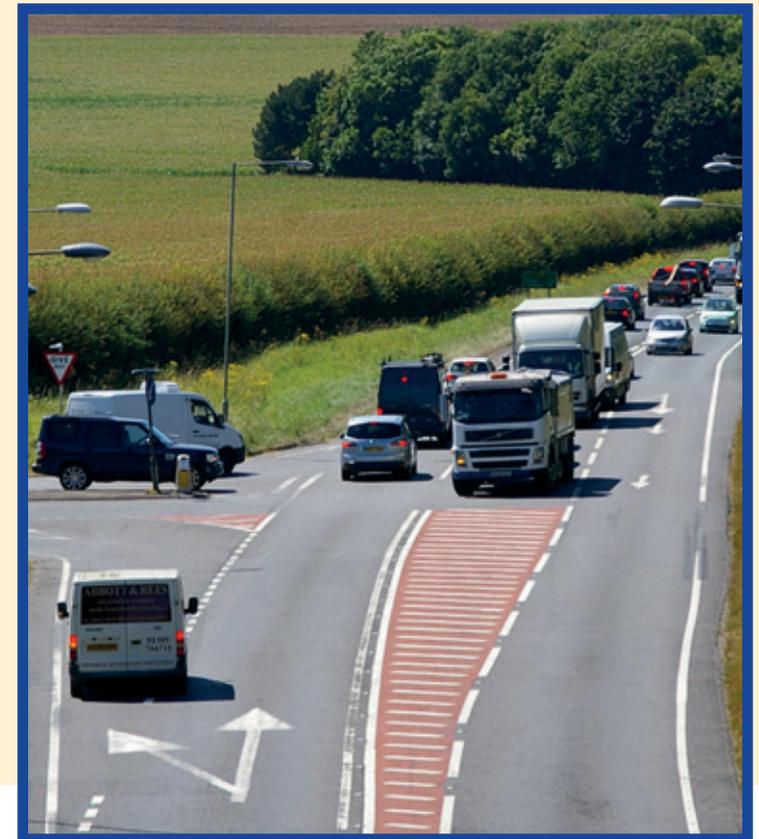

The MRN will only succeed if it is 'fit for purpose' – putting service for its users, as well as the wider needs of communities and the environment, at the heart of its planning and management, while ensuring the fitness of the asset itself and the way it is managed.

- **Fit for the user** means understanding users' expectations for a decent level of service – and then setting out to deliver on aspirations for the speed and time taken for their journeys, and their reliability and predictability. Roads in the MRN will vary by topography and current standard – so we have grouped them into three tiers according to the function they perform and the standard they offer.
- **Fit for communities and the environment** means tackling noise, air quality and severance, and integrating mitigation measures into the ongoing management of the road and its traffic.

- **Fit-for-purpose management** means making the best use of capacity and the resilience provided by the network; exploiting technology to give road users the information they need to make better decisions; controlling traffic speeds and flows through the network; and, where possible, expanding capacity at pinchpoint locations to address shortcomings in the service provided. The asset itself must be well maintained, following best practice, on a whole-life basis.
- **The safety management regime** for the network must be fit for purpose: this should include adopting over time predictive risk assessment to make the infrastructure safer and more forgiving, rather than relying only on data on past crashes to guide safety interventions.
- **Fitness for purpose of Major Roads in cities and conurbations** needs to reflect the more complex transport, planning and traffic management policies needed there, and the greater exposure and risk faced by vulnerable road users.

- **A fit-for-purpose planning regime** assesses performance against service level aspirations and other measures mentioned, and generates options for improvement or mitigation, to be evaluated for effectiveness and value for money.

These requirements for making a Major Road fit for purpose could be expressed in a high level Code of Practice,

developed in collaboration by all the network operators, and adapted as needed for the distinct tiers and other subsets within the MRN. Much is already reflected in Highways England's licence conditions and performance targets.

But achieving a fit-for-purpose MRN is not just down to the network operators. Alongside them, those authorities setting the strategy (the 'strategic clients') have a clear responsibility for making this fit-for-purpose framework effective, to ensure the MRN can perform its central role within the transport system.

The longer-term challenges

Technology and rising demand present two major longer term challenges for those collectively responsible for the Major Road Network – how best to monitor, adapt to and exploit broad and rapid technology-led change, and how to deal with rising demand for road space and consequent increasing congestion.

New technology provides network operators with much better, integrated information to manage traffic and maintain their assets, while influencing

how people and businesses make travel decisions as well as providing new choices; it brings rising penetration of 'greener' vehicles; and increasing levels of vehicle automation with prospects of improving safety, enhancing network capacity and increasing mobility. But it also brings many uncertainties, challenging network operators to judge when and how best to respond.

Given a growing population with rising mobility expectations, many of our major roads will be under ever more pressure. Investment will be needed – across the Major Road Network, not just the SRN – to address the most congested sections. But in the longer term, higher demand, in whatever form it takes, is likely to outstrip the acceptability and affordability of commensurate additions to capacity; it follows that more users will experience regular congestion as it spreads over the day and the week, with greater unreliability of journey times. Technology alone will not solve this problem – some means of demand management should, in time, feature as part of the toolkit for operating the network and maintaining service levels. There are no easy answers, but government should ensure that

it remains on top of the alternatives available.

And finally

Rather than a detailed blueprint for the future road network, this report presents instead a toolkit for taking forward the essential concepts of this report:

- the idea of the 8,000 mile Major Road Network as providing the vital accessibility and connectivity to underpin the economy at national and regional level.
- the need for a coherent and consistent approach for planning, managing and funding the whole MRN, enabled by collaboration of the key national, sub-national and local bodies.
- the need for the MRN to become fit for purpose, starting with being fit for the user.

We hope the report will help those responsible join forces to plan and deliver a better service from our major roads, that more closely matches the needs of users, business and communities.

Foreword

The Rees Jeffreys Road Fund has a long-standing interest in the future of Britain’s road system, recognising that the vast majority of travel takes place on roads. Both the health of our economy and our quality of life depend on the mobility provided by the road network – whichever modes of travel we use.

We can easily take our roads for granted – someone has to maintain them, to manage the traffic that flows on them, and to improve them when they get congested. What is far from straightforward, however, is the planning and evolution of our road system to meet future demand, to support new development, to play its part in the complex transport policies of our cities, and to provide the connectivity needs of business.

In commissioning this study, the Fund’s Trustees wanted to focus on the major roads that are so critical in supporting national and regional economies, as well as in meeting expectations about mobility and quality of life.

The focus of the study is England; over the 15 years since devolution of transport and roads to Scotland and Wales, the planning, funding and governance regimes for roads have diverged significantly between the three nations, and the Trustees did not wish to dissipate the team’s effort in trying to study three increasingly different sets of arrangements.

The Trustees endorse the report’s central idea that the definition of ‘Major Road’ must include the more important local authority ‘A’ roads as well as Highways England’s Strategic Road Network, and we agree that such a Major Road Network needs coherent and consistent planning and funding arrangements. In addition, the Trustees support the need for them to be made

‘fit for purpose’, geared to meet the users’ needs, safe, well maintained, able to make best use of capacity, and a good neighbour to the communities that they pass through.

We wanted to explore the extent to which new technologies could transform our major road system and how they might best be used in the decades to 2040. The Trustees believe that greater awareness of the challenges and opportunities ahead will make for better short- and medium-term decision-making.

This report is aimed at all those with a responsibility for or interest in England’s major roads. We believe it merits serious consideration by central and local government, the new emerging devolved bodies, Highways England and other organisations in the sector. At a time of great change, and

with the long-term commitment to infrastructure renewal, a consistent approach to the road network is much needed.

The Trustees join me in thanking our authors David Quarmby and Phil Carey for their hard work over the last two years and for this immensely valuable report.

**David Hutchinson, Chairman
Rees Jeffreys Road Fund Trustees**

October 2016

1

The Challenge

A new approach needed for planning and developing England's major roads

- England's economy, at both national and regional levels, needs a balanced network of major roads with good geographical coverage that meets the needs of business and society.
- Investment in the Strategic Road Network (SRN) is now being stepped up, but we need to determine if the focus should be extended, beyond the SRN to include a number of key local authority 'A' roads.
- Given the very different regimes between Highways England and the scores of local highway authorities (LHAs), the next challenge is to create a consistent framework for planning, managing and funding these major roads, and for facilitating effective collaboration between the different bodies to enable this to happen.
- Only in this way can the available resources be spent most effectively and the Major Road Network (MRN), as we call it, made 'fit for purpose'.
- Continuing devolution of powers to local authorities and sub-national bodies provides an opportunity to help make this collaboration work.
- Two further challenges over the longer term are:
 - to exploit to the full the capability of transformative changes in technology that will affect vehicles, travel options and infrastructure management; and
 - to find the right balance between managing traffic demand and enhancing capacity, so as to maintain reasonable levels of service on the network in the face of rising congestion.

1.1 The challenge of ensuring a well-performing road system that supports the economy

A well-performing road system meeting the needs of its users must be central to government's focus on strengthening England's economy. At a national and regional level, achieving and sustaining growth depends to a huge extent on good accessibility – and accessibility in turn is overwhelmingly provided by the road network: 89% of all personal travel and 86% of freight movement takes place by road.ⁱ And it is the main roads within that network that are the arteries for commercial traffic on which businesses across the country rely.

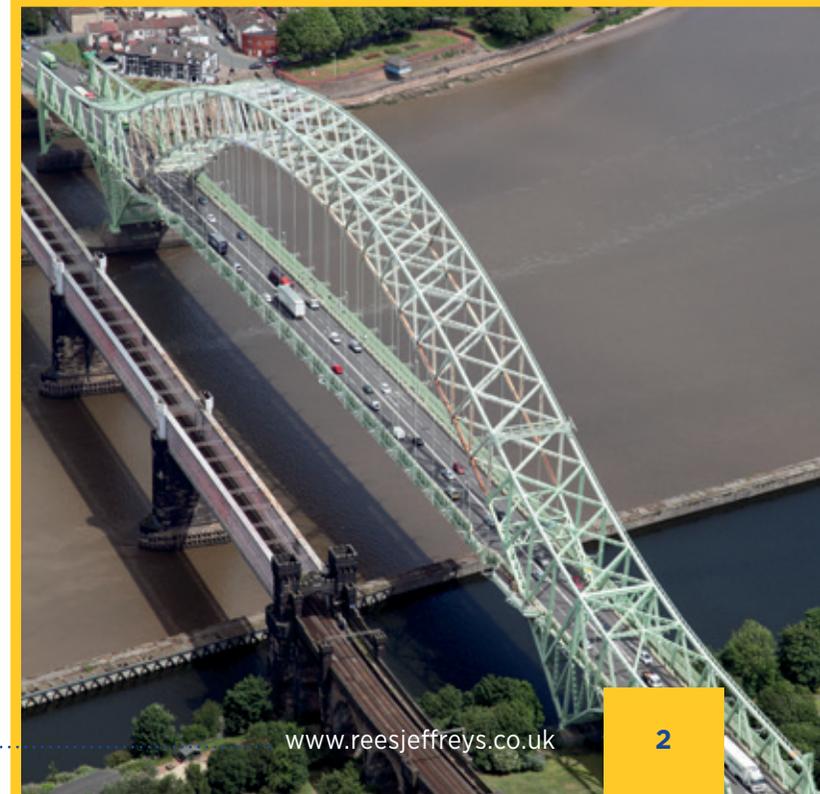

But roads can only perform well if managed as the core infrastructure within an overall transport strategy that delivers the desired objectives. This must recognise the wide range of transport modes which use roads, but must position that alongside rail, which also plays a crucial role for passengers as well as freight.

Road traffic is now at its highest level ever.ⁱⁱ Forecasting is difficult at this time, but the most recent forecasts estimate

further growth in the range 19–55% between 2010 and 2040ⁱⁱⁱ – at the higher end of this range for vans, and for traffic on motorways and rural 'A' roads – meaning that many of those arteries would be at risk of simply clogging up. Growth on urban roads is forecast to be rather lower, but chronic congestion is already a feature of some main roads in and around towns and cities – not merely in London.

Government recognises the challenge of ensuring that England's transport infrastructure overall is up to the task. A very substantial transport investment programme is well under way, with more than £70 billion having been committed to it over the six years to 2020/21, mostly to rail.^{iv} Of that expenditure, £15 billion is now being channelled into the SRN,^v through the newly autonomous Highways England. And a National Road Fund is expected to come into being in 2020, funded by Vehicle Excise Duty receipts, to support 'strategic roads' in England and consolidate that funding stability.

But this commitment addresses only part of the challenge. The 4,000 or so miles of the SRN, critical though they are in carrying a third of England's total traffic, fall well short of the full set of economically important roads, particularly at the regional level. Across the country, significant local authority 'A' roads play a crucial role as well, complementing the SRN to provide the network that matters.

1

And herein lies the nub of the problem: there exists a great gulf between the planning and funding regimes for the SRN and the less effective arrangements for the vast bulk of England's roads, managed by 153 LHAs. These local roads are significantly less well funded, on most counts, than the SRN, and are still for the most part subject to annual budget-setting, with declining revenue support and a patchwork of capital funding arrangements; what is more, they lack a comprehensive performance regime.

The challenge, therefore, is to:

- define the full network of significant roads that provide the backbone of England's economy, at a national and regional level, exploring how far beyond the SRN that network needs to go – that then constitutes our Major Road Network; and
- devise an integrated planning and funding regime for both the SRN and the local authority parts of the MRN, to maximise the potential of this MRN and to get best value for money from it; even a substantial roads investment programme, if it is focused largely on the SRN alone, will fail to provide the necessary support for economic growth.

To fulfil its potential, such an MRN needs to be planned and managed in such a way as to:

1. place current and prospective road users at the heart of investment and operational decisions – whilst requiring value for money at all times;
2. quickly become fit for purpose, and managed well so as to deliver a decent service to users and to meet the wider needs of communities and the economy;
3. ensure alignment with the objectives of sustainable growth in housing and business development, linked with spatial planning policies;
4. fully recognise the more complex, multimodal role that major roads play in our cities and conurbations; and
5. establish the consistency and long-term stability in planning and funding that infrastructure of this importance deserves.

The current momentum of devolution of powers to local government and new sub-national bodies in England may be relevant here: the emerging institutions seem well placed to exploit the MRN concept, helping to fulfil the above five conditions, and providing a basis for better and more accountable decisions that stand a chance of being taken on board owned locally.

This study takes the same 2040 horizon as the Strategic Vision underpinning roads reform^{vi} – which helps us focus on two major challenges for the longer term:

- The first relates to the effects of rapid and disruptive technology-led change on travel choices and demand, on the increasing automation of driving tasks, and on the way that road networks will need to be managed. The impacts

of autonomous vehicles are just one aspect – one that is particularly difficult to gauge – of the long-term transition to a more technology-led system of vehicle movement and management.

- The second challenge is how to deal with the expected rise in traffic congestion over this period. Whatever the uncertainties about future travel patterns, and the

prospects for growth in rail's share of total travel, the rising demand for movement due to population and economic growth may well outstrip the rate at which major road capacity can be affordably and acceptably increased. This requires a willingness over the longer term to consider methods of demand management.

1.2 How this study tackles these challenges

This report sets out how these various challenges can be best addressed, and to guide decisions about the designation, management and development of the MRN. It is not a blueprint for the future road network itself – that is for government, central and local, to determine alongside their partners and communities.

The report first analyses the growing gulf between the regimes for the SRN and for local authority roads; it then develops a proposal for an MRN designed to support

national and regional economies. We also explore the link between the processes of economic and spatial planning, and the planning of the road network.

At the heart of the report is a proposition for what a 'fit-for-purpose network' should provide – centred on what its users, and all of us in our communities, should reasonably expect.

We then consider how to make it work, creating a collaborative planning regime, and identifying the opportunity for a consistent approach to funding.

Finally, we survey the outlook for the longer term, given the technology and congestion challenges.

The mechanisms needed to put all this in place and to deliver what England needs lie within reach: an MRN that meets the needs of its users and society, serves the country's economy, and is sustainable for the longer term, through to 2040 and beyond.

2

The Growing Gulf

Roads reform is exacerbating the divide between the Strategic Road Network and local major roads

- The contrast between the planning and funding regime for the Strategic Road Network (SRN) and that for local roads is stark.
- The roads reform agenda has put in place an effective and well-resourced regime for planning and delivering successive five-year programmes of investment on the SRN, through Highways England, with associated user-focused performance targets.
- No such regime exists for local highway authorities (LHAs), who have had to cut routine maintenance as part of the Government's austerity programme, and who face complex capital funding arrangements, without the certainty of comprehensive five-year commitments.
- Greater maintenance backlogs exist on the local authority road network than on the SRN, and the quality of service to users is generally not as good.
- The coverage of the SRN varies considerably across England, exacerbating the consequences of the contrast in regimes.
- If some of the more important local authority roads are to be put alongside the SRN to create a more integrated and geographically coherent network of Major Roads, this gulf between the two planning and funding regimes needs to be addressed.

2.1 The regime for the Strategic Road Network

The Roads Reform agenda has put in place for the SRN a carefully constructed, well-resourced regime, one which makes the most of the autonomy now granted to the government-owned company Highways England. It has been given a clearly defined remit, and guaranteed funding over a five-year Road Investment

Strategy (RIS) period, which aligns well with the longer timescales entailed in delivering infrastructure projects. In addition to maintenance and operations, annual investment in improving the network alone will more than double over this first five-year period, reaching £2.2 billion in 2019/20.

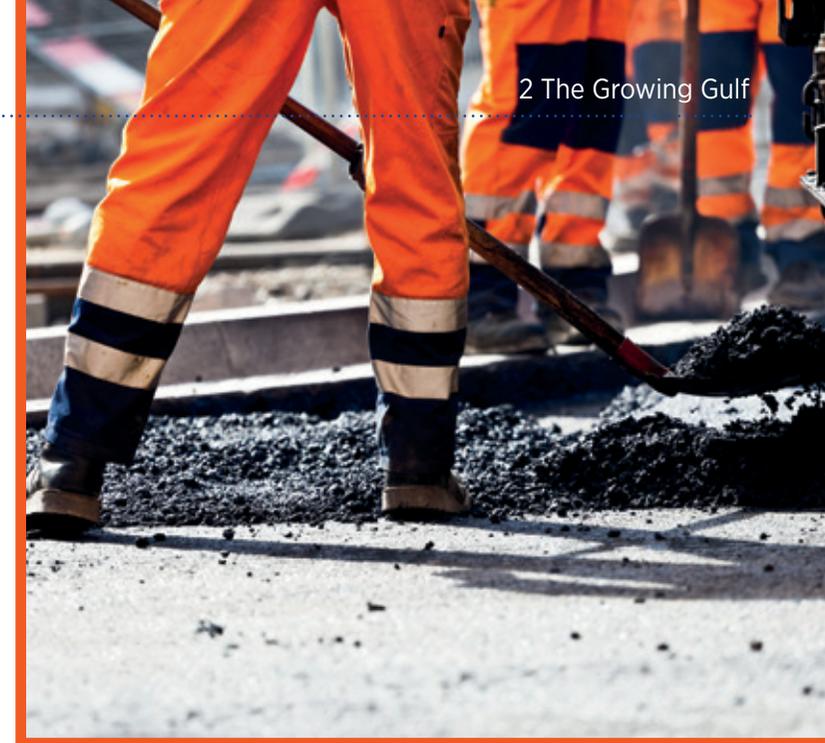

2.2 The regime for local roads

The governance and funding regime for local roads has had no such overhaul. It doesn't enjoy the same clear focus on outcomes, and has increased in complexity of late: there are now some 15 different funding pots, most determined year by year, and all having different criteria and business case requirements.^{vii}

In the 2015/16 year, outside London, only 4% of funding for capital expenditure was formally ring-fenced; little more than half is now allocated according to funding formulae, and this much is based mainly on road length and the

number of bridges needing works. The balance of funding is either scheme-led, or (increasingly) based on the LHA's performance. Total local authority capital expenditure on roads is set to change little over the period to 2019/20.¹

The revenue side of local roads is particularly difficult to assess, as only part of the funding comes from central government; receipts locally from Council Tax and parking services top this up, but the exceptional pressure on local authority budgets in recent years has pushed road maintenance revenue spend

down 16% in the three years to 2013/14; this decline is set to continue.

The uncertainty is growing: major institutional changes are emerging with the spread of combined authorities and of sub-national transport bodies, and new funding arrangements are being set up as part of the 'deals' negotiated in each case. The planned move to a regime under which local authorities retain 100% of business rate receipts by 2020 means a revolution in local government finance; its implications for central government grants are, as yet, unclear.

¹ See Supporting Document 1 (Appendix A) for the data and analysis behind this chapter.

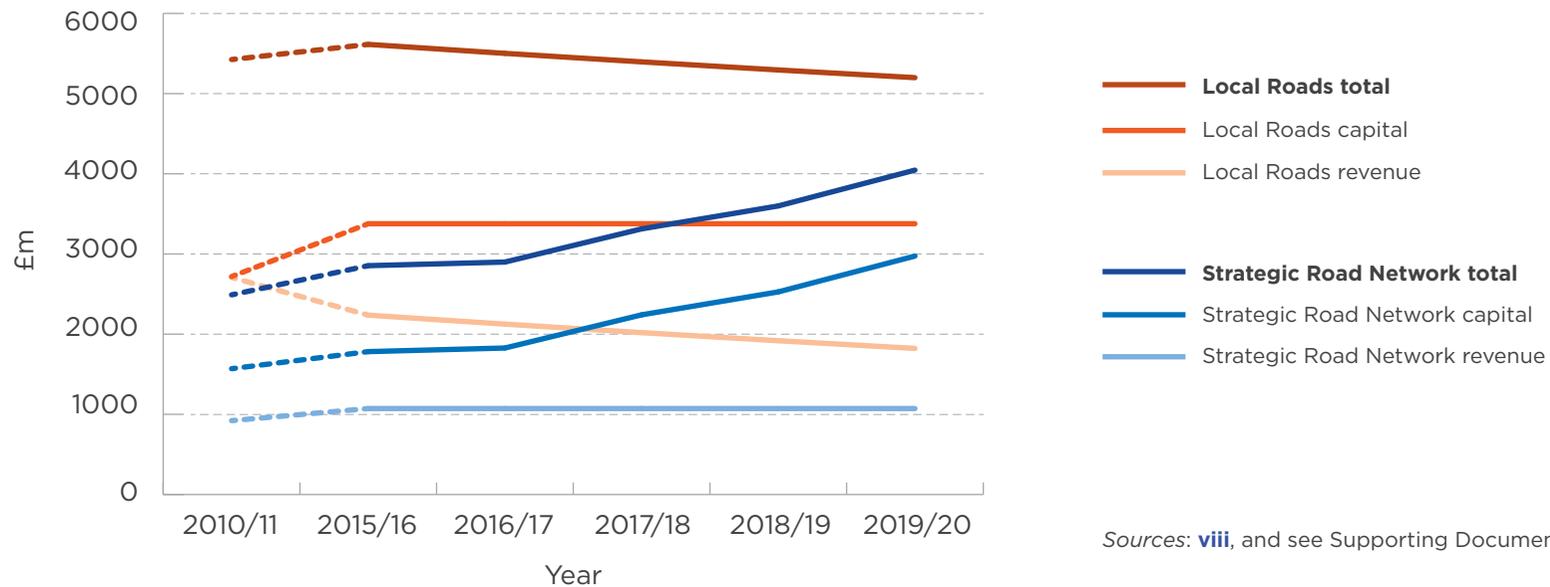

2

2.3 Comparing expenditure

The most prominent feature that comes to light when planned expenditure for the SRN and for local roads are compared is the contrast between the 67% increase in capital provision for

the SRN for the first Road Investment Strategy period (RIS1) through to 2020/21 on the one hand, and the squeeze on local roads funding on the other (Figure 2.1).

Figure 2.1: Current and forecast capital and revenue expenditure (£m) for the Strategic Road Network and all local roads

Sources: [viii](#), and see Supporting Document 1

The picture on total local roads expenditure, and on the share that goes on LHA 'A' roads (from which the subset of Major Roads will be selected), is complex. Supporting Document 1

attempts a comparison of spend, capital and revenue, between the SRN and LHA 'A' roads; this is summarised in Table 2.1.

Table 2.1: Summarised comparison of relative spend on the Strategic Road Network and on local highway authority 'A' roads

Total spend in 2015/16	£'000 per route-mile	£'000 per lane-mile	£'000 per million vehicle-miles*
Strategic Road Network	643	146	16
Local authority 'A' roads	117	51	12
Forecast spend in 2019/20			
Strategic Road Network	911	207	16
Local authority 'A' roads	108	47	11

*Per vehicle miles figures are for maintenance spend only

Source: Supporting Document 1, based on just over a third of 2014/5 maintenance-only spend for all LHA roads being on LHA 'A' roads and the small length of LHA motorway.

Total spend per SRN-mile, at £643k, is already more than five times higher than per mile of LHA 'A' road (or three times higher per lane-mile, taking account of the typically wider carriageways on the SRN). By the end of RIS1, planned spend by Highways England will have increased by more than 40%, whilst spend on local roads is more likely to have fallen. We estimate that spend per mile by then will be eight times higher on the SRN than on LHA 'A' roads.

The usual rationale for focusing resources on the SRN is the greater volume of traffic that it carries: whilst comprising only 2% of all roads, it carries 33% of all vehicle mileage (and 66% of heavy goods vehicle mileage). As an illustration, and focusing only on maintenance spend, which is the element most closely related to traffic levels, spend per *vehicle-mile* on the SRN and LHA 'A' roads is much less far apart (one third

higher on the SRN). But traffic volume is only one basis for comparing levels of spend: much of the need arises regardless of traffic flow, and local 'A' roads face additional costs arising from their more complex environment, having to:

- facilitate a wide range of non-motorised journeys not counted in traffic data;
- accommodate the consequences of utility services under their carriageways and footways; and
- provide a liveable street environment – supporting 'place' as well as 'movement' functions.

About a third of LHA A road mileage is located in towns and cities, where these considerations are most important, whereas this is true of only 7% of 'A' roads on the SRN.

2

2.4 Comparing outcomes

Despite the diversity of roads, we can draw some provisional conclusions on how lower relative funding feeds through into a poorer-quality network, or a worse experience for users:

- Asset condition:** the Department for Transport (DfT) recognises that with currently planned budgets it is not possible to clear the backlog of maintenance for local roads in England, estimated as requiring up to £8.7 billion; by contrast, plans for the SRN include fully meeting its maintenance requirement of £3.7 billion.^{viii} Whilst the headline indicator of carriageway asset condition shows approximate parity (4% of LHA 'A' roads should be 'considered for maintenance', compared with 3% of motorways and 5% of SRN 'A' roads²), this is only one part of the total road asset: account must also be taken of the more diverse legacy on local roads of bridges, foundations and general street furniture. The public certainly notice this: they see local highway condition as the second most important aspect of local transport (just surpassed by safer roads), but it causes by far the most dissatisfaction.^{ix}
- Safety:** the EuroRAP risk rating, based on accident records, is over 50% higher for LHA rural roads than it is on equivalent SRN roads that carry a comparable traffic mix (see section 5.6).

- Performance:** even allowing for the different standard of much of the infrastructure, the contrast in average delay experienced by users is striking: on the SRN as a whole, journeys take 14% longer on average than free-flowing traffic would permit;^x on LHA 'A' roads, the average delay is a 35% time penalty, on journeys that are already expected to be much slower.^{3 xi} The disparity is set to grow: average delay on trunk roads⁴ is forecast to increase by a little over a third by 2040, but by nearly half on the already slower LHA 'A' roads.^{xii}

So, the regime for local roads is more complex, less certain, and less well funded. There is evidence of poorer outcomes on LHA 'A' roads, but minor local roads may be the real losers, given that many local authorities feel obliged to concentrate their limited maintenance resources on their 'A' roads.

² This compares with 9% of B- and C-roads 'considered for maintenance', and 18% of unclassified roads, indicating how LHAs are focusing resources on their 'A' roads.

³ We have assumed average speeds of 55 mph on the SRN and 30 mph averaged across rural and urban LHA 'A' roads.

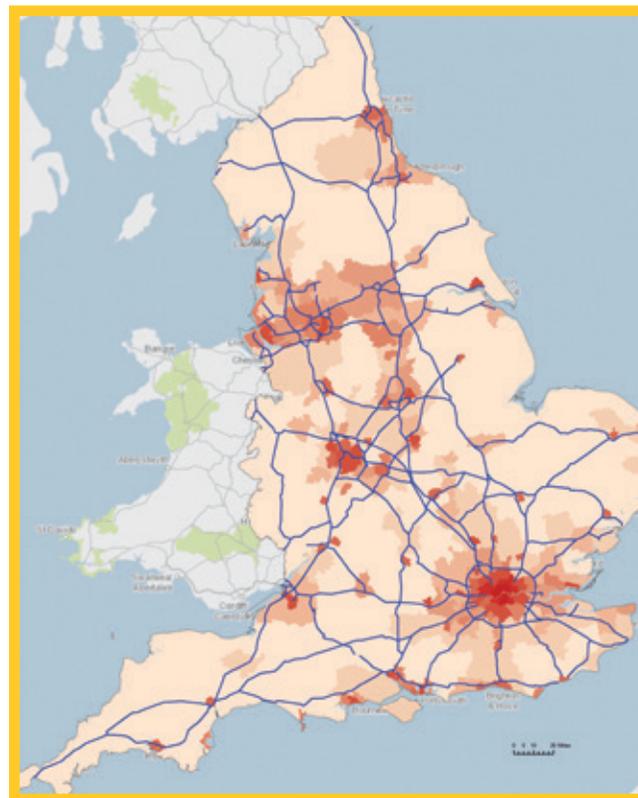

⁴ Trunk roads - 'A' roads which are the responsibility of Highways England - are part of the Strategic Road Network, alongside motorways

2.5 Uneven spread of the Strategic Road Network

The coverage of the SRN varies considerably across the country (Figure 2.2). The legacy of history, and the exemption of motorways when 30% of the total SRN was de-trunked after 1998, has left uneven coverage region by region. In South Lancashire, for example, it is a relatively dense network, almost all motorway; it is much thinner in West and South Yorkshire, and also to the south and west of London, where the development of the road network has not kept pace with economic and population growth. Highways England's Route Strategies exercise, reviewing needs across its network for the second RIS period, from 2020, might lead to recommendations for small-scale trunking or de-trunking, but there appears to be no work under way to assess more systematically whether the SRN is correctly determined.⁵

⁵ Some of the six Strategic Studies – notably on the Oxford–Cambridge Expressway – may result in some significant additions to the SRN, using corridors also picked up in our Major Road Network.

Figure 2.2: Comparison of Strategic Road Network with population density by district in England

It is this unevenness, and the fact that the SRN does not embrace all the major roads essential to underpin the national and regional economies, that makes this disparity of funding between the SRN and local authority 'A' roads so critical; it makes it all the more important to seek a definition of the network that can fulfil that task.

3

Defining our Major Road Network

Designating the roads that deliver most value

- An indicative Major Road Network (MRN) has been designated, applying objective criteria based on future traffic levels and vehicle mix to identify important main roads across England. These are the motorways and 'A' roads which most support economic activity, and provide connectivity for business and communities.
- The result is a network of some 8,000 miles, consisting of 4,200 miles of the Strategic Road Network (SRN) and a further 3,800 miles of the more important local authority 'A' roads.
- This MRN accounts for 4% of England's road mileage and 43% of all traffic.
- We have set three tiers of roads within the MRN, to reflect their different physical characteristics (limited-access highways vs common access roads), and the distinct roles they play in varying contexts (rural vs urban).
- The designation of this network does not imply that it has to be brought under the responsibility of a single body - but there will have to be an integrated and consistent regime for planning and managing it.

3.1 Introduction

A key feature of the service provided by roads is that, with the exception of a few toll roads, they form a single seamless national network, and road users are unaware of switching from the SRN to a local authority road. But they also expect a different driving experience on through routes from that on local access roads. It makes sense for users, as well as encouraging effective governance and accountability, to draw a line somewhere in that continuum of roads. The distinct, government-run 'trunk road' network (now the SRN) has its origins in the 1930s, and was supplemented by the growth of motorways, a distinct category of road. But since the 1990s it has been pared back, with the result that many major, formerly trunk, roads are now

treated in the same way as the great mass of genuinely local roads.

Road hierarchies in many other countries start with a proportionately much more extensive 'national' network: Germany has a federal network almost eight times larger than England's SRN, serving an economy that is only some 25% larger. The Netherlands' national road network is only around 20% shorter than the SRN, in an area less than a third of the size of England.

Designating our network of interest should be based on those roads that add most value, and provide greatest connectivity. This is not necessarily the same as being most heavily used by long-distance traffic, which doesn't

in itself add more value per mile than other journeys: even on motorways, only 28% of journeys (but of course a bigger proportion of total traffic) are longer than 25 miles.^{xiii} Instead, we should focus on road corridors that:

- (1) play the biggest role in local and regional economies, using the simple proxy of traffic volumes coupled with volumes of commercial traffic; and
- (2) connect the largest number of possible origin and destination pairs, also evidenced by volume of traffic, but also by ability to link up all key nodes – for example urban centres, ports and airports, and logistics hubs.

3

3.2 An objective approach

We have developed an analytical tool to test possible traffic thresholds in defining our MRN. This provides an objective basis for singling out a network of national interest. As explained in Supporting Document 2, we tested a range of options, but have settled on an intermediate level based on (a) motorway and A-road links with average daily traffic flow greater than 20,000 vehicles, along with (b) roads with as few as 10,000 vehicles, provided that at least 5% of that flow is heavy goods vehicles (HGVs) or 15% is light vans.

The raw output needed adjustments to: (1) produce a coherent network connecting all towns with population greater than 50,000; (2) remove isolated links; and (3) reflect the differential pattern of growth by region and road type that is forecast by 2040. This process of judgment has also brought in a small number of additional links, which, although falling just below those thresholds, increase the reach of the network to peripheral areas, or provide valuable resilience by backing up the most heavily trafficked corridors.

The resulting Major Road Network of just under 8,000 miles therefore puts 3,800 miles of local authority A-road alongside virtually all of the SRN, 4,200 miles⁶; it represents 4% of road mileage in England and carries 43% of all traffic (see Figure 3.1). This is significantly less than the 12,000 or so miles of Primary Route Network in England, connecting up the full set of 'primary destinations' defined by government, but not otherwise determined by traffic flow.

⁶ This is less than the 4,442 miles reported in DfT road lengths statistics, mainly because it excludes the length of slip roads and junctions; see Supporting Document 2.

Figure 3.1: The indicative Major Road Network

A key feature of the MRN is that it is determined at national level, based on objective criteria. Nonetheless, local knowledge will need to be applied across the country to validate the selection of some routes, and propose the inclusion of others. We do not envisage that this process will lead to any significant net change in the scale of the network: selected stakeholders have already expressed the view that this MRN, whose 'A' roads embrace some 30% of all 'A' roads in England, 'feels' about right.

We believe this is close to the optimal scale of network: large enough to incorporate flexibility to maintain service to users and take enough pressure off unsuitable local roads, yet small enough to concentrate investment and aspire to a clear set of standards and decent level of service.

The MRN as designated will need to be subject to periodic review, amongst other things validating the minor changes arising from differential traffic growth to 2040 by area and road type. And, as part of that dynamic process, the network should be seen as comprising corridors providing connectivity, rather than the specific alignments that the road links currently take.

3

3.3 Three tiers

We envisage three separate tiers within the network (plus a subset of the first), based on physical distinctions but focusing on the different function which each tier performs:

- **Tier 1: limited-access:** not restricted to motorways, and largely devoted to ‘movement’⁷; these roads provide links between major urban areas and facilitate the highest average speeds, so are well suited for longer-distance traffic in particular; there is a subset of:
 - **Tier 1A: limited-access – urban:** with more frequent junctions and very heavy traffic flows, which need to be more subject to the wider transport policy

⁷ See Section 5.5 for further discussion of ‘movement’/‘place’ conflicts on urban roads

framework and traffic management strategies set by the city or regional authority;

- **Tier 2: multiple-access – rural:** mainly all-purpose rural ‘A’ roads, with frontages and local access, providing links between secondary urban areas but also sometimes serving the ‘place’ needs of communities they run through; and
- **Tier 3: multiple-access – urban:** Major Roads in urban areas, with the greatest mix of user types and conflicting movements, and on some of which significant ‘place’ functions will need to be acknowledged.

Table 3.1, and the map at Figure 3.2, show an initial indicative classification of road links in the MRN.

Table 3.1: Summary statistics for composition and traffic flow on the Major Road Network

	MRN total	By SRN / LA MRN		By tier			
		SRN	Local authority MRN	Tier 1		Tier 2	Tier 3
				Non-urban	Tier 1A		
Approximate length in miles	8,000	4,200	3,800	2,900	800	3,300	1,000
Percentage of total	100%	53%	47%	36%	10%	41%	13%
Average daily flow (all vehicles)	50,032	76,068	32,439	78,613	89,576	29,913	38,804
Average % HGV	6.4	9.4	4.4	9.5	7.5	6.0	4.1
Average % vans	14.1	14.3	14.1	14.0	14.0	14.5	13.9
Indicative total traffic (billion vehicle-miles)	113	86	27	58	19	26	10

Source: Calculated using analytical tool, as described in Supporting Document 2

Figure 3.2: Indicative breakdown of the Major Road Network by tier

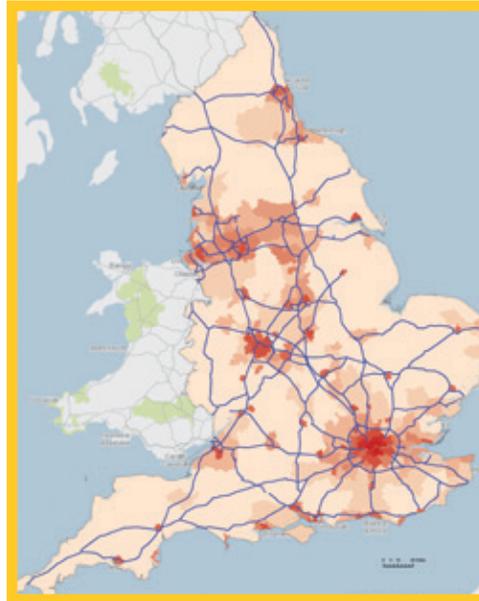

The Network has a significant presence in **urban areas** – Tier 3 combining with Tier 1A to make 23% of the MRN essentially urban, whereas little more than 10% of the SRN alone is urban.^{xiv} These urban major roads are the key connectors within conurbations, rather than main streets within cities and towns, but must still be subject to locally determined cross-modal transport policies; section 5.5 addresses how the MRN needs to adapt to this more challenging urban environment.

Source: own analysis – see Supporting Document 2

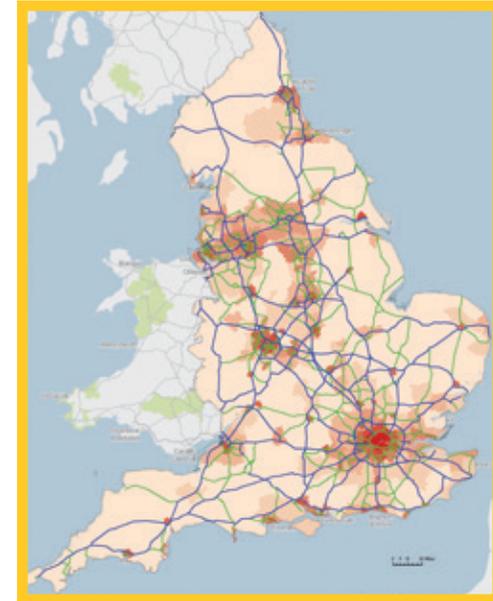

3

Figure 3.3: Comparison of coverage of Strategic Road Network and Major Road Network

And Figure 3.3 shows how the MRN serves the more densely populated parts of England much more comprehensively than can the SRN.

Strategic Road Network and population density

Major Road Network and population density

3.4 Multiple ownership

Defining a single MRN does not mean all those roads need to be under the responsibility of one body – we believe this isn't required. Most local authority roads on the MRN, as well as fulfilling national and regional roles, are embedded in their local networks and

communities, and local responsibility should be retained. We believe that achieving effective collaboration between Highways England and existing local highway authorities (LHAs) is the right and least disruptive way to proceed.

But the current levels of coordination between LHAs and Highways England do need to be stepped up – in terms of forward planning as well as day-to-day operation. Chapter 6 sets out how to meet the MRN's need for an integrated and consistent regime for its planning and management.

4

Supporting Growth

Spatial and economic planning and the Major Road Network

- Establishing connectivity and a good level of service from the MRN doesn't automatically generate economic growth: a process of 'joining the dots' of spatial planning, economic development and transport improvements is needed to capture the benefits.
- The process is not straightforward, especially in parts of the country where varying institutions - often with differing jurisdictions - hold the respective responsibilities.
- Local Enterprise Partnerships (LEPs) are tasked with bringing this together. Across the country their capabilities and degrees of integration with different parties vary; there are concerns about capacity and accountability, but the concept is valid and is already working well in many areas.
- On the basis of our consultations, the Major Road Network (MRN) - by integrating the Strategic Road Network (SRN) and important local roads - is seen as a logical tool for this planning process.
- With the establishment of combined authorities (CAs), and the prospective sub-national transport bodies (STBs), new regional mechanisms integrating spatial, economic and transport planning are beginning to emerge.
- Clear spatial planning policies are needed to head off adverse consequences that may result from transport improvements which, whilst promoting changes in the public interest, generate new pressures for development.

4

4.1 Roads and growth

The connectivity offered by major roads is crucially important in sustaining national and regional economies and in supporting economic growth, especially in peripheral areas where rail service is less able to play to its strengths. Major roads underpin productivity by helping firms and public enterprises reach the markets for their goods and services, receive supplies, access labour markets, ease journeys to work, and facilitate business travel.⁸ A higher proportion of this 'commercial transport' is carried on the SRN and on the local authority roads designated for the MRN than on the road network as a whole.

Equally, those locations with better connectivity and service provided by the MRN are likely – other things being equal – to offer better prospects for growth, both through existing firms and new development. Sustainable economic growth requires a good level of service to be available at locations on the MRN which are deemed both suitable for this growth in land-use planning terms, and suitable by business – for example, in allowing for possible clustering with similar or complementary businesses.⁹

⁸ Recent evidence of business user appetite for transport improvements includes *Going the Extra Mile: Connecting businesses and rural communities*, Federation of Small Businesses, May 2016.

⁹ See Supporting Document 3 (Appendix A).

4.2 The planning process

‘Joining the dots’ of spatial planning, economic development and transport interventions is best carried out as an iterative process, progressively identifying locations which meet land-use planning requirements, satisfy business location criteria and provide sufficient connectivity. This process will also reveal what transport interventions may be needed to make it all work, and which provide sufficient value for money.

The process is far from straightforward, especially in parts of the country where different institutions (often with differing jurisdictions) hold the different responsibilities. For example, in two-tier counties, districts hold the planning responsibilities, and counties hold the transport portfolio for their wider area; LEPs are tasked with bringing those responsibilities together with what will work for business, and leading the applications for funds to improve the infrastructure (usually transport) to facilitate growth. Many LEPs cover a wider area than individual local transport authorities, and most embrace several local planning authorities.

The LEPs’ geography had a chaotic start in 2011, and several local authorities still have to work with two overlapping LEPs. Inevitably LEPs’ capabilities and degrees of integration with their

partner local authorities vary across the country. Moreover, concerns have been expressed about their capacity to carry out the tasks assigned to them, and the effectiveness of the accountability arrangements for expenditure.^{xv} But we believe that the concept is the right one: they work well in many areas, and as the LEP movement matures it will grow in effectiveness, enabling conversations at local and regional level, getting agreement on priorities, and securing the required resources.

Separately, there is progress, too, in combined authority areas (now expanding considerably beyond the original six former metropolitan areas): all are different, but a more coherent and integrated process of aligning spatial, economic and transport planning is beginning to emerge. None yet have the statutory duty to prepare and ‘join

up’ plans of the kind that the Mayor of London is obliged to fulfil; it is the clarity and certainty of these plans over the last 15+ years that has helped to underpin London’s continuing success in business investment and housing delivery, and their integration with transport plans.

4

Informal consultation during our study with representatives of three different areas – usually involving the counties as Local Transport Authorities and one or more LEPs – has suggested that the MRN concept is relevant to them, and could help the required iterative process by bringing together their part of the SRN and the most important local authority roads.

We recognise that not all interventions to improve the MRN would necessarily lead to the intended economic growth – for example, if the barriers to growth in a particular area were not related to connectivity or decent service levels on the network. But we could be more confident of success if the planning processes were better ‘joined up’.

And it needs to be recognised that transport improvements may substantially change the patterns of travel and transport of *existing* households and businesses, as they respond to changes in accessibility; or successor occupants may be attracted who have a greater propensity to travel. This may cause more road traffic, and an increase in demand for development on the edges of towns, potentially leading to second-order consequences

of dispersal and yet more traffic. While the primary purpose of investing in major roads will be clear and justified – whether for the relief of congestion or to improve connectivity and support economic growth – clear spatial planning policies alongside it are also needed, to anticipate such second-order effects, and to head off their more adverse consequences whilst still promoting changes that are in the public interest.

5

The Fit-for-Purpose Major Road Network

What's needed for the Major Road Network to deliver its potential

- The Major Road Network (MRN) needs to be 'fit for purpose' to deliver its potential.
- First, it must be fit for all users - meeting their needs and their expectations for a decent and safe overall service, including aspirations for the speed and reliability of their journeys, varying according to tier.
- Fitness for purpose means making best use of capacity, expanding it where necessary, and maintaining the asset condition in the most cost-effective way.
- It also means fit for the communities that the network passes through, mitigating adverse impacts of noise, air pollution, severance and visual intrusion.
- Making Major Roads fit for urban areas means addressing 'movement'/'place' conflicts, and working with wider transportation policies for the urban area such as traffic and demand management measures, and priorities for certain modes.
- A fit-for-purpose safety management regime for the MRN should increasingly use predictive risk assessment methods to ensure that action and resources are focused in the most cost-effective way, with particular regard for the risks faced by vulnerable road users.
- A fit-for-purpose planning regime is one in which the network operator (or the 'strategic client') plays a lead role in generating options for improvement, identifying deficiencies in delivering the service proposition, and engaging in multi-objective assessment and evaluation.
- Highways England and the local highway authorities should consider working up a high-level Fitness For Purpose code suitable for the whole MRN, perhaps working through the UK Roads Liaison Group.

5

5.1 Fit for the user¹⁰

The MRN has to be consistently fit for purpose, enabling the effective service the country needs. It needs to operate safely, making the best use of its capacity; it needs to be a good neighbour to the communities it passes through; and it needs to be properly maintained over the longer term. But pre-eminently it must be fit for its wide range of users not just car users. The needs and characteristics of the Strategic Road Network's (SRN's) users are being increasingly understood, but local highway authorities (LHAs) have rarely been resourced to know their customers better. To bridge the gap we commissioned a literature review from the University of the West of England (UWE),^{xvi} recognising that users' characteristics don't change when they leave the SRN. This work, and other research findings around the SRN from Transport Focus and DfT^{xvii} leads us to propose six components of what users ought reasonably to expect from the MRN:

- a comfortable journey, minimising stress from, for example, a poor-quality road surface;
- a safe journey, with minimal risk of personal injury or damage to vehicles;
- reasonable expected journey time and reliability;
- accurate and relevant information on routing, hazards and delays, enabling the journey time to remain more or less predictable;
- availability of fairly priced rest and catering facilities along the road; and
- safe and seamless connection and signage to the rest of the local road network.

The priority attached to each of the above components will vary by journey length and user type, amongst other factors. The expectations of leisure users may lead to a different balance from that which is relevant to business users or commercial traffic. And the priorities and needs of the increasing proportion of older drivers¹¹ will make it essential to adhere to the highest standards of road design, needed to facilitate safe driving by all.

¹⁰ See Supporting Documents 4 and 6 (Appendix A) for more information on these issues.

¹¹ The Older Drivers Task Force report (Road Safety Foundation, July 2016) notes that there will be an 80% increase in the number of drivers in the UK over 70 between 2014 and 2035.

With the economy at the heart of the MRN's rationale, a fit-for-purpose network needs to serve the freight and service sectors well, recognising the distinction between the priorities of fleet operators and those of their drivers. Heavy goods vehicles in particular, representing only 6.4% of traffic on the MRN, have disproportionate importance and impact. They need a network that is:

- **robust** – ensuring adequate headroom at over-bridges and protection from cross-winds on exposed stretches, and maintaining across the MRN unrestricted access for vehicles up to 44 tonnes, as currently applies on the Primary Route Network;
- **reliable** – majoring on predictability of journey time, including overnight when freight flows are strong but maintenance work which closes lanes and roads is often scheduled; and
- **liveable** – given that the MRN is the 'workplace' for a substantial workforce of drivers, truck stop facilities need to be available by collaboration between the market and planning authorities.

The UWE review found that, the more defined the expectation that a road user has, the lower the resultant satisfaction subsequently reported. Currently, with no expectations set out, 89% of users report they were satisfied with their most recent SRN journey^{xviii}. But we believe road users should have clear and reasonable expectations of their journeys, so that they can plan their business activity or personal routine with some confidence – even if the reported satisfaction level then falls. Not all needs can be met, of course, and there will have to be trade-offs, particularly in respect of 'reasonable expected journey time', where the constraints are greatest.

We identify three components of journey time:

- **Expected average speed:** the average speed safely achievable over a length of road reflects both the inherent free-flow design speed and, for Tiers 2 and 3, localised speed limits, traffic signals, junctions and interaction with other traffic. As with journey times calculated by satnav devices, it is built up from the speeds normally achievable on individual sections of

the road, and forms the baseline for the journey time proposition.

- **Predictable variation from average speed:** the wide variations in traffic volumes over the course of the day, week and year are often known, and can generally be forecast, and hence the effects on journey times estimated. Thus the user's expectation would be qualified by an expected variation due to congestion.
- **Unpredictable variation from average speed:** irregular disruption (not solely accidents and infrastructure failings, but also planned roadworks and unexpected levels of traffic) also needs to be allowed for; many freight operators already make some additional provision to reflect the likelihood of unexpected delays.

This reliability standard could be quantified as the percentage extra time the user needs to allow in order to arrive on time for a set percentage of trips – a 'buffer time' index.

5

The three indicators combine to produce **a service proposition for the MRN**, but this must vary by tier; for example, the greater control which the network operator has over the limited-access Tier 1 and 1A roads means that unpredictable variation there should be much lower. We propose the following matrix of expected service levels for the four tiers, in respect of average speed (ranging from + to +++)¹², as then qualified by the extent of predictable and unpredictable variation (ranging from – to ---).

¹² The average speed banding of ‘+++/++/+’ could be expressed approximately as 60 mph/40 mph/20 mph, but more work is needed to develop the other indicators, exploiting valuable new analytical opportunities now arising from the wealth of mobile phone data on vehicle movements.

Table 5.1: Matrix of expected service level by tier

	Average speed baseline	Predictable variation: extent of congestion	Unpredictable variation: extra time needed
Tier 1	+++	–	–
Tier 1A	++	– – –	–
Tier 2	++	–	– –
Tier 3	+	– – to – – –	– – to – – –

Section 5.2 below provides an illustration of how actual performance – significant shortfalls against expected service levels in particular circumstances – may generate options for intervention.

5.2 Making best use of capacity¹³

Utilising existing capacity as efficiently as possible is a central task for the network operator, requiring 24/7 overview and engagement with users, to meet performance benchmarks derived from this framework. The performance regime set for the MRN should build on progress now being made for the SRN and should:

- recognise the complexity of traffic flow: on busy roads, flow falls once an optimum average speed is exceeded; in congested conditions the network operator should regulate speed down to the optimum to avoid instability and maximise traffic flow, as is already now well-established practice on Smart Motorways on the SRN; on multi-lane carriageways, there is scope to increase separation of traffic types moving at different speeds;
- apply primarily to area networks rather than individual stretches of road: the more extensive MRN makes greater resilience possible than can be found in the SRN alone, opening up more options for managing traffic

¹³ See Supporting Document 7 (Appendix A) for more information on this and other network operator responsibilities.

flow during disruption; this requires operating procedures, including traffic control centres, to be better integrated across the MRN; and the ability to deal with longer-term disruption caused by, for example, flooding or infrastructure defects; and

- develop a focus on maximising the number of people travelling or of total goods being transported, rather than just vehicle flow: network operators can, for example, support the development of bus and coach services through facilitating interchange hubs.

Demand for travel on the MRN – at least on Tiers 1 and 2 – is likely to increase over the longer term at a faster rate than capacity can be increased, even with a proactive approach to network development (see section 5.7 below). Network operators can still strive to meet the service aspiration by making full use of developing technologies, such as sophisticated information services for users, and by being geared up for the opportunity and challenge of

Connected and Autonomous Vehicles (see section 7.4).

Highways England's *Concept of Operations*^{xix} provides a valuable set of principles that should apply across the MRN; it aims to use the opportunities arising from technological developments to improve utilisation, availability and demand management on the SRN. Comparable guidance for the network management role of LHAs^{xx} is focussed more on the legal framework and operational responsibilities, rather than on effective capacity utilisation and the quality of the user experience. It will be important to ensure that guidance for MRN operation covers all the components of fitness for purpose that are covered in this chapter.

5

5.3 Maintaining the asset

The MRN concept is about service to the user, but underlying it all must be infrastructure that is fit for purpose – well managed so as to underpin safe, reliable and cost-effective operation. Good asset management focuses on the whole life of the asset and seeks the optimal mix of maintenance (both preventative and reactive) and improvement work.

Asset condition is about more than just carriageway quality, although that is a principle focus of user concern – it also concerns geotechnical works, drainage, structures and installed technology. This represents a complex challenge, particularly for hard-pressed LHAs.

Extensive best-practice guidance forms part of the Highways Maintenance Efficiency Programme (HMEP),^{xxi} helping all LHAs to build up their capability and achieve more with less. Self-assessment against HMEP efficiency principles is, increasingly, a criterion for allocation of maintenance block grant to LHAs

by the Department for Transport (DfT); adherence to the HMEP should in future be a precondition for an LHA operating part of the MRN.

Notwithstanding the above, guidance that is MRN-specific needs to be developed, centred on its distinctive feature of heavy traffic flow; this could bring together elements from Highways England’s forthcoming Integrated Asset Management Strategy with the HMEP guidance that already focuses on roads less likely to be purpose-built and having a broader mixture of structures and carriageway standards. Supporting Document 7 sets out some of the innovative approaches to maintenance management which could bring efficiency gains across the MRN.

Timely maintenance work would be required to sustain the quality of service from the MRN, but roadworks can significantly impair that service in the short term. Whilst LHAs have already

had to prioritise A-roads over the rest of their network, MRN status, with appropriate funding, would be expected to lead to more improvement work than has been possible so far. Users are generally tolerant of roadworks where they can see better outcomes ahead – but that doesn’t reduce the need for network operators to minimise the adverse impacts of roadworks where traffic flow is heaviest. Construction sites also increase the safety hazard: Highways England has recently trialled a response to this, seeking to change the mindset of drivers as they enter roadwork zones.^{xxii} If successful, such approaches, along with lessons from abroad¹⁴ could valuably be applied across all of England’s major roads.

¹⁴ One example is the Dutch ‘Minder Hinder’ (meaning ‘less delay’) approach, which boosts funding for selected major roadwork schemes by around 5% in order to minimise delays for users: a package of measures tailored for each scheme brings together more user-focused traffic management, joint working with adjoining highway authorities, and better communication with users throughout the process.

5.4 Fit for communities and the environment

Fitness for purpose entails more than just the user interest. The impacts of major roads and their traffic include noise, air pollution, severance, visual and landscape intrusion, and in some cases ecological impacts. There are also positive impacts of proximity to the MRN: greater accessibility is most relevant for businesses, and for the three out of four households with access to a private car; but the Major Roads will be public transport corridors too, particularly in cities. Nevertheless, for most people living or working adjacent to major roads, the negative impacts are perceived as outweighing the positive.^{xxiii} As a result there may be equality concerns in that poorer households are less able to afford the higher prices of a better environment located away from the major roads.

Noise is one of the most troublesome of the impacts directly related to traffic volume. The network operator can significantly mitigate its intrusion by the application of noise-reducing road surfaces, noise barriers and in some cases through noise insulation of adjacent buildings – all at a cost. Under the first Road Investment Strategy plan, Highways England is committed to a programme of action in over 1,000 designated ‘noise improvement areas’ of which half will be subject to ‘quiet noise resurfacing’.^{xxiv}

On roads maintained by local authorities, some noise reduction results as a by-product of using ‘thin surfacing’ proprietary products for road maintenance, but this does not achieve the maximum noise reduction possible with today’s materials. We believe that there should be a more concerted effort by LHAs to achieve substantial noise reduction in areas known to be particularly affected as a result of residential proximity and high traffic volumes, either by use of noise-reducing surfaces during maintenance or through noise insulation of adjacent buildings.

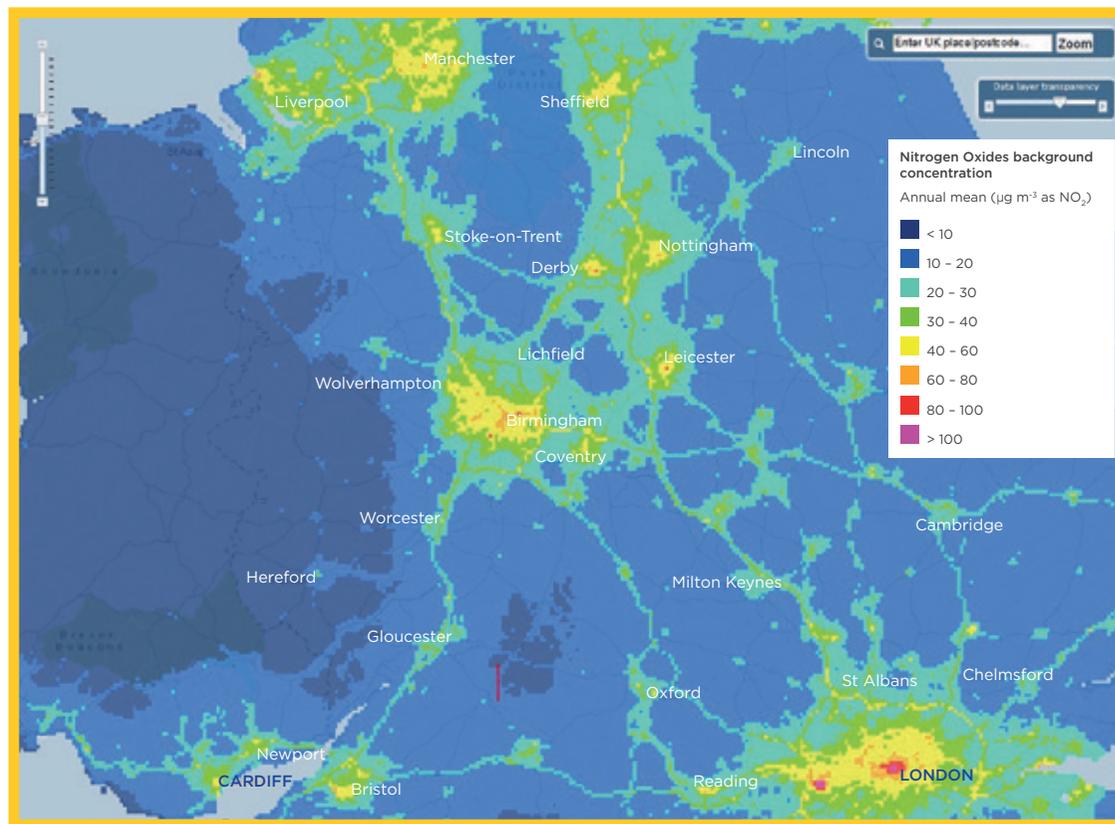

5

Air quality¹⁵ in larger cities and along some major road corridors is affected by emissions from diesel engines of NO_x (nitrogen oxides) – and NO₂ (nitrogen dioxide) in particular – and of fine particulate matter (PM_{2.5} – particulate matter of median diameter 2.5 microns or less), and is becoming the critical environmental hazard as better understanding is gained about the link between atmospheric concentrations of NO₂ and health. England currently experiences substantial breaches of the UK’s air quality regulations^{xxv} for NO₂ in London and several other cities (breach areas shown in yellow, orange and red in Figure 5.1); and some key SRN corridors (yellow in the map) are also just above the regulatory limit.

¹⁵ See Supporting Document 5 (Appendix A) for more information on this subject.

Figure 5.1: Background concentrations of NO_x London - Midlands - North corridor

Source: Annual mean NO_x (as NO₂) concentrations (background) 2014 England, Defra. Screen shot taken from <https://uk-air.defra.gov.uk/data/gis-mapping>. Breach level is 40 µg/m³

The UK Government's action plan in response to the breaches envisages that the combination of new vehicle emissions standards, coupled with the introduction of some exclusion zones for the more polluting vehicles in the most sensitive urban locations, will sufficiently lower background concentrations across the country by 2025.

Nevertheless, achieving compliance with the statutory limits by that deadline still presents a real challenge, especially in London, and given recent concerns about real-world emissions of diesel vehicles. However, the improvement in air quality expected to be achieved during the 2020s means that it is unlikely to be an issue in the evolution of the MRN over the longer term, to 2040. But in the meantime, network operators should be encouraged to mitigate localised concentrations through traffic management and speed limits, and if necessary by extending exclusion zones.

Severance is most acute for busy dual carriageway roads, especially those with high speeds, dividing communities and limiting mobility for those living adjacent to them. Mitigation of severance often involves bridges and underpasses for pedestrians and cyclists; in cities these can be grim for the user. The need for better solutions is now widely recognised, from less brutal design aimed at improving the sense of personal safety, to more frequent at-grade crossings, or even of building a deck over arterial roads, part-funded by housing or retail development on it.

On the related challenge of visual intrusion, there are several practical measures which can improve the visual impact of major roads at low cost.^{xxvi} The principles of fitness for purpose should go further, encouraging major roads to make a positive contribution to the landscape or townscape, and contributing to the well-being of users and those alongside the road.

5

5.5 Fit for urban areas

A distinct approach is needed for Tier 3 (and to some extent Tier 1A) roads in urban areas: they will need to reflect the following additional considerations not applying to Tier 1 limited-access roads or Tier 2 rural roads:¹⁶

- There must be recognition of the degree of place as well as movement that may apply to any section of a Tier 3 road, and which must guide interventions to make the road more fit for purpose in both respects.
- There must also be recognition of the wider transportation policies of the surrounding urban area, which for major roads may involve:
 - traffic management schemes which give priority to more efficient users of road space, including well-managed freight movement;
 - traffic management strategies – both individual schemes and area control systems – aimed at optimising the capacity and use of the local network; and
 - for demand management, control of parking supply and price, and the potential to charge for road use (see section 7.6 for the wider context).

A comprehensive approach for addressing the movement/place conflict is set out in the DfT's *Manual for Streets* series.^{xxvii} Subsequent to its publication, the London Mayor's Roads

Task Force^{xxviii} addressed this conflict on a network basis, establishing a 'typology' of streets and roads using a 3x3 'Street Types' matrix (Figure 5.2); the method analyses a road or street according to its relative degree of significance for movement and for place, and presents a toolbox of measures that may be applied in each box to mitigate the conflicts.

Figure 5.2: Street Types Matrix (Transport for London)¹⁷

Source: Transport for London

¹⁶ Some of these considerations may also apply where Tier 2 roads pass through smaller settlements.

¹⁷ See an explanation of street types and their use at <https://tfl.gov.uk/info-for/boroughs/street-types>

This method helps to systematically identify significant place functions of a Tier 3 Major Road – for example as a suburban ‘High Road’ – and can help justify traffic management measures, speed limits and public realm enhancements to sustain the quality and vitality of that centre, while ensuring that the movement function can still be fulfilled. It is a valuable tool, tested and refined in London, which could be used for addressing potential movement/place conflicts and improving public realm in other cities and conurbations.

5.6 Managing safety¹⁸

All these dimensions of fitness for purpose must not detract from the fundamental requirement to provide a safe service. The MRN – 4% of England’s road network – carries 43% of all traffic, but has only 16% of those killed or seriously injured (KSI) in crashes. The network includes the country’s safest roads – motorways and limited-access dual carriageways (Tier 1) – but also many busy single-carriageway A-roads, especially in rural areas, where users face much higher risks of crashes, deaths and injuries.

The risk of crashes on Tier 2 rural A-roads is related to aspects of road design and geometry as well as speed limits and the behaviour of drivers (including motorcyclists). The Road Safety Foundation’s annual reports^{xxix} highlight persistently high-risk roads, as well as featuring the most improved roads and how these results have been achieved. There are many ways in which

¹⁸ See Supporting Document 8 (Appendix A) for a more detailed treatment of this subject.

network operators can influence driver behaviour – road design, markings, signage, speed limits and enforcement; they can also make the infrastructure as ‘forgiving’ as possible to driver error, for example by installing barriers and removing the most hazardous trees.

Safety management action is informed mostly by data about collisions (mainly the STATS19 national database of police-reported injury road collisions in Great Britain), after the event (*ex post*); effective at addressing hotspots, this has brought down crash rates. But best practice is moving towards more predictive (*ex ante*) risk assessment, forensically assessing road infrastructure for its inherent crash and injury risk. The iRAP (International Road Assessment Programme) method¹⁹ is known in the UK, but little used except by Highways England, who have committed to assessing the entire SRN and acting to ensure that by 2020 more

¹⁹ See Supporting Document 8 (Appendix A).

than 90% of travel on the SRN is on roads with a 3-star iRAP rating or better. ^{xxx} A recent TRL report^{xxxi} has assessed 21 safety management models and made recommendations to DfT about encouraging and advising local authorities on using screening and predictive methods.

We believe that best-practice safety management should now be incorporating the use of predictive risk assessment methods, to help ensure that action and resources are focused in the most cost-effective way – with particular regard for the risks faced by vulnerable road users.

5

About a quarter of all KSI crashes on the MRN involve motorcyclists, who face exceptionally high risks – up to 40 times the average risk per mile faced by other road users; targeted measures, including installation of average speed cameras, can be effective.^{xxxii} On Tier 3 urban Major Roads, vulnerable road users – cyclists, pedestrians and motorcyclists – account for the majority of KSIs. Methods such as the Street Types nine-box matrix developed for London can, by framing the resolution of movement/

place conflicts, provide a rationale for protective measures even on Major Roads – such as road redesign, speed limits, segregated cycle lanes and signal modifications. With this methodology firmly in place in London, we believe that conurbations and larger cities should now be considering the use of the Street Types matrix to help frame their approaches to safety interventions, as part of the wider use of this method for addressing movement/place conflicts.

Automotive technologies already widely available in new cars, such as autonomous emergency braking, and a range of other driver-assist features, are likely to achieve significant reductions in crashes; these beneficial effects should become more significant as levels of vehicle automation increase, although we have not seen any quantified predictions of these benefits. See section 7.3 for a more detailed discussion of the latest autonomous vehicle technologies.

5.7 Developing the network

A fit-for-purpose MRN has to be a dynamic concept; investment in improving or expanding it should, as well as benefitting the user, also take opportunities to mitigate the wide range of impacts on non-users.

The network operator has the lead role in identifying options for enhancing the network. The matrix of expected service levels in Table 5.1 can provide the context for considering additional capacity or other measures to improve performance. Candidates for intervention should be brought forward where:

- there is an obvious bottleneck preventing even the average speed baseline from being met, and a cost-effective solution is practicable; or
- a high congestion factor on that stretch could be brought down through value-for-money investment to increase capacity – or perhaps by prioritising provision for usage types that maximise throughput; in such cases, and particularly on Tier 3 (urban) Major Roads, the network operator should consider possible localised demand management tools

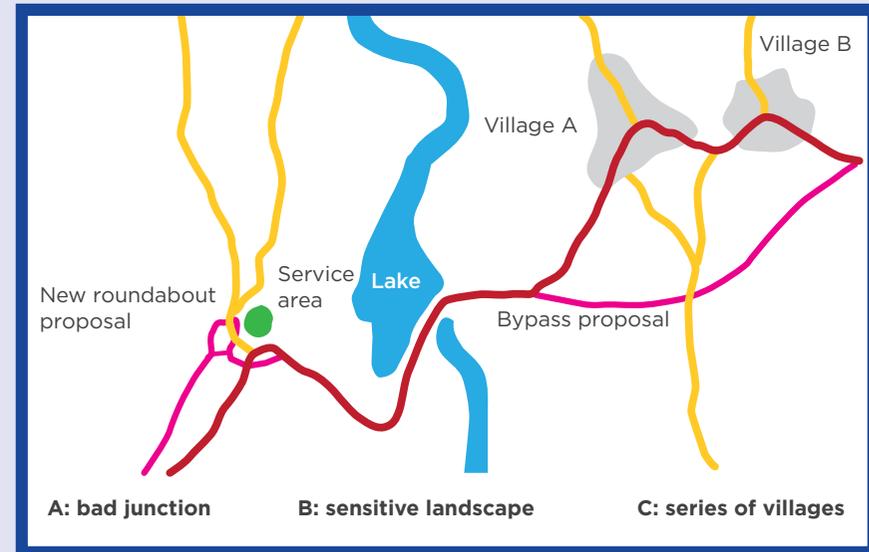

as well as improving integration (where appropriate) with rail services, and facilitating more sustainable modes where possible.

Where the strongest need for such investment in the network is identified, it could result in the upgrading of a link to Tier 1 or 1A, or exceptionally the addition of a wholly new link. More often, shortfalls below the benchmarks will persist, but users would at least be able to understand where this is the case, how large the shortfall from the benchmark is, and why it is persisting.

Example of where service level shortfalls can generate options for possible interventions

Let us take as an example a stretch of Tier 2 MRN road (in red), passing, from west to east, through (A) an overloaded junction with two local roads (in yellow) and added movements generated by a service area; (B) a scenic descent through protected countryside to cross a river near a lake; and (C) a stretch of more built-up road, through two large villages with multiple side roads. Intervention is feasible at (A), through construction of a new roundabout and a better-graded approach road from the west; and at (C), through construction of a bypass for the two villages. Both interventions would bring performance of that stretch up to the benchmark level for Tier 2. The existing road also performs below the benchmark at (B), but the protected landscape means that the only feasible intervention might be to address safety problems rather than improve traffic flow.

	A: Bad junction			B: Sensitive landscape			C: Series of villages		
	Average speed baseline	Predictable variation	Unpredictable variation	Average speed baseline	Predictable variation	Unpredictable variation	Average speed baseline	Predictable variation	Unpredictable variation
Current performance	+	---	--	++	-	---	+	---	---
Potential future performance	++	-	--	++	-	---	++	-	--

Red: road performing below benchmark for Tier 2; Green: road performing at benchmark for Tier 2

This is a logical process of option generation, to be considered within the usual business case evaluation for public capital investment.^{xxxii}

5

5.8 Fit for purpose – summary

- **Fit for the user** means understanding users' expectations for a decent level of service – and then setting out to deliver on aspirations for the speed and time taken for their journeys, and their reliability and predictability. Roads in the MRN will vary by topography and current standard – but we have grouped them into three tiers according to the function they perform and the standard they offer.
- **Fit for communities and the environment** means tackling noise, air quality and severance, and integrating mitigation measures into the ongoing management of the road.
- **Fit-for-purpose management** means making the best use of capacity and the resilience provided by the network; exploiting technology to give road users the information they need to make better decisions; controlling traffic speeds and flows through the network; and, where possible, expanding capacity at pinchpoint locations to address

shortcomings in the service provided. The asset itself must be well maintained, following best practice, and on a whole-life basis.

- **The safety management regime** for the network must be fit for purpose: this should mean adopting over time predictive risk assessment to make the infrastructure safer and more forgiving, rather than relying only on ex post data on crashes to guide safety interventions.
- **Fitness for purpose for Major Roads in cities and conurbations** needs to reflect the more complex transport and planning policies needed there, and the greater exposure and risk faced by vulnerable road users.
- **A fit-for-purpose planning regime** assesses performance against service level aspirations and other measures mentioned, and generates options for improvement or mitigation, to be evaluated for effectiveness and value for money.

This list of components of fitness for purpose of the MRN constitutes a demanding specification. In view of the firm foundations already in place for the SRN, we suggest that the network operators, perhaps under the auspices of the UK Roads Liaison Group, collaborate in developing a high-level Fitness For Purpose code appropriate for the broader Major Road Network. This could draw in particular on Highways England's knowledge and experience, given the firm foundation already contained in the company's licence conditions and performance targets.

6

Making It All Work

Planning, managing and funding the Major Road Network

- Fulfilling the potential of the Major Road Network (MRN) requires a consistent approach to its planning, management and funding.
- As we do not advocate changes of responsibility for the different parts of the MRN, delivering this consistency requires a strong collaborative approach between Highways England and the relevant local highway authorities (LHAs).
- On planning, Highways England's Route Strategies should evolve to adopt a genuinely network approach, embracing local authority Major Roads as well, and the consideration of needs and network options as a whole.
- Collaboration on network planning can be greatly assisted where devolved arrangements such as sub-national transport bodies, combined authorities (CAs) and Local Enterprise Partnerships (LEPs) are in place.
- Collaboration on network management is needed to put in place deliverable resilience strategies for managing the consequences of incidents and closures.
- Ensuring the MRN's 'fitness for purpose' falls primarily to the respective highway authorities, but there is a clear role for the 'strategic client' to translate users' expectations into service level targets and aspirations, and to plan capacity and manage demand so as to maintain that service – integrating with the surrounding network of local roads and rail as appropriate.
- The plans for a National Road Fund (NRF) raise the possibility of extending its 'strategic roads' remit to include contributions to local authority MRN roads, as well as funding the Strategic Road Network (SRN).

6

6.1 Introduction

This MRN will only fulfil its potential of supporting regional economies and enhancing accessibility for all if the *whole* of the network is fit for purpose and able to deliver the appropriate standards. This requires a consistent approach to the planning, management and funding of the whole MRN.

6.2 Planning

Collaboration on network planning on a regional basis is an essential foundation for an effective road system. Nowhere does the SRN operate in isolation from the A-roads which complement and feed it. Such collaboration would require future Route Strategies by Highways England (see section 2.5) ^{xxxiv} to evolve and adopt a true network approach, embracing the local authority Major Roads as well, area by area, and considering with the LHAs the needs and network options as a whole – rather than focusing only on the SRN route itself. The essential feature of this approach is to explore not only how improvements to local authority Major Roads can benefit the SRN, but also, conversely, how changes to the SRN can benefit local Major Roads and their users.

Current developments in the devolution of decision-making about economic, spatial and transport planning to local and sub-national bodies could make such collaboration between Highways England and LHAs more coherent and effective.

The two key types of new players are:

The **sub-national transport bodies** (STBs), enabled under Clause 21 of the Cities and Local Government Devolution Act 2016, bring together local authorities and other stakeholders to bid for transport powers – some, such as the planning of important roads, voluntarily ‘uploaded’ from the participating local authorities, or other roles added, for example the ability to address issues such as rail integration or smart ticketing.

The **combined authorities** (CAs), bodies created (under the Local Democracy, Economic Development and Construction Act 2009) by a group of local authorities for an area, who upload to them a wider set of powers than they would to an STB. Originally an initiative of leaders in Greater Manchester, the CA concept has been adopted across the English metropolitan areas, and the Government has been encouraging adoption of the CA model elsewhere in England too. CAs are the subject of ‘devo deals’ with government, most of which include the transfer of some transport powers and/or funding.

The MRN would be the logical network of regional and national roads for an STB to concentrate on, providing as it does a more broadly based connectivity than the SRN alone can. Each STB, on behalf of its local authorities, who remain the statutory highway authorities, would then lead the collaboration with Highways England on the operation and strategic planning of the MRN in their area.

One prospective STB – England’s Economic Heartland Strategic Alliance, running west and east across the South Midlands – is ready to adopt the MRN as the ‘strategic’ network for its area; and work with Highways England and the member counties on its future evolution.

Midlands Connect, another prospective STB, has been considering the MRN concept for roads in its area which runs east-west from the Welsh border to the North Sea, embracing the West Midlands Combined Authority.

Transport for the North (TfN), envisaged to become the first STB in 2017, is already designating what it calls a Key Route Network selected from the county ‘A’ roads across its area, closely based on the MRN concept. Working with the

combined authorities and counties, TfN is likely to lead the conversation with Highways England about the ‘strategic’ roads across the north of England. This partnership will oversee the strategic planning of roads, helping to ensure connectivity across the north of England, and guiding the development of priorities for investment.

The MRN, as proposed in this study, adds value as an objectively determined, nationally designated network of major roads across England. Were there to emerge special funding arrangements for the local authority parts of the MRN, alongside the SRN funding regime, then these could be accessed by STBs and by combined authorities.

Where there is neither an STB nor a combined authority, the LEP, or an appropriate grouping of local authorities, could provide an effective basis for regional transport planning. As described in Chapter 4, the MRN provides the essential main road connectivity at this level.

The five combined authorities in the north of England, and the West Midlands CA, are also designating their own Key Route Networks – a concept originally pioneered by Greater Manchester – which embrace the more significant roads within their conurbation. Each conurbation Key Route Network will be more granular and extensive than the MRN as we have defined it, as it serves a different purpose, but it will generally include the MRN roads.

6

6.3 Responsibility for ensuring the Major Road Network is fit for purpose

The dimensions of fitness for purpose for the MRN are set out in Chapter 5. The front-line delivery responsibility rests with the *network operator*, be it Highways England, a local highway authority or a combined authority. Each would ensure that their part of the MRN is:

- fit for the user, aspiring to meet specified levels of service – this means making best use of capacity, ensuring resilience and minimising stress for the user;
- fit for communities and the environment – leading to a distinct requirement to be fit for urban areas, meeting the particular challenges of Tier 3 and Tier 1A roads in the MRN;
- structurally fit – the asset maintained effectively for the longer term; and
- sufficiently safe – for users, neighbours and road workers.

In Greater Manchester, and potentially in other conurbations where the SRN is a vital part of the urban road network, the need for collaboration on the operational management of the network as a whole is being addressed in Memoranda of Understanding between Highways England and the relevant CAs. More generally, experience suggests that there is a need for stronger collaboration between Highways England and relevant LHAs on maintenance and, also with police, on the

management of incidents and major closures,²⁰ ensuring that resilience planning is more comprehensive.

But that is only part of the required regime: a higher-level body has to take the responsibility for setting the parameters for the network operator's work. Either the Department for Transport (DfT), an STB or a CA – or in some cases the local highway authority itself – fills the role of 'strategic client', responsible for securing funding, and completing fitness for purpose by ensuring that:

- user expectations overall are met and managed;
- target service levels are specified; and
- aggregate network capacity and demand are managed strategically.

Finally, and recognising that the MRN will not exist in isolation, the network operator and strategic client together need to ensure that service provided by the MRN is effectively integrated with that provided by other local roads and the rail network.

²⁰ See, for example, Highways England's statement about the M6 closure in the West Midlands in February 2016 <https://www.gov.uk/government/news/m6-junction-5-to-6-closure-4-feb-2016-highways-england-response> and the report on the same incident of the West Midlands Police and Crime Commissioner following an inquiry <http://www.westmidlands-pcc.gov.uk/media/423675/11-SPCB-07-June-16-M6-Inquiry.pdf>

6.4 Putting funding in place

A consistent approach to funding is needed, for both the SRN and the local authority parts of the MRN, to make a success of the more collaborative and integrated planning process. As Chapter 2 explains, we are a long way from that at present. Ideally, a funding regime would (a) enable prioritisation of need and value for money irrespective of administrative boundaries, and (b) provide certainty and continuity of funding over a reasonable planning period.

In 2015, the Government announced plans for the hypothecation of Vehicle Excise Duty from 2020 to create a National Road Fund, to fund ‘strategic roads’ in England.^{xxxv} So far that has been interpreted to refer to Highway’s England’s SRN. But it seems to us that the definition of ‘strategic roads’ could be extended; some flexibility already exists for Highways England, through their ability to fund “projects on local roads close to the SRN where it can be clearly demonstrated that this would help the SRN”.^{xxxvi}

With the broader MRN arguably better aligned than is the SRN to the investment objective of supporting England’s national and regional economies, there is some attraction in the idea of a future Fund more systematically contributing to the local authority parts of the MRN. It would be a logical adjunct to the integrated planning and management regime for the MRN – applying the same processes for the local authority parts of the MRN as for the SRN.

We suggest that, were a local authority’s Major Roads considered eligible for some funding contribution, either from a National Road Fund or from some other source, this should be conditional on the ability of the authority to demonstrate how it would meet the fit-for-purpose standards set for the MRN.

6

Our analysis suggests²¹ that there could be headroom in such a National Road Fund to contribute towards local authority MRN roads – if, that is, Highways England’s annual budget beyond 2020 (in the second Road Investment Strategy period, RIS2) remains similar to the level planned for 2019/20 (the highest year in the first Road Investment Strategy period). We have identified a possible surplus of £1.5 billion p.a., which would go a long way towards meeting the needs of local authority Major Roads. There may of course be several legitimate and large SRN claims on that headroom in the next road investment period, such as the Lower Thames Crossing, and other proposals arising from DfT’s Strategic Studies – but the NRF contribution to such major projects up-front could be much less than the total scheme cost given the potential for tolling and/or private financing.

²¹ England’s share of VED for 2020/21 is estimated at £5.7 billion, compared with £4.2 billion for Highways England’s annual budget for 2019/20, leaving a surplus of some £1.5 billion (from OBR Economic and Fiscal Outlook (July 2015) and Fiscal Sustainability Report (July 2014), Table 4.16 and Supplementary Data Series, plus HM Treasury Summer Budget 2015, Table 2.1.) .

In the end, it would be a policy decision by government as to whether to part-fund local authority roads on the MRN from the NRF, or whether to provide funding support for these roads from another source. Either way, the case for a systematic long-term funding commitment would recognise that the MRN:

- is the more balanced, objectively determined network, with the geographical coverage that supports the strategic goals for England’s economy better than can the SRN on its own;
- would provide a clearer and more systematic basis than the current approach of Highways England investing ‘beyond the SRN’ in preparing for the next road investment period;
- would help consolidate the role of STBs, as the MRN is the logical framework for their roads planning responsibilities; and

This move would provide a stronger basis for investment in the MRN as a whole in the coming decade, but may not necessarily provide a sustainable solution through to 2040. Section 7.5 considers policy responses to the longer-term challenge.

7

Ensuring A Sustainable Major Road Network

The challenges of technology and future demand

- There are two longer-term challenges for sustaining a ‘fit-for-purpose’ Major Road Network (MRN) for the next 25 years: first, how the huge – and in part unforeseeable – changes in technology over this period can best be exploited to help the MRN provide a better service to its users; and second, how best to deal with the expected rise in traffic congestion on the network.
- Technological change will continue to transform the travel and transport landscape – with potentially profound impacts on how people and firms make their journey decisions, on the options available in a world of ‘mobility as a service’, on how they use vehicles, and on how road networks are maintained and operated.
- Longer term prospects and timescales for autonomous vehicles remain highly uncertain. Meanwhile, with strong government support of R&D and regulatory adaptation, in the shorter term progressive implementation of ‘driver assist’ and related technologies will bring some capacity and significant safety benefits.
- Forecasting future traffic levels has become more challenging because of observed changes in personal travel behaviours and attitudes over the last 15 years which are difficult to comprehend and take account of, especially for shorter-distance travel in towns and cities.
- Meanwhile population is set to grow by 19% to 2040, and traffic volumes nationally are expected to increase in the range 19-55% on 2010 levels, according to DfT forecasts.
- Trends in traffic on inter-urban and rural roads are clearly diverging from trends on urban roads, with the former – more relevant for the MRN – showing more growth at this time.
- The demand for movement by road is likely to increase at a faster rate than capacity can be affordably and acceptably increased; congestion will therefore increase, and in time will strengthen the need to consider some form of demand management. There are no simple solutions, but government should remain informed about the alternatives available.

7

7.1 Outlook for a sustainable Major Road Network

We finish where we started – the two fundamental challenges at the heart of sustaining a fit-for-purpose MRN through to 2040. The first is how best to exploit the technology-led changes that are set to transform how people and businesses use the MRN, and how the network can be managed. The second is how best to deal with the expected rise in congestion on the network, given the likelihood that the demand for movement will increase at a faster rate than capacity can acceptably be increased.

There are great uncertainties as to how these changes will play out – and how fast – over the next 25 years, so this section goes on to consider how to embed the necessary flexibility in the regime for the MRN to ensure that it can continue to do the job required of it.

7.2 The impacts of technology

The pace of technological developments is increasing – in automotive technology, road and traffic management systems, information available to travellers and the greater focus on ‘mobility as a service’ – with the potential to bring about transformative consequences for travel choices, for the safety and capacity of networks and for network maintenance and management.

Table 7.1 considers five types of technology changes and briefly plots the transport system changes they are expected to cause, the likely effects on demand and travel behaviours, and the resulting effects on the road networks and the environment, together with a commentary on possible timescale²². It illustrates how all-embracing the effects of technology already are, with the scope of further change – particularly in the field of Connected and Autonomous Vehicles (CAVs) – being potentially considerable, but with much uncertainty attached to its end point and to its timing.

²² For further background to this table and to this topic as a whole see Supporting Document 10 (Annex A)

It is important to note that

- Most changes are likely to ease and de-stress the driving task over time (or even remove it); such changes will prove particularly responsive to the needs of an ageing cohort of drivers, and will perhaps make congested conditions marginally more tolerable. This in turn is likely to stimulate additional demand, and may increase the pressure for some form of demand management in some areas.
- Apart from a reduction in vehicle emissions (both greenhouse gases and pollutants), which is driven entirely by regulation, much of this change is being driven by the market, and regulated where appropriate. One area which depends on action by the public sector is the way in which technology is applied to the management of networks. There will in time be pressure on all highway authorities to ensure that CAVs can operate appropriately and safely (see section 7.3).

What are the implications for the Major Road Network?

Richer and more accessible information can improve the experience of road users, by optimising journey planning and increasing the predictability of journey times – as long as good-quality data, preferably soon through 5G connectivity, is available along the whole network. The opportunity for network operators to communicate in real time with vehicles on their networks, and for enhanced vehicle-to-vehicle communication, raises the prospect of a new, more sophisticated, concept of traffic management^{xxxvii}. The emergence of CAVs with differing but growing levels of automation may see the application of capacity-enhancing initiatives. But it is not clear at this stage how extensive these are likely to be, nor, taken in context, how beneficial they will turn out to be in practice.

Other developments are likely to have their greatest effects within urban areas, particularly in larger towns and cities where sufficient critical mass can be generated. These include the disruption of established means of access to car travel (owning a car, or hailing or booking a taxi) by web- and smartphone-based applications offering more flexible models (car-clubs, car-sharing, the Uber model of taxi service, and the like). And CAVs, when successfully introduced, are expected to provide new groups of users with their own access to car use – whether owned or not – as well as making it more attractive for existing user groups. This ‘mobility as a service’ concept could reduce the effect that parking scarcity has on demand, currently an important constraint which gives public transport alternatives the edge.

7

Table 7.1: Summary assessment of the impact of technology types

Technology changes	Changes in the transport system	Demand impact - travel choices and behaviours	Effect on the networks and environment	Timescale
Wide range of non-transport technologies reducing the need to travel or ship goods (eg video conferencing, 3D printing)	(No direct changes in system)	May remove some journeys altogether	Some reduction in traffic flow	Many of these technologies already well-established; further potential remains uncertain over coming decades
Better, more integrated information for travel choices, routes, journey-times, congestion, incl. for delays and incidents	Network operators can influence driver choices	Enables optimisation of travel arrangements and times; mitigates congestion effects; may stimulate new demand	May mitigate some delays and congestion, especially that related to incidents, and on interurban networks	Well established developments, continuing under market pressures
Levels of automation of vehicles (Connected and Autonomous Vehicles-CAVs)	Vehicles with progressively higher levels of automation entering into the UK vehicle parc. Uncertain rate of adjustment by network operators to accommodate change and realise benefits	Impact uncertain but probably positive response to increasing automation, raising demand especially in later stages of autonomy. Some demand likely to be stimulated by less stressful journeys, and eventually from non-drivers	Uncertain outcomes depending on how risk levels are set and the behaviour of drivers in mixed flows. Studies suggest some modest capacity benefits for urban and inter-urban roads. Big improvement in accident rates and road deaths.	Higher degrees of automation - but still with driver in control (up to Level 3) - may be widespread by 2025; Beyond that, uncertain rate of progress and market penetration, towards full automation. Governed by a range of behavioural, legal and other factors

Technology changes	Changes in the transport system	Demand impact - travel choices and behaviours	Effect on the networks and environment	Timescale
'Mobility as a service' – emergence of tailored transport, travel-on-demand	Digitally-facilitated new services emerging (eg Uber, car-2-go) which do not require car ownership. Change generally unforeseen and disruptive to existing markets	Evidence so far suggests increased use of new services, and may lead to reduced car ownership	Likely that supply will increase in response to demand where density is viable; mostly an urban effect, likely to worsen congestion	Innovation already visible today, mostly confined to larger cities. Likely to become more widespread in 2020s, but viability may be limited by population densities
Changing how road networks are managed	Optimisation of capacity, and influencing driver behaviour; improved efficiency of asset maintenance	Smoother network performance experienced by drivers: may stimulate demand; better driver information from network operators	Ability to increase capacity and throughput, reduce unpredictability, from influencing drivers' decisions. More cost-effective asset management	Network management methods are mature, but will be more widespread; extensive engagement with drivers from mid-2020s
Improved emissions of vehicles	Vehicles with reduced carbon emissions and emergence of hybrids and non-fossil fuel vehicles. Reduced NOx and particulate emissions, coupled with controlled access zones (CAZs) excluding or pricing out non-compliant vehicles	Pricing and regulatory measures will nudge drivers towards the take-up of these cleaner and less-polluting vehicles	Contribution towards greenhouse gas emissions targets; better air quality and compliance with air pollution limits, leading to better health outcomes	Some uncertainties still about the degree of carbon emission reduction by the 2030s. Air pollution limits expected to be achieved from 2025, conditional on effectiveness of CAZs

7

But the impacts go beyond demand and supply to service levels, safety and the effect on the environment:

- increasing levels of vehicle automation are already set to greatly reduce crash risk and consequential death and serious injury; and
- a steadily growing number of petrol-electric hybrid cars, and a growing but much smaller number of battery electric vehicles, along with a decade or more of regulatory squeeze, is continuing the trajectory of higher vehicle fuel efficiency with falling carbon emissions; and

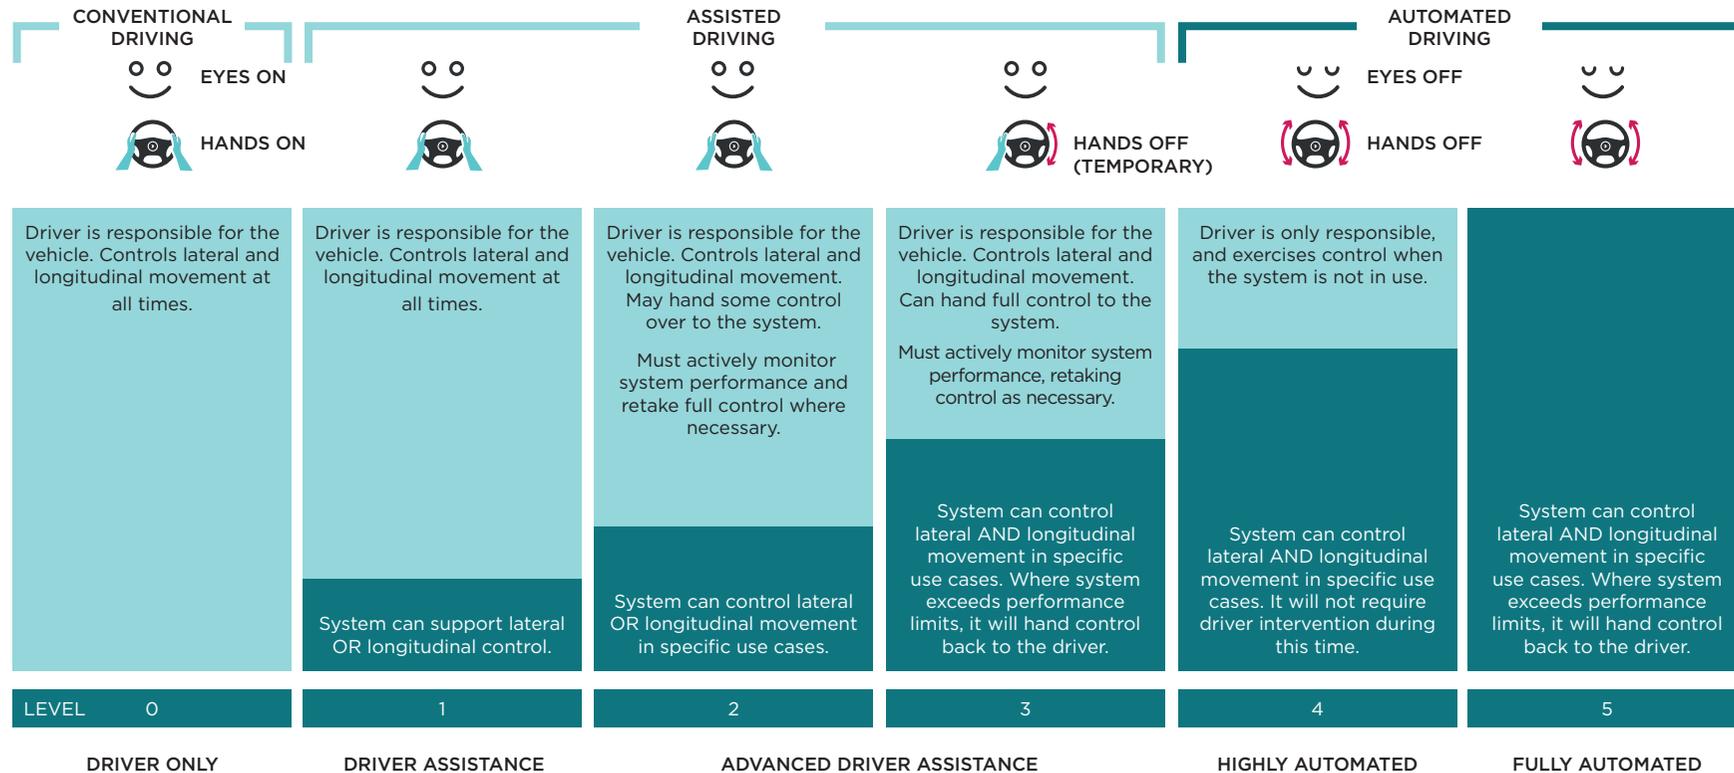

- innovation in the use of materials for road construction and surfaces is extending life and improving maintainability, with technology helping to improve intelligence about pavement condition and enabling maintenance to be planned more efficiently.

Of all the issues addressed in this report, technology is the one which is changing the fastest, in directions – and with impacts and consequences for major roads – which we cannot forecast with any confidence more than a few years ahead.

7.3 Connected and Autonomous Vehicles (CAVs)

There is currently widespread expectation that the progressive automation of vehicles, together with their connectivity, may in the long run have the most pervasive effects on travel demand and traffic behaviour, on network capacity and on users' attitudes to travel.

Figure 7.1 Defined levels of vehicle assistance and automation

Driver control
 System control

The levels of assistance and automation are adapted from the Society of America Engineers J3016 Standard "Taxonomy and Definitions for Terms Related to On-Road Motor Vehicle Automated Driving Systems" (http://standards.sae.org/j3016_201401/). While these are not formally recognised by the UK Government or the United Nations World Forum for Harmonisation of Vehicle Standards, they are seen as a helpful guide to the technology.

Source^{xxxviii}

7

Figure 7.1 is adapted by the government's Centre for Connected and Autonomous Vehicles (CCAV) from the international standard determined by the Society of American Engineers (SAE), and sets out the discrete steps towards fully autonomous vehicles. It describes the ways in which an automated system is able to cover an increasing share of the driving and vehicle control tasks.

Already low levels of automation (1 and 2) offering various forms of driver assistance are commonplace in new vehicles. Automatic Emergency Braking Systems (AEBS) – a level 3 system – are increasingly available. Such features are already having a beneficial effect on road safety, and by reducing collisions will also mitigate the occurrence of unpredictable delays and congestion, particularly on Tier 1 and 2 Major Roads. These levels of automation will also deliver safety benefits in urban networks, particularly for vulnerable road users.

A report by KPMG for SMMT^{xxxix} suggests that vehicles offering level 3 may achieve significant penetration in the UK by 2025. Level 3 is a form of very advanced driver assistance, sometimes called

'conditional automation'. While drivers may hand over control to the vehicle for short periods of time, they do not hand over *complete responsibility*, and are required to take back control of the vehicle quickly if needed. Questions have been raised about the practical implications in human factors terms of this intermediate level 3, requiring as it does the driver to remain vigilant and to constantly monitor the driving environment while the system is in control of the vehicle. The requirements and timing of the critical 'handback' process from vehicle to driver is still under close consideration by regulators. Genuine driver disengagement may only be realistic at the more ambitious levels 4 and 5 of automation, for which there is currently little consensus about timescale for large scale market penetration.

The UK government recognises the potential of automated vehicle technology (AVT) to improve road safety, enable better road capacity utilisation, and ultimately enhance mobility by giving access to those who cannot drive. The pace of development is being driven by the automotive industry,

taking an incremental approach reflected in the levels of automation in Figure 1 (although some players outside the industry, such as Google, are promoting a step-change approach).

Government policy^{xl} is to position Britain as an attractive test-bed for real world developments in AVT – for practical benefit on our congested roads, but with potential advantage for British industry too. The DfT is facilitating progressive but proportionate reform in vehicle and traffic regulation, in insurance and liability issues, and in the education of drivers; and they have recently consulted on the next steps of this reform.^{xli} Government is also actively supporting technical development in AVT sponsored by the Transport Systems Catapult and through the new Intelligent Mobility Fund, as well as promoting a range of real-world trials.

As new developments come to market, reflecting progress up the levels of automation, there is likely to be a long transition period in which many different levels of vehicle automation co-exist on the road network. This brings to the fore the need to understand real-world

behavioural and other non-technical issues. Up till now there has been little study so far of the practical implications of this for network management and capacity, nor for pedestrians, cyclists and motorcyclists – especially in urban streets—who will be navigating this mix. We urge DfT to continue to research these issues and to publish their results.

On Tier 1 limited-access roads in the Major Road Network, AVT and vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communications have the potential to bring significant net benefits. With sufficient penetration they could increase capacity and safety by facilitating more intensive network operation by the infrastructure manager. This could include the use of real-time communication, with and between vehicles or drivers, to optimise outcomes

in the event of congestion and other disruptions. The scope for platooning of vehicles on longer limited-access corridors – particularly HGVs with their professional drivers and similar performance characteristics – is to be investigated as part of the DfT's current programme.

In the context of making the MRN fit for purpose, network operators too will need to comprehend their role in maximising the potential of CAVs, in particular the reduction in collisions. They will need early clarity on how far CAVs will have to rely principally on 'reading the road' rather than 'reading the map'—the former requiring very high standards of marking and signing on the road; the latter an up-to-date database of the network to a much higher level of detail and definition than is required for satnavs.

Current thinking suggests that on-board computational limitations will lead to the latter approach, now being developed as 'HAD' (highly automated driving) maps.

The DfT's positive and comprehensive approach is to be commended. But the pace and direction of development and real-world application beyond the next 5 to 10 years remains uncertain. As progress is made towards higher levels of automation, resolving the non-technical and behavioural issues – user acceptance/adoption, the wider policy and regulatory environment, digital infrastructure – may well limit the pace of implementation beyond the time when the technology is fully deliverable, especially away from Tier 1 limited-access roads.

7

7.4 Long term demand forecasts and traffic congestion²³

Congestion already imposes substantial costs on users across many parts of the MRN at particular times of day—£2bn p.a. on the Strategic Road Network (SRN) alone.^{xliii} For the SRN, the current Road Investment Strategy (RIS) programme and the prospective RIS2 (the second Road Investment Strategy period) programme are designed to address the more significant deficiencies in capacity, both on links and at junctions. Before accounting for road improvements after the current RIS, congestion on the SRN would increase steadily as traffic demand is forecast to grow by 30-60% to 2040. Even with more ambitious schemes possible in the next decade, which could greatly improve connectivity and resilience, it is not yet clear whether congestion on the SRN as a whole could be kept in check.

The planning of major improvements on the local authority sections of the MRN is generally far less systematically structured, and without any changes to the planning and funding regime the user experience on those roads is likely to worsen. Outcomes may well differ between urban areas, where there is a wider range of policy options for influencing traffic demand, and interurban roads.

Forecasting future travel demand on major roads The context is set by the Department for Transport’s (DfT’s) Road Traffic Forecast (RTF) through to 2040,^{xliiii} the latest version having been published in 2015. Uncertainties surrounding forward forecasts have grown, as changes have become evident in

the last ten to 15 years in people’s lifestyles, attitudes to car ownership and their travel behaviours. These changes are not easy to comprehend and it is difficult to forecast their implications for car travel over the longer term—particularly for journeys in larger cities in many of which travel options have been changing most quickly. However, one of the most important drivers of future traffic growth is the forecast 19% increase in population from 2010 to 2040. Nevertheless, recent events may have increased uncertainty about macro-economic trends as well as forward population forecasts.

It is for this reason that DfT presented a wide range of traffic forecasts in the 2015 RTF (Figure 7.2), each of the five Scenarios reflecting different assumptions about future household travel behaviour or external economic factors. DfT advises against using any specific scenario as a core forecast for travel by car, and that the range of possible outcomes should be acknowledged.

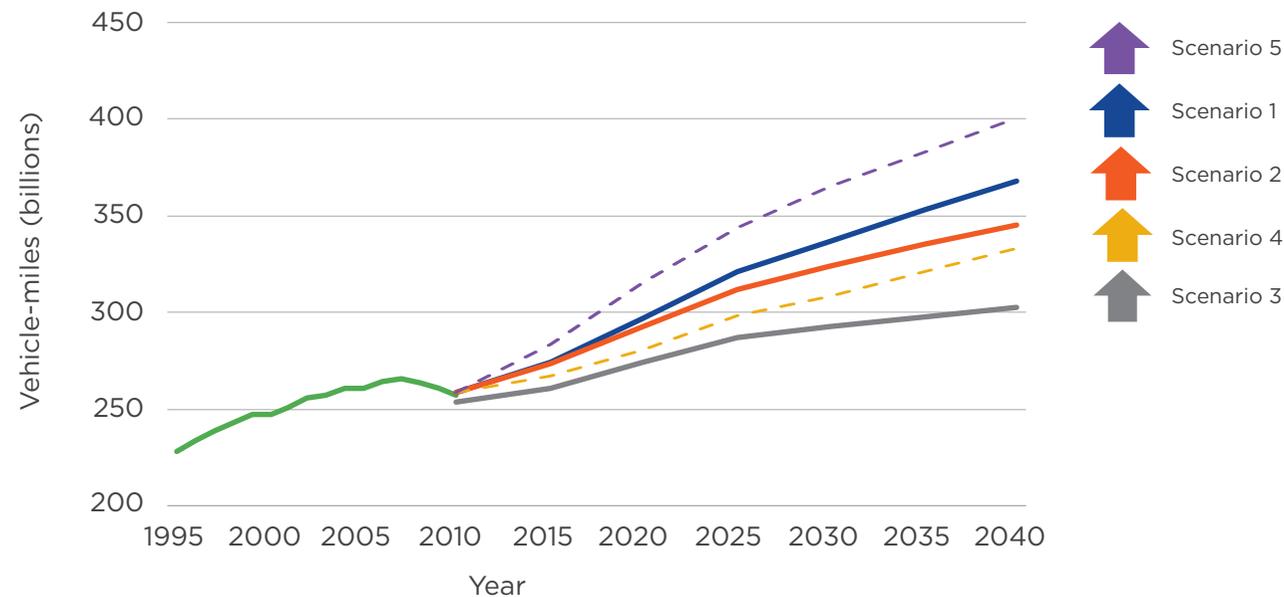

There are also particular challenges in forecasting future freight and light van volumes: HGV traffic has historically tracked GDP, but discontinuities in the trend have arisen since 2008 and remain unexplained. Light vans have shown consistently and surprisingly strong growth, and this is forecast to continue, evenly across road types and areas.

Figure 7.2 shows the range of forecasts of road traffic – all vehicles on all roads—by scenario.

²³ See Supporting Document 9 (Appendix A) for more detailed treatment of this subject

Figure 7.2 Traffic growth by scenario (billion miles, all vehicles)

Source: Road Traffic Forecasts, DfT, March 2015.

Comparison with recent traffic trends

The 2008 recession caused noticeable discontinuities in trends, and any longer-term impacts on travel behaviours will take time to comprehend. But it seems from the latest data that familiar trends may have re-emerged since then. Traffic statistics for 2015^{xliv} confirm that growth has continued to pick up consistently

since 2010: car traffic growth has averaged 0.7% per year a over the last five years, HGVs 0.4% per year and light vans 2.7% per year. These are within the range of the scenarios, resembling most closely Scenario 2 which suggests car traffic growth at 0.8% per year, HGVs 0.6% per year and light vans 2.0% per year.

Critically important for the MRN is how forecasts vary between road type (motorway/A road/ minor road) and by area type (London/conurbation/ urban/rural). While the RTF publication and supporting data contain such disaggregation by scenario, DfT again advises using ranges rather than specific scenarios.

7

Forecast growth ranges of traffic demand on SRN and local authority A roads are illustrated in Table 7.2. The figures for the SRN are based on no further network improvements beyond the RIS1 programme.

Table 7.2 Forecast traffic demand growth by road type (billion miles, all vehicles)

	SRN (motorways and trunk roads)	Local Authority 'A' roads
% Forecast growth 2010 to 2040	+29% to +60%	+13% to 51%
Average % per annum	0.9% to 1.6%	0.4% to 1.4%

Source ^{xiv}

In this table, local authority 'A' roads include both urban and rural roads. Actual traffic statistics for 2015^{xlvi} show growth of 9% on motorways over the five years 2010 to 2015 and 5% growth on rural 'A' roads. These contrast strongly with flat-lining on urban 'A' roads (and a

9% fall in London), which continues the urban trends which have become evident since the millennium.

The RTF breakdown by area type shows much less growth in urban areas than rural, but only at the bottom of the ranges. DfT recognises the concern that

has been expressed by the transport planning community at the realism of the higher urban forecasts, particularly for London; we would strongly urge DfT to continue to research this, so as better to comprehend the well-established growth differentials between types of area.

Table 7.3 Forecast traffic demand growth by area type (billion miles, all vehicles)

	London	Conurbation	Urban	Rural2
% forecast demand growth 2010 to 2040	+13% to 47%	+14% to 54%	+6% to 50%	+29% to +59%
Average % per annum	0.4% to 1.3%	0.4% to 1.5%	0.2% to 1.4%	0.9% to 1.6%

Source ^{xlvii}

Such wide ranges of forecasts at the national level make it difficult to be precise about the levels of demand likely to be faced on the Major Road Network over the coming years; in any case specific routes and local networks would always be the subject of local studies and analysis to develop the case for particular interventions.

The range of forecasts of traffic growth for the SRN reflect the fact that 90% of it lies outside urban areas. A similar, though lower, range could be imputed to the rural Tier 1 and Tier 2 roads on the local authority parts of the MRN, given the prominence of commercial transport on the MRN as a whole.

We note the uncertainty whether the traffic forecasts at the national level take sufficient account of the factors underlying the different trends in urban areas. We believe that the urban roads on the MRN (Tier 3 and Tier 1A), which are the most congested today, will see significantly less growth; it will continue, however, in those areas where population growth is strong, and with the forecast rise in van traffic.

Delays and congestion Average delays on motorways are currently low and account for a reduction from free-flow speed of only a few miles per hour – although with substantial and regular delays continuing to be a feature of certain motorways such as the M25 and the M6. Overall, however, forecast delays on motorways are set to double by 2040. Congestion on trunk roads – currently increasing journey times by 12% on average – is set to worsen delays by half as much again on average; similar patterns are to be expected on the local authority Tier 1 and 2 roads.

The existing levels of congestion on urban Major Roads – particularly in larger cities – mean that even with lower expected growth, the delays due to congestion will be significantly increased over the period to 2040, possibly by as much as 50% on average.

And as noted above, it remains uncertain how far increasing levels of vehicle autonomy may change effective capacity—or indeed may generate additional demand.

In summary, in spite of the uncertainties of travel projections in urban areas,

congestion is expected to worsen significantly across much of the MRN to 2040 if no effective measures are taken to combat it. Some mitigation will come from enhancement schemes to increase capacity or make better use of the existing capacity, and by the greater opportunities to influence travel behaviours in larger towns and cities. But if a serious impact is to be had on congestion, other demand management approaches will have to be considered.

7

7.5 The policy response – sustainable funding and demand management

The governance regime for the MRN has to be robust enough for it to become – and, most importantly, remain – fit for purpose through to 2040 and beyond. The regime has to deliver four components:

1. sufficient funding for operation of the existing network, and for improvement or extensions which are agreed to be worthwhile – without diverting resources from the rest of the local road network;
2. certainty in that funding and the specification, so that efficient, cost-effective planning and procurement is supported;
3. accountability to the user, as the key mechanism for driving service improvements by the network operators; and
4. an ever clearer strategy for demand management, one that provides longer-term solutions to congestion and avoids undesirable dispersal of economic activity and housing.

The regime now in place for Highways England and the SRN fulfils (1) and (2), and has made a good start on (3); little has been achieved yet on (4), demand management. The funding regime envisaged for the SRN from 2020 – hypothecating Vehicle Excise Duty (VED) receipts to a National Road Fund (NRF) – should provide stability and sustainability of a kind not seen since the original Road Fund, defunct since 1936. We have made the case in this report for the NRF to make a systematic contribution towards the local authority parts of the MRN as well, once the needs of the SRN have been met; the scale of that contribution would in part be determined by government decisions on VED rates. This would help to fulfil the first two requirements for the local authority parts of the MRN.

This hypothecation arrangement also potentially strengthens accountability by creating a customer-provider relationship between the user of the SRN and the organisation responsible for

its safe and effective operation and its development. But because VED payment doesn't depend on the use made of the roads, there is no price signal to the user about the cost of an individual journey, so this arrangement cannot support demand management.

The alternative approach of hypothecating a proportion of *fuel duty* instead of VED would mean the amount paid is related to the amount of road use (and the fuel efficiency of the vehicle). But to the average road user fuel duty is a largely hidden charge, and so doesn't provide much in the way of a price signal; fuel efficiency (and thus the fuel duty charge) is not sufficiently affected by congestion to make it a strong demand management tool either. Nevertheless, this is a progressive and easily collected tax that falls exclusively on road users.

However the tax base for fuel duty is set to decline as vehicles become more energy-efficient and a slowly growing proportion use alternative energy

sources: non-hydrocarbon energy sources are not currently subject to any fuel duty equivalent – a desirable policy incentive for a while, but not necessarily equitable in the longer term. Government is reluctant to raise the level of fuel duty or its reach, and so, if we accept that there are other overriding pressures on the Exchequer, hypothecating fuel duty is unlikely to provide sufficient longer-term certainty for planning the MRN or raising finance.

In the short term there is no reason for us to advocate any change from the use of VED receipts to feed an NRF – but that doesn't mean that current opportunities to explore alternative approaches for the longer term should not be explored

A direct form of road user charging – applying on all roads to avoid unintended distortions – could in theory raise sufficient funds, and also be used to manage traffic demand, subject to the pricing structure adopted. It could replace part of fuel duty, depending on how far the scheme needs to be fiscally neutral. And more finely tuned pricing could provide the impetus for

greater uptake of 'mobility as a service' solutions for personal and business transport. The proposals for road pricing in the 2000s fell in the face of public opposition: there was resistance to the perceived undermining of privacy and to the imposition of further burdens on motorists. There was also a lack of clarity about how charging would be set and where the revenues would be applied.

Major advances in charging technology since then could now enable such a system to be more reliable and less intrusive, with lower set-up and running costs; moreover, the public now seem to be used to the spread of tracking apps, such as telematics-based insurance, and large volumes of movement data are now being collected without apparently impinging on driver privacy. But there remain crucial questions as to practical policy on the acceptability of differential charging based on congestion, the extent of fiscal neutrality, and how pricing would be set and revenues used.

Alternative ways of ensuring that the MRN offers acceptable levels of service in the longer term are, if anything, less attractive. Managing demand through

physical constraints, such as controlling access to limited-access (Tier 1) roads, would have adverse consequences on other roads. Conceivably, congestion might be more readily tolerated if well-managed technology provided better information on what to expect and what to do, and enabled time spent in congested traffic to be used more productively – but this doesn't solve the underlying problem.

We are not offering a view as to which – if any – of these approaches might be adopted at some time in the future. It is important, however, that government keeps up to date in its understanding of the tools now available, and of public attitudes to change. The congestion problem is not going to go away, and neither will technology let us off the hook. The MRN will still need to be managed and developed to meet emerging needs, and made increasingly safe and environmentally benign. And the economy and our quality of life will continue to need a properly functioning Major Road Network that is fit for purpose.

8

Conclusions and Next Steps

8.1 Conclusions

- 1.** The Major Road Network (MRN), at nearly twice the length of Highways England's Strategic Road Network (SRN), provides a balanced and coherent network of motorways and 'A' roads with the geographical coverage to support England's national and regional economies, in a way that the SRN alone does not.
- 2.** Designated using objective criteria, the MRN cuts across the existing boundaries of highways responsibilities. No changes to those responsibilities are proposed, partly because of the upheaval it would cause and partly because there is a good case for the local authority parts of the MRN retaining - and increasing - local accountability.
- 3.** To be most effective in supporting economic growth and quality of life, the whole MRN needs to be planned, managed and funded in a consistent way. Therefore making the MRN concept work would require a high degree of collaboration in the planning and management of operations between Highways England and local highway authorities (LHAs) across England; the advent of sub-national transport bodies could make such collaboration both easier to achieve and more effective.
- 4.** The contrast in the current planning and funding regimes for the SRN and for local roads is stark. While there is an effective and well-resourced regime for Highways England to plan and deliver successive five-year programmes of investment on the SRN, no equivalent exists for LHAs. They have had to cut maintenance spending as part of the Government's austerity programme, and work with complex capital funding arrangements without sufficient certainty through five-year commitments.
- 5.** One approach to consistent funding could be for the

Government to use the prospective National Road Fund mechanism to part-fund Major Roads on the local authority network, as well as for the SRN.

6. The MRN provides a logical focus for integrating spatial and economic planning at a regional level, facilitated by Local Enterprise Partnerships working in partnership with local planning authorities and local transport authorities.
7. The MRN must be 'fit for purpose' – putting service for its users, as well as the wider needs of communities and the environment, at the heart of its planning and management. 'Fit for purpose' means making the best use of capacity and maintaining the asset effectively so as to achieve target service levels; keeping safety paramount; and adapting to the more complex transport and planning policies needed in cities and conurbations.
8. The licence requirements and performance metrics now in

place for Highways England capture much of what we set out as fitness for purpose; if the company delivers on these it will provide a vivid demonstration of how progress can be achieved. Formulated as best practice, it would help LHAs – in their own way – to aspire to similar standards. The UK Roads Liaison Group could have a role to play in supporting the network operators develop the 'fit for purpose' concept into a high-level code for the MRN.

9. Technology is having broad and transformative impacts: for example, on how people and businesses make their travel choices, on the emergence of 'mobility as a service', on the autonomous capabilities of vehicles, and on how network operators manage their traffic and asset maintenance.
10. The rising levels of automation in vehicles should significantly improve safety on the MRN, as elsewhere; but the potential for realising major increases in

capacity remains uncertain, as does the extent to which more stress-free driving may actually increase demand. The introduction of higher levels of vehicle automation on public roads depends on resolving a range of practical, legal, regulatory and other issues, and may hold back the pace of implementation for a long time after the technology itself is fully deliverable.

11. Over the longer term, and driven in part by 19% forecast population growth, we accept that the demand for movement by road is likely to increase 19 - 55% on 2010 levels by 2040 (but by less on urban roads). This is a faster rate than can be matched by affordable and acceptable increases in capacity; delays and traffic congestion will thus increase. Technology will not on its own solve this problem; there will be a need to consider demand management. There are no simple solutions, but government should remain informed about the alternatives available.

8

8.2 Next steps

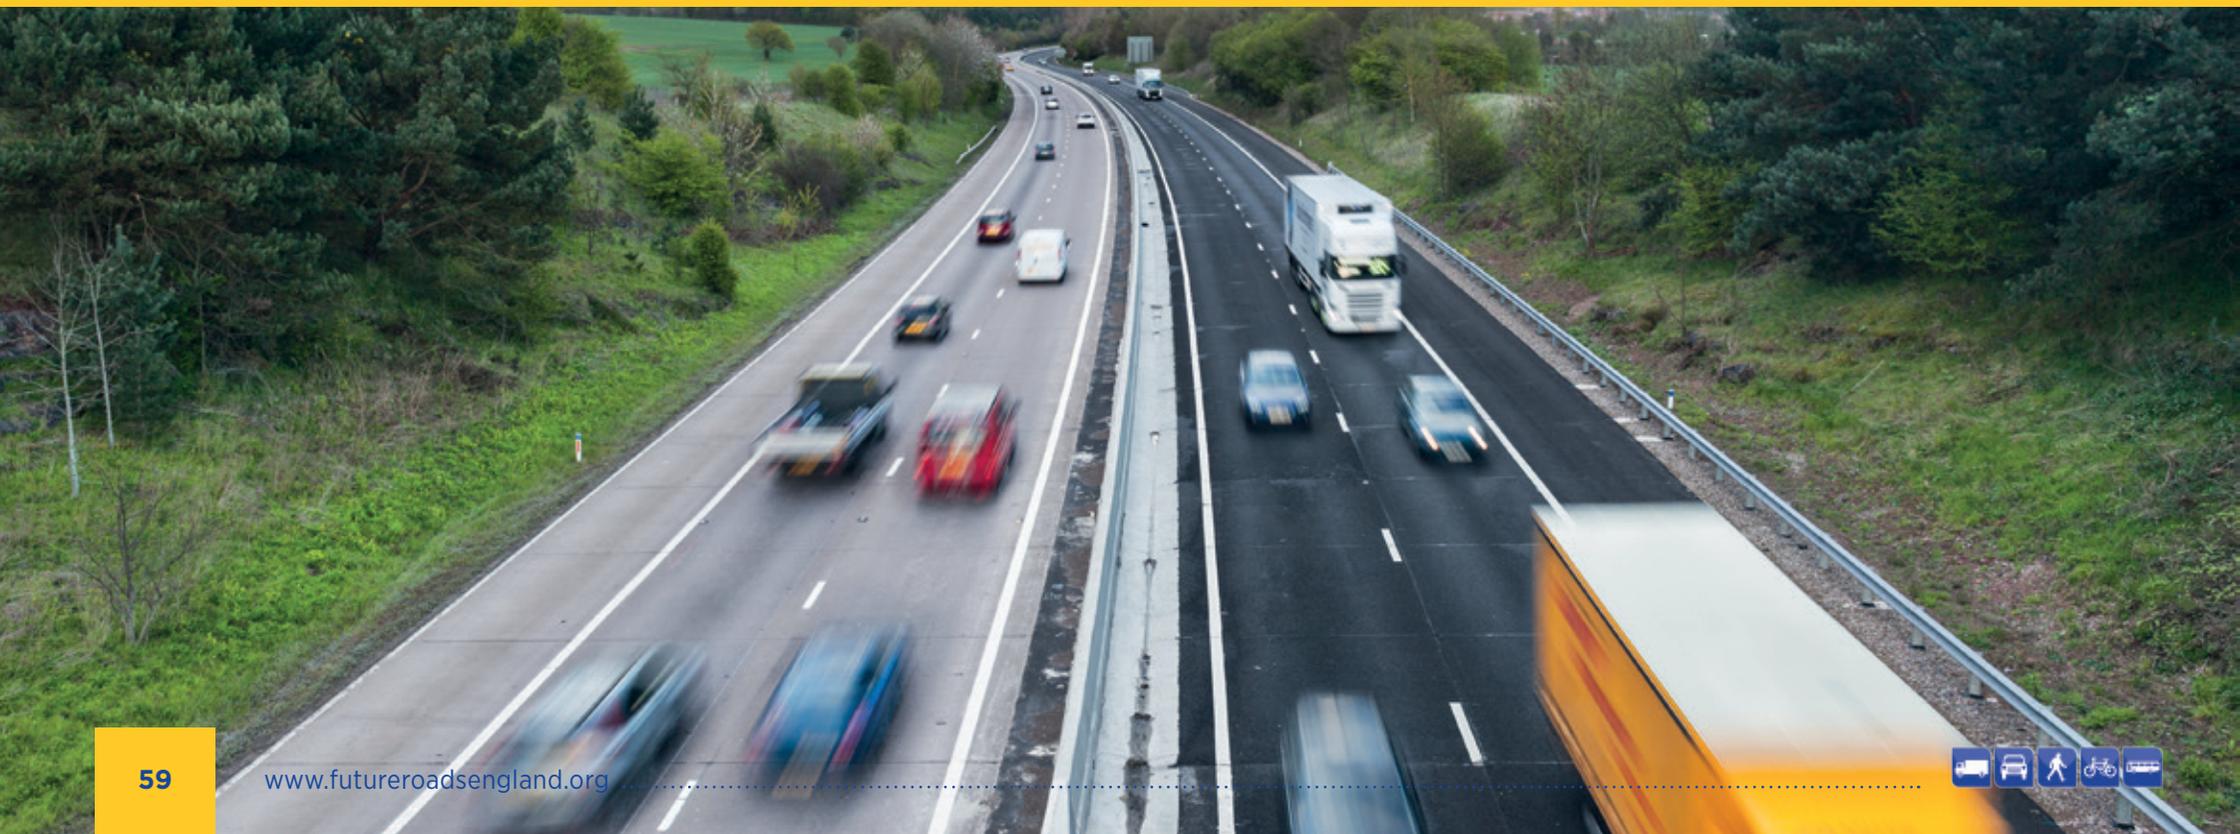

Progressing this proposition will require:

- Government, Highways England and local authorities to embrace the concept of the MRN and its rationale – and for it to be adopted for their areas by the new STBs;
- Highways England and local authorities to take on the task of collaboration on a network basis, on planning, management and operations – with government incentivising this into the next decade, including possibly

incorporating it into the remit for Highways England for the second Road Investment Strategy period; and

- Government to consider whether the prospective National Road Fund could part-fund qualifying expenditure on local authority parts of the MRN.

We also suggest that the network operators collaborate in developing a high-level fitness-for-purpose code for the whole MRN.

B: Acknowledgements

Over the two-year course of this study, we have benefited greatly from the expertise and constructive advice of a wide range of individuals, and organisations, in the field of transport policy, planning and delivery. We are particularly indebted to all the members of our Advisory Panel, past and present, who have steered us to a balanced report and have ensured that we remained focused on all key issues:

Paul Bird, formerly Director for Commissioning – Transport and Infrastructure, Essex County Council

Dr David Bizley, Chief Engineer, RAC Motoring Services

Prof Alan Braithwaite, Executive Chairman, LCP Consulting

James Byles, Asset Development Manager, Asset Management Directorate, Transport for London

Tony Gates, Director for New Business, Major Projects, Balfour Beatty

Steve Gooding, Director, RAC Foundation

Andy Graham, White Willow Consulting, and Chair ITS UK, Cooperative Vehicle Highway System Group

James Hookham, Managing Director, Membership and Policy, Freight Transport Association

Stephen Joseph, Chief Executive, Campaign for Better Transport

Prof Glenn Lyons, Professor of Transport and Society, University of the West of England

Sue Percy, Chief Executive, Chartered Institute of Highways and Transportation

Steve Salmon, Director, Policy Development, Confederation of Passenger Transport

Susan Sharland, President, CIHT and former Chief Executive, TRL

Martin Tugwell, Programme Director, England's Economic Heartland Strategic Alliance

Alan Wenban-Smith, Urban and Regional Policy Consultant

We are grateful to many others who gave us freely their time, knowledge and advice. John Dowie, Paul O’Sullivan, Graham Pendlebury and many others from the Department for Transport have been especially helpful as the study has progressed, as have, from Highways England, Nigel Edwards, Martin Fellowes and (until her retirement and subsequent appointment as a trustee of Rees Jeffreys Road Fund) Ginny Clarke. We have also much appreciated the guidance from Geoff Allister and Matthew Lugg, along with others whom we have met during the course of the Study.

The Steering Group of Rees Jeffreys Road Fund Trustees has worked hard to keep us on track: our thanks to David Bayliss, Stephen Glaister, David Tarrant and to the Chair, David Hutchinson; and to all the Trustees, for their advice and for making the study possible, and to the Chartered Institute of Highways and Transportation for providing meeting room facilities for the Steering Group. Finally, we give a special thank you to Sanjay Rana, who has provided invaluable GIS (geographic information system) expertise throughout, and to our administrator, Frances Leong, for keeping the study on the road with her unfailing support.

Rees Jeffreys Road Fund

The **Rees Jeffreys Road Fund** has, since its inception in 1950, provided support for education and research in all forms of transport. It helps to fund projects that improve safety, the roadside environment and rest facilities for motorists and other road users. The Fund has nine Trustees, all with considerable transport experience. This study has been overseen by a Steering Group drawn from the Trustees, comprising David Bayliss, Stephen Glaister and David Tarrant, and chaired by David Hutchinson. For further information, please see www.reesjeffreys.co.uk

The study has been led by **David Quarmby**, with **Phil Carey** as co-author. Sanjay Rana provided GIS expertise, and the study administrator was **Frances Leong**.

This study report should be read in conjunction with the series of Supporting Documents, listed at Appendix A. All are at www.futureroadsengland.org and at www.reesjeffreys.co.uk/transport-reports, where the Report Summary may also be found.

October 2016

RESPONSE FROM THE RSA SUSTAINABILITY NETWORK TO THE NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE

The RSA (Royal Society for the encouragement of Arts, Manufactures and Commerce) is a social change organisation whose mission is to enrich society through ideas and action.

The RSA Sustainability Network is led by Fellows of the RSA with professional interest and expertise in sustainability issues. Should you have any questions or require further information, please contact the Network Chair, Susan Harris, at susan@srssustainablebusiness.co.uk.

The RSA Sustainability Network recognises the importance of the National Infrastructure Assessment, not only for infrastructure itself, but also for the prospects for environmental sustainability, housing, and social inclusion.

We are providing responses here to some of the questions raised in the Commission's 'Call for Evidence'. The questions to which we are providing a response are indicated below.

In addition to the specific responses in this submission, we highlight the forthcoming final report of the RSA Inclusive Growth Commission for its consideration of issues that are relevant to the National Infrastructure Assessment, in particular broadening measurement criteria from narrow GVA to 'quality GVA', and for understanding the interplay between physical and social infrastructure for creating better places to live and work.

Question 1: What are the highest value infrastructure investments that would support long term sustainable growth in your city or region

We advocate a broad, nationwide approach rather than a regional or city-based approach. It is vital to develop at the outset a broad nation-wide strategy setting out which types of infrastructure development should be given priority before attention is paid to individual projects.

We are concerned with the assumption apparently underlying this question, namely that individual cities and/or regions should determine infrastructure projects that they would favour, and then the government/Commission would choose from the resulting list the ones that they approve of and are prepared to support. There may be some cases where broad regional priorities have already been agreed and where that approach is sufficient, but generally we strongly recommend that, before considering the detail of any specific project, the Commission (or relevant appointed body) must determine which areas of particular value to the United Kingdom as a whole need government input and support, at least in initial stages, if they are to flourish.

Specifically, deciding we want to build something – say HS2 or Hinckley C – because we believe it will promote “economic growth” as measured by conventional GDP accounting, and then testing it to see whether its environmental costs are too high, would be wrong. The first stage in the process should be deciding what to build, not just to make the

economy more efficient and productive (however that may be assessed), but also, and in our view more importantly, how to make it more sustainable and more circular, and then examining whether those investments would be viable and affordable.

Do we need, for example, a smart electricity grid; a truly comprehensive high bandwidth internet and extensive electricity storage more than we need a new high speed rail line? And before considering any new high speed rail line, there should be a review of likely technological developments in each of road, rail and air travel, in the short and medium terms, having particular regard to their relative impacts on resource use, environmental damage, and long term sustainability. What relative priorities should be set for road as against rail travel? Similarly, with power generation: this must inevitably in the long term become entirely renewable – how should this goal be achieved and over what timescale, including maybe what R & D facilities need to be established to support that goal, and what are the best investments to make in the meantime?

Question 3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Planning in the UK is often blamed for our failure to meet economic, environmental and social objectives. Our cities have sprawled, despite green belt policies, our main roads are clogged up, and our societies are increasingly unequal. Much of our transport and energy infrastructure is worn out, as studies by McKinsey and Company and The Policy Institute have highlighted, and the government's new Industrial Strategy stresses the need to 'better align central government infrastructure investment with local growth priorities'.

Reports such as *The State of the Cities 2016* by the European Union reveal that outside London our cities are lagging behind, in part because of relatively low levels of investment compared with countries such as Germany and France. However the explanation is not just lack of expenditure. Despite sensible policies such as the Treasury's Green Book and the National Planning Policy Framework, we fail to 'join up' public and private investment.

The NIC's National Infrastructure Assessment presents a unique opportunity to reform the way decisions on planning strategic development and infrastructure are made and implemented. We here provide our insights on why spatial planning has failed, what is wrong with funding, where we can best learn from, and what the NIC should be doing to close the gaps.

Why spatial planning has largely failed

- Provincial cities were built on the industrial revolution in the 19th century
- Cities sprawled in the 20th century into low density suburbs and villages
- Employment is fragmenting in the 21st century
- But our transport infrastructure is still largely radial and inter-city
- Transport and development are planned in silos, the regional dimension has been lost, along with the people who can join them up
- Over-dependence on short-term profit has caused both quality and quantity to suffer
- Planning disputes drag on at great expense for many years and sap our capacity to compete internationally
- We are creating Combined Authorities, without the funds to fill the gaps.

What is wrong with infrastructure funding in the UK

- We have invested too little for decades (outside London)
- Public funding is far too centralised and out of touch
- Cost Benefit Analysis neglects social and environmental impacts
- Our procurement system is antiquated, stifles innovation and probably raises costs
- Consumers are not happy at what they get for what they pay
- Private institutions will be investing in resilient cities outside the UK
- The property owners (who are the main beneficiaries) get windfall gains
- We cannot double housing output (which all parties agree is needed) without providing better infrastructure – and in the right places.

Where we can best learn from?

- Swiss cities like Zurich operate like ‘clockwork’ and are rated highly by investors
- French provincial cities like Lille and Montpellier have out-stripped Paris in population and economic growth
- German conurbations such as the Ruhrgebiet towns are models of collaboration with integrated urban transport systems eg Stadtschnellbahnen
- Scandinavian cities such as Copenhagen keep housing costs down through planned expansion along transport corridors, which is funding their new metro
- Some American cities, such as Portland Oregon, have copied European models successfully through Transit-Oriented Development

What the NIC can do

1. Publicise ‘model’ projects that offer replicable lessons
2. Bring experts and practitioners together to review findings from research into better infrastructure decision making
3. Require major investment in infrastructure such as in Oxfordshire to respond to 30 year Spatial Growth Plans
4. Evaluate strategic projects in terms of environmental and equity (social) as well as economic criteria
5. Promote new private funding sources eg infrastructure bonds to share in the uplift in land values from development
6. Set up demonstration projects to test the feasibility and cost of applying better models.

For further information on the issues raised in this response to Question 3, contact Dr Nicholas Falk nicholas@urbed.com, www.urbed.coop

By designing integrated, low carbon infrastructure we have the opportunity to achieve climate change mitigation and a healthy, prosperous society.

Question 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The achievement of consensus through thorough consultation and investigation of the relevant issues as early as possible in the planning process is the key to avoiding inefficiencies later on. A basic problem is that the initiative for development schemes almost always comes from either

developers or government, leaving others (local authorities, local communities, environmentalists, etc) to respond at a later date, when they should have been involved in the process much earlier on.

The Commission should avoid the political rhetoric which brands opposition to proposed developments as “nimbyism”. Clearly there are people who are principally concerned with their own local areas (although that is not necessarily a bad thing), but there are also environmental concerns which are widely shared, and often underpinned by international agreements and a substantial natural science evidence base, which currently are not given sufficient attention. For example, a great deal of the frustration about the possibility of Heathrow airport expansion could have been avoided if at early stage proper consideration had been given to carbon emissions and air quality issues, and alternatives found in order to reduce demand for air flights. Not tackling these issues early on has led to outcomes which are unsatisfactory for all concerned.

Similarly now, urgent attention needs to be given to flood defence arrangements in order to prepare for an increasingly unstable climate. These should not have to be added in to plans at a later stage when the need is already obvious.

The National Infrastructure Commission should make mitigating and adapting to climate change a core element of its work. An early study should be carried out as to how the Commission will carry out its Assessment in a way which is line with the requirements of the Climate Change Act.

In order to address issues about social equity and inclusion, the Commission should also make provision, as part of its methodology for assessing infrastructure needs, for a system for analysing the distributional impact (as between different income groups) of different infrastructure options. This perspective should become a routine part of the Commission’s work as it considers different infrastructure sectors.

Question 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

We highlight the importance of accurately incorporating sustainability considerations into cost-benefit analysis. Assessment methods must be robust and holistic in order to be “credible, tractable and transparent”. Many of the techniques that ensure inclusion of sustainability also help to ensure better decision making overall.

The method must consider whole-of-life. To illustrate, one of the great barriers to some “green investments”, such as tidal lagoons, has been the discount rate applied to future earnings. If the discount rate is taken to be 6%, for example, earnings arising after more than around 7 years are normally disregarded, even though one of the great advantages of tidal energy is that it will produce regular predictable renewable energy for far longer.

Whole life costing or life cycle costing (rather than simple snapshot cost-benefit analysis) is advocated throughout the sector for a variety of reasons in addition to the sustainability argument. It helps to give a realistic picture of the cost of the asset over its life, and in doing so can also aid more accurate predictions as to the likely actual lifetime. This in turn can significantly improve upon planning and maintenance, both at an individual asset level and from a national infrastructure planning perspective.

Holistic methods also help to avoid the “CapEx-OpEx divide” where capital expenditure and operational costs are considered separately, a common problem bemoaned throughout the

sector, which can lead to a “specification gap” and choices that provide less value in the long term.

Appropriate cost benefit analysis should give a “triple bottom line” (social, environmental and economic) assessment of both costs and benefits. Whilst this is necessarily complex, it is by no means unusual or prohibitive. There are a variety of tried-and-tested techniques for options appraisal and cost-benefit analysis which enable an efficient, robust assessment that effectively incorporates these considerations. For example, we direct the Commission to the work by UCL for the Institution of Civil Engineers and UK Actuary Profession on the OMEGA 3 project (<http://www.omegacentre.bartlett.ucl.ac.uk/research/omega-3/>), which examined how better to incorporate social and environmental criteria into the planning and appraisal of major infrastructure projects. Its proposals for policy-lead multi criteria analysis are detailed in the final report (<http://www.omegacentre.bartlett.ucl.ac.uk/wp-content/uploads/2014/10/OMEGA-3-Final-Report.pdf>).

As was demonstrated in the 2013 National Infrastructure Carbon Review (<https://www.gov.uk/government/publications/infrastructure-carbon-review>) cutting carbon also cuts cost – a principle advocated by the many key industry players who signed up to the Infrastructure Carbon Commitment (<http://www.greenconstructionboard.org/index.php/resources/infrastructure>). We would argue this is also the case for many other sustainability factors, where the same innovation that brings good environmental outcomes can also bring financial and operational benefits.

In addition to these considerations, we highlight that cost-benefit analysis must be conducted at the right point(s) in the process. A key sustainability issue for assessment of infrastructure is consideration of whether an asset needs to be built in the first place. Early consideration of the sustainability costs and benefits is necessary, as is ongoing revision at appropriate points in the options appraisal process as designs and needs change.

Question 28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

We direct the Commission to the key bodies within the UK (both governmental and non-governmental) that are working on Circular Economy such as the Ellen MacArthur Foundation, WRAP, the Environmental Audit Committee. POST note Number 536 September 2016 also provides some useful aggregated insight.

Given responsibility for circular economy policy at a governmental level is divided between different bodies, including: Defra, BEIS, the Treasury, local authorities and devolved administrations, it may be prudent to appoint a special advisor or representative to assist the NIC in ensuring circular economy considerations are included in decision making.

National Infrastructure Assessment call for evidence

Response to the National Infrastructure Commission, 10 February 2017

The Royal Academy of Engineering welcomes this opportunity to submit evidence to the National Infrastructure Commission (NIC). As the UK's national academy for engineering, we bring together the most successful and talented engineers from across the engineering sectors for a shared purpose: to advance and promote excellence in engineering.

The views described in this response have been developed based on a workshop and contributions by Fellows who are expert in infrastructure, systems engineering, construction, digital systems, civil and structural engineering, energy, transport, flooding and water supply. Their expertise spans research, policy making, regulation and practice, including the management of major projects. This response also builds on a number of major policy studies that the Academy has undertaken.

Through its Fellowship, the Academy has access to highly qualified individuals in the sector. Systems thinking and modelling is a particular area of expertise of the engineering profession and the Academy stands ready to offer expertise to assist the NIC with understanding interdependencies and resilience, and in particular in supporting a systems-based approach.

It is also recognised that this work is closely linked to the government's Green Paper on industrial strategy which the Academy will be responding to in collaboration with the professional engineering institutions. It is clear that business and industry rely heavily on all types of infrastructure and that underperforming infrastructure can impinge seriously on productivity. The Green Paper also highlights a marked disparity in productivity between regions of the UK. An assessment of the impact that infrastructure has on industrial performance and on regional variations will be included in the response on industrial strategy.

Primary messages:

1. **A 'system-of-systems' view is vital for ensuring the UK's infrastructure is sustainable and resilient:** A whole-system approach, alongside a whole-life cost approach, is particularly critical to the planning and delivery of the UK's infrastructure. The NIC is well placed to develop a more informed and coherent approach, based on evidence and rigorous assessment of benefits and costs, the primary focus of which should be an overview of national needs.
2. **Non-infrastructure approaches should also be considered:** Infrastructure is only one possible solution out of many for achieving the desired outcomes for the UK. It is necessary to ascertain what the UK is aiming to achieve more broadly over the next few decades, and where infrastructure, alongside other interventions, can play its part.
3. **Maintaining and operating existing infrastructure at highly resilient levels is vital:** It is critical for the NIC to focus on improving the resilience, security and reliability of existing infrastructure, as much as new infrastructure. Reuse or repurposing of existing assets will in many cases carry lower financial and environmental costs – including impacts on CO₂ emissions, air quality, noise, destruction and fragmentation of habitats and visual impact - than provision of new.

Other key messages include:

4. Infrastructure has great potential to improve individual and collective wellbeing, not only economically, but also in terms of social inclusivity, healthy lifestyle choices, and personal and national safety and resilience. Evidence-based cases for individual projects need to demonstrate direct and wider benefits and impacts.
5. There are many different interpretations of the value of infrastructure, whether it is the value society places on infrastructure, or the value that clients place on individual projects. Cost-benefit analysis provides an important tool for prioritisation, but if cast too narrowly can overlook important values (both benefits and impacts) that are associated with infrastructure projects and can neglect systemic interactions. The UN's Sustainable Development Goals could provide a basis for this assessment. The role of infrastructure as

an enabler or for releasing tension around other parts of the system also needs to be recognised and captured in the analysis of value.

6. Infrastructure is a broad and complex part of an interdependent system that cuts across sectors, and requires all its component parts to operate effectively. It is vital that sectors pull back from their silos and find ways to collaborate. A whole-system approach recognises the very significant interdependencies between classes of economic infrastructure, and to a lesser degree between economic and social infrastructure.
7. Siloed thinking will lead to abortive or poor value expenditure. UK infrastructure also cannot be considered in isolation from its connections to broader global infrastructures upon which the UK is dependent.
8. It is important to question what regulatory and non-regulatory levers are available for ensuring that outcomes are achieved. A joined-up regulatory environment is important for incentivising innovation and breaking down barriers between silos – as well as appropriate procurement and standards that enable innovation, and good definition of requirements. An understanding of performance in-use is also necessary.
9. It is a challenge to predict the future, and indeed confidence levels in forecasts for 2050 such as travel patterns must be low, due to uncertainties in the impact future disruptive technologies and other external factors that can drive change. There is no doubt that the future will be different, for whatever reason, and therefore the UK needs an infrastructure that is as adaptive, flexible and resilient as it can possibly be. The industry will need to think imaginatively and build in capacity for change, whatever that change might be.
10. Resilience, whether to extreme events, component failure or to malicious activity, is critical. We welcome the NIC's focus on resilience, and emphasise that it is vital to consider interdependencies between sectors and the risk of cascades of failure across sectors, and the importance of rapid recovery following failure. All sectors are dependent on electricity and increasingly on the internet, although much infrastructure was designed prior to the internet's existence.

Cross-cutting issues:

Question 1. What are the highest value infrastructure investments that would support longterm sustainable growth in your city or region?

11. An important role for the NIC should be to create a broad definition of value to enable the assessment of the highest value infrastructure investments. A pan-sector assessment regime is needed to allow sustainable value capture to be assessed and all risks to be placed where they are best managed. The value proposition must include economic, environmental, social and political factors and should be assessed at a range of scales – international, national, city, local and community¹. The NIC should be the champion of an improved process of project evaluation to capture the wider benefits of infrastructure. The UN's sustainable development goals could provide a basis for assessing value.
12. Improved physical connectivity, if carefully designed and implemented, can catalyse a diverse range of human activity – economic and social – that ultimately leads to raised living standards. Historically, well-targeted transport investments have contributed to GDP growth, although digital communications are now playing a greater role in GDP growth than transport.
13. There are risks associated with long-term forecasting using trend extrapolation. Historically, infrastructure has evolved through a number of technological step-changes, or disruptions – for example, railways overtaking canals, the invention of the internal

¹ See for example the HS2 Design Vision and the HS2 Balanced Scorecard for the evaluation of suppliers. A similar balanced scorecard should be developed for establishing relative values of different investments.

combustion engine and of powered flight – none of which were predicted 10 years before their invention.

14. Infrastructure assets tend to be long-lasting. The challenge today is to design with maximum adaptability, flexibility and resilience for the unforeseeable changes that will occur within the lifetime of the infrastructure. In the past, ingenuity has addressed this – for example, the railway was electrified without requiring significant rebuilding – but ingenuity applied to adaptable infrastructure could pay even greater dividends as the pace of change increases.
15. Future-proofed digital strategies should accompany all major investment projects. A digital communications strategy for UK transportation – which is not mode-specific – would improve utilisation of the transportation network through real-time information. Cross-sectoral sharing of data is vital for enabling collaboration between sectors.

Question 2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

16. International competitiveness is best achieved through:
 - good international gateways for freight and for passenger traffic
 - robust national strategic transport networks that provide good transport links between those gateways and centres of production and consumption²
 - infrastructure that attracts the skilled people to the area and enables them to work most efficiently
 - resilient infrastructure, so that investors can be sure of reliable and secure services
 - competitively priced fares and tariffs.
17. National strategic transport networks are arguably the most significant factor in international competitiveness, and their perceived efficiency is of importance to external investors. Networks need sufficient flexibility to accommodate changes in transport flows, particularly freight, driven by competition between port and airport operators and by changing source or supply markets. Road capacity is generally more flexible than rail in adapting to changes in freight movement flows.
18. When assessing improvements to international links, the approach should consider current access costs, identify the extent to which they could reasonably be reduced, and then develop schemes which can achieve this cost-effectively.
19. The UK should put in place actions to position itself as a safe and secure repository for data and provide the legal and professional structures for the secure sharing and controlled trading of non-personal data. The UK will need to build on its considerable existing capabilities in multidisciplinary innovation around data by addressing barriers that otherwise might reduce the UK's international competitiveness in this field, including the need to ensure that data sharing and the operation of data-driven systems can occur across international, as well as sectoral and organisational boundaries³.
20. Establishing the UK as the lead provider of secure cyber-physical systems would have substantial economic benefits across a wide range of sectors. Indeed, the UK has the inherent academic and industrial strengths, drawing on expertise in software engineering and systems engineering, to become the key global centre in which to design, develop and deploy the next generation of highly secure cyber-physical systems.
21. The UK should always benchmark itself against other leading nations and act on the findings. Ofcom does benchmarking well for communications infrastructure but the cross-

² In particular, such a network would help to reduce transport costs for industry and trade, by reducing congestion and increasing reliability.

³ Royal Academy of Engineering and IET, November 2015, *Connecting data: driving productivity and innovation*, www.raeng.org.uk/connectingdata

government working required to act on the issues that emerge is a challenge. Many large UK projects are lauded as having been delivered 'on time' and 'on cost' but, compared with similar projects worldwide, often take longer and cost more. On-budget performance is often achieved with large contingencies in cost and time. The NIC could help improve productivity by addressing this.

22. The link between infrastructure investment and competitiveness is poorly understood and the evidence is not as strong as sometimes asserted. More research is needed based on good data, including international data, although we recognise that this is hard to acquire.

Question 3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

23. Infrastructure must provide a service to society. There is a risk that infrastructure providers (and their engineering advisors) consider infrastructure in isolation from its role in creating better places, and also do not consider the benefits beyond the boundary of the project. Physical infrastructure should be integrated with housing and workplaces in such a way as to create high-quality environments and to avoid linear infrastructure such as railway lines or busy roads creating a physical division between communities.
24. Dedicated upfront resource would allow infrastructure to be better integrated into the wider context, and the necessary steps taken to derive best value from a new asset. Whole-life performance monitoring (for example through extensive use of sensors and shared data) will allow real life performance to be assessed and optimised.
25. Housing, workplaces and infrastructure (both physical and digital) should be considered as a single, integrated system, with the planning system as the enabler. A systems approach that considers housing and workplaces alongside infrastructure will help unlock future development potential, particularly where the housing crisis is most severe⁴.
26. It has long been known that a lack of basic infrastructure services contributes to poor physical health. Increasingly there is an understanding that improving the quality of the built environment can significantly enhance health, wellbeing and personal productivity of those who live and work in urban environments. This includes mental as well as physical wellbeing^{5,6}.
27. An aging population will require greater accessibility to and connectivity of homes. Infrastructure plans need to address the future need for health and social care to be delivered in the home using digital infrastructure, in both urban and rural communities.
28. Changing technologies, such as local energy generation and distributed storage, will change the boundary between public and private infrastructure. The design of next-generation infrastructure and buildings needs to anticipate these changes.
29. Many of the most important innovations in demand management require changes within houses and other buildings: smart meters, water saving devices, solid waste recycling etc. It is important that these innovations are built into new housing and that more attention is paid to retrofitting existing housing.

⁴ Crossrail 2 is one example of a transportation scheme enabling housing growth. Viewing housing and transportation as an integrated system would provide additional benefit to this project.

⁵ Royal Academy of Engineering, Arup and ESRC, July 2015, *Built for living: understanding behaviour and the built environment through engineering and design*, www.raeng.org.uk/builtforliving

⁶ The World Health Organization (WHO) attributes 12.6 million global deaths to unhealthy environments in 2012 with factors such as air pollution (3.7 million deaths) and physical inactivity (3.2 million deaths) playing a significant role. The UK is not immune to such effects. WHO, March 2016, *Preventing disease through healthy environments: a global assessment of the burden of disease from environmental risks*.

30. Effective land-use policy is critical. There is much to be learned from continental cities that achieve lower journey distances and a lower share of travel by car by requiring higher density mixed development and building in public transport routes from the start. A critical issue is deciding dispositions of future bulk housing to facilitate anticipated growth, which currently happens in a largely unplanned way. Better planning is needed in order for the growth to occur in such a way as to create successful places. Housing and transport need to be considered together in national space planning, and housing in its bulk form should be the basic ingredient of the National Infrastructure Plan. A statement could be required for all major infrastructure schemes demonstrating how they contribute to housing growth⁷.

Question 4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

31. Demand management is a valuable tool in sustaining existing infrastructure, effectively making existing infrastructure more productive by spreading additional demand across a longer peak or managing demand in a manner that maximises throughput.
32. Demand management is achieved by pricing and by quality of service delivered, among other measures. For infrastructure where capacity is constrained, such as transport, quality of service becomes a demand regulator. One such example is the movement of road freight that is managed around the morning and evening peak hours. Better real-time information to users helps manage demand, as users change their behaviour to avoid congested routes.

Demand management in the transport sector

33. In the rail sector, many commuter routes have significant capacity issues despite some of the highest fares in Europe. On long distance routes, train operators use techniques similar to the low cost airlines to 'smooth' loadings. High 'turn up and travel' prices are unpopular but are an essential part of that smoothing.
34. On the roads, efficient road pricing is potentially the most effective way of managing demand⁸. It is technically feasible now, but there are significant political and public barriers to implementation.
35. Demand-side measures – including demand management – are vital, as the existing supply pipeline of new infrastructure is unlikely to meet the task of keeping pace with demand growth in the near- to medium-term future⁹. An integrated strategy is needed from government that includes continued infrastructure investment in conjunction with capacity-maximising technologies and demand-side policy levers.
36. Demand management should not be considered separately from other measures, but packaged together to achieve a particular goal for a particular system since packaging can produce synergistic gains. Packaging can also allow the barriers to one measure to be compensated for by another¹⁰.

⁷ This assumes that infrastructure provision is occurring ahead of population and housing growth.

⁸ Royal Academy of Engineering Challenge Paper, November 2015, *The transport congestion challenge: getting the most out of the UK's road and rail networks*, www.raeng.org.uk/congestion. (Note: a challenge paper is not a formal policy position; it aims to promote further discussion).

⁹ Ibid.

¹⁰ For example, in London, congestion charging revenues were used to enhance the bus network which both provided synergistic gains and improved public acceptability.

Demand management in the energy sector

37. Demand side measures are as important as supply side measures in achieving a resilient energy system for the future that meets climate change obligations¹¹. Demand management needs to be considered alongside other demand side measures such as increasing efficiencies.
38. Demand management in the energy system involves controlling demand to better match energy supplies, mainly to reduce peaks in demand or take advantage of surpluses in supply. This can help to optimise the use of energy system assets and avoid local network issues as well as delivering better value for consumers.

Challenges around demand management in the energy sector

39. If well implemented, demand side measures can deliver a more efficient, lower carbon, cost-effective system with the same level of service for lower bills — a win-win situation. However, they can be difficult to implement. Large-scale, regional or local pilot schemes are critical to understanding how to unlock the potential of demand side measures, as is learning from successful initiatives in the UK and abroad. Whilst household electricity demand is declining, efforts at household energy efficiency and conservation have been rather weak. The Green Deal made very little contribution to achieving the considerable potential for reducing household energy demand, which saves households money as well as reducing the need for new supply capacity.
40. The introduction of smart meters will provide a means of managing demand, but these are just one necessary component of a 'smart grid' that is still some way off. Much more work is needed to understand better the potential of demand management in the electricity sector and ensure a reasonable and equitable return on the significant investment that will ultimately be paid for by consumers.
41. Behavioural constraints and rebound effects are two important factors that could influence the effectiveness of demand management. Other factors that should be considered include the relationship between demand management and the capacity mechanism, and the impact of demand management on fuel poverty.

Future steps to achieve effective demand management in the energy sector

42. In the immediate short term, effort is needed to bring through demand management, as well as other demand side responses, into the capacity mechanism and to learn how demand can effectively be included in markets traditionally designed for supply.
43. In the medium term, more research is needed to assess how tariffs will function best, providing a fair balance of benefits and costs between utilities and consumers, without which participation levels will be low or customers will lose out on potential savings. In particular, more needs to be understood about consumer attitudes and behaviour around time-of-use tariffs and dynamic tariffs, including consumer acceptance of automation of energy use and the impact of the price differential¹². In addition, more needs to be known about how demand management will affect fuel poverty and more general issues of equity.

¹² Royal Academy of Engineering, April 2016, *Response to the House of Commons Science and Technology Select Committee inquiry on Smart Meters*, www.raeng.org.uk/publications/responses/smart-meters

Question 5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The importance of existing assets

44. A substantial proportion of the infrastructure that will be in use in 2050 and beyond has already been built. Much of it is already a considerable way through its intended design life. This means that the maintenance, rehabilitation and enhancement of existing infrastructure must be recognised as one of the core infrastructure challenges facing the UK across all sectors. The challenge ranges from improving the energy efficiency of buildings to managing the bridges, embankments, tunnels and cuttings upon which transportation networks are totally reliant¹³. It is important to understand whether the condition and functionality of the UK's existing infrastructure is improving, stable or in decline.
45. In line with NIC's role to provide the government with impartial, expert advice on major long-term infrastructure challenges, it is vital that NIC provides a strong voice in support of making efficient and effective investment in keeping the UK's existing infrastructure working. This requires stable and well-targeted spending, coupled with research to enable the performance of existing infrastructure to be better monitored and interventions to be optimised over the lifespan of assets to minimise disruption, environmental impacts and costs.

The decision to replace or renew existing assets

46. Where an entirely new function or service is proposed, provision of new infrastructure is a reasonable assumption. However, where the capacity appears insufficient for an existing function, or the service level does not meet current expectations, then maintenance or capacity upgrade of existing infrastructure should be regarded as the base option. Reuse or repurposing of existing assets will, in many cases, carry lower financial and environmental cost than provision of new.
47. Decisions on whether to maintain existing assets, to replace components, or to adopt wholesale replacement are generally well made in regulated infrastructure businesses. In the regulated sectors, the regulatory process has in most cases incentivised infrastructure companies to make their retained infrastructure as productive and as reliable as practicable through revised operating regimes, planned lifecycle maintenance, and wholesale asset replacement. Outside the regulated sectors, there are fewer incentives to reduce the size of asset base to the minimum necessary. Furthermore, declining asset performance is tolerated because there is insufficient financial capacity to invest in non-essential short term maintenance. Examples are the substantial non-PFI elements of the defence and health estates where redundant assets are retained and other assets deteriorate, affecting the productivity of users.
48. Balancing investment in repair and maintenance with construction of new assets is best achieved by moving to a 'total expenditure' (TotEx) view of long term asset cost, rather than driving decisions based on short-term availability of capital. Regulatory authorities should keep their policies under review to ensure that they set user charges on the basis of lowest whole life system cost, and that they move to TotEx models where they have not already done so. In unregulated sectors, government should use such levers as tax regimes and planning regulations to incentivise asset owners to optimise whole-life cost through asset maintenance and planned renewal.

¹³ For example, Network Rail's planned funding for enhancement projects in England & Wales to be delivered during 2014-2019 was £11.8 billion (in 2012-13 prices). Network Rail, November 2015, *Report from Sir Peter Hendy to the Secretary of State for Transport on the replanning of Network Rail's Investment Programme*.

49. Cost-benefit analysis with sufficiently broad focus should be used to decide which interventions offer the best value for money. If maintenance is deferred, the longer term costs of asset deterioration should be considered.

Determining the true cost of an asset and its changing value over time

50. Every asset goes through a cycle of changing value. In the early stages, funds are spent in advance of the asset benefits, and the project is in deficit until it starts to function. Thereafter it yields the benefits, hopefully as planned, subject to the continuing prudent 'investment' of ongoing operating and maintenance costs. As long as those are not excessive, the asset returns value greater than cost.
51. Meanwhile, the wider economic impact of the asset is also changing progressively. Developers may take advantage of the asset to invest in a cluster around it. Public services may come to rely on the asset in planning the distribution of those services – for example, health and emergency services. The asset should therefore be revalued at regular intervals to obtain a progressive view of its true value to society, taking account of the economic, social and environmental benefits it confers. A perspective on this may be to define the full set of impacts if the asset were to be lost at short notice. The asset's value as the lynchpin of a resilient infrastructure system may turn out to be of far greater value than the asset considered in isolation.
52. Once the true value of the asset is understood, the appropriate investment in maintenance and repair can be assessed. When that spend starts consistently to exceed the true value of the asset, it is time to plan for replacement with a new asset, perhaps accompanied by repurposing of the original asset to avoid total write-off.

The impact of external factors on maintenance

53. Effective maintenance requires constant review in the face of changing circumstances. These include the effects of climate change (such as changing sea levels and extreme weather events), changes in the level and type of loading and changes in interfacing systems. Failure to do so can lead to a situation where increasing levels of defects accelerate the rate of deterioration ending in asset failure with the subsequent cost of replacement being many times that of an effective maintenance regime. Once again, a 'whole system' approach is needed and analysis and monitoring must be rigorous with due consideration of possible unintended consequences¹⁴.
54. The Digital Railway initiative and any road traffic capacity improvement measures like the 'fleeting' of trucks and/or self-driving, communicating, cars will increase the loading of existing infrastructure and thus change maintenance requirements; in most cases meaning that maintenance levels will need to be increased. In many cases, there may be a choice between increasing maintenance or renewing an asset with one that is more resilient or has higher capacity. It is vitally important that the right tools are developed to allow those choices to be well made.

Governance of maintenance and renewal

55. The boundary between maintenance and renewal is immensely important if the two fall to different entities. This was a major problem in past, with the contracting out of railway maintenance that led to Network Rail bringing maintenance back in-house¹⁵. During the railway privatisation process, Department of Transport lawyers amended the proposed

¹⁴ As an example, one of the root causes of the Hatfield derailment was the introduction of new and better riding passenger trains and a reduction in freight traffic both of which led to significant reductions in rail wear; on the face of it a benefit. Unfortunately, Rolling Contact Fatigue (RCF) which had previously been worn away before it could develop into cracks was then able to develop to the point of catastrophic failure. Network Rail's maintenance regime now includes significant rail grinding to remove RCF.

¹⁵ Railway Gazette, June 2004, *UK brings infrastructure maintenance back in-house*.

contract between Railtrack and the maintenance units to reduce the risk to the companies purchasing those units. This unintentionally led to an incentive for contractors to under-maintain and thus be able to designate assets as needing renewal, passing responsibility back to the client. NIC must be careful not to create such perverse incentives.

Question 6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

56. The ability to collaborate is partly determined by regulatory structure and partly by clients' procurement strategies. Both need radical overhaul if better collaboration and competition are to co-exist, thereby stimulating innovation and growth simultaneously. Collaboration has generally been discouraged by UK regulators in favour of competition¹⁶, while other countries take different approaches to collaboration. If incentives to collaborate are present, this will help to improve infrastructure services in the UK, and increase the potential to export services abroad.
57. Clients need to properly embrace the collaboration agenda – many clients pay lip service to collaboration, but under pressure revert to type. Clients also need to consider consultants and contractors as equals, with differing skills that are brought to bear in the best interests of project delivery. Early engagement of contractors is vital¹⁷.
58. Much of our national infrastructure, whatever the sector or geographic area, is under the ownership or stewardship of a monopoly client organisation – one such example is Network Rail. Third party investors and those who deliver projects are thus inadvertently discouraged from competing with the monopoly organisation. The result is the inefficient delivery of new and upgraded infrastructure. Barriers to contestability should be identified and removed to encourage competition. For example, the Network Rail Board has commissioned an independent review to address this issue¹⁸. Similar consideration could be given to other sectors.
59. Extensive use of Building Information Modelling (BIM), both to manage information and to enable collaboration must be mandated on all publicly-funded projects, not just central government projects.
60. The UK's future infrastructure will be driven by some major decisions – such as those to embark on major new projects – but also by many smaller decisions taken locally or on a project-specific basis. There are levers available to policy makers to positively influence local and project-specific decisions, including regulations and standards.
61. The scale of many infrastructure projects means that it is not possible to prototype solutions. This is in stark contrast to the development of products in other sectors of industry, where trials are possible in research laboratories or manufacturing facilities. For this reason, Design Standards play a vital role in the construction sector by providing the means against which the adequacy of designs is verified prior to construction.
62. The NIC should therefore maintain specific interest in the impact and adequacy of relevant regulations and standards. NIC should engage with BSI, as the UK national standards body, to review how the UK should support future standards development, particularly in the context of Brexit and the importance of the UK remaining active in European standardisation organisations, including CEN¹⁹.

¹⁶ Sector regulators such as Ofcom, Ofgem, Ofwat and the Office of Rail Regulation all have a duty to promote competition in the interests of consumers. See for example: Competition and Markets Authority press release, December 2013, *Network launched to help drive competition in regulated sectors*, <https://www.gov.uk/government/news/network-launched-to-help-drive-competition-in-regulated-sectors>

¹⁷ Transport for London's Innovative Contractor Engagement procurement of Bank Station Capacity Upgrade is an example that has led to a gradually increasing benefit cost ratio.

¹⁸ The Hansford Review, <http://thehansfordreview.co.uk>.

¹⁹ CEN is the European Committee for Standardisation.

Question 7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

63. Government funding policy often operates on too short a time scale to be compatible with infrastructure projects. It is not untypical for organisations such as the Catapults (a number of which are focused on infrastructure) to be funded for five years and then subject to review and reapplication. Businesses need to see longer term commitment to funding and strategic direction to have the confidence to commit their share of investment.
64. Funding is accompanied by restrictions – for example, a requirement that it is spent on capital. Insufficient priority is given to the need for funding for operation, maintenance and sustaining existing infrastructure.
65. Consistent funding decisions are needed for all possible solutions. A major weakness of current policy is that infrastructure is financed from one budget, while maintenance comes from another, and lower cost management measures from a third. This makes it harder to select the most cost-effective solution, and often results in an over-emphasis on less cost-effective infrastructure-based solutions.

Question 8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

66. In the case of digital communications, there has been considerable controversy over a perceived conflict between the policy of promoting competition in broadband telecommunications service provision and the desire for universal service provision. It is recognised that a degree of state support, within the parameters of existing State Aids rules, is required and this continues to be provided through Broadband Delivery UK. New entrants in rural telecommunications infrastructure markets need to be encouraged and supported through better and more practical access to existing infrastructure such as ducts, poles and backhaul. Subcontracting arrangements should be encouraged for infrastructure delivery by the larger operators drawing on the smaller lower cost providers and local community self-help initiatives should be supported.

Question 9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

67. There is a body of research around valuing resilience and interdependence that has contributed to HMT guidance in the Green Book, and continues to be a valuable resource for NIC and industry²⁰.
68. Infrastructure systems are heavily interdependent. Most visibly, this is through the reliance of one system on another system. For example, the flood protection system is reliant on the electricity system for pumping water. Systems are interdependent as part of overall process flow – for example, rail needs road or urban transport for passenger dispersal at rail termini. Systems are also interdependent as users migrate from one system to another in the event of failure, such as when telecommunications systems or data networks are subject to heavy local demand if transport systems fail.
69. A key resource is the emerging national infrastructure systems modelling capability being developed under the Infrastructure Transitions Research Consortium²¹. This will support

²⁰ HM Treasury, Valuing infrastructure spend: Supplementary guidance to the Green Book https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/417822/PU1798_Valuing_Infrastructure_Spend_-_latest_draft.pdf

²¹ NISMOD (National Infrastructure Systems MODel) is the UK's first national infrastructure systems-of-systems modelling platform and database.

the design and development of infrastructure systems based on a better understanding of availability and performance. An important aspect of that research is demonstrating the potential consequences of scenarios of infrastructure failure and disruption. Quantification of potential for disruption and systemic risks helps to justify the case for investment in resilience.

70. The degree of system planning and quality of incident management needs to be improved, both within individual infrastructure systems and between system operators. Understanding and communications between systems operators is limited, but there is potential to improve cross-system performance through more consistent operating standards and strengthened operating protocols. This could include better links between transport jurisdictions - for example, TfL and Highways England - between modes, and between infrastructure system types.
71. Infrastructure is vulnerable to failure of individual components or sub-systems, as a result of age and wear, leading to broader impacts as a result of interdependencies. The growing interconnectedness of physical infrastructure with digital systems also means that parts of the infrastructure system are increasingly interdependent and vulnerable to cyber attack or to failures in digital components, which again could lead to cascade failure²². There is a need to ensure that systems have adequate levels of cyber safety and resilience.
72. The resilience of the infrastructure systems must be considered within a changing context, including climate change, demographic change and technological change.
73. A study on interdependencies in the infrastructure system by Engineering the Future²³ concluded the following:
 - Increased technical efficiency of the infrastructure should be valued, but a focus on economic efficiency can lead to reduced redundancy and diversity, thus reducing resilience. Increased resilience comes at a cost, so given that there are limits on the extent to which government and the public are likely to be willing to pay for resilience, failures cannot be completely avoided. 'Redundancy' is often taken to be a pejorative term, but in engineering terms, redundancy is essential to ensure resilience, so that service continuity is provided even when networks are disrupted. If networks are being run at 100% efficiency then there is zero redundancy. It is important that the benefits of redundancy and surplus capacity are properly valued.
 - As infrastructure systems are exposed to different and more extreme conditions, it is highly likely that degradation and interruption of vital services will occur at certain times. Therefore, there is a need to limit the consequences of failure and accelerate restoration capabilities, both through engineering solutions and managing consumer expectations.
 - All users of these services must be consulted on acceptable service levels and the cost that consumers are willing to pay for service at a given level. Communicating to the public the limits of resilience, and the need to modify demand on infrastructure, is a major challenge for industry professionals and politicians alike.
 - Methods for prioritising vulnerabilities in the infrastructure systems are needed for effective planning. Not all parts of the country face similar risk levels or similar impacts. A resilient energy infrastructure is a priority given the interdependence of all other sections on power.

²² The Royal Academy of Engineering is currently involved in a programme of work on the cyber safety and resilience of the digital systems that support critical infrastructure.

²³ Engineering the Future, February 2011, *Infrastructure, engineering and climate change adaptation – ensuring services in an uncertain future*, www.raeng.org.uk/adaptation

The cost of insufficient resilience – energy system

74. Any significant interruption to electricity supply in the UK will have severe economic consequences²⁴. The UK is becoming rapidly more dependent on electricity, and networks, processes and value chains are becoming increasingly complex and interdependent. These trends are magnified by increasing reliance on electronic communications technologies and the internet. The potential economic and social impacts of electricity shortfalls will, therefore, only continue to increase in the future.
75. The pace of change means that our understanding of the potential magnitude of these impacts is limited. Future shifts in the energy system may further increase the UK's dependence on electricity, particularly if heating and transport become more electrified. This could heighten the detrimental impacts of electricity outages in the future.

Learning from events

76. The impact of Storm Desmond on Lancaster in December 2015 illustrates how cascade failure can occur, with wide-reaching consequences. There is much to be learned from this event²⁵:
- Different models for locating responsibility for resilience will need to be considered, whether with individuals or service providers or some combination. It is clear that additional resilience is needed; where it is located in the overall systems requires more analysis.
 - There is considerable cost associated with providing standby arrangements that may be used only a fraction of the time, and also practical challenges in achieving this, including ensuring that standby assets are effectively maintained so that they work when needed. In the transport system, there may be a need for redundancy so that there is an alternative if one particular facility is out of commission. This is now a major part of infrastructure planning in earthquake prone countries such as Japan.
 - Another option is for regulators to allow greater rates of failure in the electricity or communications systems, but to ensure that there is a rapid-response mobile back-up system allowing services to be restored on a temporary basis. It is not clear whether this responsibility should fall to the privatised telecoms sector.
 - The complexity of the infrastructure system is increased by the large numbers of participants sharing responsibilities and with different incentives to optimise their own part of the system, and the wide geographical and organisation distribution of each single critical system. Commercial or regulatory incentives – to maximise profit or minimise the regulated asset base – may work against total system resilience.
 - The UK needs to decide where it wants its infrastructure systems to sit on the resilient-efficient spectrum and to bear this in mind when changing the engineering, regulatory or management structures of the industries concerned.

The resilience of digital systems

77. Cyber security (and physical security) must be treated as a fundamental system design issue from inception and must be kept under constant review throughout the life of the asset. Multiple layers of protection are essential.

²⁴ Royal Academy of Engineering, November 2014, *Counting the cost: the economic and social costs of electricity shortfalls in the UK*, A report for the Council for Science and Technology, <http://www.raeng.org.uk/publications/reports/counting-the-cost>

²⁵ RAEng, IET and Lancaster University, May 2016, *Living without electricity: one city's experience of coping with loss of power*, www.raeng.org.uk/livingwithoutelectricity

78. Safety-critical systems using software often involve long and complex validation processes leading to approval whereas emerging cyber threats require very rapid actions to combat them. To reconcile these different requirements, a good system architecture is essential.
79. The assumption that everything should be connected to the internet should be challenged, and both the benefits and risks explored. Each connected object can add to vulnerability from cyber attacks. In this context, whole system design is again very important.

Role of the regulators, CPNI and others

80. Each national regulator should appoint a lead person to lead on infrastructure resilience and related interdependencies. Each regulator should accept a duty of resilience and work with other regulators in a more joined-up way. Resilience audits could be considered as part of the reporting required to fulfil licence obligations. The activities of regulators and the Centre for the Protection of National Infrastructure also need to be more integrated, particularly in dealing with the risks of cybersecurity. OECD or a similar body should introduce international benchmarking for resilience.

Question 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

81. Infrastructure projects are planned and viewed too narrowly. The strategic aim needs to be clear and stated at the outset. A condition of planning consent should be the requirement for project sponsors to:
- *Set out a clear project definition*: the definition must encompass the totality of the project as well as each separate phase of the project, so that each phase can be judged on its own merits. It must also clarify where the boundaries of responsibility lie between the different stakeholders involved in delivery.
 - *Identify the "intelligent" client*: the client needs to take decisions, or take responsibility for making others take decisions where they matter very much to the success of the project. Independent oversight is needed, accountable to the client, but with the robustness to be able to challenge the client as well as the delivery team.
 - *Ensure shared objectives across the team*: cohesive and collective objectives should be shared across the client and delivery partners, as part of a no-blame culture.
 - *Minimise complexity*: This requires understanding and minimising the interfaces with different stakeholders and other components of the system in which the infrastructure project is being delivered.
 - *Impose strong systems architecture and standards*: this involves early definition of a common approach and language.
 - *Demonstrate a robust approach to innovation*: clarity is needed on when technological innovations should be considered and when the technology should be frozen so as not to cause delay.
 - *Adopt a whole-life cost approach*
 - *Ensure that the right skills and learning are in place*: it is important to ensure that people in the team have the right competencies, noting that requirements may change over time. Strong succession planning, good retention of corporate memory and organisational learning are all important.

Project Boards should include appropriate non-executive members to hold the project executive to account in relation to the above requirements.

Question 11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

82. The full impact of infrastructure assets on the environment needs to be understood. This would allow better assessment of the current impact of infrastructure assets on the environment, both positive and negative, and would provide a baseline for modelling the impact of infrastructure interventions. The carbon impact of infrastructure projects is a central concern, the reduction of which remains one of the key environmental statutory duties imposed on the UK through the Climate Change Act.
83. The focus should be not just on damage limitation but positive improvements to the natural environment. This should be achieved by adopting appropriate standards and use of assessment methodologies, including benchmarking against best practices (globally as well as UK wide) in such aspects as land use and value; soil and vegetation management; remediation of land contamination and ecological impact. A whole-life cycle approach would allow a focus on sourcing of materials and material efficiency; and reuse and recycling²⁶.
84. It should be recognised that the natural environment is not just in need of 'protection' but requires proactive management and can provide, and substitute for, infrastructure services. A systems view that uses concepts of natural capital and ecosystems services would help to ensure that the natural environment was protected and improved. One such ecosystems service is the use of floodplain storage to reduce downstream flood of wetlands to improve water quality and reduce the need for costly water treatment.
85. Each regulator needs an environmental policy basis and a means of ensuring consistent advice provision across areas and regions. Furthermore, advice, priorities and measures need to be debated and coordinated between regulators. Key cross-cutting measures could be identified.
86. Effective consultation and engagement with the public and environmental stakeholders is needed from early stages of infrastructure development, to maximise environmental opportunities through the options and design stages. Targeted and robust Environmental Impact Assessment would positively and pragmatically influence infrastructure design and construction.
87. Release of infrastructure data would facilitate research and innovation by third parties.

Question 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

88. Cost-benefit analysis (CBA) is frequently misused in decision-making. Typically, a scheme is designed, assessed using CBA, and accepted if the benefit/cost ratio (BCR) exceeds a current threshold. This only tells us that the scheme was potentially worth building, but not whether it was the most appropriate solution to the problem. It also encourages exaggeration of benefits. There is a strong case for adopting an alternative, problem-based, approach. In this, the problem is identified, the potential benefit to be gained by overcoming the problem assessed, the maximum project cost determined as that which achieves at least a given BCR, and solutions sought within that cost ceiling.
89. Current cost-benefit techniques are focused on stand-alone economic infrastructure. While current evaluation techniques assume future reliable performance, they should be much stronger in validating the realistic future cost of operation, maintenance and component

²⁶ Methodologies such as BREEAM Infrastructure provide a framework for such an approach and encourage ongoing innovation and collaboration.

replacement. Furthermore, cost-benefit techniques do not recognise the value of infrastructure that is essentially enabling infrastructure, with limited or occasional use. This includes failure to value spare system capacity that will enable future maintenance or system reconfiguration to be done without impacting on service levels.

90. Cost-benefit techniques do not support investment in enabling infrastructure for sectors that contribute to overall national performance but do not in themselves earn revenue in an economic sense. Skills training, defence provision, and social and welfare provision are all areas that support the wider economy and have their own infrastructure requirement but that are poorly evaluated in their contribution to the performance of the economy.
91. A serious weakness in the use of CBA is that can be used too late in the design process to justify schemes that have already been designed. This leads to post hoc justification rather than identification of alternatives or enhancement of scheme design. It would be preferable to use CBA to determine the cost ceiling for a scheme designed to achieve potential benefits, and then consider the full range of alternatives that are feasible within that cost ceiling²⁷.
92. There is a growing concern in the transport sector that CBA focuses too much on travel time savings, and too little on wider economic, environmental and social benefits. Many of the solutions that contribute most to creating better places to live and work would not pass a current CBA test.
93. In transport projects, on the cost side, there is a tendency to over-design, which can result in unnecessary costs, while environmental costs are often overlooked. On the benefit side, considerable care is needed in assessing and interpreting wider economic benefits, which often result from the relocation of economic activity rather than generation of increased productivity.
94. Much could be learned from examining exemplar projects to identify real benefits achieved – especially wider benefits, which are difficult to quantify at the cost benefit analysis stage.

Transport:

Question 13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Anticipated changes in travel patterns

95. With the pace of development, it is almost impossible to predict with any certainty the changes in travel patterns over the next 30 years. The advent of disruptive technologies will change things in ways that we cannot currently predict. We can only extrapolate current trends and make provision for disruptions. It is reasonable to expect that travel patterns will reflect increasing urbanisation leading to increased metropolitan travel, greater need for safety, reliability and resilience, and greater need to protect against security threats.
96. Future generational differences in transportation requirements need to be recognised, as do social trends such as an increase in leisure travel.
97. Examples of specific changes include:
 - Heavy freight is reducing, and there are opportunities around alternative 'hub and spoke' models of freight.

²⁷ The successful Train Protection Warning System (TPWS) in use on Network Rail's Infrastructure was conceived and selected in this way.

- The shift of retailing from 'the high street' to 'online', with a subsequent increase in local parcel delivery services and consolidation into large distribution centres. A number of companies are experimenting with novel delivery techniques such as the use of drones, and a breakthrough could be a game changer.

98. Future projections should be accompanied by design strategies that mitigate the risk emanating from such uncertainty. As illustrated below in Figure 1, suitable design strategies can include: design for adaptability; design for robustness/resilience; and design enabling accurate performance measurement.

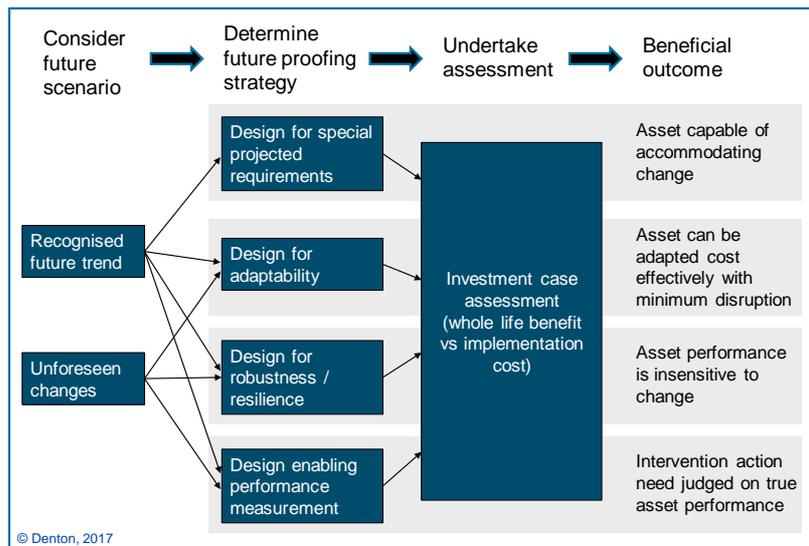

Figure 1: Design strategies for adaptability, resilience and performance measurement (Copyright: Denton, 2017)

Impact of the adoption of new technologies

99. The Transport Data Initiative (TDI) provides a very helpful focus for the many opportunities that data analytics offers across the transport sector. Data stores with the necessary data and metadata standards - interoperable across different modes of transport - remain vital. Equivalents to the resources of Transport for London (TfL) do not exist in every city.
100. The development of autonomous vehicles may make some of our current technologies redundant, while requiring newer technologies to be developed. The rapid development of self-driving road vehicles may see a shift back from rail to road, both for passengers and freight, if costs are competitive.
101. Remote video conferencing has not led to a reduction in the need for travel, despite predictions that it would. However, with the significant improvements in connectivity and bandwidth, it could be a more realistic alternative to travel in the future.
102. New technologies provide a range of means for improving the performance of the transport system²⁸, alongside regulatory or governance measures, either through maximising capacity, to make the most of available infrastructure; demand management designed to reduce congestion, especially at peak times, by displacing traffic to other

²⁸ Royal Academy of Engineering Challenge Paper, November 2015, *The transport congestion challenge: getting the most out of the UK's road and rail networks*, www.raeng.org.uk/congestion.

times of the day or less congested parts of the transport network or new technologies that offer new forms of travel or alternatives to travel.

103. A 2015 Challenge Paper by the Royal Academy of Engineering considered a range of measures that rely on new technologies²⁹, such as efficient pricing, smart motorways, connected cars, control, command and communication (CCC) technologies, and driver advisory systems (for the rail sector). Each measure was assessed on the basis of cost of implementation and potential to reduce congestion, allowing overall value for money to be determined. The main barriers to implementation were also considered.

Question 14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

104. For transport into, out of and around major urban areas infrastructure investment should first be targeted towards transport flow pinch-points. Small improvement schemes across each network make very large increases in performance as well as a wider user perception of a generally better operating network.
105. Government-supported investment in freight consolidation centres to support delivery to urban areas is essential. Consolidation of the many competing parcel delivery services would improve inefficiency both in terms of road use and energy consumption terms.
106. A number of cities such as Portsmouth and Southampton have been looking at trams following their successful re-introduction in Manchester, Sheffield, Birmingham and Nottingham. There is evidence that these are more acceptable and attractive as public transport than buses as well as being clean, and energy- and space-efficient. Rapid-bus transit is an alternative³⁰.

Question 15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

107. A comprehensive approach to multi-sectoral modelling will help to identify plausible schemes that meet social and business needs across a range of mid- to long-range mobility services. Good data sets will be a prerequisite to assessing value in an holistic manner, as will convening mechanisms for open and frank conversations about the compromises necessary for any solutions to be practicable.
108. Outside single urban areas, government support to deliver passenger modal interchange is essential. Ease of use is a major barrier, and would benefit from the introduction of common payment systems. Journey planning tools that work across systems are developing, but greater operator collaboration is needed.
109. The advent of autonomous electric cars potentially offers a major shift in transport system capability. The road transport problem could rapidly move from environmental to congestion, with electric cars being seen as a very efficient means of high quality personal mobility from dispersed areas into transport hubs.
110. Whilst Hyperloop has not yet been proven, the UK should consider this as a potential disruptive technology in future and one that has the capacity to enhance the coherence of the UK by linking Edinburgh, London and Cardiff.
111. Infrastructure to support new forms of transport such as autonomous vehicles and electric cars will be needed. The technical feasibility and cost-effectiveness of motorways with inductive loops for charging and powering electric vehicles on the go should be investigated.

²⁹ Ibid.

³⁰ Ibid.

112. Improvements in reliability, capacity and interconnectivity of intercity rail are possible provided that the links at either end provide seamless interconnection to other modes. The costs of passing through highly populated areas and high levels of environmental protection need to be de-coupled from the business case for high speed lines when making comparisons with other countries³¹.
113. The need for additional airport capacity in the South East has been analysed and debated many times. Delay is one of the biggest risks to business.

Question 16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

114. It may be easier to justify vehicle charging as part of the cost base of shared vehicles. With the advent of autonomous taxis, there may not be a significant reduction in the number of moving vehicles and congestion but clearly there would be a better utilisation of vehicles and a significant reduction in those that spend much of their life parked. A shift away from systems such as vehicle licensing towards a more use-based charge thus seems highly likely.

Question 17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

115. The highest value infrastructure investments to secure digital connectivity across the country are the antenna towers, sites, ducts, poles, local fibre access and street furniture necessary to deploy modern digital technologies including 5G. Technology trends are relatively stable in these areas. However, the policy issues are complex and likely to be controversial. Policies are needed to significantly bring down the cost, promote competition and extend reach. Even when the essential policy reforms have been made, the implementation lead times can be long. For these reasons, they should be a priority for the NIC.
116. Developments in technology are rapidly removing the historic distinctions between fixed and mobile communications services. The regulatory regime should be reformed to reflect this new reality.
117. Recognition should be given to the need to establish improved minimum standards for availability and resilience of the communications infrastructure, particularly in the context of back-up power. The role of a provider of last resort should be recognised and rewarded accordingly. Mobile and fixed communications have a vital role in containing cascade failures of infrastructure.
118. Other important steps in the UK securing digital connectivity across the country include: the introduction of 4G, including 4G spectrum releases in 2017; the introduction of fibre to the home during the period 2017 to 2019; phased releases of 5G spectrum in the years 2017, 2018, 2019 and 2020 and analog television switch-off dates, phased between 2018 and 2025.

Question 18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

119. Provision of pervasive high performance broadband access, both fixed and mobile, to both urban and rural areas, is an economic imperative for a 21st century data-enabled

³¹ Japan, Italy, France, Germany, Spain and latterly China have all benefited from high speed rail.

economy. The government, following Ofcom recommendations, is moving towards a Universal Service Obligation at a minimum of 10Mbits/sec download speed by 2020. There should be a commitment to regular review, with the possible potential upgrade of this minimum. Government should place greater emphasis on supporting local initiatives and smaller providers.

120. 5G has the potential to transform digital connectivity across the UK in the near future but only if the regulatory regime is also transformed. The need for access to enabling physical infrastructures must be addressed at an early stage. There has been a failure to resolve some of the underlying regulatory issues that will enable the benefits of modern communications to benefit all in society, although the issue of radio spectrum has had much attention. The vision and plans for 5G and the ongoing evolution of communications infrastructure needs to break down the silos between fixed and wireless communication technologies and regulatory models.
121. The release of radio spectrum at the 3.6 GHz band offers a huge opportunity for data transfer 'on the move'. A combination of measures will be needed to deliver the leap in performance including exceptionally wide radio channels, spectrum sharing, policies to reduce small cell costs, better access to sites and a framework for aggregating public and private 5G small cell coverage. Significant regulatory innovation will be needed.
122. Policy makers must embrace the entire 5G fabric - including optical fibre backhaul and the integration of new 5G components with the existing 4G and WiFi - to unlock really high performance. Coverage and its quality will be the single biggest issue for policy makers in the 5G era.
123. There is a view that if digital connectivity is viewed as a utility, there is a risk that price pressure may deter investment. Pricing needs to reflect demand, and some areas may have lower demand or lower levels of fibre backhaul. Economies of scale are needed for capital expenditure. At the operational expenditure level, there is growing choice in service providers such as mobile virtual network operators (MVNO's), service providers, Internet of Things specialists and retail distribution.
124. The shape of the market will change over time, with key players including not only providers of network coverage, but also providers of billing and customer care, data security and devices. Currently regulation tends to favour international internet players at scale versus network investors.

Energy:

Question 19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

125. Over the next decade, the UK needs to invest in testing and proving key 'next step' options for low carbon heating ahead of major infrastructure roll-out in the 2030s and onwards. There is no 'silver bullet' solution for replacing current domestic gas boiler arrangements as economics, effective technical performance and consumer value propositions are all driven by local factors including the specifics of the building fabric, occupancy and use and the availability of heating sources whether electricity, gases (including hydrogen), waste heat (district heating networks) or biomass. Critically, there will be significant economic benefit from seeking opportunities to integrate heating systems with the rest of the UK energy system – particularly utilising waste heat from industrial installations (including power stations) and linking to central hydrogen production facilities which can service power, heat and transport demands.
126. While the widespread delivery of decarbonised heat only needs to be implemented post 2030 to meet UK climate change goals, considerable effort is required pre-2030 to build

consumer and investor confidence and industrial capability. The Energy Technologies Institute (ETI) has identified practical steps in this period as including:

- gradual deployment of heat pumps and biomass boilers particularly for off-gas grid homes
- continued development of district heating solutions in suitable localities, particularly where a waste or another cost-effective heat source is available
- continuing emphasis on building energy efficiency measures, including cost-effective retrofits, actions to ensure thermal efficiency in new buildings (for example, building codes) and development of consumer-friendly controls and installations
- investigation of repurposing the gas grid to carry hydrogen and the necessary retrofits required in homes and to the gas system, noting that hydrogen at this scale can only realistically be supplied in combination with carbon capture and storage (CCS)
- progressing a range of solutions for industrial heat (at a range of scales) including biomass, combined heat and power and CCS.

127. As set out in the 2015 report by the Royal Academy of Engineering, political decisions must take account of long technical and investment timescales³². Large-scale changes in the system must be carefully planned and based on solid evidence, ideally from community- and regional-scale pilot schemes. Clear, credible and costed strategies need to be laid down against which industry can deliver.

128. The physical, decontamination and human costs of decommissioning the existing petro-chemical supply chain need to be addressed, if successful de-carbonisation is achieved.

Question 20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

129. The most effective 2050 'zero carbon power sector' will be integrated with the national and local heat, transport and industrial sectors so as to maximise the synergies and opportunities from effective operation of an integrated set of systems – reducing costs and increasing the resilience of all these critical sectors and operations.

130. The effective integration of the various systems is of greater value than setting definitive goals for the make-up of the individual elements. For example, the widespread deployment of a CCS network allows continued use of gas for power generation, provides the platform for large scale economic production of hydrogen (for power, heat and transport) and offers a route to decarbonising major industrial emitters – overall saving around 1% of GDP per annum. Effective decision making in support of such an integrated system implies a need for considerable expertise in system-level modelling, planning and analysis – capabilities being developed and implemented increasingly effectively through the UK's engineering and academic base.

131. Within an effectively integrated structure, the power sector would most likely be based on a balanced mix of generation approaches - primarily:

- nuclear (large and potentially smaller modular reactors)
- gas or biomass fuelled plants linked to CCS
- wind (on and offshore), and
- further interconnectors.

In addition, hydrogen-fuelled turbines can offer vital flexibility in the medium term (with hydrogen storage providing large-scale energy storage) noting that the most efficient route to production of large volumes of hydrogen is from natural gas linked to CCS. Other renewables are likely to play supporting roles limited by resource availability and distribution, such as solar and marine, including tidal lagoons.

³² Royal Academy of Engineering, October 2015, *A critical time for UK energy policy: what must be done now to deliver the UK's future energy system*, A report for the Council for Science and Technology, <http://www.raeng.org.uk/publications/reports/a-critical-time-for-uk-energy-policy>

132. There are currently serious risks in the delivery of the optimal energy system for the UK. The whole energy system faces massive changes to deliver against all aspects of the 'trilemma' — cost, security and decarbonisation. Time is of the essence, with decisions taken now affecting what the system will look like in 2030 and beyond³³. The Royal Academy of Engineering ³⁴ has recommended urgent actions for policy makers to take.
133. Real-world demonstrators are vital for understanding how technologies will integrate and, most importantly, how different options will function effectively for all stakeholders. Failure to carefully plan the development of the whole energy system will result, at best, in huge increases in the cost of delivery or, at worst, failure to deliver.
134. There could potentially be transformative technologies that would result in a step-change in delivery up to 2050 or beyond, such as nuclear fusion.

Question 21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

135. The primary impacts of greater penetration of low carbon vehicles are likely to be a continuing reduction in the need for liquid fuel supply infrastructure and a steady increase in the demands placed on the electricity distribution network for power supply to recharge vehicles – both full electrics and hybrids.
136. Powertrain efficiency improvements alone continue to deliver a ~1% p.a. improvement in fuel efficiency; coupled with additional innovations this should lead to a reduced liquid fuel demand irrespective of the feedstock being fossil or biofuel based. This has implications for the refining sector as well as the fuel supply infrastructure needs.
137. Perhaps more than in any other sector of the UK energy system, there remain major uncertainties in the rate at which consumers and operators will elect to take-up low carbon vehicles and infrastructure solutions need to be aligned to this uncertainty with a focus on delivering optionality and flexibility across the system rather than a specific, single solution. Prior to trials, it is difficult to predict whether the combination of smart control and vehicle-to-grid (V2G) strategies will be sufficient to avoid the need for significant distribution network upgrades.
138. Managed charging of plug-in vehicles will be critical to mitigate the need for major distribution network upgrades and additional peak demand generation capacity. This needs to be trialled at large scale and the economic benefits case to be developed. Similarly, the benefits that V2G release of stored energy could bring need to be evaluated through real-world trials.
139. Hydrogen fuelled vehicles may also form part of the UK mix but their widespread introduction will be primarily driven by manufacturer decisions on vehicle development and the availability of fuelling infrastructure. The former cannot be controlled at a national level; it can, however be influenced through clear, long-term policy signals. These could address the nature of a low carbon transport system post 2030 and the mechanisms by which this could be delivered most efficiently as part of an integrated, system-wide approach to energy delivery and demand management. Should hydrogen be adopted at scale for generation, industrial or domestic heating then the necessary distribution system would also serve as the major part of a hydrogen vehicle refuelling infrastructure.
140. Electrification is already well underway on the railway system, but large scale EV roll-out could result in an overall doubling of current electricity demand levels (averaged over the year) and would require substantial upgrades in the distribution system³⁵. It would also

³⁵ Ibid.

require a step change in battery performance, in terms of storage capacity, cost, lifetime and recharging time.

141. Beyond private passenger transport, other areas of transport, such as long haul and heavy duty transport remain the most difficult to decarbonise and will likely rely on the establishment of sustainable biofuels or hydrogen.

Water and wastewater (drainage and sewerage):

Question 22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

142. There is a growing risk of drought as a result of population growth and increase in per capita consumption, environmental drivers that reduce abstractions and the changing climate, with possible consequential effects on households, businesses and the economy more widely. The environment suffers if too much water is abstracted.
143. The 2014 Water Act introduced a duty of resilience for the sector, but there is still a need to understand the level of resilience required in relation to droughts and extreme events and floods. Various actions are needed to make the sector more resilient: reducing or shifting demand, reducing leakage and increasing supply. The latter would require new infrastructure and new technologies such as new reservoirs, desalination, reuse of waste water or large-scale inter-basin transfers.
144. A systems view is needed of the whole water cycle, in order to address the following opportunities and challenges:
- cross-sector collaboration – for example, this would be of benefit in reducing energy use by the water sector. Future solutions such as desalination, reuse of waste water and bulk transfers all have an energy use associated with them, and therefore integrated solutions which benefit both sectors will be becoming increasingly valuable
 - differing perspectives of the various stakeholders, including water companies, government, the regulators and customers.
 - the need for environmental protection - the environment itself is a national asset, and the value of maintaining it in a clean, resilient state is an important consideration
 - the interactions between water supply and wastewater – waste water can be viewed as a resource.
145. A national solution is required that accounts for regional and local variations in resilience, and provides a clear course of action for delivering long-term resilience. It should take into account the condition of assets, customer expectations, climate change and demographic change. It would also need to consider the structure of the industry, the role of the regulator and business planning cycles.
146. A national adaptive plan - recommended in a study on resilience by Water UK³⁶ - would support ongoing water resource management plans and provide a broader view of requirements. This approach would require cooperation between companies that are operating in a competitive market. There is more work needed in establishing how such a plan would function in practice.
147. A combination of interventions is required; there are no universal solutions. Interventions need to be chosen on the basis of their cost-effectiveness at reducing risk to water supplies and their robustness and adaptability in the face of future uncertainties. There is potential for further action to reduce water use and reduce leakage.

³⁶ Water UK, September 2016, *Water resources long-term planning framework (2015-2065)*.

148. Further strategic supply resources are likely to be required at some point in the future, depending on changes in demand and climate. Supply options like inter-company transfers may help to improve resilience, but their effectiveness at reducing risk in widespread droughts needs to be carefully analysed.

Question 23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

149. Design of drainage systems is highly place-specific. Enlargement of existing systems in urban areas is very expensive – as has been seen in the Thames Tideway tunnel system. Therefore, measures that can keep storm water out of sewers are likely to be cost-effective, such as Sustainable Drainage Systems (SuDS) or dual systems that take foul waste and rainwater in separate sewers.
150. Regulatory arrangements governing the uptake of SuDS are weak. A dual system would be more efficient and adaptable – but retrofitting such a system would be very costly and would require a long-term commitment. The NIC should consider whether a long term commitment to a dual system is desirable.

Question 24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

151. A whole catchment approach is required because interventions at one point in the catchment can have impacts elsewhere. Whole catchment approaches have been promoted for example through River Basin Management Plans and Catchment Flood Management Plans. For the time being however, the different catchment functions have not been dealt with in an integrated way. Promoters of infrastructure have not worked in an integrated way, which means that opportunities for multi-purpose infrastructure have not been accessed. Modelling, simulation and optimisation methodologies now provide the opportunity for catchment management to be effectively analysed and optimised.

Flood risk management:

Question 25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

152. The level of resilience should depend on the value of the assets being protected and the potential for disruption. A national perspective is required. When analysed at that scale, extreme floods are not at all rare. For example, analysis conducted for the National Flood Resilience Review³⁷ demonstrated that the probability of a flood that is so severe that it reaches or exceeds the Extreme Flood Outline (roughly a 1:1000 year return level) occurring on a river somewhere in England or Wales during a 10-year period is approximately 90%. The probability of a flood of this severity occurring on a river somewhere in England or Wales in any given year is approximately 20%.

Question 26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

153. Natural Flood Management (NFM) has been shown to have some effect on reducing flood peaks in small catchments in small- to medium-sized floods. The evidence of effectiveness is weak for large floods and large catchments. That is not just because large enough NFM experiments have not yet been carried out – it is also the case that the effectiveness of NFM tends to diffuse downstream. NFM does however bring significant co-benefits, notably habitat creation/restoration and improvements in river water quality, which may reduce water treatment costs.

³⁷ HM Government, September 2016, *National Flood Resilience Review*.

154. The National Flood Resilience Review, and Property Level Flood Resilience Action Plan, were published by Government in September 2016. These reviews – created in partnership with stakeholders from the public, private and third sectors – show that for the short, medium and longer term, it is critical to embrace the whole system in a joined-up way, and to consider national flood management schemes alongside permanent and temporary defences, river dredging and other interventions. For this, system modelling and system design work is key.
155. A combination of measures will be critical for meeting the challenge of climate change. Whatever measures are put in place, it is inevitable that a proportion of buildings and critical assets will be at risk of flooding. Therefore, embracing resistance and resilience at a property or asset level is essential, requiring a change in culture and behaviour by government, business and the public.

Solid waste:

Question 27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

156. The main financial incentive in the solid waste sector is the landfill tax. This has been very successful in incentivising the development of recycling and recovery infrastructure, and could be seen as an exemplar of using taxation to achieve environmental outcomes. The landfill tax rate increased rapidly under the 'escalator' scheme, but has now stabilised. At present, the tax rate appears to be a sufficient incentive to recycling and recovery, but this should be kept under review as the costs of various waste management routes vary over time. Any dilution in proximity principle³⁸ and producer pays principles could threaten efforts to drive innovation in recycling and recovery.
157. Lack of clarity on renewable energy (heat and power) incentives is a big obstacle to funding of large scale waste infrastructure. Clear financial incentives and commitment to them based on sound strategies are key to delivering funding. For example, regulatory and financial incentives could be better aligned to drive recovery of heat from waste. Policy places emphasis on schemes that will deliver power AND heat but financial incentives for heat supply no longer exist.
158. Improvement in recycling performance from commercial and municipal waste will likely require intervention to help drive recycling of difficult materials such as mattresses, plasterboards, light fittings etc. This could interface with circular economy objectives.
159. There needs to be a closer alignment of the regulatory drivers and opportunities for improvements in sustainable commercial and industrial waste management alongside municipal waste management to promote opportunities for local authorities and businesses working in synergy.
160. Measures to eliminate uncertainties in market economics and regulatory frameworks through clear end of waste criteria and statutory certainty (especially in the run up to Brexit) would kick start infrastructure funding, including funding for innovation.
161. It is unclear how the move to further devolution will affect the waste management sector. Opportunities for improvement in waste management funding and infrastructure development across the public and private sectors should be at the forefront of objectives and target setting for devolved bodies. Opening up opportunities for further prudential³⁹

³⁸ The Proximity Principle highlights a need to treat and/or dispose of wastes in reasonable proximity to their point of generation.

³⁹ Local authorities can borrow to invest in capital works and assets so long as the cost of that borrowing is affordable and in line with principles set out in a professional Prudential Code.

borrowing for devolved bodies or innovative public financing mechanisms would provide the necessary kick-start in funding.

162. The scale of infrastructure for waste is generally best suited to development control at a local authority level but the network of infrastructure available to deliver on a national level needs national government (or a national body) oversight and facilitation to deliver a cogent and strategic network of facilities. National imperatives are not always apparent, or given enough weight, at the local level.
163. The availability of excess energy-from-waste capacity in Europe has incentivised export of UK waste in recent years (thereby reducing waste landfilled), at the expense of developing UK-based treatment capacity. Whether or not this situation persists depends on regulatory factors (particularly post-Brexit) as well as the capacity of the European market.
164. Most waste operators still see there to be a 'capacity gap' in the UK, particularly for commercial/industrial waste treatment. Most municipal waste streams are already contracted, and the commercial/industrial market is less predictable, with fewer long-term contracts. This makes it more difficult to secure financing for new facilities.
165. The landfill tax incentivises innovative technologies, insofar as they represent alternatives to landfill, but does not explicitly support innovation as opposed to proven technologies. In most cases, the constraints on innovation are technical and financial, rather than regulatory. Regulations need to permit innovation and allow alternatives to landfill, but at the same time manage the risk to the environment. Increased landfill tax may also lead to waste producers seeking to maximise the use of exemptions and other low-cost, non-landfill disposal and recycling routes.
166. Waste producers have a legal duty of care to ensure that their waste is managed lawfully, although formal 'producer responsibility' schemes apply to only a limited number of sectors. Increasing the amount of waste falling within such schemes could improve recycling rates and also contribute to the circular economy, although this may impose additional costs on business and consumers.

Question 28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

167. One of the greatest barriers to establishing and driving a more circular economy is that the UK's measures of success are built upon a linear model. Measures of 'growth' are linked to consumption of good and services. Greater reuse and recycling of goods, which lies at the heart of a circular economy, will by definition reduce demand for new goods and will deliver negative economic growth as currently measured. A major rethink of the UK's (and the world's) economic model is required if a circular economy is to be encouraged.
168. A more circular economy could be achieved if the following were in place:
 - *Better data to understand 'material' flows* – government and business need much better data to understand how raw material and products track through into wastes and by-products. A more systematic approach to gathering data is needed across UK.
 - *Better data to understand the costs and benefits* – many models are unproven, while emerging models are still evolving, alongside the costs and benefits. Greater sharing of outcomes from projects would help business and society understand the potential.
 - *Awareness of various circular economy and practical business models* – there needs to be greater awareness of the models that exist, the success factors and lessons

learned. The infrastructure sector has much to learn from the manufacturing sector, for example.

- *Business Innovation and agility* - global leaders such as Unilever are driving innovation and have the resources to achieve this. SMEs struggle with resources to develop concept, test, build business model, engage wider business community and market product.
- *Financial support* – is needed to help start-up/SME companies move conceptual models through to commercial delivery. For example, small start-ups with a strong concept may need support in aligning products and services to Tier 1 companies to address quality assurance, supply chain requirements and market engagement.
- *Quality protocols* – replacement of new products with materials and goods that include re-used or recovered components must be able to demonstrate 'like for like' environmental, quality and safety requirements. In some cases, this challenge is perversely affecting new CE materials from making progress into established markets.
- *A consistent approach to developing CE across UK* - devolved governments and the UK government are pursuing different programmes of implementation, whereas many businesses and their supply chain span the UK. This can discourage action.

169. In relation specifically to infrastructure, the following are barriers to the circular economy:

- There are established ways of delivering key infrastructure when it comes to materials and resources and waste. Many of these approaches are starting to accommodate CE models, such as for example, deploying innovative materials like cement-free or low-carbon concrete and redeploing cut-and-fill spoil across projects. However, making the transition from delivering a construction product to a construction service will take time as current commercial models perpetuate themselves and downcycling is still prevalent. A material loses more value each time it comes to the end of its life and ends up in a lower value application.
- A common misconception is that infrastructure lifecycles are too long – for example, 120 years – to consider end of life. However, many infrastructure components have much shorter lifecycles, and can be monitored and replaced, recycled or refurbished. For example, most modules may have a 20-30 year lifecycle, like an electric line or a steel barrier or a road surface pavement. It is the infrastructure footprint that has a long life-cycle and that can stretch to hundreds of years, though may have different applications in that time period – for example, roman roads and viaducts.
- One barrier to wider implementation and scaling up of circular economy approaches is the current lack of an effective programme or corporate-level measurement or metric of success, although these are currently in development.
- There is a belief that statutory design guidelines are sometimes inflexible and procurement rules can inhibit innovation – this is true to some extent, but innovative approaches do get piloted. A more serious problem is corporate inertia and risk appetite preventing pilot scaling beyond project trial.
- Infrastructure-specific cost benefit models for the deployment of the circular economy approach are still work-in-progress, however, the benefits are numerous, and include: significant reduction in raw material extraction; better productivity from existing resources; smaller amounts of waste to landfill; competitive advantage; decongestion of logistics pathways; avoidance of the need for remediation; broader environmental benefits.

Appendix

We gratefully acknowledge the contribution of Fellows of the Royal Academy of Engineering to this response, who attended a workshop and/or provided written contributions:

[Names of contributing Fellows redacted].

Royal Institute of British Architects response to National Infrastructure Commission Call for Evidence

The Royal Institute of British Architects champions better buildings, communities and the environment through architecture and our 40,000 members. We provide the standards, training, support and recognition that put our members – in the UK and overseas – at the peak of their profession. With government and our partners, we work to improve the design quality of public buildings, new homes and new communities.

1. The RIBA welcomes the opportunity to respond to the National Infrastructure Commission's (NIC) National Infrastructure Assessment Call for Evidence.
2. The RIBA's response to this consultation is focussed primarily on adding detail to the issues we raised at the NIC's two initial workshops on energy and flood risk management.
3. Our evidence additionally addresses the cross-cutting issues identified in the Call for Evidence relating to designing, planning and delivering infrastructure to create better places to live and work, and how the interaction between infrastructure and housing can be incorporated into this.

Energy

4. **An ambitious national energy efficiency scheme represents the best investment for achieving a sustainable balance between energy demand and supply.**
5. The RIBA is very pleased the NIC has recognised housing as a key infrastructure issue. However, the only way to make our built environment fit for the future is to fully integrate built environment energy efficiency within the UK's Infrastructure Plan.
6. We hope that the NIC will use this opportunity to set out an ambitious national energy efficiency scheme of buildings to be embedded within the National Infrastructure Plan, which represents the best investment for achieving a sustainable balance between energy supply and demand.
7. No other investment can stimulate as much economic growth and create jobs in every constituency in the UKⁱ. A programme to make UK domestic stock energy efficient would provide net economic benefits of £8.7 billion. This is comparable to the economic benefits of investments in HS2 Phase 1, Crossrail and new roadsⁱⁱ.
8. Deploying infrastructure funds to support a national energy efficiency programme could create up to 108,000 new jobs, doubling the number of jobs in the sector to 260,000ⁱⁱⁱ. Apart from generating significant economic growth in all regions of the UK, energy efficiency investment would also boost Britain's energy security by reducing gas imports by 26%^{iv}.

-
9. The benefits of investing in energy efficiency could go deeper and further than other more visible infrastructure schemes that are already being financially supported by government. The large net economic benefits outlined above excludes the added value of this approach through many of its social benefits, such as health and wellbeing improvements; and its critical ability to address national challenges of safeguarding energy security and tackling climate change.
 10. By investing in energy efficiency building stock, Government can substitute for expenditure on more visible elements of energy investment like power stations, energy storage and the grid, through more effectively reducing demand.
 11. The private sector is already paving the way towards a low carbon future. The RIBA would like to see the implementation of a very successful large scale retrofit scheme in the UK based on the successful Energiesprong model which is currently benefiting 111,000 properties in the Netherlands^v.
 12. The innovative whole house retrofit scheme helps homes achieve net zero energy levels through clicking on off-site manufactured building envelopes onto existing properties. It is a market driven initiative funded by savings delivered via a contractor-guaranteed energy performance contract. Plans are underway for housing associations and local councils in London, Birmingham and southern England to pilot the large scale carbon neutral retrofit of at least 1000 properties by January 2018.
 13. Despite its knowledge, expertise, and established business models, the private sector is not able to implement large-scale roll out of energy efficiency measures without Government intervention. The success of Energiesprong in the Netherlands relied on central Government starter capital which has helped develop economies of scale and enabled the business to work through any teething problems to achieve higher energy savings in energy costs than initial costs of the retrofit^{vi}.
 14. Other reasons for Government intervention in driving a national energy efficiency programme are long-established. Many energy efficiency installations have a long asset life, while the private sector looks for shorter-term payback. Much of the private sector also does not consider externalities such as carbon benefits, and struggles to secure business without long term policy for energy efficiency.
 15. Over £100 billion had been allocated to support infrastructure projects over the next 5 years under the Spending Review 2015^{vii}. The publicly funded investment programme should prioritise the upgrade of existing building stock, minimising the energy demand of new buildings through maximising fabric energy efficiency, and driving up standards and quality control to ensure buildings perform as designed.
 16. Research has shown that if a refurbishment incorporates advanced energy-saving techniques, designed and administered by suitably trained architects, this has the potential to reduce overall energy usage in retrofitted domestic and non-domestic buildings by up to 90% with as little as 3% additional cost over a standard refurbishment that would have a relatively poor impact on energy use.^{viii}

17. There is a clear case that energy efficiency delivers value for money and added value. By accepting and embracing domestic energy efficiency as infrastructure the benefits could potentially go further and deeper than those offered by more visible infrastructure schemes that are already being financially supported by government.

Flood Risk Management

18. **Existing investment in flood risk management can be better utilised if a holistic approach to water management and flooding was supported.**
19. Flooding, droughts and watercourse pollution are all signs of stress where developed areas have a troubled interaction with the natural water cycle. The way places and drainage systems are planned and designed can either exacerbate or mitigate these issues by either facilitating or disrupting the natural water cycle.
20. This basic relationship between cities and water is often overlooked in planning and design decisions, leading to costly investments in flood defences that have limited effectiveness, and in outdated urban water and sanitation infrastructure that perpetuate the problem.
21. Green infrastructure, water resilient design, and spatial planning are the raw ingredients of ‘future-proofing’ infrastructure and cities against excess water and flooding, as they harmonise the built environment with its water cycle.
22. Sustainable Drainage Systems (SuDS) are a more cost-effective and environmentally friendly alternative to our current sewage infrastructure. There is widespread evidence that SuDS can efficiently deal with surface water, and can already be delivered cost-effectively^{ixx}. During the passage of the Housing and Planning Act, the Government committed to a review into the use of SuDS in new developments.
23. However, we need to go further than green infrastructure and start joining the dots between flood risk management and water resource management, and start putting water at the heart of discussions about what makes places great to live.
24. Water Sensitive Urban Design (WSUD) supports healthy ecosystems, lifestyles and livelihoods by creating buildings and public spaces that can utilise the most appropriate source water for their use. This helps take pressure off existing infrastructure by limiting the amount of water entering sewers and the need for water abstractions.
25. WSUD features bring additional social, economic and environmental benefits – e.g. helping to reduce energy demand of cities through water features that help cool buildings down. Its successful and growing application in the UK and various countries around the world (Australia, Singapore, New Zealand) demonstrate WSUD can be applied at all scales, from a single house to an entire city, and retrofitted to existing developments as well as built in from the start^{xi}.

26. Through its multi-functional benefits to communities WSUD could link flood defences with urban regeneration and development. This approach could help to increase private sector investment in flood risk management, which in turn could help to address the estimated £1bn shortfall in flood defence barrier funding. Many of our members are already pioneering such approaches and we would welcome a meeting with the NIC to explore WSUD's potential to drive infrastructure investment value for money further.

ROYAL TOWN PLANNING INSTITUTE:

RESPONSE TO THE NATIONAL INFRASTRUCTURE COMMISSION CALL FOR EVIDENCE

10 February 2017

Introduction

The Royal Town Planning Institute champions the power of planning in creating prosperous places and vibrant communities. Our 24,000 members are from the private, public, academic and voluntary sectors. Using our expertise and research we bring evidence and thought leadership to shape planning policies and thinking, putting the profession at the heart of society's big debates. We set the standards of planning education and professional behaviour that give our, wherever they work in the world, a unique ability to meet complex economic, social and environmental challenges. We are the only body in the United Kingdom that confers Chartered status to planners, the highest professional qualification sought after by employers in both private and public sectors.

Two Overarching Points

We thank the NIC for the opportunity to respond to this consultation. We provide answers to selected questions in the call for evidence are set out below (at page 3). But we also have two overarching points to make regarding (A) the need for high-level agreed outcomes and (B) the nations of the United Kingdom.

A. The need for more detailed high-level outcomes

We touch on this in further detail under question 1. But addressing the questionnaire to the needs of individual cities and regions can only go so far. We appreciate the NIC call for evidence was issued in October 2016, but now with the UK Government's draft proposals for an Industrial Strategy, the emerging 25 Year Plan for the Environment (and to a rather lesser extent also the Housing White Paper) there is a need for much stronger *coordination* between these strategies, and also. We explored the issue of the lack of coordination between major government strategies in our [Map for England](#) research and pilot project in 2012, and have made the argument for more coordinated spatial decision-making in [previous RTPI papers](#).

In the past, national infrastructure choices have been sub-optimal in part because:

- the consultative processes have been unnecessarily confrontational because of the *ad hoc* nature of the project justification;

- there has been no real basis for taking account of cumulative national or city-regional impacts and benefits, because of the project-based (and trend-based) assessment processes involved (as exemplified by the decisions on an estuarine airport);
- investment has tended to reinforce the problems of “peripheral” regions and areas, which is to say their relative neglect in investment and consequently lower growth and productivity;
- opportunities for growth by creating new markets and new demands **where the return on investment may be higher** have been overlooked.

The solution of these problems is made more difficult by the limitations on the NIC’s formal role, which is limited to making an Assessment, rather than identifying, through helping central government to coordinate its various key strategies (industry, housing, environment etc) so as to reach **more detailed agreed national outcomes**. The NIC could then recommend how these can be achieved through infrastructure investment. Unless this challenge is addressed there is a continued risk of *ad hoc* selection on a project by project basis, which would in all likelihood tend to replicate some of the problems of the past.

We do not consider that the three objectives of the NIC (on economic growth across all regions, competitiveness and quality of life) really provide a sufficiently detailed steer to overcome past weaknesses in decision-making.

One way then that these objectives could form a more useful basis for assessment is to develop them such that they make reference to the *spatial* dimensions of infrastructure investment decisions, in two main respects: how infrastructure could help to achieve the objectives set out in government strategies; and (relatedly) how infrastructure could generate the greatest returns on investment including by being directed to areas and regions that might benefit most (for example in terms of improved productivity and quality of life). This would provide a much stronger rationale for infrastructure decisions which might help to resolve some of the issues noted above.

B. Nations of the UK

The UK NIC consultation refers to the Commission has having a remit for the whole of the UK. However, a recent consultation considered proposals to create a National Infrastructure Commission for Wales (NICfW) to provide independent and expert advice about infrastructure investment in Wales. We have assumed that the National Infrastructure Assessment for Wales will fall within the remit of the NICfW. We are trusting that the way that the two commissions work together will be clarified. We note that the UK NIC Call for Evidence makes no mention of the NICfW where it refers to how projects and submissions will be considered and assessed. If the NICfW and the UK NIC is to have a role appraising the merits of submitted evidence and projects in Wales then its work programme needs to be closely co-ordinated with that of the NDF. (An example of the issues at stake is given in our response to question 10.)

A similar issue arises with Scotland. The Scottish Government is consulting on a [White Paper for Planning](#). This has objectives around 3.31-3.31 national level infrastructure coordination (at 3.31), especially the final bullet under 3.33, ‘encourage better coordination of development plan strategies and infrastructure capital investment plans and programmes.’

However there is no reference in the Scottish White Paper to the UK National Infrastructure Commission.

Therefore we consider the UK National Infrastructure Commission should provide a clear guide to where decision making powers lie for initiating and regulating the different forms of infrastructure at the level of the UK, the devolved bodies and regional/local authorities plus private companies. This will help make it clear where co-operation arrangements are needed.

Consultation Questions

Cross cutting issues

Q1 What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Whilst the needs of any *particular* city or region is a matter that needs to be taken into account it does not reflect following:

- the competitive future of the nation needs to relate to the networked system of cities, and not cities acting in isolation;
- there are issues that can only be addressed at a national scale in terms of identifying needs and aspirations e.g. the implications of rebalancing the economy and social opportunities. The NIA cannot be founded on a bottom-up set of proposals alone. It needs a clear set of national spatial priorities;
- Whilst these matters are in part reflected in the post hoc evaluative methodologies, it is in fact an *ex ante* consideration in developing the strategy – i.e. it is integral to the option formulation and strategy making process.

Therefore, there is a higher order and overarching question:

“What potential ranges in distribution of people and jobs in 2050 needs to be planned for and supported by new infrastructure investment?”

Q3 How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Planning for infrastructure should be done at a wider than local-authority level; at city region scale. This is because people and goods cross local boundaries very regularly, and few of our towns and cities are self-contained entities. Our paper on [Strategic Planning](#) sets out general principles on how this should work and specific recommendations for UK nations.

Planning for infrastructure, and in particular its relation with housing, is rendered difficult by the high level of fragmentation in infrastructure provision. While local planning authorities have a pivotal role in housing provision, their attempts to coordinate infrastructure agencies (including even other departments of their own councils) are frequently frustrated by:

- Reluctance or refusal to engage (especially in the face of huge day to day pressures)

- Agencies following single-issue agendas set by far-away Whitehall departments or company boards

We touch on this further in our responses to Question 23 on water but it applies across the board.

The single simplest answer to this problem is for control of local infrastructure to be devolved to cities and counties so that the necessary *local* connections can be made and “heads banged together”. We refer to Hamburg below (Q7). Hamburg is interesting in the citizens voted in 2014 to remunicipalise the energy sector.

Recommendation 8 of our policy paper on [delivering large scale housing](#) suggests using incentives (rather than just sticks) for local areas to deliver large scale housing. Guarantees over transport infrastructure would be a good example of such an incentive. Not only this, but infrastructure can be used to unlock suitable sites by providing certainty to house builders, who can contribute to paying back the infrastructure costs from the gain in uplift in land value.

There is frequently-held view that infrastructure should be provided to *support* housing. This is usually expressed (e.g. by transport planning organisations) as “tell us where the housing is going and we will provide transport for it”. Whilst this approach is undoubtedly appropriate in the case of infrastructure which is not location-specific, to take this view for transport infrastructure is to miss serious opportunities for synergy and to regard the territory of the country in a curiously “flat-earth” fashion. It also places undue reliance on the ability of developer contributions to pay for transport investment.

The almost unique attributes of transport infrastructure are such that it should often be **leading development location choices, not following them**. The outplay of this approach is to say “where are we providing additional infrastructure capacity [anyway, for wider national considerations], and how can the best use of those locations be made for homes and jobs? It is beginning to emerge in some of thinking around Crossrail 2 and the Oxford-Cambridge corridor.

Integrated housing and infrastructure plans need to be long-term and flexible enough to cope with uncertainty – using a managed adaptive approach (see Chapter 5 of the Thames Estuary 2100 plan). The plan should be tested using sustainability appraisal.

Q7 What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Linking decisions on infrastructure spending to local commitments on housing delivery (see above) would be one way to improve.

Another way would be assisting public authorities to acquire land or make use of their own land in order to capture the land value uplift that arises from development, to fund infrastructure. Whilst a number of examples of this type of model exist for bespoke projects in the UK (e.g. Stratford and the Olympic Park), we have previously drawn attention to a number of other international examples, not least in our 2015 report [planning as a market enabler](#).

As an example, the financing of HafenCity in Hamburg depended upon the passing of a law by the city state parliament that allowed for the creation of a 'City and Port' special fund for the development of both HafenCity and a new container terminal. Publically-owned land in HafenCity was transferred as an asset into this fund, which was subsequently borrowed against in order to finance the construction of the container terminal. HafenCity is thus directly linked to the construction of new port facilities, a relationship seen as being important in securing political consensus.

While major public investments such as a tube line extension, schools, a new university, a concert hall and museums are financed by various City State government departments, the special fund is used to finance the infrastructure road building, bridges, public spaces, flood defences, marketing and the relocation of businesses where necessary essential as a condition for further private sector investment. Land sales are used both to finance the running of HafenCity GmbH and to pay back loans raised against the City and Port fund. Total public expenditure of approximately €2.4B has been complemented by private investment totalling approximately €8.4B.

Q10 What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

We have stated in our work on [delivering the value of planning](#), that constant changes to the planning system are hampering planners' ability to carry out their work effectively. They can also tend to benefit the groups in society able to afford to understand them. So any change should be fully justified and proportionate to the disbenefits.

A dedicated system for national infrastructure was established in the 2008 Planning Act. Its performance since has been a mixed one. On the one hand a lot of projects have gone through the time-bound process and have been expertly reported on by the Planning Inspectorate. On the other hand (until some recent changes were made) the threshold for some projects seemed to be very low, forcing short lengths of railway through the process; whilst HS2 (and South East airport capacity to date) have not used this process. Further weakness in the current system is the division of infrastructure into very small segments (e.g. rail divided from road; air divided from both). The creation of national policy statements – originally intended to follow the 2008 Act closely – has been long drawn out.

Further consideration should be given to whether housing is defined as national infrastructure.

Arrangements for infrastructure planning across the borders of the UK Nations have not worked in all situations. For example a bypass of Pant-Llanymynech on the A483 south of Oswestry has been repeatedly identified as a key priority for the Welsh Government but not by the DfT. The issue of such cross border links was addressed in detail a few years ago by the Select Committee on Welsh Affairs and their report with recommendations (and subsequent follow up work) should be of interest to those preparing the new UK wide strategy.

Q11 How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

A Natural Capital / ecosystems services approach could be explored to ensure that benefits to the natural environment are assessed properly. The work of the Natural Capital Committee should be integrated or more closely linked with the National Infrastructure Commission.

National infrastructure should contribute positively to the Government's 25 Year Plan for the Environment and provide net gains in biodiversity. For flooding, the Government should accelerate its whole catchment approach.

Green and blue infrastructure can deliver some of the benefits traditionally achieved by 'hard' infrastructure (such as flood defence and air quality management), while providing additional benefits and fewer risks.

Q12 What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

There should be a level playing field in funding assessment methodologies, so that one type of infrastructure (e.g. roads, railways) isn't given more weight or have a lower public funding threshold than another (e.g. climate resilience). The Commission should also take account of the embodied carbon of infrastructure, including decommissioning, in order to fully consider the costs and benefits of proposed projects.

We have said in our response to DfT consultation on the [Wider Economic Guidance Impact update](#) that methodologies should enable a better connection to be made between the economic and strategic case for transport investment setting out exactly what local, regional and national objectives the scheme is trying to solve.

In considering various demand management options (e.g. road pricing, restrictive parking, and smaller projects to encourage sustainable travel and modal shift) there should be consideration of how these should be valued when compared to investment in major new infrastructure including the opportunity costs not investing. Similarly, public health impacts should be factored into the appraisal process, e.g. the benefits of investment in walking and cycling infrastructure versus and the costs of motorised travel.

Transport

Q13 How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

The role of autonomous vehicles (AVs) needs evaluation in a range of different contexts, and is probably an under-researched area as far as its relationship to urban planning is concerned. Much of the research has seemed to be influenced by developers of AV, rather than by cities themselves.

Where the problem is city congestion, will simply changing the driving method reduce congestion? Careful analysis is needed to understand the role of "tidal" flows at peak times. AVs would need to travel back to suburbs empty where there are strong tidal flows, but where multiple orbital movements are in play, AVs might be used in both directions. Nevertheless in this scenario there would be a greater impact on land needed for car parking than on congestion.

In a motorway context AVs could mean greater throughput of vehicles.

In a rural context AVs could assist with the problems of public transport access – but only if ownership and control is strongly constructed in the community interest.

Q14 What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Investing in intra-urban walking, cycling and clean public transport (electric / hydrogen powered buses or light rail), and investing in inter-urban rail.

Consolidated freight / logistics hubs. We could see a useful return to the Victorian principle of break of bulk at key locations in the city. Large inter-city movements of freight by either rail, road or AV, could be broken up into small loads suitable for penetration into dense urban environments by electric vehicle or cargo bike.

Congestion in major urban areas is a serious constraint on economic productivity and leads to air pollution and poor quality living spaces. Policies that reduce car use in urban areas so that freight can move around more effectively. Congestion charging, low and ultra-low emissions zones, walking and cycle infrastructure, public transport that can shift large volumes of people.

Q15 What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Light rail / rapid transport bus. Investments that reduce car use again. We would advise against thinking simply in terms of “connecting people” if this is viewed as connecting existing people. Infrastructure investment is a way influencing where *future communities live*. **In general we would say infrastructure needs to lead, not follow.**

Energy

Q20 What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

This has been set out in the [Zero Carbon Britain report](#) from the Centre for Alternative Technology (CAT).

It is critical to note that - whatever the generation mix – a zero carbon energy sector will only be feasible if coupled with strong demand reduction policies in the buildings and transport sectors. This will need to include robust policies and financial mechanisms to drive the energy efficiency retrofit of existing buildings, and energy efficiency and low-carbon standards for new buildings, which enable an increase in housing supply while meeting the emissions reductions objectives of the 2008 Climate Change Act.

Renewable energy is playing an increasing role in meeting UK energy demand. However, changes to renewable energy policy and subsidy have created uncertainty for developers. Delay and conflict can be reduced by creating an indicative framework of preferred development areas for renewable and other energy supply and infrastructure.

We need a mix of renewable energy technologies including tidal lagoons, offshore and onshore wind and solar. These should be connected via a smart grid which incentivises domestic energy use during off-peak hours with preferential rates, and includes storage in electric vehicles.

R&D in storage technologies a key component.

Q21 What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Vehicle electrification would be likely to place additional pressures on the energy sector and increase the need for demand reduction in other sectors of the economy. The electrification of vehicles will need to be coupled with land use policies that continue to resist sprawl and promote compact settlement patterns which reduce the need to travel, and support public and active travel. Compact settlement patterns also permit new electric vehicle charging infrastructure to be provided more efficiently.

Water and wastewater

Q23 What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Wastewater re-use should be clearly prioritised before new reservoirs, groundwater abstractions or desalination is considered. Sustainable Drainage Systems (SuDS) reduce strain on drainage and sewerage systems, while delivering a range of additional benefits.

Better arrangements are needed to align planning for water and waste water capacity and housing growth. At present the regulation arrangements of OFWAT militate against forward provision of infrastructure ahead of housing delivery because the regulator insists on very high levels of certainty before being prepared to sanction investment by water companies. Since funding arrangements are only set once every 5 years, unless schemes already have full planning permission in the short window available, all the costs of providing capacity fall on developers. It is not possible for local authorities to run their local plan processes to coincide with a national time table dictated by the regulator. This at best causes delay in getting housing permitted, while developers seek to reduce such costs. OFWAT should have an obligation to

- a) Be involved in the local plan process
- b) Fund any sites allocated in local plans

The current risk averse behaviour contributes to delay.

This issue is equally applicable to providing gas and electricity distribution capacity for new housing growth.

Q24 How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Integrating the various plans that water companies and the Environment Agency make, perhaps on a statutory basis at the scale of catchment areas. Consider combining with devolved flood risk management spending.

Reference should be made in the section on water and sewerage to the new arrangements set out in the Wales Bill, currently awaiting consent. These arrangements include a new protocol to be agreed by the UK and Wales Governments.

Flood risk management

Q25 What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

The UK should consider flood risk over a 80-100 year time period, which aligns more closely to the life-span of major flood defence infrastructure and the impacts of climate change. With our long coastline, dispersed development pattern and multiple sources of flooding, it is inappropriate to have one standard of protection. However, we should adopt a more formal targets of protection for different types of land use and development e.g. 1 in 100 years (annual probability) for essential infrastructure, 1 in 200 (sea flooding) and 1 in 100 years (river flooding) for housing, based on current definitions in the NPPF and guidance. An appropriate target for surface water and groundwater flooding should be agreed, perhaps 1 in 30. These targets should take climate change into account using the latest projections.

In addressing flood risk management, options around changes to upland management of land to reduce the speed and volume of run-off need to be able to be evaluated against the building of new flood defences. This issue is of particular significance as a cross-boundary issue between Wales and adjoining regions of England.

Provisions to help relocation and adaptation of existing communities and infrastructure in vulnerable places.

Transparency on how the sequential and exception tests are being applied by local planning authorities, and monitoring/enforcement of development to make sure that stated flood mitigation measures are in place.

RESPONSE FROM THE RSA SUSTAINABILITY NETWORK TO THE NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE

The RSA (Royal Society for the encouragement of Arts, Manufactures and Commerce) is a social change organisation whose mission is to enrich society through ideas and action.

The RSA Sustainability Network is led by Fellows of the RSA with professional interest and expertise in sustainability issues. Should you have any questions or require further information, [job title redacted], [Name redacted], at [email address redacted].

The RSA Sustainability Network recognises the importance of the National Infrastructure Assessment, not only for infrastructure itself, but also for the prospects for environmental sustainability, housing, and social inclusion.

We are providing responses here to some of the questions raised in the Commission's 'Call for Evidence'. The questions to which we are providing a response are indicated below.

In addition to the specific responses in this submission, we highlight the forthcoming final report of the RSA Inclusive Growth Commission for its consideration of issues that are relevant to the National Infrastructure Assessment, in particular broadening measurement criteria from narrow GVA to 'quality GVA', and for understanding the interplay between physical and social infrastructure for creating better places to live and work.

Question 1: What are the highest value infrastructure investments that would support long term sustainable growth in your city or region

We advocate a broad, nationwide approach rather than a regional or city-based approach. It is vital to develop at the outset a broad nation-wide strategy setting out which types of infrastructure development should be given priority before attention is paid to individual projects.

We are concerned with the assumption apparently underlying this question, namely that individual cities and/or regions should determine infrastructure projects that they would favour, and then the government/Commission would choose from the resulting list the ones that they approve of and are prepared to support. There may be some cases where broad regional priorities have already been agreed and where that approach is sufficient, but generally we strongly recommend that, before considering the detail of any specific project, the Commission (or relevant appointed body) must determine which areas of particular value to the United Kingdom as a whole need government input and support, at least in initial stages, if they are to flourish.

Specifically, deciding we want to build something – say HS2 or Hinckley C – because we believe it will promote “economic growth” as measured by conventional GDP accounting, and then testing it to see whether its environmental costs are too high, would be wrong. The first stage in the process should be deciding what to build, not just to make the

economy more efficient and productive (however that may be assessed), but also, and in our view more importantly, how to make it more sustainable and more circular, and then examining whether those investments would be viable and affordable.

Do we need, for example, a smart electricity grid; a truly comprehensive high bandwidth internet and extensive electricity storage more than we need a new high speed rail line? And before considering any new high speed rail line, there should be a review of likely technological developments in each of road, rail and air travel, in the short and medium terms, having particular regard to their relative impacts on resource use, environmental damage, and long term sustainability. What relative priorities should be set for road as against rail travel? Similarly, with power generation: this must inevitably in the long term become entirely renewable – how should this goal be achieved and over what timescale, including maybe what R & D facilities need to be established to support that goal, and what are the best investments to make in the meantime?

Question 3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Planning in the UK is often blamed for our failure to meet economic, environmental and social objectives. Our cities have sprawled, despite green belt policies, our main roads are clogged up, and our societies are increasingly unequal. Much of our transport and energy infrastructure is worn out, as studies by McKinsey and Company and The Policy Institute have highlighted, and the government's new Industrial Strategy stresses the need to 'better align central government infrastructure investment with local growth priorities'.

Reports such as *The State of the Cities 2016* by the European Union reveal that outside London our cities are lagging behind, in part because of relatively low levels of investment compared with countries such as Germany and France. However the explanation is not just lack of expenditure. Despite sensible policies such as the Treasury's Green Book and the National Planning Policy Framework, we fail to 'join up' public and private investment.

The NIC's National Infrastructure Assessment presents a unique opportunity to reform the way decisions on planning strategic development and infrastructure are made and implemented. We here provide our insights on why spatial planning has failed, what is wrong with funding, where we can best learn from, and what the NIC should be doing to close the gaps.

Why spatial planning has largely failed

- Provincial cities were built on the industrial revolution in the 19th century
- Cities sprawled in the 20th century into low density suburbs and villages
- Employment is fragmenting in the 21st century
- But our transport infrastructure is still largely radial and inter-city
- Transport and development are planned in silos, the regional dimension has been lost, along with the people who can join them up
- Over-dependence on short-term profit has caused both quality and quantity to suffer
- Planning disputes drag on at great expense for many years and sap our capacity to compete internationally
- We are creating Combined Authorities, without the funds to fill the gaps.

What is wrong with infrastructure funding in the UK

- We have invested too little for decades (outside London)
- Public funding is far too centralised and out of touch
- Cost Benefit Analysis neglects social and environmental impacts
- Our procurement system is antiquated, stifles innovation and probably raises costs
- Consumers are not happy at what they get for what they pay
- Private institutions will be investing in resilient cities outside the UK
- The property owners (who are the main beneficiaries) get windfall gains
- We cannot double housing output (which all parties agree is needed) without providing better infrastructure – and in the right places.

Where we can best learn from?

- Swiss cities like Zurich operate like ‘clockwork’ and are rated highly by investors
- French provincial cities like Lille and Montpellier have out-stripped Paris in population and economic growth
- German conurbations such as the Ruhrgebiet towns are models of collaboration with integrated urban transport systems eg Stadtschnellbahnen
- Scandinavian cities such as Copenhagen keep housing costs down through planned expansion along transport corridors, which is funding their new metro
- Some American cities, such as Portland Oregon, have copied European models successfully through Transit-Oriented Development

What the NIC can do

1. Publicise ‘model’ projects that offer replicable lessons
2. Bring experts and practitioners together to review findings from research into better infrastructure decision making
3. Require major investment in infrastructure such as in Oxfordshire to respond to 30 year Spatial Growth Plans
4. Evaluate strategic projects in terms of environmental and equity (social) as well as economic criteria
5. Promote new private funding sources eg infrastructure bonds to share in the uplift in land values from development
6. Set up demonstration projects to test the feasibility and cost of applying better models.

For further information on the issues raised in this response to Question 3, contact [Name redacted] [[email address redacted](#)], www.urbed.coop

By designing integrated, low carbon infrastructure we have the opportunity to achieve climate change mitigation and a healthy, prosperous society.

Question 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The achievement of consensus through thorough consultation and investigation of the relevant issues as early as possible in the planning process is the key to avoiding inefficiencies later on. A basic problem is that the initiative for development schemes almost always comes from either

developers or government, leaving others (local authorities, local communities, environmentalists, etc) to respond at a later date, when they should have been involved in the process much earlier on.

The Commission should avoid the political rhetoric which brands opposition to proposed developments as “nimbyism”. Clearly there are people who are principally concerned with their own local areas (although that is not necessarily a bad thing), but there are also environmental concerns which are widely shared, and often underpinned by international agreements and a substantial natural science evidence base, which currently are not given sufficient attention. For example, a great deal of the frustration about the possibility of Heathrow airport expansion could have been avoided if at early stage proper consideration had been given to carbon emissions and air quality issues, and alternatives found in order to reduce demand for air flights. Not tackling these issues early on has led to outcomes which are unsatisfactory for all concerned.

Similarly now, urgent attention needs to be given to flood defence arrangements in order to prepare for an increasingly unstable climate. These should not have to be added in to plans at a later stage when the need is already obvious.

The National Infrastructure Commission should make mitigating and adapting to climate change a core element of its work. An early study should be carried out as to how the Commission will carry out its Assessment in a way which is line with the requirements of the Climate Change Act.

In order to address issues about social equity and inclusion, the Commission should also make provision, as part of its methodology for assessing infrastructure needs, for a system for analysing the distributional impact (as between different income groups) of different infrastructure options. This perspective should become a routine part of the Commission’s work as it considers different infrastructure sectors.

Question 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

We highlight the importance of accurately incorporating sustainability considerations into cost-benefit analysis. Assessment methods must be robust and holistic in order to be “credible, tractable and transparent”. Many of the techniques that ensure inclusion of sustainability also help to ensure better decision making overall.

The method must consider whole-of-life. To illustrate, one of the great barriers to some “green investments”, such as tidal lagoons, has been the discount rate applied to future earnings. If the discount rate is taken to be 6%, for example, earnings arising after more than around 7 years are normally disregarded, even though one of the great advantages of tidal energy is that it will produce regular predictable renewable energy for far longer.

Whole life costing or life cycle costing (rather than simple snapshot cost-benefit analysis) is advocated throughout the sector for a variety of reasons in addition to the sustainability argument. It helps to give a realistic picture of the cost of the asset over its life, and in doing so can also aid more accurate predictions as to the likely actual lifetime. This in turn can significantly improve upon planning and maintenance, both at an individual asset level and from a national infrastructure planning perspective.

Holistic methods also help to avoid the “CapEx-OpEx divide” where capital expenditure and operational costs are considered separately, a common problem bemoaned throughout the

sector, which can lead to a “specification gap” and choices that provide less value in the long term.

Appropriate cost benefit analysis should give a “triple bottom line” (social, environmental and economic) assessment of both costs and benefits. Whilst this is necessarily complex, it is by no means unusual or prohibitive. There are a variety of tried-and-tested techniques for options appraisal and cost-benefit analysis which enable an efficient, robust assessment that effectively incorporates these considerations. For example, we direct the Commission to the work by UCL for the Institution of Civil Engineers and UK Actuary Profession on the OMEGA 3 project (<http://www.omegacentre.bartlett.ucl.ac.uk/research/omega-3/>), which examined how better to incorporate social and environmental criteria into the planning and appraisal of major infrastructure projects. Its proposals for policy-lead multi criteria analysis are detailed in the final report (<http://www.omegacentre.bartlett.ucl.ac.uk/wp-content/uploads/2014/10/OMEGA-3-Final-Report.pdf>).

As was demonstrated in the 2013 National Infrastructure Carbon Review (<https://www.gov.uk/government/publications/infrastructure-carbon-review>) cutting carbon also cuts cost – a principle advocated by the many key industry players who signed up to the Infrastructure Carbon Commitment (<http://www.greenconstructionboard.org/index.php/resources/infrastructure>). We would argue this is also the case for many other sustainability factors, where the same innovation that brings good environmental outcomes can also bring financial and operational benefits.

In addition to these considerations, we highlight that cost-benefit analysis must be conducted at the right point(s) in the process. A key sustainability issue for assessment of infrastructure is consideration of whether an asset needs to be built in the first place. Early consideration of the sustainability costs and benefits is necessary, as is ongoing revision at appropriate points in the options appraisal process as designs and needs change.

Question 28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

We direct the Commission to the key bodies within the UK (both governmental and non-governmental) that are working on Circular Economy such as the Ellen MacArthur Foundation, WRAP, the Environmental Audit Committee. POST note Number 536 September 2016 also provides some useful aggregated insight.

Given responsibility for circular economy policy at a governmental level is divided between different bodies, including: Defra, BEIS, the Treasury, local authorities and devolved administrations, it may be prudent to appoint a special advisor or representative to assist the NIC in ensuring circular economy considerations are included in decision making.

National Infrastructure Commission
The National Infrastructure Assessment Call for Evidence
February 2017

Name and Position: [name redacted]

Name of Organisation: The RSPB

Address: The Lodge, Sandy, Bedfordshire SG19 2DL.

Tel: [telephone number redacted]

E-mail: [email redacted]

SUMMARY

The natural environment and green infrastructure must be considered alongside grey infrastructure. In taking decisions on new infrastructure the Commission must firstly look for demand reduction solutions to avoid the need for new infrastructure. Opportunities to make use of natural solutions should be sought before delivery of new built infrastructure. If new infrastructure is required, biodiversity must be conserved and enhanced through rigorous application of the mitigation hierarchy. In addition, the Commission should consider all opportunities to deliver enhancements to biodiversity and the green infrastructure network and consider green infrastructure as an essential type of infrastructure in its own right. It is difficult to divorce strategic decisions on infrastructure from development locations. As such, we believe a spatial approach to infrastructure planning at a national and sub-national level is essential – helping to avoid impacts whilst planning for enhancements at the right spatial scale – this could include ecological network mapping.

These principles form the basis of the overall approach the Commission should take to the National Infrastructure Assessment and they provide the context for our response to specific questions.

We have responded to questions covering planning and governance, transport, energy, water and wastewater, flood risk management, and solid waste.

INTRODUCTION

1. The Royal Society for the Protection of Birds (the RSPB) is the charity that takes action for wild birds and the environment. We are the largest wildlife conservation organisation in the country with over one million members. We own or manage 151,954 hectares of land for nature conservation on 213 reserves throughout the UK. We believe that sustainability should be at the heart of decision-making. The RSPB's policy and advocacy work covers a wide range of issues including planning policy, climate change, energy, marine issues, water and agriculture.
2. The RSPB previously provided comments on the National Infrastructure Commission's The National Infrastructure Assessment Process and Methodology Consultation in August 2016, and consultation on the National Infrastructure Commission in March 2016 which formed the basis for this response. Our recommendations in these responses form the basis for our comments below.

RESPONSE TO QUESTIONS

Q3 How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

3. The NIC's objectives to 'support sustainable economic growth' and 'to improve quality of life' will be particularly important here. We provided a proposed definition for these objectives in our August consultation response. For example, long term sustainable economic growth must include meeting our climate change targets as well as our biodiversity commitments and 'quality of life' should include scope to protect and restore biodiversity, provide adequate high quality green infrastructure alongside development, ensure new infrastructure supports individual health and wellbeing as well as considering the needs of future generations.
4. Decisions on new infrastructure should start from the premise of whether there is a need for new built infrastructure or whether a demand reduction solution would be more suitable. All new infrastructure should be designed to avoid impacts on our most important sites for wildlife (see our response to Question 11) – rigorous application of the mitigation hierarchy will be key. Furthermore, in designing and planning new infrastructure, opportunities should be taken to deliver improved green infrastructure of benefit to both people and wildlife. Delivery of enhancements alongside new linear built infrastructure provides scope to connect to existing and create improved ecological networks – new infrastructure must deliver a net gain in biodiversity. This could be achieved through a spatial mapping approach – identifying ecological networks and using these to support decisions around infrastructure (details in Q20). The ecological datasets used as part of our Energy Vision Report could support decision-making, helping to inform a non-statutory national spatial strategy for infrastructure.

Green Infrastructure

5. Green infrastructure is a critical component of infrastructure that helps to create better places to live and work. Opportunities to implement wildlife-rich green infrastructure, either as part of new infrastructure or through retrofitting, can help tackle biodiversity loss, climate change and improve human health. High quality green infrastructure – which is accessible and wildlife-rich – benefits both the natural environment and maximises the health and well being benefits for residents.
6. For example, obesity is a growing burden on the NHS and it has been shown that those with easy access to nature are three times more likely to participate in physical activity and 40%

less likely to become overweight or obese¹. The Monitor of Engagement with the Natural Environment's (MENE) Annual Report from 2013-14 survey highlighted that 45% of people asked stated that one of the main reasons they went into the natural environment was for health or exercise. A further 29% said they visited the natural environment to relax and unwind². This highlights the importance of having accessible natural environments around housing developments to both support exercise regimes but also to support people's mental health and wellbeing. Thus new built infrastructure and new housing developments must account for the existing stock of green infrastructure and ecological networks and look to provide enhancements where possible.

7. The benefits of nature on people's mental health are widely reported within scientific literature; however, recently it has become apparent that the quality of the natural environment may be more important than the quantity of it. People are twice as likely to report low psychological distress when living close to quality green space compared with those living near low quality green space³. Therefore, it is important not only to plan for easy access to green spaces in our living environment but also to improve the quality of these green spaces – incorporating greater levels of biodiversity in our green spaces could be one way to achieve this. This will not only improve mental health outcomes and general wellbeing but it will help to create new habitats for biodiversity across the UK and in particular in our urban areas.
8. Accessibility to green spaces around housing developments is not only important for reducing health inequalities but there are links between economic deprivation and limited access to nature, which could then lead on to health inequalities⁴.
9. Green infrastructure is also important in ensuring the UK is resilient to extreme weather by reducing rainfall run off rates and overall temperature. It contributes to tackling air quality, and supports regenerative, resilient green cities. Green infrastructure enhances the resilience of 'grey' infrastructure networks as well as improving reliability and reducing risk.
10. Examples of the benefits of including green infrastructure with linear infrastructure include (from the Linear Infrastructure Network [LINet]):
 - Storm and flood prevention by attenuating water flow.
 - Bank stabilisation, as low water using vegetation stabilises soil.
 - Perceived noise attenuation and visual barriers.
 - Shading and cooling.
11. The Government has committed to release of funding to support housing and new infrastructure, including through the £2.3billion Housing Infrastructure Fund. **The Commission should advocate for a proportion of this money to be made available to deliver new and improved green infrastructure and support demand reduction measures** (such as designing and constructing highly energy efficient new buildings) to reduce the need for new infrastructure.

⁴ Allen, J. (2013) Health Inequalities and Open Space. Presentation. UCL Institute of Health Equity.

Sustainability Standards in new housing

12. The Commission should promote the highest standards of energy efficiency in new buildings, which will reduce the need for new energy infrastructure. This is particularly important for large-scale housing proposals such as Garden Towns and Villages, which should be planned to be sustainability exemplars, including a significant component of green infrastructure.
13. The Commission should also highlight the role that integrated urban design such as Sustainable Urban Drainage Systems (SuDs) could have, including on reducing pressure on urban wastewater treatment (for example, through upgrading the status of SuDs to critical infrastructure). This would complement the Government's commitment (through the Housing and Planning Act 2016) to undertake a review of SuDs.

Housing Delivery

14. Understanding the different mechanisms for housing delivery and how these fit together will be essential – e.g. through local and neighbourhood plans, strategic spatial plans prepared by combined authorities, release of land by public sector bodies, growth points and large-scale housing such as Garden Cities. We have previously recommended that the Commission prepares a 'light-touch', non-statutory UK-wide spatial strategy or framework for future infrastructure priorities – this could be used to view housing and infrastructure priorities in a national context (maps could be used to overlay major housing proposals alongside infrastructure to ensure the right infrastructure is being targeted to areas of greatest need). The spatial strategy should incorporate environmental constraints and opportunities such as important sites for wildlife (e.g. Natura 2000 sites, nationally designated sites and locally important sites) and identify potential areas where new networks of green infrastructure could be delivered. Strategic spatial plans (or sub-national plans) prepared by combined authorities offer particular opportunities to plan for new housing and infrastructure, whilst protecting and enhancing ecological networks in a strategic way. Opportunities to 'use and improve' the UK's stock of natural capital (as outlined in the Industrial Strategy Green Paper) should also be taken when planning for housing and new infrastructure – making use of 'natural infrastructure' in place of hard, engineered solutions. **A spatial mapping approach is essential if opportunities are to be fully realised.**

Sustainable Transport

15. Providing a range of sustainable transport options will help people make more sustainable travel choices. The NIC should work with housing providers to support housing developments which are located to reduce the need to travel by car and through maximising accessibility to public transport, reallocating road space to pedestrians, cyclists and public transport, improving public transit connections and embracing real-time travel information to support public transport users. Building a more robust, accessible, low-carbon transport system will help to deliver health improvements and reduce carbon emissions and pollution and ultimately deliver better places to live and work.

Q4 What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

16. Whilst we recognise that there is potential for behavioural constraints and rebound effects to reduce the success of demand management, we do not consider that these should be seen as inevitable barriers to substantial progress. Technological solutions and policy options are, and will become, available to minimise the impact of such issues. As such, when developing our recent 2050 Energy Vision, which used the UK DECC 2050 Calculator to model future energy scenarios, we opted for the maximum level of energy savings

improvements available⁵. The assumptions that the Government made in respect of the maximum potential for demand management are explained in associated documents that can be accessed via the [‘classic calculator’ interface](#)⁶, by selecting the question marks.

17. Q22 provides additional information on options for water demand management, including water metering, water reuse and greater efficiencies in agricultural use. Additional evidence on water demand management is provided in the Blueprint response, of which RSPB is a signatory.

Q10 What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

18. The planning process (both under the Town and Country Planning Acts and the Planning Act 2008) enables public engagement and the consideration of environmental issues in the development process, so that development takes place in the public interest. These features are fundamental to planning systems in the UK.
19. We understand that the NIC will not have a planning role and is not subject to planning processes and procedures. However, as set out in the recent Housing White Paper, the recommendations of the NIC will be given careful consideration by the Government and when endorsed will be a statement of Government Policy (this will be made clear through revisions to the National Planning Policy Framework). Where recommendations have wider implications for planning regimes, the Government will highlight any further steps needed to take forward the recommendations into the planning process.
20. Whilst we understand the desire to ensure infrastructure is delivered as efficiently as possible and on time, this must not be at the expense of due planning process. In particular:
 - The public should have an opportunity to respond to Endorsed Recommendations and the revision of or preparation of new National Policy Statements.
 - The Commission should fully engage the public with decisions on infrastructure proposals to be determined at a local level and public consultation should begin as early as possible.
 - The Commission in preparation of the Vision Report, NIAs and specific infrastructure studies should clearly set out what planning regime is anticipated and how the public will be consulted.
21. The role of high level appraisal techniques such as SEA and HRA and the evaluation and appraisal of infrastructure priorities will be key, however, to be effective, appraisal must start as early as possible in the process (i.e. form an integral part of the NIA and visioning document) and be used to appraise proposals (including any of a spatial nature). We reiterate earlier recommendations – SEA, HRA and public consultation must take place before Endorsed Recommendations are published. Furthermore, SEA and HRA should be used as ongoing tools to inform and support the NIAs and priority/specific infrastructure studies.
22. However, we recognise there could be better use made of spatial planning (at every scale, but particularly national and sub-national) to assist with the optimal location of infrastructure, both grey/built and green infrastructure. Through processes such as the UK National Ecosystem Assessment and the development of the Marine and Coastal Access Act (2009) the UK has developed a greater understanding of the potential delivery of multiple benefits

⁵ Except for average home temperature where we opted for reduction in temperature to 17°C rather than the minimum available of 16°C

⁶ <http://classic.2050.org.uk/pathways/>

from land use decisions. In the UK, spatial data on land cover, environmental features and socioeconomics is available at ever improving resolutions. This information is already being used to help determine the location and importance of natural capital. It should become routine, when considering development decisions, to consider spatial information and the interaction between both complementary and competing uses. As mentioned in our response to Q.3, we see a role for the NIC in preparing a light-touch non-statutory UK-wide spatial strategy/framework for infrastructure and for the NIC to work closer with combined authorities preparing strategic spatial plans. Clearly there must be scope for public consultation on and assessment of key decisions emerging from any national strategy/framework.

23. The RSPB is a member of LINet, which is submitting a more detailed response to Q10 outlining the importance of green infrastructure as a tool for enhancing the resilience and reducing the whole life costs of national and local linear infrastructure assets. LINet sees green infrastructure as of over-arching strategic importance and a current gap, or missed opportunity in the NIA approach and have thus chosen to respond to Q10. LINet recommends that valuation of the multiple benefits derived from incorporating well maintained and designed green infrastructure should be taken into account as an important part of infrastructure investment, such as quality of place, flood risk and air quality management, enhanced physical and mental health, energy and pollination. We recommend that the Commission maps high level green infrastructure priorities as part of any national strategy/framework and works closely with combined and local authorities as they develop their own strategic spatial plans to ensure green infrastructure is properly considered.

Q11 How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

24. The NIC should ensure that demand reduction is central to its vision for each infrastructure sector to minimise the need for infrastructure in the first place. It is crucial that infrastructure is delivered in a way that avoids harming wildlife (as mentioned earlier, application of the mitigation hierarchy will be essential), and where possible opportunities to enhance biodiversity are maximised. This requires strategic spatial planning to identify locations with the least impact (avoiding impacts as a first principle), and through expert-informed ecological network and habitat management plans to maximise the biodiversity gains at infrastructure project sites. We believe that the NIA has an important role to play in supporting the outcomes in the forthcoming Defra 25 Year Plan, helping the Government to fulfil its commitment to restore biodiversity in a generation.
25. At a time when biodiversity is in trouble, with over half (56%) of UK species assessed have declined since 1970, while more than one in ten (1,199 species) of the nearly 8000 species assessed in the UK are under threat of disappearing from our shores altogether⁷, we cannot afford to give any form of development a “free pass” to damage our environment. Poorly planned built infrastructure can seriously harm wildlife, adding to existing pressures, including those caused by climate change. Developments should avoid the most important sites for wildlife such as Natura 2000 sites, which are protected under the EU Birds and Habitats Directives, as well as nationally designated sites such as SSSIs, ASSIs and locally important wildlife sites.
26. All infrastructure should have a goal of net gain for biodiversity. Many infrastructure companies, including LINet members (such as Network Rail and Highways England), have adopted policies for securing ‘net gain’ from development (or are considering adopting this, such as Transport for London). Net gain projects deliver quantifiable and measurable

⁷ State of Nature Partnership (2016). State of Nature report. <http://www.rspb.org.uk/our-work/conservation/conservation-projects/details/363867-the-state-of-nature-report>

benefits for biodiversity as well as providing a range of wider environmental enhancements, such as flood risk mitigation, enhanced air quality and opportunities for public engagement with the natural environment.

27. Mapping exercises like the one undertaken for the [RSPB's 2050 Energy Vision](#)⁸ help to give an indication of the low-ecological risk areas for potential development which can inform strategic planning. However, thorough environmental assessment of potential site-specific impacts (alone and in combination with other developments) should always be carried out, and relevant stakeholders consulted. Whilst we did not include network infrastructure in the scope of our Energy Vision mapping, it is important that the impact of different grid solutions are also mapped, in conjunction with generation developments. We consider that those responsible for grid development should be encouraged to commit resources to environmental protection and enhancement, in addition to existing work on visual amenity. Further details on how to avoid or minimise impact of grid infrastructure on nature are provided in the recently updated Birdlife Position statement on Powerlines and Grid Development (provided with this response).
28. To take the example of energy infrastructure (such as onshore wind and solar farms or grid substations), there are often opportunities on suitable sites to provide new or improved habitats for wildlife, whilst power lines can be managed to support wildlife corridors. More research is needed to identify best management techniques, and site appropriate actions. However, there is potential for land used for energy infrastructure to be managed to boost insect numbers, provide feeding and nesting opportunities for birds and small mammals, and enhance other ecosystem services such as carbon storage, pest control and pollination. We are currently working with Anesco to enhance our understanding of bird usage of solar farms compared to surrounding agricultural fields. National Grid's [Natural Grid](#) project is exploring how biodiversity enhancements can be achieved on land around substations that is otherwise neglected.⁹ Some examples of best practice grid infrastructure that are being progressed across Europe are provided on the Renewables Grid Initiative [website](#).¹⁰ We are part of the Renewables Grid Initiative aiming to encourage infrastructure development that facilitates emission reductions whilst avoiding or mitigating impacts on wildlife.
29. From the European context, the following are useful case studies of ecological enhancements of grid infrastructure. We would like to see this approach to grid network development and maintenance in the UK.
- 'Creating Green Corridors' Belgian best practice case study¹¹
 - Green Corridor Projects - see the Life Elia website¹²
 - 50 Hertz (Germany) case study of their work on Ecological Aisle Management – see separate document attached to the submission email.
30. Other examples include:
- Ecological management and butterflies¹³
 - Landscape connectivity and bats¹⁴
31. Perhaps some of the greatest opportunities to contribute to enhancing the natural environment through infrastructure can be seen in flood risk management. There are

¹⁴ <http://onlinelibrary.wiley.com/doi/10.1111/1365-2664.12034/pdf>

abundant examples of schemes that make a significant contribution to flood risk, whilst also providing homes for wildlife. This is not a new concept: the Ouse and Nene Washes provide essential flood storage at the same time as being internationally important sites for breeding and wintering water birds. The RSPB helps to manage active washland sites on behalf of the Environment Agency in the Dearne and Aire valleys. The RSPB, UK Coal and Leeds City Council also worked together to transform the St Aidans opencast coal mine into a flood storage area and country park.¹⁵ It now supports breeding bittern and black-necked grebe amongst other species.

32. Opportunities to build habitat for wildlife through green and blue infrastructure in towns and cities are abundant. Sustainable Drainage Systems (SUDS) as part of a wider green infrastructure network can be designed to provide green spaces for recreation, commuting and enjoying natural space during normal conditions but protect homes, businesses and infrastructure from surface water flooding and overloaded drains following heavy rain. The RSPB and WWT produced a guide for local authorities and developers on how to design SUDS to maximise benefits for people and wildlife – The Commission should encourage adoption of SUDs to maximise multi-functional benefits, including for wildlife.¹⁶ The new Housing White Paper proposes increased densification in urban areas – all opportunities to enhance biodiversity, including through use of SUDs should be promoted.
33. It is important to note, that if not carefully designed, new infrastructure can provide a pathway for non-native invasive species to colonise new habitat. This risk is particularly acute for the water environment. Examples include water voles, which often hang on in isolated urban wetlands because they are less accessible to American mink and native white-clawed crayfish, which have been lost from most of our waterways due to disease and competition from non-native crayfish. As a general rule, the opportunities and advantages of improving connectivity will outweigh the risks but poorly designed schemes can offer little to our native wildlife while carrying the risks described above. Examples of where the recommendations of the NIC need to consider these risks would be around inter-basin water transfers where there remains a significant risk of aiding the dispersal of harmful non-native species between currently isolated catchments.

Q12 What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

34. The UK government already has good guidelines on cost benefit analyses. We have several key recommendations to improve the existing the cost-benefit analysis process.
 1. Ensure that experienced environmental economists are engaged.
 2. Commission some work to refresh the extant evidence base.
 3. Use all available data-sources for non market benefits with appropriate caveats and sensitivity testing.
 4. Augment incomplete assessments up front with narratives and visual data representations which provide the decision maker with an understanding of the scale of the data-gap and its potential impact.
35. Problems found in the implementation of the UK government's guidelines, are often from inconsistent consideration of environmental issues. This is usually caused by:
 - A lack of usable data or;
 - A lack of the necessary skills and knowledge in those carrying out the work (particularly outside of DEFRA).

¹⁵ <http://www.mineralandwastepanning.co.uk/st-aidans-intelligent-recovery/article/1184827>

¹⁶ https://www.rspb.org.uk/Images/SuDS_report_final_tcm9-338064.pdf

36. The skills problem is readily solvable by engaging an experienced environmental economist (suggestion 1), but data-gaps can be more complicated. In some cases more regular investment in monitoring and research could help plug the gap. Much of the primary valuation work relied on is now getting old and is in need of updating (suggestion 2).
37. HM Treasury green book guidance provides good guidance on the incorporation of environmental values when considering the full range of social costs and benefits of any project. A key challenge remains the limited practical application of this guidance across Government. A major challenge remains valuing important, but frequently hard to measure (and price) non marketed impacts (externalities and pure and partial public goods). The approach is often to ignore hard to evaluate impacts. One alternative is to use CBA as part of a broader multi-criteria decision framework which incorporates qualitative factors. A second is to use sensitivity analysis and explicit presentational means of reflecting uncertainty around impacts which are highly significant but hard to measure precisely (i.e. the carbon flux of land use change). With policies, as well as projects, it is frequently easier to measure the costs, however, this can disadvantage environmentally beneficial projects where the financial, or economic impacts are more certain than the environmental impacts. Green book guidance is currently being updated to include natural capital and, we hope, to provide additional guidance on environmental impacts. **This guidance needs to be adopted across Government.**
38. In the past (such as for Marine Conservation Zones) commissioned valuation data was entirely ignored. Environmental valuations are sometimes considered too thin and we would also contend that similarly questionable assumptions regarding standard economic estimates are used regularly. Questionable assumptions regarding markets are maintained since they enable some estimate to be made rather than none. Failing to offer the same terms to environmental estimates implies a hierarchy of importance which could not be supported if stated explicitly. We recognise that at times a great deal of uncertainty is involved in building a cost benefit analysis but instead of ignoring important estimates they should be used alongside an explicit expression of uncertainty and with relevant caveats. Rather than presenting simple average cost benefit results, the summary should engage directly with a range of possible values and some estimate of the certainty which comes with them (suggestion 3). Clever use of visual presentation could help the reader to engage with this complexity.
39. Finally, in some cases significant impacts, such as floods or biodiversity change, cannot be appropriately valued and included in a cost benefit analysis. More careful presentation can help ensure that important impacts are not simply lost. By highlighting missing information at the front of any reports and providing context for the impacts these gaps can be made salient to the reader. For instance - if biodiversity is not valued then quantitative negative or positive impacts on biodiversity and how that will in turn impact on obligations such as the Aichi targets could be used. Infographics can also be used to progress the narrative and ensure that where a CBA is incomplete the reader understands the importance of that missing information. NEF attempted to do this for the Marine Conservation Zones.¹⁷

TRANSPORT

Q13 How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

40. The RSPB supports demand and emissions reductions within the transport sector. In order for these to be achieved, changes will be required to the types of transport used and the behaviour of transport users. The focus on low emissions vehicles in the recently published

¹⁷ <http://www.mseproject.net/infographic-ia>

Industrial Strategy is a positive signal. In the forthcoming Emissions Reduction Plan Government can set out some of the changes that will be required to reduce both demand and emissions.

41. Analysis undertaken for RSPB shows that a shift to high-speed rail could deliver significant carbon savings relative to road transport¹⁸. However, these savings vary depending on the policy framework that is applied. The highest level of savings can be delivered if the top speed of HS2 is limited, if city centre stations are favoured over parkway stations and if full use is made of the freed up capacity on conventional railway lines, particularly if this is used for freight rather than commuters.
42. On roads, there will need to be a rapid shift to low emissions vehicles. Transport has been identified as one of two areas where emissions reductions have not been sufficiently delivered¹⁹. Analysis has identified that progress in the 2010s (investment in charging infrastructure and declines in the costs of batteries) has been positive, but that policy certainty is lacking for the post-2020 period²⁰. New policies to support this sector will be required. The use of electric (and other low emissions) vehicles represents an exciting opportunity for the UK to lead the way. However, electrifying the vehicle fleet could place a burden on the power grid and will require that the UK's power grid be decarbonised as much as possible, as fast as possible, in order to deliver emissions savings in the transport sector.
43. The RSPB is concerned that future decarbonisation of road transport might be delivered by a reliance on biofuels. Experience and evidence have shown that due to direct and indirect land use change biofuels, in particular crop-based biofuels, can result in impacts on the natural environment and can fail to deliver greenhouse gas emissions savings²¹. Therefore, the contribution of land-based crops should be phased out to zero by 2020 and the overall contribution of biofuels should be at most a limited one.
44. All transport infrastructure developments, like energy developments, pose a potential risk to the natural environment. Measures should be taken to ensure that demand reduction is prioritised so that impacts on the natural environment are avoided and minimised. Otherwise inappropriate development could result in lengthy and costly delays for developers.

ENERGY

Q19 What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

45. Compared to power, heat has been identified as one of the areas where sufficient decarbonisation progress has not yet been made²². The forthcoming Emissions Reduction Plan is an important opportunity for Government to set out measures to achieve this. The RSPB considers that delivering technologies to decarbonise heat is an important requirement. However, decarbonised heat solutions need to rely on the most sustainable fuels and technologies in order to deliver the best value.
46. For example, bioenergy should play at most a limited role in the decarbonisation of heat, whether used in domestic boilers, in combined heat and power boilers for local heat networks or as biomethane injected into the grid. This is because many types of biomass used for energy can result in significant adverse impacts on the natural environment and also fail to

¹⁸ <http://www.greengauge21.net/wp-content/uploads/The-carbon-impacts-of-HS2-final-2012.pdf>

¹⁹ <https://www.publications.parliament.uk/pa/cm201617/cmselect/cmenergy/173/173.pdf>

²⁰ http://www.green-alliance.org.uk/resources/Future_low_carbon_investment.pdf

²¹ <http://www.birdlife.org/europe-and-central-asia/black-book>;

https://ec.europa.eu/energy/sites/ener/files/documents/Final%20Report_GLOBIOM_publication.pdf

²² <https://www.publications.parliament.uk/pa/cm201617/cmselect/cmenergy/173/173.pdf>

deliver their promised emissions savings; some types of biomass can even result in emissions increases relative to fossil fuels²³. Evidence produced by the UK Government has shown that some types of biomass can result in emissions up to three times greater than those of coal, even forty years after combustion²⁴. There is only a limited supply of sustainable biomass available and heat is one of the most efficient ways of using this limited supply²⁵. Only the most sustainable types of bioenergy should be used (for example wood should be restricted to FSC only-wood) and all biomass for energy needs to fully account for all of its emissions, including those released upon combustion.

47. Government also needs to take a strategic overview of the different demands being placed on this supply (from the transport sector, the power sector, the wider bioeconomy and the heat sector) in order to determine the most efficient use. This overview will help to deliver the highest value decarbonisation of heat and the highest value use of this limited biomass resource. The recent call for evidence on the bioeconomy was a welcome step.
48. The Committee on Climate Change has identified that other measures are required in the coming years in order to deliver the best value decarbonisation of heat²⁶. The use of local heat networks for dense urban areas, and the deployment of heat pumps for homes off the gas grid make sense. Any electrification of heat will provide best decarbonisation value when they rely on a decarbonised power sector. In addition, measures to deliver low-carbon heat will, the Committee concludes, work best when combined with energy efficiency measures for homes (this is particularly true of heat pumps). In order for hydrogen for heating to be delivered, CCS will be required for the production of that hydrogen. Government intervention may be necessary in order to support the initial roll-out of CCS installations. Locating these near existing industrial areas may make sense, and would fit with the 'clustering' approach identified in the Government's recent draft Industrial Strategy.

Q20 What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

49. Establishing an effective zero carbon power sector will include vastly increasing the proportion of energy that we use from renewable and zero carbon sources, as well as greatly reducing our overall energy demand, combined with a substantial restructuring of our grid network. However, it is crucial that this energy revolution is delivered in a way that avoids harming wildlife. With biodiversity in trouble, we cannot afford to allow development to damage our environment (see Q11).²⁷ Poorly planned energy infrastructure can seriously harm wildlife, adding to existing pressures, including those caused by climate change²⁸. A power sector which does not take into account impact on biodiversity, and therefore consequently damages the health of the UK's natural capital, would not be an effective or sustainable power sector in the long-term.
50. In the RSPB's [2050 Energy Vision](#) we set out how a low carbon energy future could be achieved in the UK, whilst limiting impacts on sensitive wildlife and habitats. We have done this using pioneering, peer-reviewed mapping techniques to assess where renewable energy

²³ <http://www.birdlife.org/europe-and-central-asia/black-book>

²⁷ https://www.rspb.org.uk/Images/stateofnature_tcm9-345839.pdf

²⁸ Pearce-Higgins J & Green R (2014). Birds and Climate Change: Impacts and Conservation Responses. Cambridge University Press, Cambridge.

can be located with low ecological risk, based on current understanding and available data. For technologies not mapped as part of this project, we have analysed key ecological risks and estimated the capacity that could be achieved with low risk for wildlife. Based on this research, we have developed three 2050 energy scenarios using the DECC 2050 Calculator, that meet UK climate targets with low ecological risk – as well as maintaining energy security and costing a similar amount to other decarbonisation pathways, showing that this can be done.

What does this look like?

51. Our research sees both onshore wind and solar energy playing a major role: these technologies have substantial potential for growth in harmony with nature. Whilst there are real challenges with siting fixed offshore wind turbines due to high ecological sensitivities in shallower waters in addition to a lack of sufficient data on the risks in some areas, particularly further offshore, up to 115 TWh/year could be generated at low ecological risk if sited carefully, with much of this capacity off the coast of England. Further significant capacity could also be unlocked through the commercialisation of innovative new technologies such as floating turbines. Tidal stream and wave power could unlock further renewable energy potential and provide a reliable, sustainable source of energy if commercialised in harmony with nature.

52. The following table outlines the maximum annual energy output that we estimate can be produced by the renewable technologies we have mapped, at low ecological risk:

Renewable energy technology	Annual energy output at low ecological risk in terawatt hours per year (TWh/year)
Onshore wind	140
Solar farms	246*
Bioenergy crops	23*
Offshore wind (fixed)**	69 – 115
Offshore wind (floating) **	5,044 – 5,558
Wave energy	42
Tidal stream**	17 – 176
TOTAL	5,558 – 6,277***

*Precautionary estimate taking account of land-use change and potential impacts on food production of using agricultural land for energy. Bioenergy figure includes electricity and heat generation.

**Figures presented as a range to take account of the increased uncertainties surrounding offshore renewable energy development.

***This total does not include bioenergy crops, as they would require land also assumed to be available for solar farms. Solar farms are prioritised in this table, as they generate more energy per unit area. See the full Technical Report²⁹ for more details of our approach to each of these estimates.

****A previous version of this table contained in our August 2016 NIC Consultation response had incorrect units. This update should clarify all units in TWh/yr, GW equivalent figures are available upon request.

53. To enable the transition to zero carbon energy, the UK’s grid network will require significant investment in new and upgraded connections, alongside smarter system management to integrate new sources of renewable electricity. More connection between UK countries and interconnection with other nations will be needed, to optimise how we use renewable energy.

²⁹ https://www.rspb.org.uk/Images/energy_vision_technical_report1_tcm9-419581.pdf

Distribution networks will need to become smarter to integrate more decentralised generation and enable demand-side response.

How could this be achieved - generation?

54. In order to achieve an effective zero carbon power sector in harmony with nature we would need to see the UK Government and Devolved Administrations set a bold target of 100% low carbon energy by 2050, including high levels of renewable energy. Clearer policy on renewables could mobilise nearly £57 billion of investment from 2021 to 2026³⁰. For this target to be delivered in harmony with nature we consider onshore wind and solar to be crucial, as well as new technologies such as floating offshore wind. Installing solar on the available 147 million square metres of London's rooftops could generate 23 per cent of London's power and support an estimated 6,400 full time jobs a year until 2030³¹. We want to see Government continue to support these industries and stop supporting fossil fuels, so that economic incentives work for nature and the climate. We will also need to eliminate energy waste, as this will reduce the need for new energy infrastructure that poses risks to wildlife. and to transform low carbon heat and transport for instance by shifting to electric vehicles and electric heating. The overall economic and social benefits of electric, connected and autonomous vehicles could be in the region of £51 billion per year by 2030, with the potential for the creation of 320,000 industrial jobs³².
55. We also need to ensure that bioenergy supplies are sustainable and do not impact on important habitats, Evidence suggests that many types of biomass can result in harmful impacts on the natural environment caused by both direct and indirect land use change. See Q19 for concerns on biomass. Thus the cost-effectiveness of biomass as a carbon reduction strategy should be reviewed. A study undertaken for the Natural Resources Defence Council shows that, by 2020, biomass will be a more expensive renewable choice than onshore wind or solar, even when the grid balancing costs of these less flexible renewable technologies are taken into account³³.
56. To facilitate the roll out of technology changes in harmony with nature, the UK Government, the NIC and devolved administrations need to identify suitable sites for renewable energy development with low risk for wildlife, in a similar way that we have with our pioneering and peer-reviewed mapping techniques. This would help Government to understand the capacity of different technologies that can be achieved without damaging important areas for nature conservation, and could use this to develop roadmaps for decarbonisation in harmony with nature. This process could be aided by the help of a task force bringing together experts from industry, Government and civil society organisations.
57. **To ensure that this process is scientifically robust, we urgently need to improve the ecological evidence base – particularly in the marine environment –** so that we better understand the most important sites for wildlife and the impacts of renewable energy infrastructure. New technologies such as floating offshore wind turbines could unlock significant renewable capacity with low ecological risk, and Government should promote low carbon, low ecological impact innovation to advance these solutions (accompanied by robust environmental monitoring).

³² SMMT, 2015, 'Connected and autonomous vehicles: the UK economic opportunity'

³³ <https://www.nrdc.org/sites/default/files/uk-biomass-replace-coal-clean-energy-ib.pdf>

How could this be achieved - transmission?

58. To enable an effective transition to zero carbon energy, the UK's grid network will require significant investment in new and upgraded powerlines, alongside smarter system management to integrate new sources of renewable electricity. More connection between UK countries and interconnection with other nations will be needed, to optimise how we use renewable energy. Distribution networks will need to become smarter to integrate more decentralised generation and enable demand-side response.
59. Where transmission issues cannot be resolved with upgrades or smarter system management, any new transmission lines deemed as essential must be carefully progressed to minimise impact on wildlife to avoid degradation of our natural capital. The length of new powerlines should be minimised, whilst also ensuring that routing of the lines avoids sensitive areas. Appropriate assessments through the use of SEA, HRA and EIAs should be carried out, and powerlines should be designed and constructed in line with national standards and international agreements.

Q21 What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

60. Increasing use of low carbon (in particular electric) vehicles means that decarbonising the power grid is an important priority in order to ensure that vehicles run on genuinely low carbon electricity. However, if the demand for electric vehicles is a driver for decarbonising the electricity grid, then the renewable energy to achieve this decarbonisation will need to be delivered in harmony with nature.
61. Investment will be required in order to deliver the infrastructure that is needed for this transition to electric or hybrid vehicles. The former Energy and Climate Change select committee identified that the greatest need for expansion in charging points could be in rural areas.³⁴ In addition, they identified that better understanding is needed of the burden on the electricity network, in particular where clustering could occur (this would be where electric vehicles become popular in a local area, creating a pressure point on the power grid). However, electric vehicles may also provide an exciting opportunity to deliver a more flexible energy system. Electric vehicle batteries that are connected to the grid can provide storage during low-demand troughs, while providing excess capacity during peak periods. Such a smart approach could actually help to better balance the power grid. But, the environmental impacts of certain types of battery production should not be ignored: some of the materials required to produce electric batteries for homes, vehicles or the power grid can require minerals (such as lithium) and other materials that, when mined, risk significant environmental damage.
62. Some vehicles may rely on hydrogen. However, for this hydrogen to be delivered in a low carbon way could require carbon capture and storage (CCS) infrastructure to be delivered. CCS could be most efficiently delivered, with least impact on the natural environment through its footprint, if it is clustered in existing areas where there is industry already. Therefore it could serve existing heavy industry or power infrastructure, while also creating a byproduct of hydrogen for use in the transport (or heat) sector.
63. The RSPB is concerned that low carbon vehicles could result in an increase in the use of unsustainable biofuels. Coupled with demand for a limited sustainable biomass resource from other parts of the energy sector (for heat or power) unsustainable pressure could be placed on the natural environment. Evidence shows that biofuels can result in significant

³⁴ <https://www.publications.parliament.uk/pa/cm201617/cmselect/cmenergy/173/173.pdf>

harm to the natural environment and that many types of biofuels deliver meagre emissions savings or even result in increases in emissions relative to conventional fuels³⁵.

WATER AND WASTEWATER (DRAINAGE AND SEWERAGE)

Q22 What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

64. The Water UK [Water resources long-term planning framework](#) looked at the resilience of long term water supplies and concluded that significant effort and investment was needed to ensure droughts did not impact on consumers, businesses and the freshwater environment.³⁶ One of the most effective tools they identified to boost resilience is rigorous demand management through household metering.
65. Currently, only half of the households in the country pay for water based on the amount they use. The percentage of metered households needs to increase significantly if we are to empower consumers to control their own water bills, and incentivise water efficiency. Under current legislation, water meters cannot be introduced on a universal basis in large parts of the country, even when it is clear that they could go a long way to securing long term resilience of regional and national water supplies. Water companies should be able to introduce universal metering if, after consultation with customers through the existing Water Resources Management Plan and Business Plan processes, it is found to be the most affordable option for customers overall, as well as being the best option for water resources management and resilience.
66. We refer the NIC to Waterwise's recent water efficiency strategy document for further ideas and case studies around demand management ([Water efficiency strategy for the UK](#)³⁷).
67. The UK now lags behind other countries such as Germany in the deployment of water reuse technology. Rainwater harvesting has the potential to form a component of Sustainable Drainage Systems (SUDS) as well as reducing pressure on potable supplies. Despite technology being widely available, it is not routinely installed in new developments. Addressing the lack of regulatory drivers behind Sustainable Drainage Systems would provide a greater incentive for developers to incorporate rainwater harvesting systems.
68. Improved water efficiency measures on farms, including but not limited to storage, could make a significant contribution to reducing water demand in some of our most water stressed environments. The Environment Agency produced Rainwater Harvesting: An on-farm guide.³⁸
69. Securing reform of the abstraction system, ensuring that water use better matches water availability and that the needs of the environment are properly accounted for, will prove the strongest driver of investment in improved water efficiency. It may also drive a reassessment of crop choice in many locations, with aquifers in many drought prone regions, including those underpinning internationally important wildlife sites such as around the [Norfolk Broads](#)³⁹, under pressure to supply water demanding crops such as salads.

³⁸ www.swarmhub.co.uk/index.php?drid=4291

³⁹ <http://freshwaterhabitats.org.uk/news/catfield-fen-ea-minded-refuse-damaging-abstraction-licences/>

Q23 What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

70. Water companies are required to produce long term (at least 25 year) [Water Resource Management Plans](#) to ensure that water supply systems are sufficient to meet future demand and resilient to climate change and other pressures.⁴⁰ While rivers and groundwater sources are still over abstracted and water companies need to do much more to ensure they secure adequate resources without harming the environment, the WRMP process is beginning to drive a more forward looking, collaborative and innovative approach to ensure the needs of people and the environment are met in relation to water supplies. We believe a similar process for wastewater is essential to address the outstanding and significant problem of sewage pollution in rivers and streams. The Government should require water companies to produce, consult on and publish statutory long term wastewater management plans that secure the delivery of resilient wastewater services.
71. The RSPB is a strong advocate of the use of Sustainable Drainage (SUDS) techniques in new and existing development. The NIC is encouraged to refer to the recent CIWEM review which we have supported.⁴¹ The Ciria's Susdrain website provides a library of useful resources and guidance including a report jointly produced by the Lead Local Flood Authorities for South East England.⁴²
72. Whilst we certainly sign up to the broad consensus that national legislation around SUDS is not working and needs to be revised, we believe schemes will only meet their full potential in contributing to more attractive, greener and wildlife-rich towns if Local Planning Authorities set out in guidance what additional benefits they want to see from SUDs.

Q24 How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

73. This is a very broad ranging and challenging question and deserving of a consultation in itself. It is certainly one of the areas that we think the NIC could make the greatest contribution to as we still see issues of water quality, water availability, flood risk management and nature conservation treated separately with insufficient scrutiny of whether land use policy is adequately incentivising outcomes that could contribute to all of these. Whilst it is widely recognised that the catchment is the ideal scale at which to undertake and integrate water management activities to achieve more for less (see Defra 2013 [Catchment Based Approach](#)⁴³ or Dieter Helm, 2015, [Water Catchments](#)⁴⁴) it can be argued that, to date, we have failed to make it happen, and certainly to make it happen effectively.
74. Strategic plans, such as [River Basin Management Plans](#)⁴⁵ (RBMPs) and [Flood Risk Management Plans](#)⁴⁶ (FRMP) have been seen by Government and statutory agencies as a requirement to report on progress towards meeting obligations under the relevant directives, rather than the strategic planning tools they were originally intended to be. RBMPs report that we are failing to reduce diffuse pollution, especially from agriculture, and make use of derogations available under the Water Framework Directive (WFD) to push back deadlines but fail to critically assess whether the right tools are being used and whether we have

⁴⁰ <http://www.water.org.uk/policy/water-resources/water-company-plans>

⁴² http://www.susdrain.org/files/resources/other-guidance/water_people_places_guidance_for_master_planning_sustainable_drainage_into_developments.pdf

⁴³ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/204231/pb13934-water-environment-catchment-based-approach.pdf

⁴⁴ <http://www.dieterhelm.co.uk/natural-capital/water/water-catchment/>

⁴⁵ <https://www.gov.uk/government/collections/river-basin-management-plans-2015>

⁴⁶ <https://www.gov.uk/guidance/flood-risk-management-plans-what-they-are-and-whos-responsible-for-them>

achieved an effective balance between depending on voluntary land use change and the use and enforcement of existing legislation. This results in a widespread failure to manage water effectively because those who pollute are rarely paying the cost of that pollution. This failure has been recognised by the water sector, with companies increasingly attempting to intervene, on behalf of their customers, at a catchment scale to address a range of issues.

We believe what it needed is:

- **Better integration of governance around water management.** The RSPB is concerned that the frequent focus on reform of flood risk management agencies can be a scapegoat for wider failings. There is no doubt that ongoing cuts to the Environment Agency budget has left it unable to properly fulfil its role as an environmental regulator but we have seen little evidence that a different body with access to the same resources would have done any better at getting value out of its flood risk management budget. If you were starting from scratch today then we might support splitting the regulatory and flood risk management functions but complex restructure now risks diverting resources away from delivery and attention away from a broader and more urgent need for policy reform. One option to achieve better integration without wholesale reform is offered by [Dieter Helm's Catchment Operator Model](#), which could aid greater integration without pre-empting a question around the value of wider structural reform.
- **Better integration of planning at a catchment scale.** As mentioned above, we currently have multiple plans covering the catchment area but insufficient integration. The key plans are River Basin Management Plans and Flood Risk Management Plans. These can and should be better or fully integrated with a view to them better informing where investment would achieve benefits across multiple outcomes. This is critical, not only to guide effective land use planning but also to facilitate an approach to cost benefit analysis that is able to consider all of the benefits a project could deliver, rather than being seen through a single lens of water quality enhancement or flood risk management.
- **A stronger regulatory baseline that is adequately enforced** by our regulators to tackle inappropriate and illegal activities within a catchment. The Urban Wastewater Treatment Directive has been one of the most effective pieces of legislation to come out of the European Union. It has driven a transformation of urban waterways to the extent that many beneficiaries are unaware of the proportion of water in their river that is treated effluent. Since confirmation that we will be leaving the European Union some sectors have questioned the value of core elements of the Directive. Conversely, successive governments have failed to address diffuse pollution from rural land use. This has been because the presumption that the polluter should pay the cost of addressing pollution has not underpinned agricultural policy. Farmers, able to pass the cost of dealing with diffuse pollution on to water companies, have not been faced with any meaningful incentive to change. In our opinion this represents a clear market failure. Several Government reports⁴⁷ back up our view that the current system is failing and resulted in WWF and Angling Trust instigating a Judicial Review of whether the Government's dependence on measures that its own analysis showed were not working meant that it was in breach of its obligations under the Water Framework Directive.
- **Better targeting of funding so that it can, and does, deliver multiple benefits and addresses problems at their source rather than dealing with their consequences.** More funding should be diverted to solutions that deliver flood attenuation, water quality and biodiversity benefits at source rather than separate funding streams that deal with consequences, such as providing enhanced water treatment or ever higher flood walls.

⁴⁷ <http://adlib.everysite.co.uk/resources/000/264/031/diffuse-consult-govresponse.pdf>

That is not to say that full integration of funding is possible or even desirable. Countryside Stewardship is an effective way of recognising the contribution that many farmers make to improved biodiversity and recognises that these outcomes are not rewarded through normal market mechanisms. However, agri-environment schemes are limited in only compensating farmers for income foregone and for that reason, work well when farmers share the ambition of the scheme but fail when outcomes are more dependent on the scale or location of deployment. Farmers interested in agri-environment schemes are often not those responsible for the greatest contribution to pollution – here proper enforcement of existing regulation would work best.

- Action to reduce flood risk, beyond avoiding practice that increases risk, could be funded to a greater extent by beneficiaries of that action through the facilitation of Payment for Ecosystem Services (PES) schemes. Core flood risk grant in aid is generally allocated efficiently according to the certainty that the intervention will work and the value of the benefit derived. However, there is a failure to look beyond those core outcomes at whether changes to the design of schemes intended to benefit wildlife, reduce pollution or alleviate flood risk could make a wider contribution. For example, woodland planting can provide a natural flood management and wildlife benefit but only if those outcomes are built into the initial design of the scheme.
- Catchment measures to reduce downstream flood risk often fail to attract funding from core grant in aid because there is a greater degree of uncertainty around the outcome. Because projects based on catchment interventions are generally cheaper than hard engineering schemes, the cost of modelling to increase certainty makes up a much larger proportion of the overall project cost. However, requiring the Environment Agency to assess where natural flood management could contribute to the effectiveness or longevity of engineered schemes whenever such a scheme is funded could bring significant benefits for a small fraction of the total project cost. Achieving improved outcomes through mechanisms such as those described above involves a wide range of stakeholders and potentially draws funding from multiple sources. A carefully designed facilitation fund helps to cover the initial costs incurred by organisations willing to work with multiple landowners and funders to deliver those outcomes.
- **Greater partnership working at a catchment scale.** As noted above, involving local communities and stakeholders in planning, decision making and delivery is critical. Catchment Partnerships already exist through the [Catchment Based Approach](#)⁴⁸ (CaBA) but their effectiveness varies widely. So far they have been able to access a small amount of funding from the Environment Agency but this has been confirmed on a year by year basis and usually towards the end of the financial year. A very modest amount of dependable core funding to cover the secretariat costs would go a long way to ensuring those partnerships can look beyond their short-term security to drive greater stakeholder engagement and longer term planning.

FLOOD RISK MANAGEMENT

Q25 What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

75. Whilst not wanting to detract attention from the critical need to reduce the impact of flooding on people's lives, it is worth noting that, despite serious flooding in the UK over the last two decades it has caused very little loss of life. We rightly focus on the need to improve our resilience in the face of a changing climate but it is worth recognising that, compared with

⁴⁸ <http://www.catchmentbasedapproach.org/>

historic floods in the UK and the current situation in many countries in the world, we are good at addressing the biggest threats posed by floods.

76. Whilst we are aware that many attendants to the recent NIC workshop on flood risk management thought that the Government should aspire to deliver a set level of resilience to future flooding, in practice we think that will be difficult to achieve without a significant shift away from current policy, which is to deliver the maximum flood benefit from a defined budget, to one where the level of resilience is defined and budget and policy are set to meet that standard.
77. However, we welcome the shift from a sole focus on flood defence to a broader view that recognises the importance of making communities, businesses and infrastructure more resilient to flooding.
78. This recognition that universal flood defence is not attainable has, in our opinion, not been matched by sufficient recognition that not all floods are equally damaging. Indeed, many of our most important wildlife sites are associated with regular shallow winter floods. These have been farmed landscapes for many generations. In places like the [Lyth Valley](#)⁴⁹ in Cumbria, a failure to make adequate distinction between investment in protecting homes and essential infrastructure and investing in agricultural land drainage results in suboptimal decisions being made about where public investment in flood risk management should be directed. Much of this investment is through special levies on local communities, rather than central Government grants, but it is our view that those communities are often not given the information they need to make informed choices. There is valuable learning from the Netherlands 'Room for the River' programme where farm buildings have been relocated to higher ground in recognition that fields will periodically flood.
79. Similarly, whilst we accept that river maintenance is needed in some circumstances, to improve conveyance around critical pinch points, much of the discussion in the media continues to react to a call for river maintenance rather than the more important debate about whether land use planning incorporates enough room for water during and after extreme rainfall events. This principle is fundamental to the '[Room for the River](#)'⁵⁰ programme in the Netherlands and the '[Blue Green City](#)'⁵¹ principles in the UK. This will require difficult decisions around where to invest in defence, where to provide support in improving resilience and where to remove or step back defences.

Q26 What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

80. The evidence around the effectiveness of natural flood management is growing and our ability to incorporate it into our arsenal of approaches to reduce flood risk will increase.⁵²
81. There is an important distinction to be made between upstream measures designed to 'slow the flow' of water and downstream measures designed to make 'room for the river' and increase capacity to store flood water. Reconnecting rivers with their floodplains, new washlands, stepping back embankments and incorporating green infrastructure in urban areas to take flood water are all forms of natural flood management but we know they work and they will be critical if we are to avoid the worst impacts of future floods.

⁴⁹ <https://www.rspb.org.uk/our-work/our-positions-and-campaigns/campaigning-for-nature/casework/details.aspx?id=tcm:9-295709>

⁵⁰ <https://www.ruimtevoorderivier.nl/english/>

⁵¹ <http://www.bluegreencities.ac.uk/>

⁵² <https://www.gov.uk/government/publications/working-with-natural-processes-to-reduce-flood-risk-a-research-and-development-framework>

82. When commentators talk about the lack of evidence that natural flood management works, they are usually referring to upstream measures. There is a growing body of evidence that they can be very effective but that the effect depends on a complex array of factors, including the size of the catchment, topography, geology, soil type and critically the duration and magnitude of the storm. Specific interventions such as installing in-stream features to stretch the storm hydrograph and reduce its peak need to be carried out in the right place and in sufficient quantity if they are to be effective. They will prove invaluable in certain catchments, when sufficient thought can be put to their design, location and maintenance (see [Pickering](#)⁵³ and [Belford](#)⁵⁴) but we are unconvinced that an unplanned approach to their deployment as part of an agri-environment scheme would be able to deliver that.
83. We believe that the greatest gains could be delivered by preventing damaging practice and recognising the role of land use change in slowing flows into streams and rivers and making use of 'natural infrastructure'. The creation of new native woodland and scrub, the restoration of blanket bogs and restoring rivers can contribute to flood management objectives but they will do so alongside restoring biodiversity, sequestering carbon and improving water quality. Because they deliver a wide range of benefits, there are a wide range of organisations and landowners interested in building the shared evidence base, delivering projects and contributing to ongoing costs.
84. There is much that can be done by removing perverse incentives for managing land in a way that increases flood risk. For example, landowners who allow scrub to regenerate on their land or intentionally take flood water are ineligible for basic payments under current CAP rules. Measures to conserve soils, such as banning high risk crops such as maize on vulnerable slopes, maintaining broad hedgerows and buffer strips, can also contribute to reducing flood risk by slowing the rate at which water flows of hillsides and preventing silting up of watercourses.

Q28 What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

85. The RSPB is a founding member of the Aldersgate Group and our thoughts on this are in line with their report Resilience in the Round.⁵⁵ A major barrier is the current over- reliance on voluntary approaches to deliver policy outcomes. RSPB research demonstrates that voluntary approaches in practice are very rarely effective⁵⁶. We believe that the current drive for deregulation and using regulation only as a last resource will undermine the Government's ability to achieve aspirations around the circular economy, increasing resource efficiency or engineering waste out of productive systems.

National Infrastructure Assessment Call for Evidence: Response of Behalf of RWE Generation UK plc

Dear Sir/Madam,

This response is made on behalf of RWE Generation UK plc ("RWE Generation"), which owns, operates and maintains a portfolio of gas, coal and biomass power stations together with a portfolio of smaller open cycle gas turbine and combined heat and power generation assets in the UK. RWE Generation UK plc also owns a number of closed power station sites in the UK which may be redeveloped for electricity generation or other purposes.

Our response to the call for evidence questions is attached. If you have any queries on our responses then please contact the undersigned in the first instance.

Yours faithfully

[name redacted]

[job title]

RWE Generation UK

National Infrastructure Assessment Call for Evidence - RWE Generation response

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?
Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.
2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

The international competitiveness of all economies is underpinned by that economies' relative cost of energy, such that those countries with a relatively higher cost of energy will be disadvantaged internationally. That cost of energy is highly influenced by the regulatory frameworks and market structures that surround energy production, transportation and supply. Competitive market structures provide the most efficient means of ensuring that the costs of the UK energy infrastructure do not inhibit the international competitiveness of UK industry. These costs can be minimised, to the benefit of the UK economy, by reducing the burden of regulation and policy on the energy sector. Unfortunately both current and previous governments have tended towards poorly constructed piecemeal interventions that have unintended consequences, which in turn propagate further piecemeal interventions, as evidenced by the abundance of policy changes introduced in reaction to the volumes of new build reciprocating engines, fuelled by gas and particularly diesel, that have proliferated in the first few capacity auctions. These ad hoc interventions are the result of hasty policy formulation and implementation and lead to market inefficiencies such as inappropriate investments, stranding of assets and potential failure to meet targets for e.g. de-carbonisation and energy efficiency. The cost of these inefficiencies will be borne by either the energy consumer and / or the tax payer, making the UK less competitive internationally. A more holistic approach to policy formulation and implementation, for example looking at whole system impacts rather than small segments in isolation, supported by honest and open consultation with both the energy sector and academia should ensure that any inefficient use of assets and resources is minimised, and international industrial competitiveness is not unnecessarily impeded.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?
4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?
Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

We have no view on the maximum potential for demand management, however we believe that extensive reliance on demand management is symptomatic of a poorly performing economy that is not competitive. Demand management in the context of energy is fundamentally a form of efficiency, either through time-shifting of economic activity such that the same level of output can be achieved at a lower cost, which is to be encouraged, or acknowledging that the value of that economic activity is effectively less than the cost of production. As stated above in answer to Q2, international competitiveness is underpinned by the cost of energy. If demand management has value then, by implication, the cost of energy is high, and that production will almost by definition be less competitive internationally. Consequently reliance upon demand management within an industrial sector should be seen as an

indicator that that sector is likely to be less internationally competitive than similar sectors overseas that aren't reliant on demand management.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

This will depend upon the types of assets in question, since technological advances do not affect all assets equally. Those assets that are technologically immature will have a relatively high initial capital cost and may have higher maintenance and repair costs. As technologies mature, their capital costs decrease through time as efficiencies and economies of scale are discovered and implemented. This can clearly be seen in the costs of photovoltaic cells over the last decade, which reduced by ~60% within 3 years.

UK solar PV cost reduction, 2010-2014 (4kW system)

Source: "UK solar beyond subsidy: the transition" July 2015, Renewable Energy Association http://www.re-a.net/resources/pdf/206/UK_Solar_Beyond_Subsidy_-_The_Transition.pdf

It may be more efficient to replace such assets earlier in their lives to take advantage of the rapidly reducing capital costs. However, as technologies mature, efficiencies, innovation and economies of scale are developed within the maintenance and repair cycles of those assets. Hence it is more efficient to maintain and repair existing assets for the bulk of their economic life.

However, externalities such as de-carbonisation need to be taken into consideration when making the economic choice between maintaining existing assets and construction of new. The most efficient way to ensure that those externalities are taken into consideration is to ensure that efficient markets are developed to allow participants to price them appropriately in to their economic choice between maintain / repair or replacement, thus striking the most efficient balance between the two.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by "funding", the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that "can be funded" but "will not be financed" refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties.

General government financing policy (i.e. the issuance of gilts) is out of scope.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

We believe that the most effective way of ensuring resilience is to ensure that planning within and across sectors is done over an appropriate planning horizon. In sectors such as energy generation and water, even 30 years is far too short for strategic infrastructure planning when considering the impact of a project individually and in combination with others. For example, the potential for multi-sector 'water assets', such as major reservoirs or major water transfer systems, that will last for decades will also very likely affect major power station operations or future developments and so the full impacts need to be addressed through cross-sector collaboration and understanding at all stages of a project.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The Planning Act 2008 has established an efficient new process for the consenting of major infrastructure projects (NSIPs). The existence of a clear statutory timeframe for decision making in particular represented a major positive shift, leading to the consenting of projects with greater certainty. Further improvements could be made to this process if statutory timeframes were introduced for post consent variations, such as non-material changes to a Development Consent Order, and if the requirements for the post consent variation process were, as a whole, simplified. Additional benefits would result from promoting the use of the Rochdale envelope and the building of flexibility in the wording adopted in Development Consent Orders.

In relation to environmental assessments linked to planning consents, we consider that is particularly important for the Environmental Impact Assessment processes under the national infrastructure planning and town and country planning regimes on the one hand, and the marine licensing regime on the other to be made compatible, so that marine licensing concerns and information requirements are understood on the screening and scoping procedures initiated under the planning regimes. This would avoid unnecessary delays and duplication. In relation to other environmental assessments, such as the Habitats Regulation or the Water Framework Directive Assessments, it is paramount to strike an appropriately balance between sustainable development (and the need for major energy infrastructure) against potential impacts which could be minimized via mitigation or compensatory measures.

It is also essential that the NIC recommendations leading to the future review of the Energy National Policy Statements, and in particular of EN-1 and EN-2, recognise the need for diversity in the UK energy mix and the vital role of fossil fuels (and specially the role of new gas power plants) in providing reliable and flexible electricity during the UK transition to a low carbon economy.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: "credible" improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. "Tractable" improvements are those that can generate usable quantitative outputs. "Transparent" improvements are those that do not rely on 'black box' modelling and assumptions.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing "regime" refers to the current market, competition and planning frameworks. "Digital communications" includes both fixed and mobile connectivity.

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Without the correct valuation of the carbon content of heat, traditional methods of providing heat will always be less costly than providing decarbonised heat. Any move towards the bulk decarbonising of heat needs to be done in the context of the international competitiveness of the UK economy, as such the UK should be promoting appropriate international carbon markets such that the UK's efforts to decarbonise heat, transport and electricity, which are to be applauded, do not disadvantage the UK economy as a result.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.

We believe that properly designed and internationally supported carbon markets are the only the route by which all sectors of the economy can efficiently decarbonise. Furthermore, the fact that such a market will be difficult to implement does not mean it's the wrong thing to do. We do not currently have a vision of what a zero-carbon power sector in 2050 looks like, as it is likely that it will include technologies of which we are as yet unaware, but we are sure that properly designed markets will provide the right incentives for the appropriate innovation and investments to take place to deliver the necessary decarbonisation.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The consequences of decarbonising the transport sector will depend upon the form of decarbonisation, be it via hydrogen fuel cells, as being seen in the Far East, or by electrification and decarbonising electricity generation, the current chosen route of the US and Europe. Both these decarbonisation vectors will likely require significant investment in transmission and distribution networks, given that hydrogen production is only likely to be economic at scale, renewable electricity sources are by necessity remote from large population centres, and refuelling of cars is inherently a decentralised activity. However the investments in these parts of the value

stream will differ significantly – one being the transportation of a highly volatile gas, the other being wires for the transmission and distribution of electricity. Whilst much of current US and European interest and investment has focused on electric vehicles, very few electric vehicles are currently active on the roads, so in truly strategic timeframes it is difficult to predict which technology choice will be adopted at large scale, and as such there is a significant risk of embedding economic inefficiency through asset stranding. Ultimately this will be decided by consumer behaviour and preference, so to understand which technology is likely to fare better, one needs to understand how each technology is viewed by consumers.

Water and wastewater (drainage and sewerage):

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Abstraction reform is a welcome initiative. However, the delay in developing detail creates uncertainty for potential developers of water dependent infrastructure and needs to be resolved. It will drive much creative thinking, particularly on how to resolve the competition for scarce water resource in low flow or drought (and these are different). Given the vital importance of thermal power plant dependent on water in contributing to power sector resilience we would be looking for comfort on relaxation of regulatory constraints on abstraction (either through 'hands-off flows' or standard catchment rules) in power sector system stress events. In general we are looking for the rules for operation of reform to be such as to provide sufficient confidence in sufficient volumes of water with sufficient reliability to make the next generation of freshwater thermal power plant investable. The role of well-established and 'firm' discharges in underpinning low flows in major lowland rivers needs to be recognised, effective control of any potential for them to be rerouted or withheld that would affect dependent users or the environment need to be established, and the EA approach to the EC Water Framework Directive relating to low flows needs to be clear and consistent with the aquatic environment to which society has evolved over several decades.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

In our view the 'whole catchment' approach is one means of breaking down the traditional siloed approach to planning. However, this runs the risk of bottom-up driven decision making. This is illustrated by the downgrading of the role of the 'regional' River Basin District Liaison Panels which have the potential to consider more strategic approaches. Whilst there is certainly an important role for catchment level approaches, this does not mean that river basin district scale considerations are not important. Thermal power plant represent very large point influences (when considered at catchment scale) whose societal contribution needs to be recognised at the national level. This may render them potentially difficult to deal with in catchment scale assessments.

Water Planning is currently done primarily through Water Company Water Resources Management Plans, though initiatives such as Water Resources East are attempting to promote a multi-stakeholder approach. There are many difficulties to overcome to make such approaches effective, not least being the different regulatory structures applying to different sectors, such as public water supply, power and agriculture.

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

Solid waste:

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A "circular economy" is an alternative to a traditional 'linear economy' (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

Open letter to the National Infrastructure Commission to accompany input by Resources & Waste UK to the National Infrastructure Assessment “Call for Evidence”.

Thank you for this opportunity to provide early input to development of your first National Infrastructure Assessment. Resources & Waste UK is a collaboration between the Chartered Institution of Wastes Management and the Environmental Services Association – the professional institution and trade association at the heart of the sustainable wastes and resources management industry. We identified this Assessment, alongside the Defra 25 year Environment Plan and the UK Industrial Strategy as key steps in development of this sector and a more “Circular” or resource efficient economy for the UK. We are therefore pleased to note that “Solid Waste” is recognized as one of the 6 key sectors in this first Assessment.

Our response to your call for evidence is attached as Annex 1 to this letter, and follows the framework of questions in your call for evidence. However, we also recognize that waste and resources management is complex, especially in the way that it affects businesses in all sectors as well as households, local authorities and not-for-profit organisations. Therefore, while we have addressed the specific questions you have raised regarding this sector and delivery of a more circular materials economy, we want to stress four main points: the rapidly developing role of this sector; our need for new generations of infrastructure, services and technologies; current trends in infrastructure; and our developing relationships with partners and customers both up-stream and down-stream in complex resource flows.

i). **The developing role of the industry.** This is an industry in transition. Efficient collection, and removal of wastes from businesses and households – to protect local environmental quality - remains as important as ever, but the objective has changed quickly in 2 decades from safe and efficient waste disposal to one of keeping resources working and putting wastes back to work wherever possible. We have become a critical step in supporting resource efficiency and resource security in an increasingly resource-constrained world. If we are to maximise our value to the UK in environmental, social and economic terms this industry will need new technologies and infrastructure to manage end of life products and materials.

ii). **The main drivers.** Patterns of consumption and production continue to change, involving modern and often complex materials and a shift away from ownership to services. Product and process design will also be driven by the need to be more resource efficient in the future to protect feedstocks and costs of inputs as well as to reduce overall environmental costs of outputs. Our industry has to follow these changes carefully and work with supply chain partners to help present resources and energy back into the market and to stimulate uptake of those resources by businesses. However, rather than technologies and population or economy growth, the most important driver in solid wastes and resources management is policy. The EU has provided long term vision and stability for environmental and resources policy whose next phase will be driven through the Circular Economy package. Scottish and Welsh resource management policy has developed in line with – and sometimes beyond – likely EU objectives. English policy has not, and the status of the Circular Economy package under the UK’s exit from the EU and how the Government’s ambition to “leave the environment in a better state than it found it” will be delivered, is uncertain. Unfortunately, that uncertainty comes at a time where change is necessary but where lead times for new services and / or infrastructure stretch well beyond the current 2019 and 2020 policies in place. The Commission will need to consider both market pulls and pushes as well as likely future policy in anticipating future infrastructure needs in this industry.

iii). **Current Trends.** Current UK investment in new recycling and treatment capacity for solid waste is low. This is a particularly pressing concern for the treatment of residual, non-recyclable, waste. High landfill tax levels have led to pan-industry plans to steadily move away from landfill, and we anticipate around 80% of existing landfill capacity to close between 2015 and 2020. We also currently export over three million tonnes (and rising) of refuse-derived fuel to treatment plants in other parts of Europe – a trade that this industry believes is now approaching saturation and which could be frustrated by the UK's exit from the EU. Meanwhile, investment in recycling infrastructure is also low – faced with uncertain future policy and weak materials markets, and we estimate that around 15% of existing recycling capacity is likely to close by 2020 as it ends its planned life. Investment in new domestic waste treatment capacity is therefore crucial.

New energy from waste plants have lead in times of at least four to six years, other technologies at least 2 years and often more. We must make decisions now about new treatment capacity or else we will unwittingly enter a situation where the only viable option for treating much of our “residual” waste – ie that left after re-use and recycling - in the 2020s will be by opening new landfills. This would reverse the policy direction of the past two decades and put us out of step on waste management policy with much of the rest of the developed world.

iv) **Relationships with other resource cycle partners.** In assessing future needs for waste processing infrastructure the Commission will need to take industrial demand into account for secondary (ie recycled) materials and waste-derived energy in all of its forms. In the long run – but within the time-frame of this Assessment - virgin resources will be increasingly constrained as a business feedstock. Under these conditions a more circular materials economy should create its own demand for the outputs from this industry. In the short term however, those demands will need to be stimulated – hence the importance of policy in shaping the future of resources management, and the need for whole-cycle engagement in resource efficiency and security.

The links between this Assessment and the Defra 25 year Environment Plan and the UK Industrial strategy are therefore especially important. Between them, these initiatives add up to more than a waste and resource management strategy and we urge the Commission to work across other Government Departments to make and maintain those links.

Thank you again for the opportunity to present this initial input to development of the Assessment. We look forward to continued close working with you.

On behalf of Resources & Waste UK

[title redacted]

National Infrastructure Assessment Response by Resources and Waste UK

Cross-cutting issues	
1	Not covered
2	<p>Q: How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?</p> <p>A: Efficiency and security of resource management in the future is a key element to the UK Industrial Strategy and R&WUK wishes to see a strong link between this Assessment and the Industrial Strategy and Defra 25 year plan. We highlight two issues of interest:</p> <p style="text-align: center;">1. The importance of wastes and secondary resources as a “catalyst for Growth”</p> <p>The value to the UK economy gained and to be gained through more efficient and effective waste and resource management is recognized in the Defra publication “Resource management: a catalyst for growth and productivity” (February 2015) [https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/401453/resource-management-catalyst-growth-productivity.pdf].</p> <p>This report concludes:</p> <p><i>(p 3). Over the past decade the value we extract from managing our waste resource has increased significantly - The GVA/tonne of waste managed by the sector has risen from £32 in 2004 to £43 in 2012 (after adjusting for inflation), representing a 33% increase in real terms over the 8 year period. There has been a significant reduction in waste arisings and relatively stable GVA over the period. And</i></p> <p><i>(p 6). Domestic reprocessing, where commercially viable, could add further value in the UK, supporting jobs and growth, and contribute to improving the UK trade balance – Where commercially viable domestic reprocessing allows value to be added to recovered material in the UK. This provides a source of jobs and investment; improves the UKs trade balance (compared to not collecting/recycling the material) by reducing the need to import raw and recovered materials from overseas; and contributes to UK resource security. The tight economic climate in the recycling sector at present highlights some of the challenges faced by domestic reprocessors, but also the value of supply chain collaboration, which gives industry the confidence to invest.</i></p> <p>R&WUK welcomed this analysis of the sector. UK Governments should commit to a full periodic review of this analysis to complement future work of the Commission for this sector.</p> <p style="text-align: center;">2. Export potential</p> <p>The UK has a significant potential for export of expertise in sustainable resources and waste management. The 4 UK nations were recognized as the fastest improvers in municipal waste recycling in the EU in the first decade of this century, and this experience is valued in many other countries around the world where a similar transition to more sustainable waste and resource management is needed. This potential is recognised by UK Trade and Investment and we will be</p>

working with them to develop case studies and opportunities to showcase UK competence in this area as a priority sector for export growth.

3. Strategically Important Materials

Both UK Government and the EU have identified materials which will be key to future industrial and economic development but which for reasons of scarcity or unstable supply chains could be a rate or success-controlling factor. See for example The EU Commission list, extended to 20 materials in 2014: https://ec.europa.eu/growth/sectors/raw-materials/specific-interest/critical_en. R&WUK advises both this Infrastructure Assessment and the Industrial Strategy to note the importance of these materials - and others less critical but still important in economic development terms which could and should be outputs from the waste and resources management sector of the future. "Other" outputs would include materials ranging from secondary aggregates to plastics and paper plus energy in all its forms including heat. Competition for strategically important materials will intensify over the period covered by these two plans making resource efficiency and resource security key concerns for many sectors and technologies.

4. Secondary Resources: Quality, Quantity and Location

The UK should benefit from the economic and trade potential from its wastes. That requires infrastructure and technologies capable of presenting materials back into the economy at the quality and quantity demanded by customers rather than continued reliance on export of materials – part processed or wholly re-processed.

3

Q: How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

A: The individual facilities required for more sustainable management of UK wastes and resources are likely to be much smaller scale than those required for other sectors included in this assessment eg transport networks or energy generation and distribution. Landfill sites typically attract economy of scale in their operation and grew steadily in size and annual input throughout the second half of the 20th century. Many were – and are – many millions of tonnes total capacity and receive(d) wastes at a rate of many hundreds of thousands of tonnes per year. Waste treatment facilities tend to be small and have smaller annual capacities to receive wastes. A-typically, a very large energy from waste facility might accept 300 to 400 thousand tonnes of waste per year. Many facilities such as for materials sorting or for biological treatment will accept much less – sometimes only 20 thousand tonnes per year. As we move rapidly away from our reliance on (and availability of) landfills in England we will need a sophisticated network of waste sorting and treatment infrastructure, with materials moving between more than one facility in its transformation from waste to resource, and designed to meet both waste and secondary resource objectives.

Such smaller plants may lend themselves to be planned for provision of a service across a smaller area – possibly serving a single local authority or an individual customer. However, our wastes need to be viewed more as valuable resources and an input to UK industries in the future. R&WUK therefore believes the provision of services and infrastructure to manage our wastes economically and effectively needs to be matched with planning for use of the secondary resources they generate including materials and energy. The economic and employment importance of these resources should mean that the infrastructure needed should be matched with business demand for resources

and land allocated for them. This would be better done at a regional or sub-regional level within England rather than allowing a sub-optimal network to be developed through a large number of very local plans. The system also needs to recognize that high transport costs – especially for heat but also for many lower value materials – means there is a strong argument for co-location of facilities generating secondary resources with industries wanting to use them as a feedstock. This is a tier of planning currently missing from the English planning system. The Commission should note that a duty to co-operate exists between local authorities and preparation of their local plans but this is no substitute for planning for resources and economic development at a larger scale.

The Commission should note, for example, the rapid growth of “refuse-derived-fuel” exports to other EU Member states (see below under Q 28) which represents a negative value to the UK with costs of export and treatment typically £60 to £80 per tonne for a fuel which has roughly 50% of the calorific value of coal and a high biogenic (ie non-fossil) carbon content. See Defra’s “Energy from waste A guide to the debate” (February 2014) (revised edition): https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/284612/pb14130-energy-waste-201402.pdf .

The Commission should also note the reliance of this sector on good design of the built environment and of housing in particular, allowing space for storage, separation and collection of waste materials in a condition suitable for re-processing into high quality secondary materials. Too many developments consider waste collection requirements at the very last stage of design, if at all, making contamination between waste streams and lower quality outputs more likely.

4

Q: What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage

A: R&WUK believes there is significant potential for demand management for waste services and infrastructure for municipal and for industrial and commercial wastes through:

- Better design of products and processes including increased secondary material content and design for end-of-life reprocessing
- Design and skills / infrastructure for managing wastes further up the Waste Management Hierarchy including maintenance, repair and re-use
- Improved separation and presentation of waste materials for processing.

These are recognized in the EU Communication on the Circular Economy and in the February 2016 Scottish Government “Making Things Last” strategy [<http://www.gov.scot/Resource/0049/00494471.pdf>]. The Scottish Government identify barriers and potential solutions at each stage in the product life cycle and are exploring development of regulations and further interventions to deliver a more circular materials economy, starting later in 2017.

	<p>R&WUK has identified a number of priority interventions needed by UK or national governments – often best planned implemented and monitored at a pan-EU level to provide businesses with a level playing field – and these are set out in Qn 27 below.</p> <p>We particularly highlight the potential of</p> <ul style="list-style-type: none"> • Extended producer responsibilities which are relatively under-developed in the UK compared to other EU Member states • Direct charging for municipal wastes (so-called “pay-as-you-throw” or “save –as-you-recycle” schemes) – unused in the UK and actually prohibited even for pilot schemes. The Commission should note that local government is seeking full clarification regarding which waste services could be subject to charging as a direct result of budgetary constraints. • Fiscal instruments including variable VAT to encourage secondary materials use or re-use and repair • Product standards including longevity and minimum secondary materials content. <p>UK and English governments have introduced demand-side measures especially the single-use carrier bag 5p levy which retailers report has cut consumer demand for bags by 80%, and with an immediate impact in beach litter by bags. Defra is reported to be considering a deposit and refund system for drinks packaging – both plastic and glass – and is currently consulting on a product prohibition through a ban on plastics micro-beads in cosmetic and similar products. They have at the same time ruled out a levy on disposable coffee cups, despite their clear impact on littering and waste generation. Rather than an ad-hoc approach to individual products and materials we need to see a clear strategy for materials efficiency and waste prevention / better management through the EU Circular Economy strategy. We remain committed to support Defra and the UK Government in development and adoption of that EU level policy and strategy.</p>

6	Not covered
7	Not covered
8	<p>Q: Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets? The National Infrastructure Assessment Call for Evidence 9 Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.</p> <p>A: The financing of sustainable resources and waste infrastructure and services is currently too focused on the public sector, and on local authorities in particular. This has arisen because of the long term reliability of public sector waste management contracts – collection contracts typically run for 7-plus years (often tied to the serviceable lifetime of collection vehicles involved in these contracts), treatment and infrastructure contracts can run for 25-plus years dictated by the high capital cost of infrastructure and its serviceable life-time. Industrial and commercial wastes management contracts are often much shorter-term, usually renewed annually or even ad-hoc, especially for small or non-steady-state arisings.</p> <p>R&WK wishes to highlight three important infrastructure funding issues to the Commission:</p>

1. The role of extended producer responsibility (EPR)

R&WUK advocates (see below) a shift towards extended producer responsibility such that businesses responsible for design, manufacture and sales of products and materials accept a greater responsibility for those products and materials at the end of their useful life – ie when they become waste. This would represent a significant shift away from strong reliance on local authorities who – for example – currently shoulder roughly 90% of the end of life costs for managing packaging wastes. This is in stark contrast with other EU Member states and EU objectives for the future of extended producer responsibility in their Circular Economy” policy and regulation package (proposed Waste Framework Directive Article 8(a)) currently under negotiation.

2. The role of the Green Investment Bank

R&WUK has welcomed and supported the role of the Green Investment Bank and their potential to encourage investment in waste and resources management infrastructure by others. We await the conclusion of the Bank’s privatisation and note the concern expressed by the Environment Audit Committee and others (January 2017) regarding the future focus and operation of the Bank. Our meeting with the Bank on 23rd January 2017 confirmed that despite continuing uncertainty relating to the privatization it continues to operate, and has invested in waste related projects in all 4 UK countries in 2016 and continues to manage a pipeline of projects for further investment.

3. Barriers to investment

Policy and regulatory uncertainty

Clear and medium to long term policy clarity and direction is need to support future investment in the waste and resource management sector, particularly as much of investment (aside from the collection of municipal waste) is now expected to come from the private sector. However, England currently lacks a formal strategy for waste, and any policy objectives still applicable from the 2007 Waste Strategy and the subsequent 2011 review (such as the 50% recycling target in the EU Waste Framework Directive) only extend to 2020. The 2011 review also removed statutory recycling targets on local authorities, weakening the case for public sector investment in recycling infrastructure.

The impact of policy uncertainty is acknowledged by government; as Defra notes in its 2015 ‘Resource Management: a catalyst for growth report’

(https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/401453/resource-management-catalyst-growth-productivity.pdf):

“...Decisions on investment in new infrastructure are made by market participants based on their assessment of future demand and supply and financial viability. Expectations about future Government policy, including in relation to waste and resource management, affects those assessments and therefore influence investment decisions. A key source of policy uncertainty concerns the framework for policy determined at European Union level.”

While there is now more clarity on the policy framework likely to come from the EU in the shape of the EU Circular Economy package, Brexit has introduced a new source of uncertainty about the long term future of waste and resource policy in the UK. This is likely to impact on an investment landscape that was already constrained (see below); an assessment made by the trade body the

	<p>Environmental Services Association (see 27.3 (iv) below) suggests that there is almost no new public sector procurement of recycling infrastructure through their members currently in the pipeline for England.</p> <p>Risk and return on investment</p> <p>Increased price volatility in secondary materials markets in recent years (see R&WUK priority under Q27) is also undermining the potential return on investment for recycling infrastructure and discouraging private sector companies from investing. Appropriate risk mitigation or risk-sharing mechanisms have yet to be developed.</p> <p>A further factor, as noted in the 2011 report ‘Rubbish to resource: financing new waste infrastructure’ by Associate Parliamentary Sustainable Resource Group (http://www.policyconnect.org.uk/apsrg/sites/site_apsrg/files/report/332/fieldreportdownload/apsrg-rubbishtoresource.pdf), is the “complexity of the inherent risks associated with waste infrastructure, including technology, planning, construction, policy, off-take and input tonnage”.</p>
9	Not covered
10	<p>Q: What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?</p> <p>A:</p> <p>Development control and Permitting</p> <p>ESA member companies confirm that development control planning through local authorities generally delivers well-founded decisions in individual planning permission applications, and Environmental permits through the Environment Agency, although both are subject to delays and slow decisions.</p> <p>Planning permission applications for waste management infrastructure can be complicated and there are examples of serially-delayed decisions and where decisions have been frustrated by differing objectives of authorities in two-tier areas. Examples of both are well known across the industry and details can be provided separately to the Commission is needed.</p> <p>R&WUK is clear that planning authorities and the environmental regulators must be properly resourced to be able to complete their roles efficiently and effectively. We have repeatedly voiced our concerns over the level of resourcing of the Environment Agency and our concerns re the recent suspension of their “end-of waste” panel is such a case. The panel helped businesses with often very difficult decisions as to when materials are “waste” and therefore subject to full waste controls – or where they can be managed in the same way as any other raw material. The panel was originally reported as “suspended” for 3 months but now appears to be fully withdrawn.</p> <p>Strategy development</p> <p>England has an out-dated “Waste” strategy (2007) and no regional or sub-regional planning for wastes or resources and their link to economic development. Rather than calling for development of an England Resources Strategy R&WUK sees significant potential in this Infrastructure Assessment especially if it is fully co-ordinated across Government with other key strategies also under development, and particularly:</p> <ul style="list-style-type: none"> • The UK Industrial Strategy

	<ul style="list-style-type: none"> • The Defra 25 year Environment plan • The BEIS Bio-Economy Strategy • The forthcoming Carbon Reduction Plan to complement the 5th Carbon Budget. <p>R&WUK urges the Commission to co-ordinate its work with that of other departments as above as a powerful way of recognising and realising the potential for economic, social and environmental benefits achievable through improved wastes and resources management. We would also like to see monitoring and reporting frameworks for all of these strategies, and their formal review cycles to coincide with the UK parliamentary term.</p>
<p>11</p>	<p>Q: How should infrastructure most effectively contribute to protecting and enhancing the natural environment?</p> <p>A: The whole objective of wastes and resources management are:</p> <ol style="list-style-type: none"> 1. To protect health and environmental quality locally 2. To protect the broader environment including impacts of resource use and waste management on issues such as climate change, carbon / climate change gas (ccg) emissions, water use etc 3. To improve resource efficiency and resource security especially in strategically important materials as well as energy and other materials, and to reduce demand on primary raw materials which often have high environmental and/ or social costs which are not internalized in prices paid for goods or services.. <p>The objectives of a more “circular” materials economy are identified clearly in the EU Circular Economy Communication issued by the EU Commission in December 2015 [http://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:52015DC0614&from=EN]</p> <p>The Government has stated its objective of being the first to leave the environment in a better state than it found it and R&WUK urges the government to confirm its commitment to the future of a more circular materials economy through the EU Circular Economy package and by making clear that there will be no diminution of environmental standards or weakening of environmental law as a result of the UK exit from the EU.</p> <p>This call for evidence also highlights key sectors with infrastructure needs which are likely to be important markets for secondary materials in the UK. Transport infrastructure and much of the built environment should be important in generating demand for secondary aggregates, metals etc. This assessment should encourage those markets through promoting development of procurement guidance, specifications and standards in those industries. The demolition industry in the UK has a good and improving performance in materials recycling and this may be an aspect of resource efficiency the Commission will want to explore more fully.</p>
<p>12</p>	<p>Q: What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent? Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.</p>

A: Cost benefit analysis for wastes and resources management is poorly developed at both UK and EU levels. Infrastructure and service provision is predominantly policy-driven with analysis applied at that level. Various models have been developed including by the EU, Scottish Government, the Mayor of London and others for life-cycle assessment of plans and strategies especially for carbon accounting. Outputs from different LCA models are often difficult to compare. They often rely on different assumptions, rely on very detailed information input and analysis, and often still exclude potentially important considerations such as “embodied water” in products and services. Development and adoption of standardised approaches to life cycle costing and reporting are included in the Action Plan associated with the EU Circular Economy package and we urge UK government to support LCA development at that level.

At a strategic policy level, there are also question marks over the Treasury’s approach to cost-benefit analysis in the context of sustainability. This issue is considered in detail in the Environmental Audit Committee’s 2016 Sustainability and HM Treasury inquiry report (<https://www.publications.parliament.uk/pa/cm201617/cmselect/cmenvaud/181/181.pdf>), which concludes that:

“The Treasury’s technical and political framework for assessing environmental interventions is geared towards favouring short-term priorities at the expense of long-term environmental sustainability, even when it could lead to higher costs to the economy in the future. In part, this is because its framework does not take account of long-term benefits adequately. Ministers cannot make well-informed decisions unless they have access to all relevant information including long-term costs and benefits.

“The Treasury needs to improve the way it captures and takes account of long-term environmental costs and benefits. It must ensure that it has the best available evidence when making decisions about specific interventions, for example, by including wider costs and benefits and establishing a consistent framework with which departments can provide supplementary evidence in addition to NPV calculations. It should also make more use of relevant independent advisory bodies during spending reviews to scrutinise bids and green-check – a systematic environmental stress test – initial high-level assessments prepared for Ministers to inform their decision-making.”

Solid waste

27

Q: “Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?”

A: NO

Resources & Waste UK (R&WUK) is a partnership created by The Chartered Institution of Wastes Management (CIWM) and the Environmental Services Association (ESA) in 2014 because of the absence of the right policy framework for delivery of a more circular resources economy in the UK.

27.1 R&WUK priorities and progress 2015 - 2016

The first publication by R&WUK (May 2015) was our “Sustainable resources and waste management: priorities for the incoming UK Government” report:

[http://www.resourcesandwasteuk.co.uk/docs/RWUK_Priorities_for_the_new_UK_government.pdf]

R&WUK considers that there are 6 priority areas where policy and performance need to be aligned to successfully deliver a more circular materials economy:

1. **Support and improve waste collection/recycling performance**
2. **Improve the climate for investment in circular economy infrastructure to deliver sustainable growth and jobs**
3. **Boost domestic demand/markets for recyclates**
4. **Create the right regulatory balance between hitting waste criminals hard and reducing burdens on legitimate business**
5. **Greater government co-ordination of resources and waste policy**
6. **Engaging positively in policy development for resources and wastes at a European level**

All 6 priorities are inter-linked and progress will be needed in all areas to ensure that secondary materials are captured at the right cost, that treatment infrastructure is available to manage them in the right places to present materials of the required quality back into the market(s) – in order to meet current and likely (policy and market-driven) future objectives. Progress in these areas will hopefully drive innovation at all points in the materials cycle – from product design and manufacturing processes through to end-of life re-processing, and will shift responsibility for funding future infrastructure and services more fairly to those who gain benefit from making and selling them and to consumers.

R&WUK has prioritised its work across all 6 priority areas. Of these, the fight against crime unites all parts of the industry. It undermines all aspects of responsible resources management, including the business case for new and improved infrastructure and services. The cost of waste crime was estimated to be over £500Million per year in ESA's "Waste Crime: Tackling Britain's Dirty Secret" report (2014)

[\[www.esauk.org/reports_press_releases/esa_reports/ESAET_Waste_Crime_Tackling_Britains_Dirty_Secret_LI_VE.pdf\]](http://www.esauk.org/reports_press_releases/esa_reports/ESAET_Waste_Crime_Tackling_Britains_Dirty_Secret_LI_VE.pdf) and we urge the Commission to recognize the impact it has on planning and investment for future resource efficiency and security. Important cross-sector work is underway to fight waste crime including government support, the regulators and the industry itself, but more remains to be done.

Drawing on our analysis of our 2015 priorities we would also highlight work in 3 areas in particular:

27.1.1 The need to stabilize markets for secondary materials. This includes our September 2015 report: "Managing the Risk From Secondary Materials Price Movements" [http://www.resourcesandwasteuk.co.uk/docs/Eunomia_RWUK_SRM_Price_Risks_Report_Sept_15.pdf] and an on-going working group exploring best practice and case studies in public / private sector waste contracts., This work complements the WRAP-led Collection Harmonisation programme and Food Waste Action Plan, all of which draw on aspects of waste management contracts.

We conclude that stable secondary materials markets and prices are essential to support performance and future infrastructure and services, and that they in turn must be supported by stimulated demand for secondary resources including materials and energy. However, the best contracts practice work we leading can only promote commodity price

risk sharing between public and private sector partners. At best this is a coping mechanism. Longer term solutions are needed including the use of extended producer responsibility schemes designed to reflect market conditions and / or schemes such as the Scottish materials brokerage scheme [<http://www.zerowastescotland.org.uk/brokerage>] which would require government intervention at either an England or whole-UK level.

In the meanwhile price volatility in secondary materials markets, especially for some plastics, has been an important factor in failure of some waste re-processing activities and poor performance in post-consumer plastics collection and recycling (See Guardian article October 2016) [<https://www.theguardian.com/environment/2016/oct/15/british-households-fail-to-recycle-a-staggering-16m-plastic-bottles-a-day>]

27.1.2 The role of extended producer responsibilities (EPR) in the future management of end of life products and materials. Our work to date on this subject includes:

- ESA research “The Role of Extended Producer Responsibility in Tackling Litter in the UK” (September 2016):
[http://www.esauk.org/esa_reports/20161011_The_Role_of_Extended_Producer_Responsibility_in_Tackling_Litter_in_the_UK.pdf]
- ESA research “ a Discussion of the UK PRN/PERN System for Packaging Waste and Possible Alternatives” (September 2016)
[http://www.esauk.org/esa_reports/20161018_A_discussion_of_the_UK_PRN_PERN_system_for_packaging_waste_and_possible_alternatives.pdf]
- ESA convened stakeholder day to discuss EPR for packaging November 2016.
- CIWM research: “Packaging Waste Recovery, a European Comparison” (July 2016)
[<http://www.ciwm-journal.co.uk/downloads/Packaging-Waste-Recovery-A-European-comparison.pdf>]

The Board has also noted the value of the Green Alliance report “Recycling reset: how England can stop subsidising waste” (January 2017) [http://www.green-alliance.org.uk/England_recycling_reset.php], which also highlights the importance of the role of extended producer responsibility in transferring the cost and responsibility for managing end of life products and materials away from the public sector and onto manufacturers and retailers.

We conclude that extended producer responsibility is relatively under-developed in the UK compared to many EU Member States as shown in the comparison included in a report published by Eunomia: “A Resourceful Future – Expanding the UK Economy” (Sept 2016). The cost of EPR schemes in the UK falls disproportionately to the public sector, with many other EU Member State schemes requiring full end-of-life costs to be borne by businesses responsible for placing those goods on the market in the first place. This will be a requirement of the EU Circular Economy package currently under negotiation under Art 8(a) of an amended Waste Framework Directive if approved. We have urged UK Governments to

support this move to ensure that the cost of future service and infrastructure for resources and wastes management fall more fairly to businesses in future.

27.1.3 The importance of data, monitoring and forecasting especially for future infrastructure and service design and delivery. Our work in this area includes:

- CIWM research “ EU Recycling Rate Harmonisation” (October 2015)
[<http://www.ciwm.co.uk/Custom/BSIDocumentSelector/Pages/DocumentViewer.aspx?id=QoR7FzWBtisamYEcWSfL6SxAJRLAPT9vt6uxsHjHU7ByWoeYsllctad7OZaPM7fU%252fxM46wVw%252bYA%252bHKKEszcQzSWI9o7Hb%252fdN%252fu5HymgvSsk686sGxFrGOKK6SnNaS99IVIm%252f66R8v%252fjCr87Np6h5YY7aw1O8fJ1q3QS0Q561wNoh0fAZ2hWvQ%253d%253d>] which has emphasized the importance of standardized definitions and data / reporting standards across all EU Member States to avoid misleading comparisons between reported recycling, landfilling or recovery performance for wastes.

Welsh Government municipal waste recycling statistics include recycling of “incinerator bottom ash” whereas England statistics do not. While this would only make a roughly 2% difference in the superior Welsh recycling performance reported (64% June 2016 cf England’s 44%) due to relative under-reliance on EFW for waste treatment in Wales – this does serve as an example of the importance of standard data and reporting requirements both within the UK and across the EU. Without it comparisons in recycling or other waste / resources management are difficult and / or mis-leading.

We are pleased to note early progress made by the EU under the Dutch and Slovenian presidencies in this area.

- CIWM research “Commercial and Industrial Waste in the UK and Republic of Ireland” (October 2013)
[<http://www.ciwm.co.uk/Custom/BSIDocumentSelector/Pages/DocumentViewer.aspx?id=QoR7FzWBtisamYEcWSfL6SxAJRLAPT9vf9UOxY7TX%252bRvV%252ffsIKIsqU2EtUq%252bj7oCo87Wof%252fbs9PqCytSgZ5tfRfy2%252bBshoiDu7f882AjZtqLLztRjeHBL8ywUdWYhRgk>] which concluded there could be a waste treatment capacity shortfall in the UK of between 5 Million and 15 Million tonnes by 2020 without early action.
- CIWM research report: “[Waste on the Front Line - Challenges and Innovations](#)” (February 2015):
[<http://www.ciwm.co.uk/Custom/BSIDocumentSelector/Pages/DocumentViewer.aspx?id=oS0dqUqTFI59be4ZqTMWn2qeSjzQKkOO%252f3x9%252bb3eWbE0k4f7wJMLwzV7kdIOwHthWKsgwQ1RSnpNThqCj18a8EUVb7KTzrb1C8XdktfOCJZ9M7SQdQu3hqf3u%252by49u837kGcfEQxBQywrhx0Wkl8cV7p9ErbkOaq0ow%252bhsD4gUBoaip8oMvlchj2OEJdFDewJSEBNy713%252fk%253d>] This report highlighted the impacts to date and forecast to 2020 on waste services in local authorities. Local government budgetary constraints since that time have cut even deeper into local waste services contributing to the first recorded decline in the UK recycling rate since records have been kept and makes R&WUK increasingly concerned that current recycling targets for municipal waste (50% by 2020) are now unlikely to be met without significant investment in services and infrastructure or changes to definitions and

reporting standards (See Defra digest of 2016 waste data)

[https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/577716/FINAL_Stats_Notice_Nov_2016.pdf].

The Board also note research undertaken by individual ESA member companies exploring forecasted waste arisings and availability of infrastructure to treat it in the UK, including:

- SUEZ research report “Mind the Gap, UK Residual Waste Infrastructure Capacity Requirements 2015 – 2025” (2014) [<http://www.sita.co.uk/downloads/MindTheGapReport-SITAUk-1402-web.pdf>].
- Veolia / Imperial College Research report “Waste Infrastructure Requirements for England” (March 2014) [https://workspace.imperial.ac.uk/environmentalpolicy/Public/NV%20Veolia/IC2014_waste%20report.pdf].

These studies concluded a similar likely waste treatment infrastructure shortfall to that identified in the CIWM / Ricardo AEA study – SUEZ reporting a 5.7 Million tonne capacity gap for residual waste treatment by 2025, Veolia / IC reporting important regional under-capacities.

The Green Investment Bank also reported in “The UK Residual Waste Market” (July 2014) [<http://www.greeninvestmentbank.com/media/25376/gib-residual-waste-report-july-2014-final.pdf>] that “merchant” treatment capacity (ie catering for C&I waste arisings) of between 4 million and 7.7 Million tonnes would be needed by 2020.

These reports need to be considered in the light of the rapid growth of “refuse-derived-fuel” (“RDF”) exports to other EU member states from the UK in the last 5 years to energy recovery plants especially in the Netherlands and Denmark. This trade has now grown to over 3 million tonnes of RDF per year (see Letsrecycle.com report January 2017) [<http://www.letsrecycle.com/news/latest-news/rdf-exports-three-million-tonnes-2016/>] Continued long term export of this material may be frustrated by trading arrangements with the EU post-Brexit. Alternative – preferably UK based – infrastructure may be needed to manage that waste in future, albeit waste that presents a potential benefit to the UK either as materials or as energy. Whilst industry led analysis as above concludes that the UK faced(s) important waste treatment infrastructure gaps over the next 5 to 10 years, DEFRA has also concluded that no further support for infrastructure development was needed for local authorities in order to meet the 2020 Landfill Directive target. R&WUK agrees that the Landfill Directive target has been successfully met, but that this is specifically for municipal wastes only. Uncertainties regarding continued RDF exports and likely closures of existing waste recycling capacity, coupled with likely higher future targets for landfill diversion and improved management of wastes further “up” the waste hierarchy leaves R&WUK clear that the additional UK waste treatment infrastructure is needed – even in the short to medium (10 years) term.

Analysis and forecasts of wastes arisings and infrastructure needs for all wastes will be a major concern for this Assessment.

27.2 R&WUK Priorities for 2017 onwards

Over the next two years R&WUK will focus on 3 particular priorities:

27.2.1 This industry urgently needs medium term clarity on objectives / policy. Current policy objectives for waste and resources management generally only reach to 2020 in England (longer term objectives have been set in both Scotland and Wales). Planning and procurement cycles in waste and resources infrastructure are relatively long in the UK. Relatively simple and small scale infrastructure such as an anaerobic digestion plant typically takes 2 to 3 years to gain planning permission, an environmental permit and to be constructed / commissioned. Larger and more complex plant such as EfW facilities can take up to 10 years to deliver into operation, and sometimes much longer (see cross-cutting Q 10 above).

As noted in the Defra “Resource Management: A Catalyst for Growth” report:

“...Decisions on investment in new infrastructure are made by market participants based on their assessment of future demand and supply and financial viability. Expectations about future Government policy, including in relation to waste and resource management, affects those assessments and therefore influence investment decisions. A key source of policy uncertainty concerns the framework for policy determined at European Union level”

Defra confirm that they remain fully committed to negotiations at a European level on the Circular Economy Package. Their understanding is that this package and the amendments it will make to waste-related EU Directives including the Framework and Landfill Directives will be completed and adopted by the EU before the completion of UK “exit” negotiations under Article 50 of the Treaty of Rome. If that is the case then the status of those changes and their treatment under the Great Repeal Act will be crucial. R&WUK remains committed to working with Defra as the UK representative in those negotiations as this is likely to be the most important driver of UK waste and resource management policy and the planning and delivery by this sector.

Most recent advice from Defra regarding these negotiations (at their stakeholders meeting on 23rd January 2017) confirms progress made in fundamental issues such as definitions and recording / reporting, as well as negotiating positions regarding objectives such as municipal recycling rates and limits on future landfilling.

Given the uncertain timing of the circular economy package and its status under the Great Repeal Act – and the long lead times involved in this sector – we are calling on the Government to make a clear statement that it will not seek to cut existing waste management targets after EU exit, in line with their recent statement regarding their climate change commitments ie no diminution of standards post EU exit.

Concerns regarding the status of UK environmental legislation post EU-Exit were raised in the report of the Environment Audit Committee (4th January 2017) and echoed by an R&WUK press statement [<http://www.resourcesandwasteuk.co.uk/news.php>], although the Defra Minister Therese Coffey confirmed in the Commons debate on packaging on 23rd January 2017 that the Government assumes that negotiation and adoption of the Circular

Economy package will be completed before the end of the Article 50 EU exit process – and that they are engaging in that negotiation accordingly.

Defra Minister for waste Therese Coffey has suggested in response to a written question in the House (16th January 2017) that waste policy and legislation in the UK may need to be “re-shaped”. We anticipate further detail may be included in development of the Defra 25 year Plan, and we await consultation on the framework for that plan early this year. R&WUK advises that any such “re-shaping” should be sensitive to the need to develop policy continuity across the UK wherever possible in this sector and of the development of policy at an EU level under the Circular Economy Package.

27.2.2 The UK and English Government must co-ordinate and deliver on its plans for the development of this National Infrastructure Assessment, the Industrial Strategy and Defra 25 year Environment plan. The timing of consultations and development work on those strategies appears to have been frustrated by the demands on government resources under the EU exit preparations. Our sector recognises the importance of these plans and of their co-ordination. Between them these could be more important than the “resources strategy” called for by R&WUK in its 2015 priorities document. In particular we see that the delivery of secondary resources at the right quality from this sector should be a key consideration in the Industrial strategy as an economic development advantage for UK businesses and to strengthen future resource security. We therefore see clear links between this National Infrastructure Assessment and the UK Industrial Strategy.

The Commission should note that both Scotland and Wales have more up-to-date and ambitious waste and resources (“Circular Economy”) strategies than does England. The Scottish strategy “Making Things Last” was published in February 2016 and Scottish Government have signaled an intention to begin work on regulations under that strategy later in 2017. Welsh Government is currently engaged in a review of their waste and resource management policy. The latest Waste Strategy for England was published in 2007 with a policy review in 2011.

27.2.3 The importance of Extended Producer Responsibility (EPR) R&WUK are calling on all 4 UK governments to explore the development of extended producer responsibilities at both UK and EU levels. The Scottish circular economy strategy [<http://www.gov.scot/Publications/2016/02/1761>] recognised the potential importance of EPR and the fact that such schemes are better planned and operated at least at a UK level rather than in the individual countries.

R&WUK calls for:

“All 4 UK governments should work together to design and implement UK-wide Extended Producer Responsibility schemes for packaging and additional materials / products which:

- Incentivise better design/use of secondary raw materials/longer product life
- Shift the burden of end-of-life product management more fairly across the value chain
- Increase the level of recycling and recovery for materials / products covered

- UK Governments should set out the overarching objectives, monitoring and reporting frameworks, and formal review cycles to coincide with the UK parliamentary term.

27.3 Early R&WUK Inputs to the Commission

R&WUK has been pleased to work closely with the Commission team regarding waste and resources data and potential metrics for sustainable resources and wastes management across sectors. We are working with the team to help design and deliver the waste sector workshop on 28th February 2017.

In our presentation to the Commission in November 2016 we highlighted:

- the strategic importance and value - in social, environmental and economic terms - of developing a more “Circular” economy, including resource efficiency of products and services, and resource security.
- the importance of policy in shaping this industry and the circular economy in general and the need for interventions at all points in the materials cycle
- The importance of interventions including market “pull” mechanisms - designed to increase industry demand for secondary materials / resources well as “push” mechanisms designed to improve output quality and quantity of secondary materials from this industry
- Current trends in English waste and resources infrastructure under the current policy framework including:

- LANDFILL:** The number of available sites is dropping rapidly. There were over 1,000 in England & Wales mid 1990’s (pre Landfill Directive); ESA member companies now estimate there will be just a few dozen within 3 years – leaving some areas of the country without any landfills at all. Total landfill capacity was around 20m tonnes in 2015. This is anticipated to almost halve by 2020, before dropping further to just 6 million tonnes in 2025 and 4 million tonnes in 2030. This is a predictable response to a policy framework designed to move waste away from landfill and further “up” the waste hierarchy. However, alternative waste and resources infrastructure has not been delivered at the rate required to fully accommodate waste being diverted from disposal for all reasons noted above including policy uncertainty and a lack of strategy and strategic planning. If this is allowed to continue landfill gate fees will rise sharply as capacity falls faster than demand.

The Commission should also note that number and age of closed landfill sites will continue to rise. These represent a significant long term monitoring and management responsibility for both public and private sectors

- INCINERATION / ENERGY RECOVERY:** projects under PFI / PPP are in construction to 2018/9 and Defra’s annual waste management statistics show an important increase in energy recovery from waste over the last 5 years in the UK. There is a growing reliance on export of refuse derived fuels to other EU Member States but the continued viability of that market financially and legally hinges on many factors including EU exit negotiations.

- iii. **COMPOSTING / ANAEROBIC DIGESTION:** development of infrastructure in the UK has slowed as a result of factors such as feedstock availability (eg through low growth in separated food waste collections by local authorities as a response to spending constraints) and uncertainty over energy policy and future tariffs.
 - iv. **RECYCLING:** There is currently no public procurement underway for recycling plants through ESA members and this is expected to continue for the next 3 to 5 years. ESA estimates that without action, by 2020 waste could cost local authorities and businesses an extra £260 million - £485 million per annum, depending on the value of recyclates and cost of landfill. 15% of the UK's current recycling capacity will close during this timeframe as it comes to the end of its life and is not replaced. This would further reduce household recycling rates by 5% and lead to the loss of eight thousand jobs. This would almost certainly result in the UK missing its recycling targets.
 - v. **MARKET INSTABILITY** and plants currently unprofitable and / or closing. UK has a strong reliance on export of secondary materials which is likely to continue even if demand for secondary materials in the UK is stimulated.
 - vi. **REUSE:** This is the hardest part of the hierarchy to measure and report on but has important social and environmental benefits. Much of the re-use industry and infrastructure is relatively immature and represents a potential for the future.
 - vii. **PREVENTION:** significant potential exists in prevention of Industrial & Commercial waste through improved product and process design. Consumer product design needs to be driven with resource efficiency and end-of-life management in mind through voluntary and mandatory schemes including Extended Producer Responsibility.
- The importance of planning for resources management and security of supply alongside economic development at a larger-than-local scale ie regional / sub-regional.
 - The importance of data, information and metrics standardization and provision through readily-accessible means. Our conclusion is that data are readily available and reliable for municipal wastes (approx. 10% of the total UK waste) but not so for industrial and commercial (I&C) wastes. Various sample surveys of I&C waste have been completed by the 4 UK Governments but these are highly “granular” and do not allow direct comparison or time-series analysis of changes. R&WUK support all aspects of improved waste data collection and reporting including through electronic means such as the EDoC (Electronic Duty of Care) system: [<https://www.edoconline.co.uk/>] We believe this will continue to be an early priority for the Commission under the EU Circular Economy policy package.
 - The Relatively small scale and dispersed nature of future waste and resources management infrastructure, using a range of different technology options – compared to other sectors under this infrastructure assessment.

We look forward to more detailed input to the Commission's work in this assessment

(i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process

A: R&WUK have identified the most important barriers to delivery of a circular economy under Qn 27 above. In addition we would point to:

1. Circular Economy Strategies

Barriers to delivery of a more “Circular” economy are clearly identified in the EU Commission Communication “Towards a Circular Economy” (Dec 2015) [https://ec.europa.eu/priorities/jobs-growth-and-investment/towards-circular-economy_en]

They are also addressed in the “Making Things Last” circular economy strategy for Scotland (February 2016) [<http://www.gov.scot/Publications/2016/02/1761>] and we would recommend that the Commission take note of proposals from the Welsh Government in their policy review in 2017.

2. REBUS Project

The Aldersgate Group report “Amplifying ACTION ON Resource Efficiency (EU Edition) (January 2017) [file:///C:/Users/Steve_I/Downloads/EU%20Edition%20-%20Amplifying%20action%20on%20resource%20efficiency.pdf] explores the economic and environmental benefits for the EU if circular economy practices were adopted on a large scale across three separate scenarios: no new initiatives; current trajectory; and “transformational change”. They conclude that:

“With transformational change, there is the potential for a total of €324bn gross value added (GVA) created, a reduction in material demand of 184 million tonnes, an additional 172 million tonnes of material use avoided and a reduction in emissions of 154 million tonnes CO2 eq by 2030” [across the EU]

The report estimates UK GVA gains by 2030 to be worth £86B.

3. Employment Opportunities arising through a more circular economy

The employment opportunities which could be realised within the UK through a more circular economy are covered in the Waste and Resources Action Programme (WRAP) / Green Alliance report: (January 2015) “Employment and the Circular Economy – Job creation in a more resource efficient Britain”

[<http://www.wrap.org.uk/content/employment-and-circular-economy>]

Their report concludes that by 2030 moving to a more circular economy could:

- require an extra 205,000 jobs;
- reduce unemployment by around 54,000; and
- offset 11% of future losses in skilled employment.

Alternatively, under a transformational scenario where there was a more extensive expansion of circular economy activities, by 2030 adoption of a more circular materials economy could create over half a million jobs, reduce unemployment by over 100,000 and potentially offset around 18% of the expected future losses in skilled employment.

With regard to the waste and resources management sector itself – the Defra “Resource management: a catalyst for growth and productivity” report includes an estimate from David Palmer-Jones, Chairman of the Environmental Services Association (2013) – “Going for Growth – A Practical Route to a Circular Economy”:

“A circular economy, where the UK increasingly re-uses and recycles the resources it already has, could help generate 50,000 new jobs with £10bn investment, boosting GDP by £3bn”.

We are clear, therefore, that resource efficiency and security through feedstock provided by this sector should be a key priority under the UK Industrial Strategy, and we urge the Commission to recommend that through this Assessment.

4. Re-use and Repair

Most infrastructure issues associated with waste and resource management will concentrate on recycling and recovery activities in the “waste hierarchy”. The hierarchy is transposed into UK law through the [The Waste \(England and Wales\) Regulations 2011](#) in Regulations 12, 15 and 35. Waste prevention and preparation for re-use sit higher in the hierarchy. The infrastructure for these activities are unlikely to be the concern of this Assessment due to their small scale, simple technologies, and almost uniquely local service delivery. However, the Commission should take account of the social as well as environmental and business advantages of these steps in the hierarchy and the impact that they could have on the need for other waste treatment and disposal infrastructure in the future. Recent work in this area includes CIWM research: “Re-use in the UK and Ireland” (2016) [<http://www.ciwm-journal.co.uk/downloads/Reuse-in-the-UK-and-Ireland-WEB.pdf>].

Energy:

19 Q: What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

A: Energy recovery from wastes to generate electricity only cannot exceed roughly 30% energy efficiency. However, the export of heat from such process – with or without electricity generation - can improve energy recovery from the waste fuel to greater than 80%. Waste to energy plants with an overall fuel efficiency above 65% can be classed as a “recovery” operation under the EU Waste Framework Directive (for calculation see CIWM technical note : <http://www.ciwm.co.uk/ciwm/knowledge/the-r1-energy-efficiency-formula.aspx>), or Defra’s “Energy from waste A guide to the debate” (February 2014) (revised edition): [https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/284612/pb14130-energy-waste-201402.pdf] .

Only a sub-set of UK EfW plants are classed as a “recovery” (“R1”) operations. Many are designed and built ready for heat export but have no convenient and reliable heat customer within

practicable reach – practicable because of the technical and financial difficulty in transporting heat over any distance. We recommend that EfW infrastructure should be planned alongside other industrial development with customers for heat and secondary materials developed at the same or adjacent sites to take advantage of these outputs (see response to Q 3 above).

The Commission should also take note of the potential for generation of biogas from organic wastes which can be used to generate electricity (and of course heat) as well as for injection to the grid, subject to stringent quality standards or used as a transport fuel. All of these depend on the biogenic fraction of wastes from municipal as well as commercial and industrial waste sources which are a renewable rather than fossil form of carbon, and – as in the case of replacing diesel with biogas as a transport fuel – have other associated emissions advantages. The Commission may wish to consider biogas generation infrastructure needs in the light of feedstock availability, especially post-consumer food waste, as well as the UK Carbon Reduction Plan under the 5th Carbon budget and plans for air quality improvement.

We urge the commission to consider de-carbonisation and other environmental quality advantages achievable through collection and biological treatment of these biogenic waste fractions.

Priority 1: Support and improve waste collection/recycling performance		
Government should:	Response	
Consult on the potential benefit of reintroducing statutory local government household waste recycling or landfill diversion targets	No action	
Review potential opportunities for efficiencies to be achieved through increased harmonisation of collections services	Picked up by previous Minister Rory Stewart. WRAP-led harmonization report launched at RWM 2016, 6 associated Action Plans still with WRAP – now seeking approx. 10 funded pilot collection projects with authorities.	
Introduce meaningful pilot schemes of ‘pay as you throw’ for household waste to test the validity and potential impact of its broader introduction	No Action but has been included in early 2017 Chief Govt Scientist report through drafting of Municipal Waste chapter by CIWM.	
Support the increased roll-out of separate food waste collections and improvement in capture rates	Supported as part of the Harmonisation programme – now seeking up to 10 pilot schemes via WRAP-led Foodwaste Action Plan. Business case for savings crucial issue for most local authorities. BEIS Bio-economy consultation launched Dec 2016.	
Provide targeted support for the worst performing local authorities to help them overcome specific challenges in increasing recycling rates in urban environments	No action	
Amend the UK’s Packaging Regulations to ensure that the polluter pays principle applies and Obligated Businesses pay fully for the recycling of their materials	Consultation underway on targets but no fundamental review – could be covered as part of the Defra 25 year plan. UK lobbying for “lighter touch” EPR including voluntary schemes in discussions re Art 8(a) at EU level.	
Maintain funding for WRAP and other relevant organisations to deliver information and advice on waste and resource efficiency to businesses	Government funding specific WRAP projects. WRAP has moved onto charitable status.	
R&WUK and the industry will:	Action	
Work with WRAP and other partners to develop a new national-level communications strategy aimed at householders	Communications included as part of all work elements under the Harmonisation programme and as a specific working group under the Foodwaste Action Plan. CIWM and ESA fully engaged in both processes. CIWM input via advisory group to refreshed “Recycle Now” campaign and Recycle for Wales Advisory Group Full R&WUK social media support for all WRAP programmes.	

Strengthen relationships with other parts of the supply chain to boost resource efficiency in all parts of the UK economy	RWM event being developed to be increasingly relevant / attractive to “customer” sectors, plus expansion of “Ambassadors” Group to cover customer sectors RightWasteRightPlace project expanded to include “Ambassadors” from customer sectors eg construction.	
Continue to support the objectives outlined in the Responsibility Deal agreed in 2011 to help businesses to manage their waste more sustainably	ESA completed all of its actions under the Responsibility Deal, including changes to its code of practice and embedding information on its web site. Defra has also completed many of its actions through e.g. introduction of MRF regs and ongoing work on EA and waste crime. Most actions completed on both sides but progress no longer monitored by Defra.	
Priority 2: Improve the climate for investment in circular economy infrastructure to deliver sustainable growth and jobs		
Government should:	Response	
Strengthen strategic planning for waste and all secondary materials (including the energy embedded in residual waste) at a national level, for example by including waste in the National Infrastructure Plan	Waste included as a priority in the National Infrastructure Assessment – but confined to England as it is a devolved policy area – forthcoming Defra 25yr plan and BEIS Industry Strategy. Scotland: Circular economy strategy published Feb 2016 Wales: policy review underway.	
Support planning for waste and resource management at a larger-than-local level by linking it to economic development planning and strengthening the ‘duty to co-operate’ requirement on local authorities	No action	
Issue a Call for Evidence on the design, operation, costs and benefits of landfill bans or restrictions across the EU to inform policy development on this style of intervention across the UK	No action	
Recognise the potential risk, articulated by a number of leading industry stakeholders, for future gaps in waste treatment infrastructure and ensure that a robust monitoring process is in place such that need and provision can be assessed in a reliable and timely way	Waste recognized as a priority in the National Infrastructure Assessment (England-only). R&WUK input to assessment of possible metrics and to waste / resources data strengths and weaknesses.	
Explore additional financial support and de-risking mechanisms to encourage service and infrastructure provision to meet any capacity shortfalls – including a full review of the role, funding and performance of the Green Investment Bank	Green Investment Bank review underway but unlikely to address de-risking objective. Widespread industry concern over privatization of the Bank. R&WUK attended March 2016 briefing and has asked for another briefing (January 2017).	

Use its first Finance Act to introduce new tax allowances for waste infrastructure expenditure to offset the loss to the industry of Industrial Building Allowances	No action	
Amend the Energy Act to equalise support under the Contracts for Difference regime for all technologies which use residual waste or waste-derived fuels	Energy tariffs turbulent including Dec 2016 changes to RHI No appetite to remove the distortion caused by differential support to different technologies.	
Amend the CRC Energy Efficiency Scheme to exempt recycling, sorting and reprocessing industries	No action– proposal is to abolish the scheme in 2018/19.	
Introduce a planning obligation on new developments to use local area heat networks	No action	
R&WUK and the industry will:	Action	
Co-operate with Government in generation and provision of waste and resource flow data and forecasts to support assessment infrastructure and services needs for waste	R&WUK engagement with National Infrastructure Assessment for waste – seeking opportunities for further input. Priorities document expected June 2017. ESA has ongoing discussion with Defra about data issues and has sanity checked Defra data prior to publication to ensure estimates are based on sound assumptions.	
Fully engage with the review of the GIB's impact to date and its future role	Meeting arranged January 2017	
Undertake and publish research into mechanisms to support the UK reprocessing sector	R&WUK research report re secondary materials market instability published May 2015 – public / private sector contracts “best practice” group convened (CIWM-led). ESA research into extended producer responsibility for litter published September 2016. ESA research into extended producer responsibility for packaging published October 2016. ESA convened stakeholder day to discuss EPR for packaging November 2016.	
Work with public bodies to improve data mapping of material flows and support and promote the continued uptake of the Electronic Duty of Care (edoc) system	CIWM direct support for EDoC Management Board and Technical Advisory Group plus promotion of up-take. Case studies include Hereford Council. Up-take of EDoC by industry limited.	
Priority 3: Boost domestic demand/markets for recyclates		
Government should:	Response	

Increase the specifications for recycled content and products in Government Buying Standards	commitment (through the Waste Prevention Plan) to seek to <u>reuse</u> furniture etc before buying new, reflected in the relevant GBS.	
Lobby our EU partners to support amendments to the Principal VAT Directive to lower rates for products which contain higher recycled content	No action	
Issue a Call for Evidence to explore options for varying Excise Duties on products depending on their recycled content	No action	
As part of reforms to the PRN system, introduce measures to incentivise the use of recycled content in packaging (i.e. by reducing the size of the obligation for those packaging manufacturers which use recycled content)	Some action proposed re materials targets but no measures to promote increased secondary materials use. This may be considered as part of any forthcoming EPR review under the Defra 25 year plan.	
Support mechanisms to provide more stable secondary materials markets and to spread future materials price risks across the supply chain to encourage development of infrastructure, services and markets	Role of local authority collection and recycling contracts under the WRAP Harmonisation, WRAP Foodwaste and R&WUK secondary materials price stabilization – working group set up, led by CIWM.	
Review the effectiveness of Voluntary Agreements as a mechanism for driving sustainable behaviour in the supply chain	No action although DEFRA have proposed a greater role for voluntary EPR schemes in Circular Economy discussions at EU level.	
R&WUK and the industry will:	Action	
Undertake and publish research into mechanisms to reduce exposure to volatile commodity markets	R&WUK report “Managing the Risk From Secondary Raw Materials Price Movements published June 2015. Working Group on local authority contracts set up and led by CIWM.	
Provide best practice examples in tendering, partnership working and collaborative approaches to markets and procurement	Full CIWM and ESA input to working group above.	
Priority 4: Create the right regulatory balance between hitting waste criminals hard and reducing burdens on legitimate business		
Government should:	Response	
Maintain and build on the progress that has been made to date by making waste crime a policy and funding priority	Waste crime recognized as a priority in all 4 UK governments.	
Explore measures to shift the cost of regulation firmly towards persistent poor performers in the industry, reward good	Permit charging schemes increasing range of charges to reward good performance and penalize poor performance.	

<p>practice and raise standards through monitoring, compliance and permit charge schemes</p>	<p>Scotland: SEPA's new charging scheme aims to penalize poor performers but offers little reward to good performers.</p> <p>Wales: similar to EA.</p> <p>N Ireland: fees and charges scheme under consideration by DAERA allied to measures designed to deliver 'Better Regulation'. No further details available.</p>	
<p>Continue to financially support waste crime units within UK regulators, which would provide a strong return on investment</p>	<p>England: Medium term funding secured for the Environment Agency.</p> <p>Scotland: SEPA's waste crime team funded through SEPA's overall budget. EU LIFE+ funding secured to improve approaches to tackling waste crime. SEPA lead role in Interpol waste crime group.</p> <p>Wales: Natural Resources Wales has received some additional funding from Welsh Government. Funding figures not published.</p> <p>N Ireland: To continue with dedicated Environmental Crime Unit. The specialist services of a crime analyst to support the work of NIEA on waste crime. Continue with close liaison and cooperation with partner enforcement agencies throughout the UK and ROI.</p>	
<p>Empower regulators with full cost recovery abilities</p>	<p>Enhanced package of regulatory powers for Environment Agency and Natural Resources Wales introduced October 2015.</p>	
<p>Strengthen local authority powers to address waste crime, including fixed penalties and surveillance powers</p>	<p>Fixed penalties for flytipping introduced for England May 2016 now used by 50% of authorities plus powers to seize vehicles used in flytipping.</p> <p>Scotland: local authorities have long used powers under the 1990 EPA to issue penalties for flytipping.</p> <p>Wales: 6 week consultation on FPNs for flytipping launched Jan 2017.</p> <p>N Ireland: Status Quo. No further progress to report.</p>	
<p>Strengthen the Fit and Proper Person requirements and enforcement for waste management including technical competence and explore the use of targeted financial assessments and guarantees to protect the environment and public purse from illegal waste management and abandonment</p>	<p>2016 consultation delayed several times – now anticipated in 2017....latest proposals not visible to R&WUK.</p>	
<p>R&WUK and the industry will:</p>	<p>Action</p>	

Share intelligence with environmental regulators to assist them in targeting illegal activity	<p>ESA has shared intelligence with EA on ongoing basis. Feedback from Members suggest not always satisfied that this is followed up on appropriately.</p> <p>ESA up-date to “Dirty Secret” report underway.</p>	
Work to promote best practice and raise standards of compliance across the industry through the provision of appropriate training, seminars and other learning opportunities	<p>CIWM / WAMITAB technical competence scheme expanded and updated March 2016.</p> <p>CIWM / ESA scheduled training programme maintained and improved.</p> <p>CIWM / ESA joint funding and ESA management of the RightWasteRightPlace project.</p> <p>CIWM support for EDoC Management Board to help reduce crime / raise awareness.</p> <p>Cross-industry collaboration in major resources and waste management events throughout the UK.</p> <p>CIWM working with Chief Fire Officers Association to launch new fire prevention planning and response training / competence.</p>	
Priority 5: Greater government co-ordination of resources and waste policy		
Government should:	Response	
Introduce a co-ordinating unit, such as an Office of Resource Management, led by a senior Minister to ensure strategic cross-department policy making on waste and resources	<p>No Action</p> <p>Potentially superceded by:</p> <ol style="list-style-type: none"> 1. BEIS Industrial Strategy 2. NIA (England-only) 3. Defra 25 yr Environment plan 4. Govt Chief Scientific Advisor report <p>merger of EPR team from BEIS into Defra.</p> <p>N Ireland: Waste team cut hard.</p> <p>Clear Government lead in Wales and Scotland.</p>	
Commit to a full review of the 2007 Waste Strategy for England, informed by commissioning an independent Stern-style review on resource efficiency and security	No Action	
Develop and expand the national Waste Prevention Plan to strengthen the policy focus at the top of the hierarchy, including re-use and remanufacturing	<p>No action by Defra</p> <p>Scottish Government launched “Making Things Last” Feb 2016 plus funding for initiatives.</p>	
R&WUK and the industry will:	Action	
Map the sector’s future skills requirements and potential gaps	ESA Members have worked with EU Skills through its RISKI forum and have completed this exercise at a high level.	

	This has not been widely disseminated.	
Work with public bodies to improve data mapping of material flows and support and promote the continued uptake of the Electronic Duty of Care (edoc) system	CIWM support for WasteDataFlow and EDoC including 2016 webinars.	
Priority 6: Engaging positively in policy development for resources and wastes at a European level		
Government should:	Response	
Confirm that regardless of any renegotiated of terms with the EU, it fully acknowledges and supports the role of EU-level environmental policy and regulation and will actively engage in the development, monitoring and further review of the EU Circular Economy Package in particular	Government (Defra) confirms it is still actively engaged in EU Circular Economy negotiations but no overall confirmation of UK policy positions is available for comment. ESA and CIWM engaged in occasional workshop events organized by Defra / BEIS.	
Develop and articulate a coherent and positive position on the future EU circular economy package which reflects the opinion of all four UK national Governments	Routine liaison maintained between all 4 UK governments.	
Require fair and consistent data standards, metrics and reporting under all appropriate EU-driven targets to allow realistic comparison between Member States' performance and to support the review and development of evidence-based policies and interventions.	Maintained as an early priority in Circular Economy development by both Dutch and Slovenian Presidencies.	
Argue for the introduction of longer term financial instruments to drive behaviour change on resource consumption across the whole supply chain from raw materials through to supply and use of recycled materials or recovery of value from wastes. This should include assessment of the potential for differential VAT rates for materials, raw materials levies and the development of new or tightened Extended Producer Responsibility mechanisms	No action	
Support the development and monitoring of Improvement Plans for Member States who cannot meet the various targets under the	No action	

<p>appropriate EU Directives, Regulations etc. Compliant states must be able to see that the needs of non-compliant countries are recognised but that over time all Member States will drive for the same standards and levels of achievement</p>		
<p>R&WUK and the industry will:</p>	<p>Action</p>	
<p>Fully support Government in all appropriate EU negotiations</p>	<p>ESA and CIWM engaged in occasional Defra / BEIS workshops. Government “not engaging in a running commentary” on the negotiations.</p> <p>ESA active via FEAD.</p>	
<p>Provide data and information as evidence for policy development and to allow full reporting to support monitoring and review of UK performance and the effectiveness of EU policy and interventions</p>	<p>ESA published strategy report in summer 2016 which included data and information to support policy development.</p> <p>ESA and CIWM both participate in BREF development and have helped EA closely on waste treatment and Incineration BREFs.</p> <p>CIWM report on calculation methods for municipal recycling reporting published October 2015.</p>	
<p>R&WUK will actively seek opportunities to promote the UK sector’s interests and views at a European level to influence the circular economy agenda</p>	<p>ESA active via FEAD.</p> <p>CIWM active via ISWA.</p>	

National Infrastructure Assessment, Call for Evidence

The Scottish Futures Trust was established in 2008, operating at arms' length from the Scottish Government to improve the efficiency and effectiveness of infrastructure investment in Scotland by working collaboratively with public bodies and industry, leading to better value-for-money and ultimately improved public services.

We have restricted our submission to digital communications which we consider to be a sector of economic infrastructure particularly important to Scotland. That is not to say that we don't consider any other areas of infrastructure to be important, but simply that this area is where SFT's perspective may be most relevant to the work of the Commission.

Many areas of infrastructure policy, prioritisation, funding and delivery are devolved and your cross-cutting themes cover a number of these areas. Should the Commission wish to discuss these areas with the Scottish Futures Trust we would be pleased to do so.

Response to Questions 17 & 18 - Delivering digital connectivity as a Utility

1. Introduction

SFT is supporting Scottish Government to establish a roadmap for delivering a world class digital vision for Scotland¹, for which it is imperative that both consumers and enterprises in Scotland have access to enhanced digital services and mobile connectivity. A report commissioned by SFT² in 2015 identified that the potential impact of achieving such a world leading position would be to increase GDP in Scotland by c£13bn (or 10% per) annum, and would require both infrastructure and devices to achieve:

- Seamless delivery across fixed and wireless platforms;
- A quality of service and user experience commensurate with other leading and modern digital economies; and
- Investment into Scotland's digital infrastructure that will guarantee the country's future competitiveness, as well as its ability to provide enhanced public services and opportunity to its citizens.

A key aspect to this work is to assess a wide range of potential interventions that could be considered to enhance the opportunity for public and industry investment in digital infrastructure across Scotland; these interventions include UK and Scottish Government policy and legislation and Ofcom regulatory measures. It is important to note, that whilst the emphasis of this submission is focused on the situation in Scotland, many of the issues and suggestions identified could equally apply to many other parts of the United Kingdom.

¹ A summary of the progress made to date can be found in the attached document, http://www.scottishfuturestrust.org.uk/files/publications/Taking_the_Connected_Highway.pdf

² The economic and social impacts of enhanced digitalisation in Scotland, July 2015. http://www.scottishfuturestrust.org.uk/files/publications/Impact_of_digitalisation_in_Scotland.pdf

2. Background

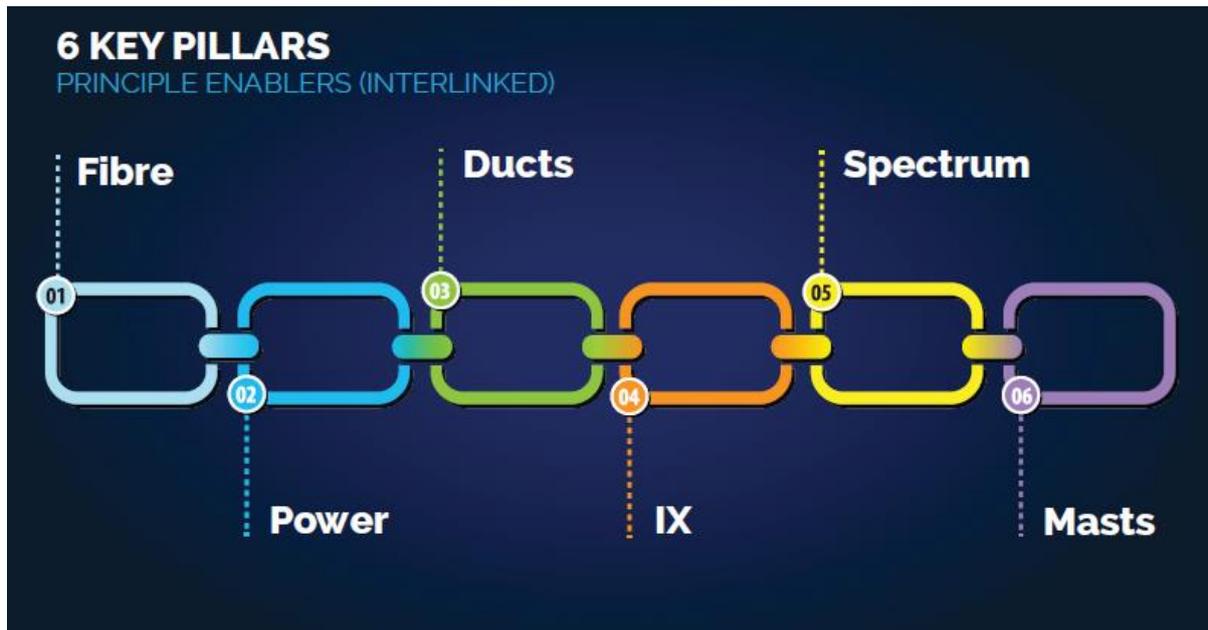

In recent years the demand for digital activity and data has increased significantly and with it the demand for seamless broadband and wireless connectivity. The telecoms industry has seen considerable recent developments with the emergence of ‘quadplay’ and structural consolidation across wireless and fixed platforms. Convergence has also changed how people access services, and indeed Over the Top (OTT) content has grown exponentially over the last few years³. It is the case that the promotion of effective and sustainable competition has delivered efficient investment and widespread availability of services for a considerable number of consumers across the UK over the last 10-15 years; for some there has been significant improvement in terms of superfast broadband and 4G coverage, alongside growth in the number and types of connected devices. However, a collection of studies⁴ by Ofcom and others, suggest that in “non-competitive” areas of Scotland and other parts of the UK, the regulatory strategy driven by competition, has not delivered the same positive consumer outcomes, nor the necessary investment to maintain and upgrade network infrastructure to support a digital economy. This has a detrimental impact upon the economic performance of such areas. In these areas, the evidence would suggest that the user quality of experience is one of unreliable broadband and mobile connectivity services in many parts of Scotland. This experience is replicated in both the consumer and business connectivity markets, therefore there is a strong case to ascertain whether adequate investment and innovation has been delivered into those, primarily regional markets. Whilst improvements to current provision are an important focus for Ofcom and government, actions taken now will have a clear impact upon the future telecoms investment and capability in Scotland; and so, any policy of regulatory measures need to account for future investment, not only for current customer needs.

3. Market and technology drivers

Although 5G technical standards have not yet been agreed, we know that the next generation of networks will rely heavily upon six key components, illustrated below:

³ Ofcom: Strategic Review of Digital Communications, July 2015

⁴ Example studies include: Ofcom: SRDC Discussion Documents, July 2015; Business Connectivity Market Review, May 2015; Ofcom Analysis of Operator Data, May 2015 (as detailed in the SRDC 16 July 2015; Communications Market Report: Scotland, August 2015; Jigsaw Research: SME experience of communications services – a research report, October 2014; Infrastructure Report 2014, December 2014; Saville Rossiter-Base: Quality of Customer Service Report, December 2014; Which?: Broadband Advertising speeds not up to speed; Broadband Services for SMEs: assessment and action plan, June 2015; Federation of Small Businesses: The fourth utility, July 2014; and Ofcom presentation: Ofcom’s Strategic Review of Digital Communications, October 2015.

The six pillars outlined above are the essential elements of the infrastructure needed to support 5G connectivity. Although many of the standards are still being developed, it is clear that 5G networks will represent a genuine step change in mobile connectivity. The International Telecommunications Union has defined that 5G ready networks will be capable of supporting speeds of up to 20Gbps. If this is to be delivered in Scotland, our digital infrastructure will need to be enhanced.

Existing copper infrastructure will be unable to support such high speeds. **Fibre** is the critical component, with a need for fibre to reach as far into the network as possible, whether to small cell locations on street furniture or buildings or to rural masts.

However, it is not all about fibre. The ability to access, and more efficiently install, underground **ducting** is critical to enabling the proliferation of fibre. It will require collaborative working between industry and the public sector to ensure that all opportunities to deploy ducting in the right place at the right time are exploited, especially when planning new developments and buildings.

There will be a need for a significantly higher concentration of **masts** and antennas, particularly in urban areas, to deliver the headline user experience described above. This will need the co-operation of government and local authorities to provide more readily available access to street furniture and other infrastructure to enable deployment. All of this will need to be underpinned by a densely-structured fibre network and the latest in ultrafast millimetre-wave (mmWave) technology.

Due to the higher data demand transferring between a significantly greater number of devices and antenna, a more effective and efficient use of **spectrum** will need to be identified; and there will need to be more spectrum capacity made available to cope with that demand. All of this new energy-hungry equipment will require innovation to ensure that there is sufficient **power** supply in both urban and rural areas. Support for sustainable energy supplies and battery **power** technology will be a key success factor.

The amount of data and content being used by consumers is growing rapidly and this trend will continue in future as new, smart technologies grow and the Internet of Things becomes a reality. This will require near instant access to data; and for that content to be closer to the user. Relying on

information being stored at **internet exchanges** in London or Manchester will not deliver the anticipated 5G user experience. That will require peering at Internet Exchanges located in Scotland, which is why we have already invested to support the growth of IXScotland – the first Scottish internet exchange. Likewise, delivering international connectivity for Scotland will be key to delivering resilience, speed and opportunity.

The internet of things sits across the pillars, drawing upon the various infrastructure elements. We are working with Scottish Enterprise and CENSIS – the Centre for Sensor and Imaging Systems – to look at options for developing a national network to support the Internet Of Things. These ‘things’ (whether sensors, switches or machines) can be integrated into just about anything – from cars to street lights; manufacturing equipment to livestock. The information generated can improve business efficiency, influence service delivery and genuinely improve people’s lives.

None of these 6 pillars are new; but the way in which they will need to mesh together as a unified digital network is. Government, regulators, businesses and the telecoms sector in particular need to work together to enable that integration to happen in Scotland. That will be key to delivering a world class user experience.

4. Potential areas to consider

In its Strategic Review of Digital Connectivity, Ofcom identified a clear vision for future telecoms provision that has much in common with the Scottish Government’s digital vision, and we are working with Ofcom to establish what more can be done from a regulatory perspective to enable this vision to become a reality. The Strategic Review identified a number of further enhanced remedies, however based upon consumer outcomes and projected future user requirements, we believe there is scope for Ofcom to be increasingly proactive as regards regulation of the market and how this will be applied over the next ten years. Ofcom is increasing its presence in Scotland and this is a welcome broadening of its resource base and recognition of the potentially differing market conditions across the UK. There are a number of additional areas where Ofcom could enhance regulation beyond the current competition focused approach, that include:

- a. Consideration of more locational remedies to address the digital infrastructure deficit in Scotland and stimulate innovative investment and service coverage.
- b. Completion of a fully comprehensive assessment, for both premise and mobile service provision, to determine whether the competition based regulatory approach to infrastructure is delivering the advertised user experience across the geographies of Scotland and the UK.
- c. The development of comprehensive consumer metrics at a granular localised level to include coverage, availability (both geographic and population based), as well as other aspects such as customer satisfaction, quality of experience, contention and resilience.
- d. Development of a more active requirement (or burden of proof) on operators to demonstrate delivery of actual user experience as opposed to planned or predicted experience.
- e. The establishment of a more comprehensive mapping of infrastructure ownership as well as monitoring of current and future industry investment plans, to enable the regulator to better inform the development of future interventions or enabling legislation.
- f. The development and publication of a future technology implementation roadmap to enhance regulatory strategy and policy thinking going forward.

- g. Ofcom has consulted on its preferred approach to the future structure of BT Openreach, and final consideration should reflect the following aspects:
- i. Separated from the rest of the BT Group as a functioning standalone operating entity. The potential for shared ownership with external parties could also be considered;
 - ii. Stand-alone governance arrangements with a separate board that contains external representation (possibly from wider industry or representing the wider public interest) set up to oversee the operations and performance of Openreach. Such an approach would see Openreach having its own constitution;
 - iii. Requirement to develop and publish an investment plan that reflects the needs and investment priorities of wider industry players and not just BT Group, and for this to be updated on a rolling 5-year infrastructure investment plan that includes investment in renewals and new infrastructure; the EAB and Ofcom would then monitor performance against this plan;
 - iv. Returns to be driven by and, if necessary, regulated on the basis of the long term infrastructure assets of the new standalone business. This basis of a future rate of return should also take into account the significant levels of public sector infrastructure investment made in the current fibre assets of Openreach;
 - v. Ability to raise finance separately from BT Group to meet investment requirements;
 - vi. Ability to enter into joint venture arrangements for services and investments;
 - vii. Requirement to re-invest surpluses into infrastructure enhancement, with possible link to regulatory relief in competitive markets, based upon a regulated return;
 - viii. Requirement to invest in fibre only products to ensure a future-proof investment plan is developed;
 - ix. Introduce an enhanced regulatory and monitoring regime in relation to consumers and service providers;
 - x. Requirement to ensure input/output equivalence access (in relation to services, data provision and investment plans) is available to all operators; and
 - xi. Requirement to provide not only PIA to ducts and poles but also to offer dark fibre as a product at both the access and backhaul level to ECC undertakers; and
 - xii. Requirement to work with all MNOs to understand the required infrastructure to support mobile connectivity and how this can be put in place.
- h. The following elements should be considered in developing and designing future release of spectrum:
- i. Benefit valuation – there is a trade-off between short term primary funding generated through an auction bidding process versus a focus on wider and longer term secondary order economic, social and fiscal benefits that could be delivered. This could be also be assessed by for example by encouraging and rewarding plans by providers to accelerate investment in the underlying infrastructure
 - ii. Geographical Use – sharing of spectrum if not in use by an operator
 - iii. Geographical Obligations – that can be used to require investment in targeted areas such as an “outside-in” approach, priority on transport routes, or differential obligations on a geographic basis
 - iv. Spectrum capping - It may be of value to cap future auctions dependant on what spectrum is being auctioned and the amount available to mobile operators, such as 700Mhz to allow fair competition across the network providers. The emphasis could be on how operators will use the spectrum actively and effectively. “Banking”

spectrum could be discouraged unless there is a clear worldwide recognition that a certain band will be used for future network innovation. .

- i. Building upon locational regulation, Ofcom should also consider what additional powers and approaches it needs to enhance and strengthen its regulation role, and indeed it may wish to look more widely at regulation of other sectors across the UK (e.g. water, electricity, gas, rail) for comparison and potential adoption of elements of these.
- j. With regards to the current considerations in relation to a Broadband Universal Service Obligation:
 - i. The underlying principle should be that it ensures a genuinely universal right of access and be funded from as broad a base as is deemed feasible;
 - ii. The user experience should be considered in relation to download and upload speeds, alongside other factors such as resilience, latency and current and future contention rates;
 - iii. The performance and requirements of a USO should be benchmarked and updated on a regular basis;
 - iv. It could be delivered through many different technologies, fixed or wireless, depending on the underlying nature of existing and future infrastructure as well as geographic and localised considerations;
 - v. Due consideration should be given as to how other regulated industries such as electricity and postal services apply universal service obligations and what approaches and / or lessons can be learnt from the application in these sectors.

We would encourage an overarching policy and regulatory strategy and framework that seeks to (i) understand local markets and economic conditions; (ii) uses both ex ante and ex post measurement to gauge service delivery; (iii) reduce the cost of finance to support investment; and (iv) endeavours to meet the digital aspirations of all communities. Within this framework, Government and Ofcom should consider local economic bottlenecks as well as a national assessment of bottlenecks. Such an approach will have different effects on competition, and likewise, delivery. Over reliance on competition will leave many parts of the UK lagging in digital investment and in levels of digital service.

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London
EC3M 8UD

10 February 2017

Dear Team,

NATIONAL INFRASTRUCTURE ASSESSMENT: CALL FOR EVIDENCE

We welcome the opportunity to respond to the above Call for Evidence. This response is on behalf of the ScottishPower group and is particularly relevant to our thermal and hydro generation, renewables and networks businesses.

We support the high level objectives of the National Infrastructure Commission (NIC). In particular, we agree that an independent NIC can help to promote a better quality of discussion on future infrastructure projects, and, in turn, ensure that decisions are made in a timely fashion and on the basis of robust analysis and evidence. A key aspect of this will be helping to promote a political consensus around long-term infrastructure plans.

Clearly, the National Infrastructure Assessment (NIA), setting out the NIC's assessment of long-term infrastructure needs, will be at the heart of this important work. As the NIA has the challenging task of horizon-scanning for future infrastructure issues over an extensive time period, up to 2030 and beyond, we have focused our response on some of the key developments and areas that we currently see as being important as part of the transition to a low carbon economy, namely:

- Facilitating an effective switch from coal to gas generation in the power sector consistent with the Government's commitment to restricting coal generation in the early 2020s and taking it off the system by 2025;
- Continuing deployment of cost effective large scale renewable generation through the 2020s, including offshore and onshore wind in suitable locations;
- Promoting a greater role for storage to support a smarter power system, including greater deployment of large-scale storage such as pumped storage;
- Whilst recognising the potential role of interconnection, ensuring that overseas generation competes with domestic generation across interconnectors based on a level playing field and maintains an appropriate balance between our reliance on domestic generation and interconnection in terms of ensuring security of supply and resilience;

ScottishPower, London Office, 4th Floor, 1 Tudor Street, London EC4Y 0AH

[contact details redacted]

• Conducting further analysis and policy work on how best to address cost-effectively the huge challenge around the decarbonisation of heat, taking into account research on consumer views and demand;

• Undertaking further analysis and research on the potential large-scale uptake of electric vehicles in terms of wider system and infrastructure impacts and needs.

We have attached an Annex containing our views on the questions specific to the energy sector and on some energy-relates cross-cutting issues.

If you have any questions regarding any aspect of this response, please do not hesitate to contact me.

Yours sincerely,

[job title redacted]

ScottishPower response to energy questions and energy-related cross-cutting issues**ENERGY****Question 19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?**

The decarbonisation of heat is a difficult problem and it is not yet clear whether the most cost-effective solution has been found. It would be premature to focus on one particular technology until there is a clearer idea of how technologies will develop and perform in the future. The timing of decisions on large scale roll out will inevitably be linked to when there is confidence in the availability of a cost effective way forward that consumers and industry will accept.

In particular, we are some way from having low carbon solutions on heat that are competitive on cost and performance with a modern condensing gas boiler. This suggests that the gas pipeline infrastructure will be with us for some time to come and that consumers who do not have the option of mains gas will tend to be more accepting of current low carbon heat technologies than those who do. We therefore believe that it is beneficial at present to focus the application and demonstration of innovative technologies (such as heat pumps) in off-gas grid areas.

Question 20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

We support the Government's continuing commitment to progressing with cost-effective decarbonisation, consistent with the provisions of the Climate Change Act 2008 (and as reflected in the Government legislating for the 5th Carbon Budget for 2028-32). This commits the UK to a 57% reduction in emissions on 1990 levels by 2030 which involves substantial decarbonisation of the power sector by the 2030s.

This means that there will need to be continuing progress towards the decarbonisation of the power sector in the 2020s, building on the delivery to date and planned for the rest of this decade. We see continuing to develop and deploy renewable technologies at scale as being a key part of this, including offshore and onshore wind. Given that onshore wind is the lowest cost large-scale low carbon technology, we strongly consider that its continuing deployment in the 2020s should be promoted provided it is taken forward in appropriate locations where there is public support.

Throughout this process, affordability will be critical. It is a statement of the obvious that if an option is unaffordably expensive, it will ultimately get scaled back until it is affordable. Successful decarbonisation can only be achieved within cost parameters that are feasible.

Accordingly, we would stress the need for caution and robust cost assessment when considering the potential role of novel high cost options in the transition to a low carbon economy, particularly given the difficulty of delivering such projects through some form of competitive allocation. For example, the Government is currently considering these important issues following the recent publication of the Hendry review into the strategic role of tidal lagoons in the UK.

In this context, we would highlight the importance of such competition taking place on a level playing field in the various markets (such as the Capacity Market and the ancillary service markets) that will procure the capacity that the system requires to cost effectively balance supply and demand. One aspect of delivering effective competition based on a level playing field involves having a clear overview and understanding of the interactions between the various markets, possible revenue streams and charging regimes. A good example of this relates to the important work currently being done by both BEIS and Ofgem on addressing

As we outlined in our response to your Call for Evidence on System Flexibility at the end of 2015, when considering the delivery of flexibility we think it is important not to be technology-specific, but rather develop functional specifications that can be met using various technologies. For example, 'flexibility' is about the speed of response and the magnitude and duration of response, rather than any given specific technology. Indeed, this kind of approach facilitates the promotion of competition between technologies thereby promoting cost-effective delivery.

Smart power and promoting effective competition

On the role of interconnection, we are fully supportive in principle of the potential benefits arising from trade with Continental Europe through greater cost-effective interconnection. However, as with all efficient linking of markets to facilitate international trade, it is essential that this takes place based on a level playing field if the benefits are to be realised in a cost-effective and economically efficient way.

In the case of the GB electricity market, we consider that there are number of dimensions of the charging and taxing regime, as well as the regulatory framework for interconnectors, which have the effect of distorting the market in a way that creates a fundamentally uneven playing field between domestic generation and overseas imported generation. Taken together, these various elements significantly disadvantage domestic generation in its competition with imported electricity from overseas generators. We consider that this issue will need be addressed over the medium term and would note that Brexit could provide additional scope to take this work forward.

We consider the most promising approach would be to develop a Cap and Floor mechanism (similar to that already available to investors in interconnectors) to support investment in new PSH (and other large scale storage technologies).

In this context, pumped storage hydro-electric (PSH) and battery storage have very different characteristics and will have complementary roles in this future mix of flexibility assets. Both can provide a range of benefits including improved system operability, reduced network congestion costs, reduced CO₂ emissions and improved security of supply. However pumped storage can be deployed at scale, has an exceptionally long operating life and is particularly well suited to applications requiring longer discharge times. It is therefore likely that the optimal future mix will involve significantly more pumped storage capacity than is installed at present and, if overall system costs are to be minimised, it will be important to remove barriers to the further development of PSH.

This drive towards further deployment of low carbon generation will need to be complemented by investment in new large scale gas generation, storage and potentially other innovative technologies so as to deliver security of supply and system flexibility in an energy system that is based on a higher volume of intermittent renewable generation. The requirements for storage are likely to apply on differing timescales: minute by minute to address short term fluctuations in supply or demand, and over a period of hours, to smooth out slower moving variations in supply or demand, typically within a day.

the 'hidden subsidies' to small-scale embedded generation (through the grid charging regime and current structure of the CM supplier obligation) which significantly distort outcomes in the Capacity Market.

Question 20. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Significant uptake of electric vehicles (EVs) could have significant implications for the electricity system, particularly local distribution networks, if there are high concentrations of EVs in any one area. Charging of these EVs will, therefore, need to be carefully managed and it will be important to strike the right balance between managing this charging through price signals and possibly an element of direct control by distribution network operators (DNOs).

Whilst the long term aim should be for consumers to be able to choose when to charge their EVs based on time-of-use price signals facilitated by smart meters, if EV usage grows strongly it may be necessary in some cases in the medium term to provide DNOs with the ability to have an element of direct control over these resources (possibly mediated by the supplier) so as to limit the need for (otherwise unnecessary) local network reinforcement.

However, this clearly raises important issues in terms of consumer control and this will need careful consideration including robust and widespread trialling evidence around what different types of consumers in different areas might or not might find acceptable. For example, consumers may be cautious about any arrangement that risks leaving their car with insufficient range at a time when they want to make a journey. It will be important to monitor the impact of EVs on the electricity system over time as uptake increases.

CROSS-CUTTING ISSUES

Question 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The Planning System is critical to the successful delivery of national infrastructure priorities, in terms of an efficient and timely consenting mechanism and to ensure that projects can move smoothly from consent through to construction and operation. Whilst we consider that the Planning Act process is operating effectively, there are a number of areas where small improvements could be beneficial in terms of increased flexibility and efficiencies.

There is an opportunity to address matters of importance to the successful and efficient delivery of infrastructure priorities through the National Policy Statements (NPS). Many of the current NPSs are to be updated shortly and there could be a role for the NIC in providing evidence on particular sectoral requirements. In this context, we welcome the projected 30 year timescale of the NIA, and it is important that any review of the NPS's also consider the long term energy infrastructure requirements.

The NIA should also look to review thresholds for nationally significant infrastructure projects (NSIPs) and the introduction of a more proportionate approach to applying the requirements of the Planning Act 2008. For example, in terms of thresholds, consider the height of a 132kV overhead Trident wood pole line (on average 12m) and that of a 33kV overhead wood pole (standard height of 10m). If the Trident wood pole is installed over a distance of 2km or

more a Development Consent Order (DCO) consent is required. However, a 33kV overhead wood pole line only requires s37 consent under the Electricity Act 1989. We would argue there is less of a difference between the 33kV and 132kV wood poles when comparing a 132kV Trident wood pole with a 132kV tower (on average 26m). The likely environmental impacts for wood poles are significantly less and we would therefore suggest reviewing the appropriate consenting process to remove all 132kV wood towers from the DCO process.

We would also welcome a more proportionate approach applied to different schemes coming through the DCO process. For example, the precautionary approach advocated by the Planning Inspectorate can lead to some projects, which are at the lower end of the threshold, requiring DCO consent during the Examination stages. This can over-complicate the process and stretch resources for all those involved including Interested Parties.

A more proportionate approach in the NSIP process for material and non-material changes to DCOs would also be helpful. There is an eight month statutory timeframe for material changes to DCOs but no statutory timescale for non-material changes to DCOs. We acknowledge that efforts are made to ensure timely and robust decisions for both material and non-material changes to DCOs. However, current figures show that non-material decisions can take up to ten months with an average of seven months for determination. We would recommend a three month timescale for decision-making for non-material changes to DCOs. This would allow sufficient time for consultation and would be proportionate to the level of impact proposed by minor, non-material changes.

We also consider that it would be timely to review the planning system in respect of some of the primary and secondary legislation. With regard to key planning legislation, there could be some efficiencies in consolidating a number of new provisions introduced through legislation since the 1990 Town and Country Planning Act. This could include listed building consents.

10 February 2017

SGN Response to National Infrastructure Assessment Call for Evidence

Dear Sir/Madam,

SGN welcomes the opportunity to respond to this National Infrastructure Assessment Call for Evidence. As you may be aware, SGN manages the network that distributes natural and green gas to homes and businesses across Scotland and the south of England. We deliver a safe, secure and reliable gas supply to 5.9 million customers through 74,000km of pipeline.

We welcome that the Commission has identified that decarbonising heat at an affordable cost is one of the UK's pressing infrastructure challenges. It is only recently the scale of this challenge has started to be fully appreciated. With peak heat demand around four times greater than peak electricity demand, there is a growing weight of evidence that low carbon solutions which utilise our existing gas network infrastructure will allow for the decarbonisation of heat in the most affordable way.

We now believe there is a significant opportunity for the Government to look beyond the widespread electrification of heat, and towards a low carbon transition aligned more closely to its priorities to deliver secure and affordable energy to customers. The injection of renewable gas, such as biomethane and hydrogen into the gas networks, will allow UK customers to continue to benefit from our existing gas network infrastructure, a uniquely flexible asset already built to meet peak heating needs.

Our response focuses on question 19 posed by the commission relating to the highest value solution for decarbonising heat, and question 21 on the energy implications for low carbon vehicles. If you have any questions on the points raised please don't hesitate to contact me by email at [email redacted].

Kind regards

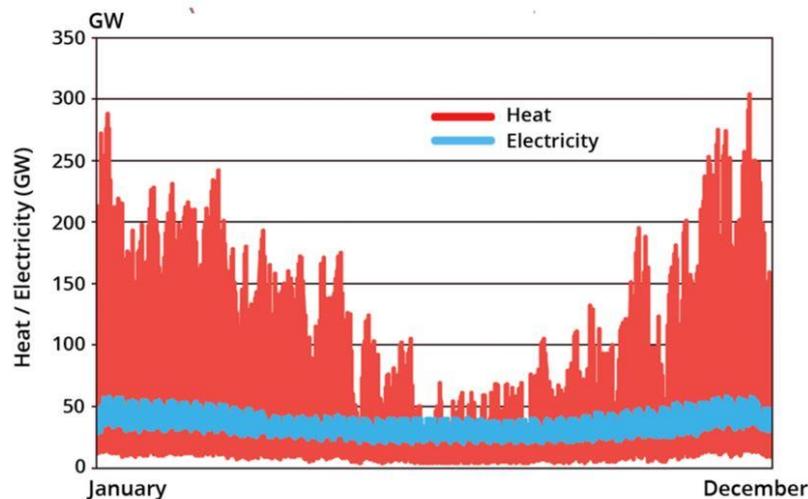

[name redacted]
[job title redacted]

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

As noted previously, we welcome that the Commission has recognised that the decarbonisation of heat is one of the UK’s most pressing infrastructure challenges. With peak heat demand around four times greater than peak electricity demand, ensuring this continues to be met in an affordable way will require detailed consideration of the energy infrastructure required.

We know we need a solution which is clean and meets the country’s 80% carbon reduction target from 1990 by 2050. We also want it to be affordable and able to continue to meet peak demand on the coldest of days too. But to understand what might be the highest value solution for decarbonising heat, we feel it is crucial to understand how heat demand is met today.

Heat demand today accounts for around 45% of total UK energy needs¹. While electricity demand remains fairly constant throughout the year, heat demand is around four times higher than peak electricity demand in winter. Currently the UK’s gas network infrastructure allows these extreme peaks in heat demand in winter to be met in an affordable way, with customers paying a third of the price per unit of gas, than for electricity.

Source: DECC’s “Future of Heating” strategic framework, 2012.

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/48574/4805-future-heating-strategic-framework.pdf.

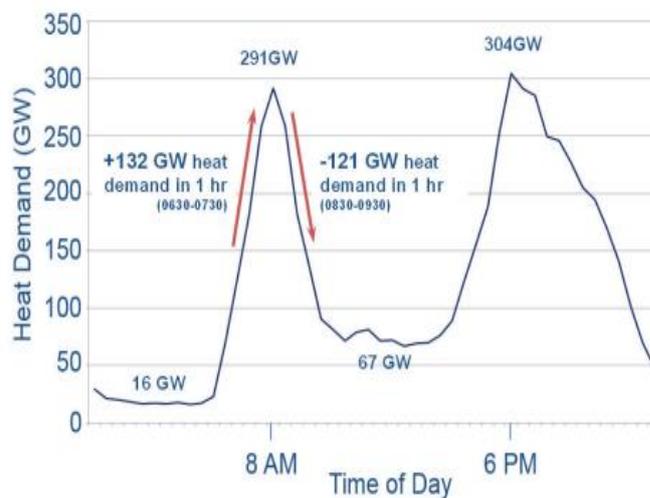

With almost 85% of homes and many businesses connected, the UK benefits from one of the most extensive gas networks in the world. As well as being extensive, the gas networks also provide a means to transport three times more energy over the course of the year than the electricity networks. Without the gas networks we simply wouldn’t have the means to transport the vast amounts of energy required during peak periods.

The gas networks are also a uniquely flexible part of our energy infrastructure. On a cold winters day the gas networks have the ability to ramp up to just over 130 GW in just an hour to allow peak heating needs to be

¹ DECC (2015) Energy Consumption in the UK, 2013 data

met. To put that into context, peak UK electricity demand is less than 60GW². These very large swings in heat demand can be met because of the capability of the gas system to store significant volumes of energy and then quickly convert this into heat as required.

Recent research by Imperial College suggests the gas network is capable of storing 50,000 GWhs of energy at any time, whereas, the electricity system is only capable of storing 27 GWhs of energy³. This independent study also suggests the cost of storing electricity is also at least 2,000 times more expensive than gas (on a £/MWh basis). Therefore, there is a growing weight of evidence that low carbon solutions which utilise our gas network assets will allow us to decarbonise heat in the most affordable way.

Source: Robert Sansom, Imperial College (2011)

We believe that there is now a significant opportunity for the Government to develop a strategy to decarbonise heat which is more closely aligned to its priorities to deliver secure and affordable energy to customers. The current strategy published by the former Department of Energy and Climate Change (DECC) in 2013 suggested a large proportion of future heat demand would be met by electric heat pumps. This would require significant investment in additional electricity generation and reinforcements to the electricity networks to allow it to transport the volumes required. This has been shown to be a pathway that would be very expensive⁴. These costs would ultimately be passed on to customers via their energy bills.

Heat is inherently a local issue and therefore the decarbonisation of heat is likely to require a portfolio of solutions depending on a range of location specific factors. The electrification of heat may be the most appropriate solution to decarbonise heat in certain areas. This could be for households off the gas grid who currently rely on high carbon fuels such as heating oil or coal and have sufficient space for an air or ground source heat pump. In off gas grid areas, the disruption caused by the work that would be required to upgrade the electricity network to meet the large increase in demand, may also be more acceptable to customers.

³ <http://www.imperial.ac.uk/media/imperial-college/research-centres-and-groups/icept/Heat-infrastructure-paper.pdf>

⁴ https://policyexchange.org.uk/wp-content/uploads/2016/11/PEXJ4810_Too_hot_to_handle_09_16-V2-WEB.pdf

Electric heat pumps are capable of being more efficient than gas boilers, taking advantage of the latent heat that exists in the ground, water or air. However, research has shown that efficiencies tend to vary considerably in real life scenarios, and also fall in line with temperatures⁵. This means that heat pump efficiencies are likely to be at their lowest at times of peak heat demand which could add to the level of electricity network reinforcement needed.

At the moment electric heat pumps (£8,500–£13,000) are considerably more expensive than gas boilers (around £2,500)⁶. Although heat pump costs may fall slightly, research has shown that the majority of households would still need substantial financial help to install one⁷. The additional insulation and larger radiators that would be required within homes for heat pumps to operate efficiently would also be costs that would be passed on to customers. The difficulty to date in deploying heat pumps suggests that public acceptance could be a major barrier to future heat solutions which require large changes in behaviour.

Fuel Poverty and Affordability

Ensuring heat continues to be affordable will need to be one of the key considerations when determining the highest value solution for decarbonising heat. Currently, the cheap and reliable nature of the heat delivered by our gas network infrastructure has very important implications for fuel poverty. SGN and the other Gas Distribution Networks (GDNs) play a key role in combating fuel poverty by extending our networks to fuel poor communities. This Fuel Poor Network Extension Scheme (FPNES) administered by Ofgem continues to be recognised as one of the most effective tools to combat fuel poverty.

Extending the network for these kinds of connections can both reduce heating costs removing people from fuel poverty and reduce carbon emissions from homes which were previously heated using oil or electricity. Because heating your home by gas is around 3 times cheaper than using electricity, consumers can save over £400 per year. We have provided over 30,000 of these connections since the FPNES was introduced in 2008. Across GB 91,203 of these connections will be delivered over the course of the RIIO-GD1 price control period which runs from 2013-2021⁸.

As our gas network infrastructure is largely underground, it is also highly resilient. The gas network is over 99.9% reliable, with unplanned outages expected once every 40 years⁹. This level of reliability is important in meeting the heating needs of vulnerable customers, particularly during winters where the UK experiences severe storms and interruptions to power supplies can occur.

Green Gas

The injection of renewable gas, such as biomethane and hydrogen into the gas networks, will allow UK customers to continue to benefit from our existing gas network infrastructure already built to meet peak heating needs.

Biomethane (also known as green gas) is produced by the breakdown of organic material such as food waste or crops by anaerobic digestion. Once cleaned up to remove contaminants it is injected into the gas network and used like natural gas for heating and cooking. It is already helping to decarbonise the gas flowing through the UK’s gas networks. It is also helping to diversify supply sources, in turn reducing the reliance on imports, increasing security of supply, as well as stimulating economic activity and employment.

By taking the carbon element out of the gas flowing through the networks, customers can be provided with a low carbon heating solution without the need for new heating systems in their homes. Unlike other low carbon heat options, the use of green gas requires no expansion of gas or electricity networks, saving money for consumers.

Having led the way in the development of green gas, we already have over 160,000 homes supplied, with a target to increase this to 250,000 homes by 2021. Out of the 60 fully registered UK projects, we have 30 biomethane sites connected to our network. The Renewable Heat Incentive (RHI) scheme has enabled the UK to become the fastest growing and most innovative biomethane market in Europe.

A recent decision to limit the support available under the RHI to projects that primarily use crops as feedstock could reduce the number of new biomethane projects coming online. As a lot of food waste is locked into long term contracts, we urge the government to align its waste policy to the changes in the RHI, to ensure sufficient feedstock remains available. While we welcome the news that the RHI tariff for biomethane will be raised back up in April 2017, in order to continue the impressive growth seen in recent years there is a need for more stable levels of support, and clarity on how biomethane will be supported beyond 2021.

Real-Time Networks

We recognise the gas networks will need to become more flexible as we move to a lower carbon future with a greater integration of renewables. We are therefore undertaking a project to develop a ‘real-time network’

that can support a greater volume of renewable gas like biomethane and hydrogen¹⁰. This will be achieved through the installation of sensing technologies in a section of our network in the Medway towns in North Kent.

As greater volumes of renewable gas are injected into the network, we will need to measure the energy content of the gas in the grid, rather than just the traditional flow and volume. The sensors will measure variables including flow, pressure, temperature, and gas quality. As well as enabling greater volumes of renewable gas into the network, the flexibility will increase the gas network's ability to adapt to the future energy needs of GB.

Hydrogen

Hydrogen is an emerging green energy source which we believe could offer a high value solution to the challenge of decarbonising heat. It would leave no carbon footprint as the combustion of hydrogen with oxygen results in water and heat. In the short term this could be blended with natural gas in the network, offering many of the same benefits as biomethane in terms of making use of our existing gas infrastructure to decarbonise heat.

There is a growing role of hydrogen within other gas distribution grids and we must aim to maximise its potential in the UK. Current legislation only allows for the blending of 0.1% hydrogen by volume with natural gas within the UK gas network¹¹. Studies have shown existing appliances can operate safely with up to 10% hydrogen by volume¹². In Germany, up to 10% hydrogen is already permitted within the gas distribution system utilising renewable electricity produced at times where supply exceeds demand to split water to produce hydrogen.

A research project we were involved in called Hyhouse, investigated the potential safety risks of using the gas as a heating fuel. The results of the project showed that hydrogen 'poses no significant increase in risk to methane' if released in a domestic environment¹³. The use of hydrogen within the UK gas networks is also not a new concept, as it made up around half of the old town gas mix.

In the longer term there is the potential to convert the low pressure gas distribution networks to 100% hydrogen networks. A key advantage is that the gas distribution system would need minimal modification, as old metal pipes are already being replaced by plastic ones which are potentially suitable for the transportation of hydrogen, at low pressure with very low losses¹⁴. It is envisaged the majority of the low pressure distribution network will be made up of plastic polyethylene pipe by 2032 as a result of the Iron Mains Risk Reduction Programme (IMRRP).

Hydrogen is a technology that would benefit from a holistic whole systems approach to decarbonisation as it could make a significant contribution to reducing emissions in both the heat and transport sectors. SGN is committed to a 100% hydrogen network demonstration in Scotland. We are currently undertaking feasibility

studies for 3 sites, seeking to select the most economic and viable location to construct the world's first hydrogen network¹⁵. Each site will be scalable and will look to utilise the hydrogen infrastructure in place for other applications including hydrogen vehicles and Combined Heat and Power (CHP) applications.

KPMG Report - The UK Gas Networks role in a 2050 Whole Energy System

There is a growing weight of evidence that solutions which utilise our existing gas network assets will allow us to decarbonise heat in the most affordable way. In 2016, the Energy Networks Association (ENA) who represent the electricity and gas network operators in the UK and Ireland commissioned KPMG to produce a report on 'The Gas Networks role in a 2050 whole energy system'¹⁶.

The study looked at four possible pathways that the heat sector could be decarbonised; evolution of gas networks and green gas; prosumer (self-generating energy solutions); diversified energy sources with different technologies used across the country; and electric future with a switch to electric heating technologies like heat pumps.

The report found that injection of renewable gas into the grid, such as biomethane and hydrogen, offers significant cost savings against alternative low carbon heating sources. It was also shown to be the most practical option in terms of technical feasibility and importantly, the most acceptable to customers and society. Customers place great value on the convenience and reliability of the way heat is currently provided¹⁷. The report highlighted this as an important consideration in future policy decisions.

The analysis called for gas and heat innovation and funding to continue, especially in areas that help to firm up the understanding of options for 2050. It also recommended that transport decarbonisation policy be more closely integrated with power and heat decarbonisation policy.

Policy and Regulatory Decisions

The UK Government is developing work considering long term heat decarbonisation and the impacts on infrastructure requirements the different option, or mix of options would have. This will, over the coming years, gather evidence and analysis and try to fill key gaps relating to options such as future of the gas grid, electrification of heat and district heating. Policy decisions on heat from the UK Government are not expected to be made until the next Parliament i.e. 2020.

As suggested by the Committee on Climate Change (CCC) in their recent report on 'The Next Steps for UK Heat Policy', action is needed now in order for informed decisions to be made during the next Parliament (2020-2025)¹⁸. We believe it is crucial the UK Government takes forward the CCC's recommendation to commence a significant programme of work on options around converting the gas grid to hydrogen. This will allow for decisions to be made on rolling this out at scale in the next Parliament.

¹⁵ <http://www.smarternetworks.org/Project.aspx?ProjectID=2051>

¹⁶ <http://www.energynetworks.org/assets/files/gas/futures/KPMG%20Future%20of%20Gas%20Main%20report%20plus%20appendices%20FINAL.pdf>

¹⁷ [Hoggett, R., Ward, J. and Mitchell, C., 2011. Heat in homes: customer choice on fuel and technologies. Study for Scotia Gas Networks, Energy Policy Group, University of Exeter, Exeter.](http://www.scotiaenergygroup.com/heat-in-homes-customer-choice-on-fuel-and-technologies)

¹⁸ <https://www.theccc.org.uk/publication/next-steps-for-uk-heat-policy/>

We would like to see much closer working between the Scottish Government and the UK Government as they work to identify the highest value approach to long term heat decarbonisation. While we strongly welcome the Scottish Government's interest in SGN's practical demonstration of a 100% hydrogen network in Scotland, we feel the evidence being gathered by the UK Government can help inform the Scottish Energy Strategy currently being consulted on. This is particularly important as decisions on the future of the gas network itself are reserved to the UK Government (whatever gas is transported through those pipes)¹⁹.

The Gas Distribution Networks are currently half way through the current eight year RIIO-GD1 price control period set by Ofgem which began in 2013. The next price control period, RIIO-GD2 will commence in March 2021, providing a fast approaching deadline for regulatory decisions on the gas networks covering the eight-year period out to 2029. While we welcome the UK government's re-assessment of the best value option to decarbonise heat, there is a need for some clarity in terms of policy direction as soon as possible due to the long term nature of network investment.

While delivering a low maintenance fit for purpose gas network for the future will not require significant new investment, it is important that the IMRRP continues at current levels. Under this programme significant sums are already invested to replace metal gas mains with modern plastic pipes. We believe it is crucial this programme is continued at current levels during the RIIO-GD2 price control period to ensure potential least cost routes to UK heat decarbonisation utilising our gas network infrastructure are kept open.

If the decision is made to repurpose the gas network to transport hydrogen, the costs of this could be absorbed into the normal regulatory processes of the gas industry. This would involve the capital and operating costs of the hydrogen supply being accounted for in the appropriate regulatory settlements, on a similar basis to the current IMRRP.

For all of the main approaches to heat decarbonisation, Carbon capture and storage (CCS) is likely to be vital in order to remain compatible with our climate change targets. This is either because of the need to significantly increase electricity production at the required new power stations, if electrification were to be deemed the highest value solution, or to produce decarbonised hydrogen.

We therefore see it as essential the government support CCS development across not just the power sector but also heat and transport. As identified in a recent report to the Secretary of State on 'Lowest cost decarbonisation for the UK economy', having the option to begin converting the gas network to hydrogen in the 2030s requires CCS transport and storage to be in place during the 2020s²⁰.

21. What are the implications of low carbon vehicles for energy production, transmissions, distribution, storage and new infrastructure requirements?

In order to meet our climate change targets in the most efficient way we believe there is a need for greater integration between the transport, electricity and heat sectors. For example, there could be a huge

¹⁹ <http://www.gov.scot/Resource/0051/00513102.pdf>

²⁰ http://www.ccsassociation.org/index.php/download_file/view/1043/508/

opportunity to use our existing gas network infrastructure to provide a cleaner, quieter and cheaper alternative to diesel.

Currently, 25% of total greenhouse gas (GHG) emissions comes from transport, and of that, around a quarter is produced by heavy goods vehicles (HGVs) and buses. But because these vehicles actually account for only about 1.5% of all road traffic in the UK, their emissions are disproportionately high. Whilst electrification is one of the leading options to decarbonise transport in smaller vehicles, it is not a practical solution for HGVs and buses. Compressed Natural Gas (CNG) is currently the leading option in this area. As well as being cleaner and quieter than diesel, it is also 30% cheaper.

Utilising biomethane in HGVs can unlock additional benefits in terms of the carbon benefits achieved. The Renewable Transport Fuel Obligation (RTFO) has suffered because support has been restricted to biomethane transported straight from the source of production to the vehicle being fuelled. We welcome the Department for Transport's (DfT) intention to make biomethane injected and delivered by the gas distribution network eligible for support if it is then used as a transport fuel.

A host of British retailers including John Lewis have recognised the cost and carbon benefits of converting its fleet of long distance HGV fleets to run on CNG. The first high pressure CNG filling station which opened at Leyland in Lancashire last year is capable of filling over 500 HGVs a day. CNG is also a leading solution to green the UK's bus fleet and there are already 34 CNG buses and over 100 taxis benefitting from a gas refuelling station connected to our network in Reading.

There could also be an important role for hydrogen as a future transport fuel as it produces no harmful emissions, emitting only water vapour. As well as improving air quality, hydrogen vehicles are also quieter and smoother to run. Hydrogen can be produced by electrolysis, utilising green electricity to split water into its constituent parts, oxygen and hydrogen. We are a partner in the Aberdeen Hydrogen Bus Project, Europe's largest demonstration of hydrogen fuel cell buses. The fleet of 10 hydrogen buses is part of an initiative which aims to commercialise hydrogen fuel cell buses across Europe.

With less than half of the British rail network electrified and electrification proving expensive, there is increasing focus on the potential for CNG or hydrogen to decarbonise rail transport. This is in particular for the large number of diesel trains operating on routes that do not attract the volumes of traffic that would make electrification viable. CNG or hydrogen trains could therefore provide a lower carbon solution to reduce emissions from transport, taking advantage of our existing gas network infrastructure. The world's first zero-emission, hydrogen powered train is expected to enter service in Germany next year.

As mentioned in our answer to question 19, hydrogen is a technology that would benefit from a holistic whole systems approach to decarbonisation.

11 Broad Street West
Sheffield
S1 2BQ**

10 February 2017

Dear Sir/ Madam

NATIONAL INFRASTRUCTURE ASSESSMENT: CALL FOR EVIDENCE (FEBRUARY 2017)

The Sheffield City Region (SCR) is strongly supportive of the NIA Call for Evidence and recognises that infrastructure is key to unlocking and driving the SCR's economic growth. Our Strategic Economic Plan (SEP) sets an ambitious target to increase GVA to £3.1bn by 2025. To secure these outcomes we will deliver enhanced infrastructure, supporting an attractive environment for businesses and residents.

We have a strong track record in infrastructure delivery through our existing SCRIF Programme (Sheffield City Region Investment Fund), valued at £650m. This infrastructure investment is unlocking the following benefits for the City Region:

- GVA (£) 2,974m
- Private Sector Leverage (£) 956m
- Jobs Created Number 20,452 (net)

In November 2016, we launched an early commission call for new projects to the existing programme and the Combined Authority has just approved a further £46m of projects, delivering significant additional benefits to the SCR including:

- GVA (£) 561m
- Private sector leverage (£) 213.5m
- Jobs Created 4109 (net)
- New homes 1978

The SCR's future infrastructure requirements are contained within our recently launched Integrated Infrastructure Plan (IIP), this plan is the first of its kind in the country. The IIP recognises the full range of infrastructure requirements needed to unlock growth.

This plan clearly articulates and evidences the diverse range of opportunities that our infrastructure investment will unlock in the City Region and identifies £28bn of infrastructure investment opportunities surrounding the SCR's growth areas and these opportunities are presented as spatial packages. Our IIP recognises the need for a focus on multiple infrastructure types to enable a comprehensive understanding of SCR's challenges and opportunities, whilst aligning itself with national agendas such as HS2, Northern Powerhouse and Transport for the North as well as alignment with Local Plans and Strategies.

A programme led approach is proposed, utilising a single collaborative commissioning approach linked to integrated funding sources to drive the delivery of schemes. This is to ensure that the SCR has appropriate infrastructure governance arrangements in place to deliver a pipeline of infrastructure projects in the short, medium and long term as efficiently as possible and on time.

I attach a copy of the Sheffield City Region's Integrated Infrastructure Plan to inform your evidence base. The SCR would welcome the opportunity to work with the National Infrastructure Commission in the future and the IIP provides a real opportunity for the Government to work with the SCR to progress infrastructure investment.

Yours faithfully

National Infrastructure Commission
The National Infrastructure Assessment Call for Evidence
A Shropshire Response, 10th February 2017

Email [email address redacted]

Foreword

This response sets out to be a collegiate response, submitted on behalf of Shropshire Council, and supported and informed by response also being made by Herefordshire Council. The Herefordshire and Shropshire responses have both been shared with the Marches LEP and strengthened by input from the LEP, making these very much partner and partnership documents from the Marches subregion.

As will be noted by the National Infrastructure Commission, there are commonalities of views, as befitting our shared approaches in the subregion, as well as additional local detail from a local authority perspective. The Shropshire response is further informed, for example, by evidence already given to the National Infrastructure Commission through the regional workshop held by the West Midlands Combined Authority (WMCA) on 19th January 2017.

The Council previously made submissions to the Infrastructure Commission in response to calls for evidence with regard to energy and electricity, and with regard to northern connectivity (8th January 2016). The following extracts from the latter submission provide the context for the submission that we now make.

“As a large, rural and sparsely populated county (310,000 population; 0.96 persons per hectare (Source: ONS mid- year estimates, 2014), Shropshire is dependent on a good, well connected and integrated road network, which links to rail networks and to airports. Travel to work patterns across our porous borders indicate large numbers travelling for work to the West Midlands, to the South and East, and North and North West, to Cheshire, Staffordshire and Manchester and beyond, as well as into Wales.

“This Council has previously made submission to the BIS Select Committee Inquiry into the Government’s Productivity Plan, and was one of just two rural unitary authorities to do so, the other being Cornwall. We have already commented to that Committee as follows: “In welcoming the forthcoming new long-term National Infrastructure Plan (NIP), Shropshire Council advocates that Government follows the

Natural Capital Committee recommendation for incorporation of natural capital into each of the economic infrastructure sectors including energy, flood defences and water, and for an investment programme for natural capital to explicitly feature in the NIP. (paragraph 4.1 of the Shropshire Council response)

“Shropshire sits within the Marches LEP, one of the largest geographical LEPs in the country covering the local authority areas of Herefordshire, Shropshire and Telford & Wrekin. It is an area of both urban and rural assets; Hereford, Shrewsbury and Telford are the principal urban settlements which provide employment and social opportunities, supplemented by market towns and villages, whilst the landscape supports a rural economy of farming and tourism and attracts people to live and work in the area.

“This natural landscape itself presents a tangible economic asset, given the actual and potential positive value of natural capital. For this reason, we advocate including the actual and potential positive value of natural capital as a specific measure to aid productivity growth, using measures such as site based natural capital assessments.

“The physical realities of a geography that includes the River Severn and upland and hill areas, with a dependency on key arterial routes through the region that are liable to flooding, causes practical challenges around transport connectivity exacerbated by ongoing challenges around digital connectivity.”

The Marches forms the southern boundary of the Northern Gateway, where the subregion directly adjoins Chester West and Chester and Cheshire East, whilst Shropshire and the Marches is equidistant to Manchester and Birmingham and is closer to Chester than Worcester. The Marches also forms the western boundary of the Midlands, and benefits from close proximity to a number of other urban centres: Stafford; Stoke-on-Trent; Worcester; and Cheltenham/Gloucester/Bristol.

Looking to the devolved administration, and to national and international borders, the Marches plays a key role linking England and Wales with towns located on the periphery of the Marches, including: Wrexham; Welshpool; Newtown; Abergavenny; and Monmouth, and through the A483 and A55 to Holyhead and Ireland.

These strategic links mean that the Marches has a role to play in the regional, national and international economy. The following responses have been made with regard to the twenty-eight questions posed by the NIA in its Call for Evidence for the UK’s first ever National Infrastructure Assessment (NIA). We would be pleased to provide any further information or clarification of the points that we make. Thank you.

Twenty Eight Questions

The questions that the Commission has identified to assist respondents in focusing their submissions to this call for evidence are set out below, with responses.

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support longterm sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

A contention from the Shropshire and Marches region would be that infrastructure investments are most likely to lead to long term sustainable growth in the region where there is collaboration and ongoing engagement between the private and public sector, taking a long term view rather than a piecemeal project by project approach, and reframing that view in the light of local evidence. Such an approach relies not only upon the collective acquisition and forensic analysis of local data, but also the recognition at national level of the importance of utilising this intelligence to better understand local geographical, demographical and political realities and shape national policy accordingly.

In Shropshire, by way of illustration, we work within the Marches LEP and with neighbouring authorities for mutual benefit, and continue to exploit opportunities to do so, including those that arise around transport, housing and digital infrastructure, and around land assets and natural capital, including water quality and supply.

The Marches LEP, with Herefordshire, Shropshire, and Telford and Wrekin, the local authorities working within the LEP, are Non-Constituent Members of the WMCA.

As will no doubt have already been advised to the NIA through its evidence-gathering workshop in Birmingham in January, it is the combined impact of metropolitan Constituent Members, Local Enterprise Partnerships and Non-Constituent members, working together to deliver step changes in productivity, growth and public sector reform across a broad geography, that makes the WMCA approach unique. The collective effect is to: *"provide the scale and capacity to respond to the opportunity of devolution and go further and faster in enabling economic growth."* The strength of the Combined Authority is very much in its geographical and economic diversity and a strong shared ambition expressed through the Strategic Economic Plan.

In terms of Shropshire's connectivity to the West Midlands, ongoing investment in both the road and rail network east/west will continue to be a priority.

Similarly, Shropshire also looks north through the Northern Gateway Partnership, with particular reference to links being made and continuing to be made between the Midlands Engine and the Northern Powerhouse, where HS2 rail transport may already be thankfully in the pipeline as a key regional and national project, but could also usefully be considered an anchor for associated infrastructure planning in the short and long term.

Turning to road transport, the anticipated Shrewsbury North West Relief Road (SNWRR) would provide a new single carriageway road in the north-west quadrant of Shrewsbury. Links between the north and west of Shrewsbury are very poor; this affects local commuters and longer distance business and freight traffic, moving between northern business areas and the North West, and Wales. Together with the A5 and A49 bypasses, the Oxon Link Road and the Battlefield Link Road, the SNWRR would provide the missing link to provide a complete and strategically significant (in SRN terms) outer bypass of Shrewsbury.

All long distance through traffic would be able to avoid the town completely. In addition it would complete Shrewsbury's distributor ring road, which would aid the high volumes of orbital Shrewsbury traffic, travelling to or from different locations in the suburbs. The SNWRR will support a number of local policies, including the three main objectives of the Shropshire Local Transport Plan (2011-2026), economic growth, carbon reduction, and promoting healthy, safe and confident communities.

Such is the interdependency between transport, housing and digital connectivity, particularly in a large rural county such as Shropshire, that the highest value investments may be said to be as much about the potential value to be gained from sustaining and supporting our communities, as they are about transport for people, goods and services to and through the region.

Investments which support the provision and location of housing that will encourage young people to make their homes here are part of the equation, along with appropriate land supply for businesses, assured water and energy supply for both, and the digital connectivity required to support day to day life for those who live here and work here, and the businesses wishing to attract people to visit here.

Our Connecting Shropshire Programme Manager, Mr Chris Taylor, comments that: *"There is a wide and diverse range of opportunities, particularly across economic growth, created by the investment in next generation access networks (NGA)¹. Some of these metrics remain unquantifiable locally but national statistical data supports evidence that investment in improved broadband and mobile network is a significant contributor to national GVA growth and inward investment."*

¹Next Generation Access - capable of delivering 30 Megabits per second

However, rural reality continues to present practical challenges. An example would be the planned extension of local full fibre broadband networks, where we have responded to the recent DCMS call for evidence, extract below:

"We have noted the recommendations made by the National Infrastructure Commission in its recent report about achieving 5G, "Connected Futures", particularly the commentary about the role of local planning policy, and calls for the effective integration of transport and digital infrastructure to hasten establishment of 5G across both rural and urban areas.

“5G remains, however, in our view a long-term technology that will predominately benefit urbanised environments rather than rural hinterlands. We would very much want to stress that, although 4G services have been available in some geographies since 2012, many rural parts of Shropshire and neighbour counties still have not spot or partial coverage areas. The Council does not accordingly see 5G at this moment as a solution to current data/voice coverage issues in the county.

“Whilst there are potential benefits for LEPs to seek collaborative delivery plans to address poor 4G coverage and new 5G coverage in urbanised landscapes, including major shared highway routes, the new technology development has limited opportunities in addressing infrastructure in rural areas.”

2. How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Rural counties such as Shropshire, who have distributed business communities, are now completely dependent on having access to ubiquitous digital infrastructure in order that they compete equally both locally, regionally, nationally and in the worldwide markets.

One such example of this is rural tourism, where the subregion recently responded to the ongoing inquiry into rural tourism by the EFRA Select Committee, commenting on behalf of local businesses that: *“visitors increasingly wish to access the internet throughout the day as well as make and receive mobile phone calls. Rural tourism businesses need easy access to the internet for business and marketing purposes. A Herefordshire business made the comment that the WiFi code is one of the first things a guest asks for as they walk in the door.”*

As far back as 2015, in the collegiate response to the BIS Select Committee about Government’s Productivity Plan, we also made the following commentary, which remains pertinent post-Brexit to the NIA call for evidence with regard to international competitiveness and overseas markets:

“5.6 Chapter 14: a trading nation open to international investment

5.6.1 *Further support would build confidence for companies to consider international markets, in addition to the commitment to support LEPs boost exporting. Access to finance and challenges facing SMEs keen to export, eg production costs here versus Far East costs, are key factors for the British Business Bank to tackle. (point 14.6)*

5.6.2 *On inward investment, a fast track or incentives for investors to move into non-city areas could be a positive mechanism for growth, allied to local planning policies that encourage commercial enterprise and put appropriate community and business infrastructure in place. Critical to all of this is support for transport infrastructure, to not only attract people to live and work outside*

urban areas but also open rural areas up to new investors and markets at a European and international level.”

In our own early analyses of a post-Brexit UK, reported to the LGA in December 2016, we commented as follows in relation to transport infrastructure:

“Locally, two key transport issues may be highlighted here that are of direct relevance to international trade prospects post-Brexit; the A5 dualling to which local businesses have referred in the survey, and a North West Relief Road for Shrewsbury.

“The consistent dualling of the A5 is a stated priority for Shropshire Council, not least given wider regional views of this as a key road freight route to European and international markets by sea. However, as the A5 is a Highways England (HE) owned and managed asset, options for local influence over works are extremely limited. In order to exert influence over HE’s future Route Investment Strategies (RIS), Shropshire, along with LEP colleagues is actively engaged with the Midlands Connect initiative. In doing so, the A5 has been taken successfully through the first MC round of scheme prioritisation, and is now into the next round whereby Strategic Outline Business Cases will be developed for all schemes. This is being done primarily around the economic benefits that will accrue, as opposed to more traditional route enhancement triggers such as accident rates and road safety matters.

“Turning to the prospects of a north-west relief road (NWRR) for Shrewsbury, Shropshire Council has been awarded funds this week under the 2017/18 round of the Local Majors Fund as part of the Chancellor’s Autumn Statement. £950k of the total £1m cost of a refresh of the evidence base and Outline Business Case for the North West Relief Road will now be available through this fund.

“The OBC refresh will be undertaken and completed within the 2017/18 year (a prerequisite of the funding award), and will give a current and vital present day view of the viability of further investment in the road, something which has been a conceptual scheme for over 20 years. Note that this funding does not guarantee future national prioritisation for investment, or guarantee any of the considerable further funding required for construction at this time.”

The North West corridor (an extension of the East – West M54 / A5 Corridor) is currently the highest priority for Shropshire, because of its important strategic role as a freight route – in particular the Trans European Transport (TEN-T) network to Holyhead and the Republic of Ireland. We would expect this to continue to be a priority and ongoing investment on road connections here will continue to bolster the Shropshire’s, and the West Midland regions, international competitiveness, as has been identified through Midlands Connect.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Improving the physical and digital infrastructure whilst maintaining the natural capital in the county is critical to growing a prosperous economy in the Marches region, providing the conditions that will foster new medium to large businesses as well as sustaining and encouraging the businesses that already contribute to the local economy. This will include ensuring that the right employment land is available in the right locations for existing businesses to grow and for new businesses to be attracted to the county.

From a practical digital connectivity perspective, Chris Taylor comments that it is: *“...critical that all new premises (residential and business), regardless of their challenging location are connected to NGA networks by default as part of developers’ obligations. Making the requirement a planning condition would add accountability. Access to ubiquitous wireless and mobile networks should be complementary to all fixed broadband infrastructure. Priority of access should be to all main highways and transport corridors.”*

From an environmental perspective, Dan Wrench, County Ecologist, comments that:

“There is a need to consider green infrastructure either on its own merits or as a fundamental element of other hard infrastructure projects. Resilience of communities and physical infrastructure is aided by proper consideration of green infrastructure. For example, green infrastructure features built into or near hard infrastructure projects have multi-use capacity which includes capturing or slowing storm waters that impact business and can damage hard infrastructure.

“Green infrastructure can also serve local businesses as a resource for exercise which improves staff productivity and reduces absenteeism. Other means of attracting inward investment via green infrastructure is provision of clean air and a comfortable and safe working environment for business. Green walls, roofs and other features such as street trees both clean air and water, and reduce environmental extremes such as high temperatures and winds”

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

From a digital connectivity perspective, the commentary we would wish to give here is that internet data usage has continued to increase exponentially, with over 90% of world's data generated over the last two years.

The Internet of Things and 5G technology is expected to increase data volumes tenfold by 2020. This lowered costs of data storage, the increased capability of backhaul networks, has lowered Internet Service Provider costs and increased demand from consumers. More content, new creative applications, and consumer behaviour will continue to drive demand for faster networks and bandwidth over the next 10 years. There will be an expectation, unless data is compressed further, that all consumers have access to at least 100 mbps within the next 10 years.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Continuing our thread on digital connectivity, our technical expert Chris Taylor advises that: *“Existing legacy copper network provision which has supported early generation NGA deployments remains archaic and has been underinvested in. Without full renewal or replacement, preferably with fibre, then the full benefits of the public investment in fibre to the cabinet technologies will never be fully realised. Installing new NGA networks versus upgrading old is still seen in many professional quarters as more a most effective long term strategy.”*

In our collegiate response to EFRA Select Committee inquiry with regard to rural tourism, we also commented that there is a practical policy challenge around use of environmental and planning policy to strengthen infrastructure whilst protecting and enhancing the rural environment itself.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Opportunities, in whatever form they may take, will need to be informed by local geography. For example, in its 2017 Autumn statement, the Government introduced a strategic policy and initiative that could encourage new investment and competition to the telecommunications network market (Digital Infrastructure Investment Fund). This new funding will be targeted at supporting the market to roll out full-fibre connections and future 5G communications.

It remains critical that suppliers focus this new funding on supporting those geographies that remain the most challenged rather than adding competition to already well served urbanised areas.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

The following comments of relevance here with regard to funding and to housing development were made by Shropshire Council (27th June 2016) to the CLG Select Committee Inquiry into the recommendations made by the Local Plans Expert Group to improve local planning policy.

“4.7 Recommendation 37: Infrastructure Planning

4.7.1 *Shropshire Council strongly supports closer integration of the Local Plan process, infrastructure planning and developer contributions using a shared evidence base. Focussing Community Infrastructure Levy (CIL) on Local Plan priorities is consistent with the existing Shropshire approach and the potential to agree bespoke arrangements to recognise the specific requirements of large urban extensions would help to reinforce this. As highlighted in Shropshire Council’s contribution to the Rural Planning Review in April 2016, it has long been understood that the cost of providing all infrastructure needs associated with new development far outweighs the funds available through CIL and there is therefore a significant funding shortfall for infrastructure provision.*

4.7.2 *In particular, the current exemptions for self build relief have had a significant impact on a rural area, such as Shropshire, whereby the projected CIL revenue has fallen by over 60%. This, coupled with pooling restrictions on the use S106 planning obligations, means that there are real concerns within local authorities about the ability to deliver sustainable development in a context in which the ability to deliver new infrastructure is so constrained.”*

Shropshire Council would also add the following points with regard to the development of a Universal Service Obligation (USO) for broadband:

- The importance of ubiquitous broadband is clearly recognised by the telecommunications industry, business consumers and government.
- The Universal Service Obligation (USO) remains at the heart of national policy with consultation on going on who will supply service and how the funding policy will be applied.
- Any USO will need to quickly flex in order to accommodate the increased consumer demands for data and applications.
- Shropshire has contributed to a previous DCMS consultation on the matter and believes a demand side service in the open market remains critical to a fair and competitive solution for USO.
- At the heart of good service and pricing is supplier competition within a wholesale industry that remains fair and open to all retailers.

We have, further, noted the recommendations about transparency and equity from the Cities and Local Growth Inquiry conducted by the Public Accounts Select Committee, principally the following with regard to funding:

“Recommendation: Government needs to be clearer with local areas what is and what is not on offer; and what is mandatory as part of devolution deals. Government should also listen to local areas about their particular needs to avoid a ‘one size fits all’ model being imposed.

“Recommendation: As the full financial implications of devolution deals emerge, government should ensure that they are presented transparently in a way that can be compared between areas, including on a per capita basis.”

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

In the Government’s Autumn Statement (2017) the Digital Infrastructure Investment Fund was highlighted as a mechanism for suppliers to leverage equity for broadband networks. Details are still unclear on how this funding can potentially improve the current NGA projected gaps in Shropshire. Ideally, funding should include the ability for community groups to bid and leverage investment for localised network initiatives.

Shropshire Council would also ask the NIA to please note the following contribution from Herefordshire Council on this topic:

“A package approach to funding (local, LEP and national sources) to fund infrastructure projects without distorting well-functioning markets may well work. Local sources may include local authorities borrowing, asset disposal, New Homes Bonus contribution, Community Infrastructure Levy and developer contributions. LEP sources may include Growth Deal Funding and its successor funding. National sources may include departmental funding e.g. Department of Transport, and High way Agency Funds.”

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

Shropshire Council would ask the NIA to please note the following contribution from Herefordshire Council on this topic:

“To ensure that our infrastructure system is resilient to risks we recommend the following:

- Enhancing cooperation between the public and private sectors in protecting vital infrastructure system e.g. information systems supporting critical infrastructures in key economic sectors.*
- Proposing and developing ways to encourage private industry and the public sector to perform periodic risk assessments of key infrastructure systems.*
- The government adopts a common definition for resilience and disseminates a high level, top-down strategy for the development and funding of resilience activities.*

- *Increase the coordination among all levels of government and stakeholders and ensure shared understanding of regulations and standards that promote efficient and timely responses to incidents.*
- *Establish new or enhance existing public-partnerships to provide a common, agreed upon, set of sector specific goals, with clear input on feasibility and objectives.*
- *Government to work with stakeholders and local authorities to establish resilience goals, facilitate contingency planning, foster relationships, ease information sharing and garner best practices. “*

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The varying status of local planning policy arrangements means that Government will need to factor in very practical on the ground infrastructure issues, such as how extension of fibre broadband networks can operate across devolved national administrations as well as across existing and developing locally devolved bodies.

For example, in Shropshire the Local Plan situation is that consultation has just opened to inform a partial review of the Local Plan, and was reported to Shropshire Council Cabinet in January 2017 in these terms:

- *The Shropshire Local Plan currently comprises the Core Strategy (adopted 2011) and the Site Allocations and Management of Development (SAMDev) Plan (adopted 2015). These documents set out proposals for the use of land and policies to guide future development to help to deliver sustainable growth in Shropshire for the period up to 2026. However, Local Planning Authorities are required to keep under review any matters that may affect the development of its area or the planning of its development.*
- *There is a requirement to objectively assess the development needs of the County and this also permits a longer term view to be taken for the period to 2036. In addition, there continue to be significant national policy and procedural changes along with opportunities and challenges at the national and regional level which will impact, to varying degrees, on Shropshire. These matters should be addressed through a partial review of the Local Plan to help to ensure the continuing conformity of the Local Plan with national policy.*
- *This partial review of the Local Plan will provide an up to date and deliverable Plan for Shropshire. It will help to maintain local control over planning decisions by ensuring that the adopted policies and proposals will be the primary consideration for decisions about development in Shropshire.*
- *Maintaining an up to date Local Plan will further support local growth by generating certainty for investment in local development and infrastructure through a policy framework that supports sustainable development in communities across the County, during the period to 2036.*
- *A current (opened 23/01/2017) Issues and Strategic Options consultation will focus on key areas of change, and set out options for the level and distribution of new housing and strategies.*

In neighbouring local authority areas of Telford and Wrekin and Herefordshire, who jointly with Shropshire form the area covered by the Marches LEP, the Local Plan situation is different, with Telford and Wrekin currently about to undergo Examination in Public of their Local Plan. The situation will be different again in the Welsh border authorities.

Any approach that seeks to maximise the potential of public sector infrastructure, as suggested by Government in the approach of “Making public sector assets available”, will therefore need to account for these variations and perhaps look favourably on those for whom plan-making is robust and well advanced, as in Shropshire, in testing out pilots.

In addition, Dan Wrench, County Ecologist, comments that provision of ecological data to enable infrastructure projects to comply with a wide range of environmental legislation can be a time constraint. This is partly because such data is currently not open data and data providers charge to cover their time.

A small and centralised environmental levy on major projects would easily cover the funding requirements of Local Ecological Data Centres (LERCs) resulting in open data from which all infrastructure projects would potentially benefit. This would also have several spin-off benefits including open data for other users such as housing developers.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

We have referred to CIL as a developer contribution, which may potentially mitigate against impacts on the natural environment. Planning policy that itself encompasses environmental impact assessments and rural proofing, as is the case in Shropshire, can also mitigate risks.

Deployment of new infrastructure needs to be managed empathetically at the same time as the key stakeholders in the sensitive areas appreciate the business and consumer demand for better connectivity. In order to accomplish the balance, all parties need to adopt a pragmatic approach.

This view may be said to hold as good for physical infrastructure as it does for digital infrastructure.

There is a role here for utilities companies working closely with local authorities and LEPs, to develop mutual understanding and share information. For example, Scottish Power Energy Networks hold a regular Strategic Stakeholder Panel, to which Frank Mitchell, CEO, talked last week about the consequences of Brexit with an anticipated increase of 30-35% on the cost base of equipment and copper given currency and commodity changes. Increases in infrastructure costs will have an impact on energy charges by the energy suppliers. Also raised concern on availability of technical skills in the future and energy resilience as an issue for LAs.

Energy resilience emerged as a key issue along with water quality and water supply, at a Local Environment and Economic Development (LEED) Stage One workshop held by The Marches LEP in July 2014 with stakeholders including Defra's Local Nature Partnership (LNP) lead and the two LNPs serving the area.

Natural capital accounting or ecosystems accounting is seen as a practical way to inform policy on infrastructure considerations and help to measure outcomes, and is recommended to the NIC accordingly. Organisations such as National Grid have already undertaken assessments of the value of the Ecosystem Services provided by their land holdings and assessed how these values, to both their shareholders and the wider public, can be enhanced. Further information has been produced and published through the LNPs in 2016 on this practical way to protect and enhance the natural environment and to bring tangible economic benefits.

Infrastructure that leads to creation or management of grassland areas (such as roadside verges) could significantly help pollinators and also help protect remaining high quality grassland sites. The greatest gains could be achieved with the use of 'green hay' from species-rich grasslands in the creation of new grassy areas. 'Green hay' is hay that is cut and moved on the same day so as to retain the seeds with the hay.

Creation of a market in such hay from nature reserves and other high quality sites would help protect existing sites (whose farmers could charge over the going rate of species-poor hay) and also ensure that grassland creation results in high quality, species-rich habitats that also benefit pollinators and other wildlife. In effect this is an example of Payment for Ecosystem Services which is an emerging field for the enhancement of natural capital. Mention of this technique as best-practice would go a long way to protecting this increasingly rare habitat and helping pollinators.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: "credible" improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. "Tractable" improvements are those that can generate usable quantitative outputs. "Transparent" improvements are those that do not rely on 'black box' modelling and assumptions.

Shropshire Council would ask the NIA to please note that the contribution on this topic, from the Marches LEP, is that with the UK economy entering a new era, we will shortly be working in a post-Brexit landscape to deliver the new national Government economic growth agenda. In the light of this, we do very much consider that there is a need to review current cost-benefit analysis techniques, which tend to favour 'quicker wins', to ensure that infrastructure schemes, capable of delivering tractable longer term economic growth outputs, can be appropriately evaluated."

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

The expert view from Matt Johnson, Strategic Transport and Contracts Manager, Highways and Transport, at Shropshire Council, is as follows:

Within Shrewsbury, the planned development of the two main Sustainable Urban Extensions is integrated with engineering within the footprint of the development, and to enhance inter town links, with accommodation of increased short distance travel by sustainable (walking and cycling) modes.

Within the County Town of Shrewsbury, and for inter Market Town travel, there is a reasonable expectation that hybrid and electric vehicles will grow in uptake and usage. Whilst current technology suggests that there would be a predominance of local and short "within County" trips by such means, an expansion of the current limited longer distance charging network with public pump priming is already underway. It is reasonable to expect that the market will provide the necessary infrastructure along key and strategic routes within the time period being considered.

Home and flexible working and home delivery of services and goods would be expected to increase further removing the need for some considerable amount of peak time travel.

Further developments in autonomous vehicles, particularly in terms of HGV freight movements, may concentrate movements further towards key strategic routes. In a rural county such as Shropshire, the potential for growth in this technology is uncertain, but the remaining need for the "last mile" delivery of goods and freight will remain.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

Assuming a continuing reliance on road based transport, it would be assumed that zoned developments by sector, with appropriate connectivity to the SRN network would favour such development. The continued increase in light rail and metro style transport systems for personal transport, alongside appropriate accommodation for sustainable travel methods could be expected to return a high BCR when considering the wider built and public environment.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

Within those sectors currently strongly represented within Shropshire (Agri tech, food, tourism etc.), such an approach may not be the most appropriate, although a

free flowing and reliable transport network based on the local and secondary rural highway network would accrue similar benefits over and above simple geographical colocation.

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Incentivised options for alternatives to solo private car travel could be actively managed to reduce road usage in collaboration with investment in light transit and mass transit systems. Technological advances in personal information sharing and journey detail sharing giving informal agglomeration of trips can be expected to continue to rise and road user charging, managed sensitively, can be a positive influencing factor upon this.

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

The expert view from Chris Taylor, Connecting Shropshire Programme Manager, is that: *"DCMS appear to be setting a consumer expectation of fibre to the home technology and 5G wide area coverage. Whilst these would provide a blended and complementary solution in urbanised areas they will be a challenging deployment in rural counties such as Shropshire where there would be significant cost implications without State Aid."*

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing "regime" refers to the current market, competition and planning frameworks. "Digital communications" includes both fixed and mobile connectivity.

Shropshire is expected to fall into the lower quartile for national digital coverage by the end of 2017. Rural counties such as Shropshire will continue to be challenged by the ability of commercial and intervention programmes to deploy digital networks to all premises in a predominately rural county. Shropshire will continue to work diligently with the market to address broadband gaps. However, the Authority will ultimately be reliant on further government intervention to address the digital gaps that are expected still by the end of 2020.

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Heat constitutes the biggest use of energy in the UK. Integral to the issue of heat is the improvement of energy efficiency. Greater building energy efficiency reduces the need for additional electricity generation and ensures heat demand is as manageable as possible.

Uncertainties in heat infrastructure development relate to technical, economic and market challenges. Considerable investment from the public and private sectors would be required but public finances are constrained and perceived risk and uncertainty are barriers to greater private investment. Clarity in Government decision making is crucial in maintaining the confidence of investors in the UK's low carbon infrastructure.

20. What does the most effective zero carbon power sector look like in 2050?

How would this be achieved?

Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.

The UK energy sector needs to move from its centralised high-carbon power system to one that provides heat and power securely, affordably and with minimal dioxide emissions. Additional power generation capacity and improved infrastructure is required to meet increasing need and demand.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Implications perceived in Shropshire of low carbon vehicles:

- Facilities that are not only suitable but also suitably located will need to be provided, to enable charge or re-fuelling, in addition being able to do this in a timely and cost effective manner;
- Networks may need significant upgrades to increase efficiencies;
- Key routes and locations will need to be identified;
- Signposting to these will also be critical.

Shropshire Council would also ask the NIA to please note the following contribution from Herefordshire Council on this topic:

- Space requirement may increase. Access to and from potentially centralised location potentially could increase vehicle movements.
- Funding for skills development need to be made available to respond to the skills requirements for these new technologies.
- Resources for feasibility studies for any low carbon vehicle (e.g. feed stock supply, wind speed and capacity and scale of requirements) should be made available.

Water and wastewater (drainage and sewerage):

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Reference has been made to the benefits of using an ecosystems accounting approach. It is commended to the NIA as being an approach worth a closer examination.

The Marches LEP has published a natural environment investment prospectus which highlights some natural assets of the Marches LEP area. Through case-studies we demonstrate how some businesses are making good returns on investment in natural resources like water and green infrastructure.

The case-studies illustrate how intelligent use of natural resources can bring both economic and social benefit to investors which also benefit the area's work force and the diverse local communities that make their homes in the region. Please see website and the following case studies, extracted from the prospectus.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

The following case study, published in the Marches LEP natural environment investment prospectus, provides an exemplar approach:

Ricoh is a Japanese multinational imaging and electronics company with production and warehousing units in Telford. A series of pools and wetlands are being created on site which will act as a sustainable drainage scheme (SUDS) and a pollution prevention control measure to meet the forthcoming Water Framework Directive (WFD) requirements. This removes the risk of the site being shut down due to any potential pollution incidents into the local water course.

Key points:

- Site closure would cost in the region of £1m per day.
- Surface water discharge rates will be reduced by £30k per year.
- Future legislative compliance with WFD will be achieved
- The scheme will cost in the region of £500k to install
- This is a new initiative requiring initial investment to evidence the benefits.

Other benefits:

- A variety of biodiverse habitats
- Greater productivity and fewer sick days for staff who use the area for work breaks
- Demonstrable evidence of business excellence measures and Corporate Social Responsibility

- Creation of an exemplar in retro-fitted SUDS that can be used as a demonstrator by other organisations, including businesses involved in the 'Business Environment Support Scheme for Telford' (BESST)
- Much improved carbon storage

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

The following case study, also published in the Marches LEP natural environment investment prospectus, provides an exemplar approach of using Catchment Management Partnerships.

Catchment Management Partnerships deliver activity that ensures Rivers of the Marches recover to good ecological status and meet water quality standards under the EU Water Framework and EU Drinking Water Directives. These partnerships complement existing regulatory functions and also bring on board businesses and NGOs who have an interest in clean rivers and issues of flooding or drought.

Shropshire Wildlife Trust (SWT) facilitates delivery in the Middle Severn catchment (central and north Shropshire) with co-hosts Severn Rivers Trust (SRT) leading on the Teme catchment. Defra has confirmed its policy commitment to the Catchment Based Approach (CaBA) to delivering the UK's obligations under the Water Framework Directive (EU2000).

Current project activity includes a wide range of advisory, education and practical works across Shropshire and Telford & Wrekin. These deal with diffuse and point source pollution, river re-naturalising, flood management, protected species work and new ways of working, such as payment for ecosystem services. Over the past three financial years over £1.5m has been directly invested through Catchment Management Partnerships.

Overall return on investment is difficult to quantify but costs of flooding and disruption to water supply and flood impact in the agricultural sector are enormous. The financial costs of floods and pollution, referred to here for additional context, include:

- Significant economic development in the Clun and Wye catchments have been held back until water quality improvements are achieved.
- A pollution incident in 2012 in Coalbrookdale closed the River Severn water extraction point south of Telford for over 24 hours. Supplies to Telford and nearby towns were put at risk.
- Re-seeding and crop loss on a single farm due to flood water inundation can cost upwards of £10,000 annually. Estimated annual total costs across Shropshire of the impact of floods on food production is in the £100,000s.
- The UK cost of the 2007 floods to agricultural production was estimated at £50m. The vast majority of this cost is borne by the farming community.

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

No comment made at this time

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

Dan Wrench comments as follows:

"The Catchment Based Approach is working well locally. However this requires long term input to ensure our water resource is well managed. Payment for Ecosystem Services pilot projects, which compensate farmers for managing their land for water management, need rolling out more widely. Evidence is now very significant that soft engineering (tree planting, etc) is more cost effective than hard engineering in most instances and that other benefits are gained (e.g. improved assets for tourism).

"For some infrastructure Sustainable Drainage Schemes are poorly thought out and don't consider multiple benefits that such systems can achieve. All infrastructure projects should go over and above existing policy to ensure additional benefits, such as improved water supply, are optimised.

"Standardised tools should be made available that allow assessment of the impacts of a wide range of land use change on ecosystem services such as flood alleviation. The full impacts of these changes, and ideally the financial costs / benefits, can then be better evaluated. "

Solid waste:

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Shropshire Council would ask the NIA to please note the following contribution from Herefordshire Council on this topic:

"Previous and existing incentives, such as recycling targets, landfill diversion targets and landfill tax have encouraged investment in waste infrastructure by local authorities. Future targets are uncertain due to Brexit but even so the UK is unlikely to meet its existing obligation of 50% recycling of municipal waste by 2020 without further investment let alone more ambitious targets.

“Current regulatory incentives do not correctly assign responsibility; they still place the burden of cost on local authorities rather than on producers. Increased producer responsibility for packaging waste, for example, would be a big step forward to address this.”

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

Assessment of the environmental externalities of economic activity is complex and poorly communicated. At present, the public pick up the clean-up costs of private economic gain that has a multitude of externalities. The County Ecologist, also co-ordinator for the Local Nature Partnership for Shropshire and Telford and Wrekin, provides the following example by way of illustration: the public subsidise farming; farming pollutes water courses with fertiliser and pesticides; the public, through water bills, then pay to clean this up; only the farmer may be said to gain.

A recommendation to counter this would be that the “Polluter Pays Principle” should be incorporated somehow. The public would gain in lower costs all round and improved health. The costs would be greater regulation of businesses.

A further recommendation is that a natural capital market, which would be overarching to the Carbon Market, should be developed as a good way forward.

Shropshire Council would ask the NIA to please also note the following contribution from Herefordshire Council on this topic:

“As discussed above there are no current or planned incentives to allow local authorities, in particular, to achieve a more circular economy. In respect of proposed recycling targets we should also be careful not to proscribe unsustainable methods of waste management such as food and garden waste collection.”

[SHROPSHIRE COUNCIL RESPONSE ENDS]

A proposal to the National Infrastructure Commission for a 6-months scoping study for the development of Smart Water Hub Project

Digitising Water & Customer Experiences Using Distributed Ledger Technology & Smart Contracts.

Helping Cities & Companies to achieve inclusive, resilient and sustainable development via design of efficient and flexible systems, digital economic incentives & community engagement.

CALL FOR EVIDENCE

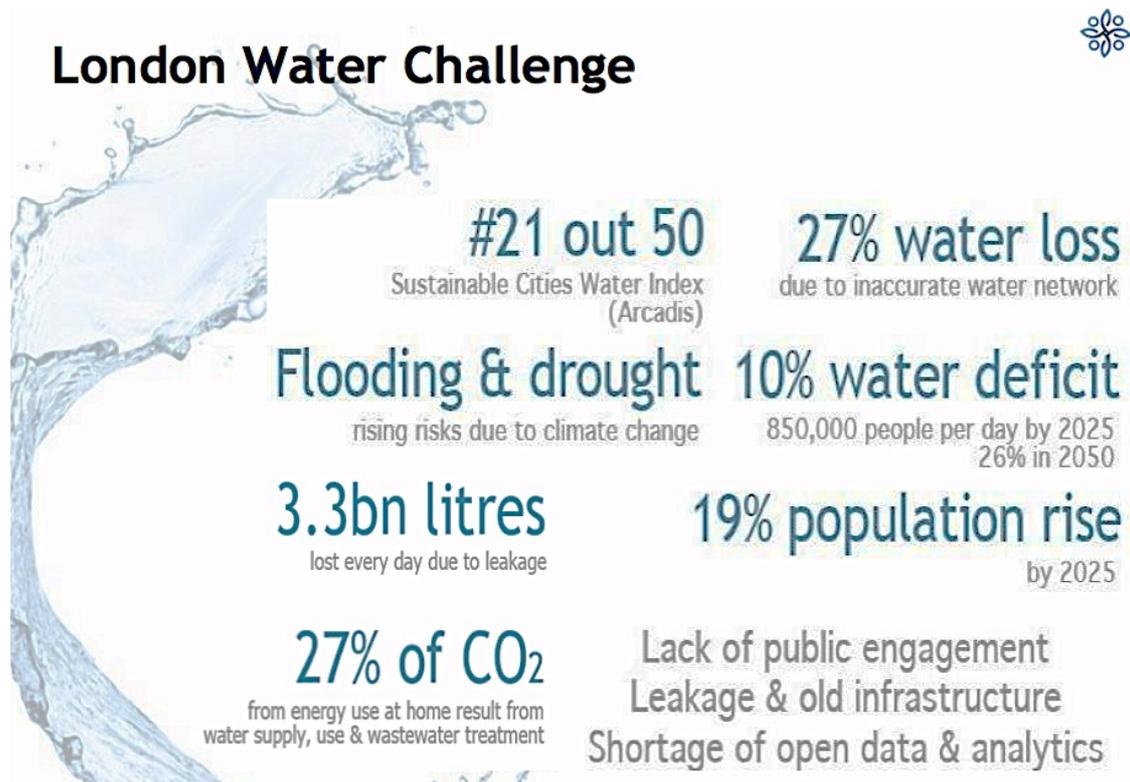

**[Name redacted]
[job title
redacted] Smart
4.0
(SCG London Ltd.)
www.smart4.tech
e: [\[email redacted\]](mailto:[email redacted])**

10 February 2017

Our Challenge

The water and sewerage sector in the UK is undergoing major changes as a result of the introduction of liberalised, regulated markets. Starting from April 2017, the non-household water retail market will be open. The sector will also benefit from further investment of £44bn into improving assets and services in 2015-2020.

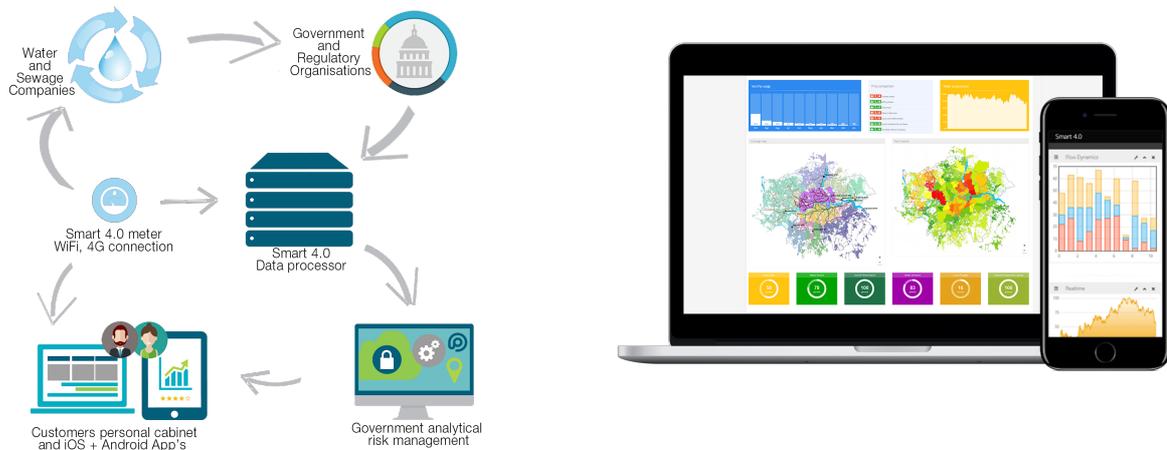

The project aims to address the existing and future challenges of the water and sewerage sector by providing digital products and services that bridge technology, market needs and sustainability. By creating a private-public ecosystem in the form of Secured Regulated Platform for water companies and their customers will build transparency, trust and mutually beneficial relations.

**Demo Prototypes Available on Request*

INTRODUCING SMART 4.0 PLATFORM

Creating Synergy of Innovation, People and Nature

The Digital Platform helps to engage with communities, by empowering individuals, private and public actors, and helps to build sustainable competitive advantage in the water sector.

It is aimed to improve interaction between stakeholders, increase operational efficiency and maximise revenues through a new functional ecosystem of technology and information, backed by IoT, cloud and distributed ledger technology (blockchain).

The platform will integrate and analyse existing and obtained data including open data, reports, real-time information, water suppliers and customers, including switching statistics and their margins. The gathered data will be allocated to individual accounts secured by private keys.

City Water Dashboard may include (by companies):

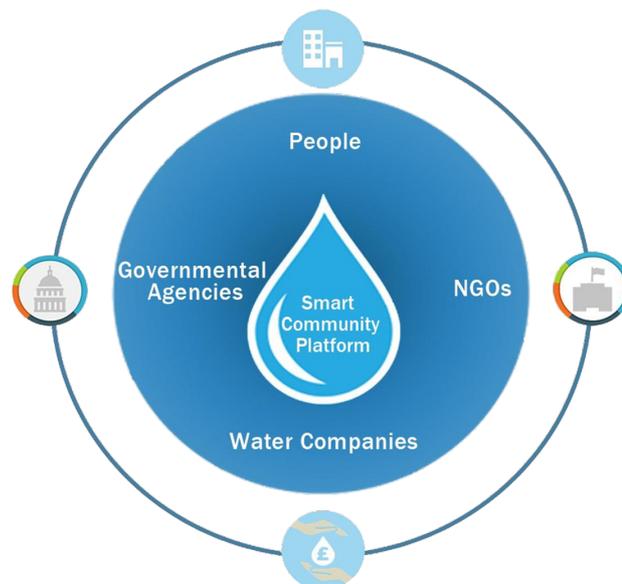

- Area coverage of water utilities (integration with energy, carbon)
- Problems
- Interactive data of water consumption in London
- Comparative analysis of monthly water consumption
- Market price comparison
- Saved amount of water

Platform Rating Dashboard

- The ratings of service suppliers may include: water quality, monthly leakage, coverage, number of clients, complaints, calls, maintenance, and level of trust.
- Ratings of customers can include: timeliness of payments, credit history, water consumption and water saving.

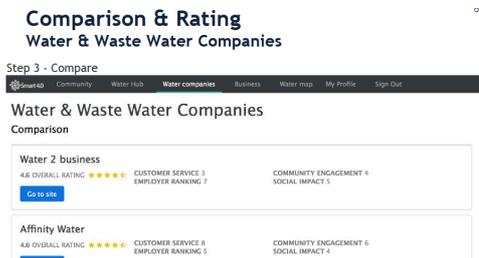

- **The Water Hub** (integration with energy and carbon), an engaging digital water community, an interactive water map and a marketplace platform for innovative solutions and services.
- **Water Credits** a monetary incentive program for customers (domestic and business) based on their water usage performance (smart meters data), community and project involvement. Potential integration with public-private incentives / local tax programmes, energy / carbon credits scheme and local trade exchange built on the custom blockchain platform. With further potential development of **green finance instruments, including water bonds (R&D stage)**.
- **Secured Personalised Accounts** for government, businesses, and customers with customised analytical reports and data on water consumption and relevant statistics.
- **Private blockchain platform** to optimise **recordkeeping, audit and compliance reporting** with a focus on disclosure of environmental impacts (sustainability indices, CSR, ESG, international ratings indices), providing multiple decision makers unified data they need to change market behaviour.

Customers and Companies Ranking: community engagement, customer service, employer ranking, social impact

Features How?

Real-time data analytics

Marketplace

Online customer service + AI (bot messenger)

Information & education

Mobile App

Online payments

Rewards

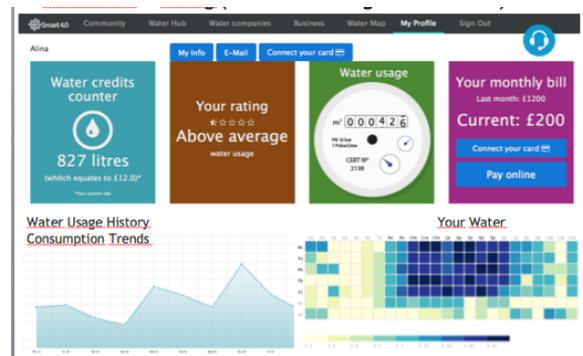

Rating systems of customers and companies

Reports & Analytics

Water Credits & Water wallet

Building Customer Centric Relationships Win-Win Model

The Smart 4.0 is designed to assist in matching suppliers and users more effectively, build long-term relationships and increase benefits for both

USERS	COMPANIES
Login to personal accounts	Public profile to manage reputation and credibility
Quick and easy integration	PR, news and company promo to enhance visibility
Follow companies to receive news and updates	Market feedback compared to peers via ratings
Real-time alerts (leaks, disruptions)	Connecting with sector specialists
Consumption trends	Communication tools, such as video and messaging
Customised savings recommendations	Targeted customer communications
Anonymous household water use comparisons	Data analytics tools
Data analytics tools	Online marketplace (services, devices)
Water Wallet (digital water credits)	Green Bonds (water flooding bonds)*

Education / Gamification

Educate individuals and corporates to address water challenges. Our comparison and service platform will show:

- Leaders in water sectors (utilities, service providers (B2B and B2C))
- Most innovative companies
- Top Individuals and companies who address the water challenges (water consumption/savings, innovation, initiatives etc.)

Value for All Stakeholders

Government Personal online account (City Boroughs):

- Full 'water balance': supply and demand
- Data analytics
- Tariffs analytics
- Easy connect to other water governmental organisations (Consumer Council for Water, Ofwat, The Water UK) and related NGOs

Companies Personal online account:

- Full 'water balance': supply and demand
- Real time data dashboards (London-specific & neighbourhood-specific)
- Data analytics
- Accurate billing information
- Optimised customer service
- Access to innovative startups

Customer Personal online account & App:

- Online control over water usage & bills
- Accurate data of water consumption & bills
- Reducing risk of leakages & problems
- Community involvement
- Easy online customer support
- Incentive tariffs (water credits) & loyalty schemes

UNIQUE BENEFITS		
<p style="text-align: center;">Governmental Organisations</p> <ul style="list-style-type: none"> ▪ Unified and processed information from all data sources: existing smart meters ▪ Customised reports and recommendations ▪ Real-time data ▪ Improved paper efficiency ▪ Increased transparency ▪ Increased data integrity ▪ Increased efficiency 	<p style="text-align: center;">Customers</p> <ul style="list-style-type: none"> ▪ Optimisation of water usage ▪ Automatisations of processes: billing, issues and complaints reporting, monthly service feedback, purchase of additional services 	<p style="text-align: center;">Utility Companies</p> <ul style="list-style-type: none"> ▪ Improved customer service ▪ Cost-optimisation (industrial level – energy consumption to supply water) ▪ Optimised timing ▪ Faster payments processing ▪ Water usage comparison

Blockchain Application for Industry (and Smart 4.0 Project)

We consider Interbit platform by BTL (www.btl.co) for use

I. Switching / Recordkeeping

Application of blockchain can help the water sector companies to manage balancing and settlement more efficiently in comparison to the existing applied methods. All information, including consumption and transactional records can be automatically stored on an immutable ledger.

Blockchain and smart contracts can potentially help the water sector companies and the government bodies to access real-time data regarding market shares, consumption patterns, management of utility bills of end consumers and other possibilities.

II. Reporting Repository / Compliance Reporting / Audit

Blockchain could be used to keep track of the steps required by regulation. Recording actions and their outputs immutably in a blockchain would create an audit trail for regulators to verify compliance.

Such a change could reduce dramatically the time and effort (and therefore cost) that financial institutions spend on regulatory reporting, as well as improving the quality, accuracy and confidence of and in the process.

Organisations could potentially being granted with a privileged digital key to obtain real-time market share intelligence / analytics of the various water providers (stored on a private blockchain) instead of having to survey providers to generate market data. Blockchain provides immutability, immediacy and transparency of information where stakeholders can be part of the real-time process instead of being recipients of post-hoc reports and analytics.

Distributed Ledger Technology (blockchain) provides immutability, immediacy and transparency of information where stakeholders can be part of the real-time process instead of being recipients of post-hoc reports and analytics. As an example, unique design of the developed Interbit (www.btl.com) blockchain platform provides powerful yet lightweight system with core **characteristics**:

- Effortless scalability across multiple networks
- True siloing of data for industry grade privacy
- Flexible redundancy across permissioned nodes
- HSM (Hardware Security Module) compatibility for transaction signing

Possible Use Cases

- * **Ofwat** and **Defra** could potentially be granted with a privileged digital key to obtain real-time market share intelligence / analytics of the various water providers (stored on a private blockchain) instead of having to survey providers to generate market data.
- * **Water retailers** need to report to **Ofwat** under the Wholesale Retail Code. By recording the data onto a blockchain Ofwat can guarantee the data hasn't been tampered with, thus enabling a greater level of transparency across the industry. This will also reduce the cost overheads associated with maintaining security around data records, as well as the overheads from the regulators to audit retailers and ensure they are not modifying data before submission.
- * For **MOSL** the blockchain can be deployed as an additional feature to their developed IT infrastructure that would simplify process of registration, customer switching and settlement between wholesalers and retailers, putting it on a single blockchain (automatic validation and confirmation of information: accounts, billing history etc.) with a different level of access to the information

Existing Applications of Interbit Blockchain Platform that we aim to use in Smart 4.0 (www.smart4.tech)

- Interbank payment networks
- Energy trading
- Public registries
- IoT

1. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Demand has to be created by all parties – mutual interests not vested or silo. Water accounts for 45% of the world GDP, 27% of Carbon emission and 33% of energy production costs. On the local level, a number of factors have to be considered.

To provide analytics and build economic models for energy and water efficiency, it is necessary to evaluate a number of factors:

1. Analyse historic and future water demands data stored and shared on blockchain to create a baseline (energy & water sector) and align it with present availability and development potential of all water resources in the country
2. Determine present availability and development potential of all water resources in the country, including alternative (desalination, water from air extraction).
3. State policy for installation of smart meters and sensors to build quantitative and qualitative data analytics and customised reports stored and shared via authorized access on blockchain (i.e. Interbit platform, www.btl.co)
4. Build interconnected smart energy and other utilities hub (i.e. by Smart 4.0, www.smart4.tech)
5. Create continuous awareness and public engagement (bottom – up approach triggered by top) where top will sustain regulatory control given importance of potable water security.
6. Reinforce public-private partnership and increase attractiveness for both institutional and private investors (both equity and fixed income)
7. Similar to transport, certain types of data has to be open source, instead of being exclusively owned by single market actors. This will create a better understanding between public and private sectors and impact the behavioural change.
8. Gamification and remuneration implemented across different levels (as part of CSR, city, district, NGOs levels) – both water and energy sectors will get an additional interest and reduce of behavioural constraints and rebound effects once the actual involvement will be rewarded via numerous possible schemes (water / energy credits, tax exemption, public leadership for both companies and individuals); intangible incentives - less time lost or better environmental outcomes

9. Use proved blockchain platform (i.e. Interbit platform, www.btl.co) to support existing initiatives and developments to implement IoT (smart technologies) and integrated ICT platforms with other sectors.
10. Consult and develop energy and water policies with international organisations, involved into the climate change risk (systemic risk) discussion (i.e. CDP, Financial Stability Board, NGOs, World Bank) along with the investors and insurers.
11. Develop social inclusion policy where infrastructure, particularly the green one, will be in heart along with the shift of the demand management

Based on the perceived information, metrics and predictions for maximum demand can be developed.

To reduce the losses of water or electricity, the following steps are indicated:

- *Use technology and analytics to detect leakages.*
- *Conscientiously and promptly repair leakages.*
- *Invest in new equipment*
- *Increase effective throughput by reducing commercial losses (smart meters, debt collection,*
- *Application of demand management*
- *Dynamic pricing based on real-time congestion*

5.How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Prioritise the resources (water -> food->energy) – the Nexus pyramid, which accounts to the National security of any state. Assess the impact of risks of infrastructure failure (i.e. drought might cost £1.2bn UK businesses/ day).

Water not only in heart of energy production and carbon emission, but also food production (70% of water accounts to agriculture, 20% for business, 10% for domestic use).

Analyse impact of digital transformation

The Boston Consulting Group: To narrow or close the infrastructure gap, governments can pull three levers:

1. Reduce infrastructure demand (if user needs for these essential public services can be satisfied in other ways, i.e. energy; however not applicable for water and transport much)

1. Build new assets
2. Optimize existing infrastructure assets via operation and maintenance (increase utility, decrease total cost by investing into technology and innovation, increase lifetime value, localise infrastructure assets).

One of the key priorities should be given to green / urban infrastructure projects that would contribute to decarbonisation, contribute to preservation of the natural resources (firstly, water) and increase resilience (micro grid projects similar to Brooklyn and Australian self-sustained villages where community can store and trade electricity internally).

Pareto 80:20 law remains constant across majority of sectors unless it is digital infrastructure where innovation takes place much more frequent in comparison to the traditional industries: 80% has to be invested into operations and maintenance whereas 20% should be new investment

Another approach to the ratio: **maintenance and repair vs construction of new assets can be developed on the asset management framework developed by BCG:**

- *Value perspective*
- *Triple bottom line objectives*
- *Whole life-cycle horizon*
- *Risk recognition*
- *Systemic scope*
- *Integrated activities*
- *Comprehensive measures*
- *Organizational integration*
- *Proactive attitude*

2. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

There is a difference between competition in the market and competition for the market. The traditional approach is based on the linear process: the disciplinary hierarchy and separation of design and construction, which leads to project failures and slow performance improvement. Instead circular process has to be built, a collaborative ecosystem where capital availability and capacity planning. There is an opportunity to improve if nearly 2/3 of construction problems can be eliminated with better communication and information. Along that it is rather important to create education opportunities for cross-sector leaders (i.e. a business-government-education facilities on the base of existing academic institutions and associations) and inclusive coalitions (i.e. transport, water, energy, food).

Cooperation between private and public sectors can be achieved via programme of market liberalisation, including a number of stages:

- Depoliticisation (decrease of bureaucracy);
- Commercialisation of operations (vendors and service providers);
- Creation of effective natural competition;
- Development of regulatory appropriate institutions to the market;
- Increasing transparency via and public involvement and compulsory reporting and ESG
- Integration traditional infrastructure (physical) with digital (ICT)
- Use private investment for public sector projects in supply of infrastructure services
- Accountability Requirements

Focusing on the technology aspect of service improvement, we would like to highlight how IoT and blockchain can address societal problems at the back-end, helping infrastructure services to be more efficient and transparent. These include provenance (producers/ manufacturers, registrars, certifiers, regulators, customers); quality control and tracking system over the system for businesses and customers. Along that energy infrastructure projects can use blockchain for energy and water procurement and sustainability, which should be an underlying goal for any infrastructure projects.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered? *Note: by “funding”, the*

Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

States have to pay attention funding policy changes that will increase productivity, support business growth, create jobs, create a healthier environment, and improve inclusiveness for all citizens. **Due to the fact of** public budgets facing continuous cuts nowadays today creating more uncertainty, additional diversified funding sources are needed.

One of the alternatives is to set up not only specific budgets for sectoral projects or place burden on the operating companies, but to create a range of dedicated maintenance funds, which receive the user taxes and disburses the money to the agencies responsible for operations and maintenance. This will allow creating a circular cycle, instead of one-time large investments. Second option is to create and appraise diversified revenue sources (i.e. road tax, MOT), and provide cross-sector support funding. Implement incentive-proof mechanisms such as indexation, and fiscal easing in combination with private investment stimulus.

Another option is Issuance of green infrastructure and other sovereign bonds to stay aligned with Global Goals for Sustainable Development and to minimise effects of Climate Change risks.

Grants remain a traditional funding instrument for mainly for the road and public transport / transit projects, utilities, and some other capital expenditures.

Project bonds or mini-bonds, issued by local municipality, construction, utility and other infrastructure service companies can increase community involvement and short-term liquidity to contribute to the operations and maintenance aspect.

Funding policy mix should include assessed portfolio above-mentioned instruments, with priority on green infrastructure renovation and “delayed” operation and maintenance projects (water sector, transport), which provide national security and improve international competitiveness of the country.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

There number factors that can result in failure of finance of infrastructure projects, including failure of effective functioning of PPP due to existing policies, unsound investment climate, heavy tax and fiscal burdens. Another reason is the lack of investable projects where projects are not properly planned and designed. To address this problem, a risk-management approach and finance planning have to be in place in order to create right incentives among various stakeholders. Three key risks include: high initial risks illiquidity, the time profile of cash flows (ROI), and liquidity. The efficient distribution of risks and returns along with careful design of economically rational financing structures would increase private investor interest and mitigate failure of investors' involvement. A pipeline of investable projects would help large institutional investors to plan and participate in the upcoming projects accordingly. Additionally, an effective re/utilisation of capital markets resources can also increase infrastructure finance and providing interest among a broader group of investors.

Many Infrastructure projects are often complex and involve a large number of counterparties (i.e. water sector) where a high level of bureaucracy and private interests exist. To address this challenge, a level of competition and necessary legal base should be provided in order t attract no only local but international investors. Privatisation of existing infrastructure assets, pure public procurement, economy and policy transformation in order to attract additional sources of private investment and finance. Focus on green infrastructure, decarbonisation and sustainability projects or upgrade existing ones may attract additional investment; however sound judicial, legal base should provide a framework of accountability, reporting, transparency and cost-benefit analysis of such initiatives. Also focus on development on cross-sectoral infrastructure projects with high share of digitalisation (ICT) with service/customer oriented strategy may attract additional interest and commitment from both local and international finance and investment organisations.

Depending upon the stage of the project, there are a number of alternative sources should be endorsed by policy initiatives:

1. initial stage: mezzanine investors, banks (syndicated loans), development banks, export credit agencies
2. operational phase: bond financing and other FX debt instruments

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? *Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.*

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

In the era fourth industrial revolution connectivity and information accessibility in the form of shared digital information is among fundamental principles that would ensure resilience of cross-merged infrastructure system. McKinsey and Imperial College studies suggested that any new project should include a high level of connectivity and integrity with other data collections points, and should openly available without additional expenditure. To provide immutability, security distributed ledger technology (Interbit platform, www.btl.co) and real time portals that connect all stakeholders in a gamified way (comparison, rating, community and social impact, UNGC principles, accountability rating) may add value and traction (i.e. Water Hub by Smart 4.0 www.smart4.tech).

To prevent external risks and problems, caused by and natural disasters as an increasing climate change, state should must identify and assess those risks and to develop cross-sectoral master plans (open data) available for cross-parties (insurance and reinsurance companies, investment finance institutions, and academic institutions along with others). A different set of measures can be applied:

- structural measures that include construction of protective barriers and maintenance /renovation of existing facilities. Cost-effective or non-structural measures comprise of effective nature use (forests as natural prevention), creation of natural buffer zones and development of resilient design codes for future projects, reconstructions and upgrades (brownfield and greenfield).

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Natural capital is the most fundamental of the core forms of capital (fertile soil, , mixed forests, productive land and water resource, good quality freshwater and clean air). With increased risk of climate change, which became a systemic risk, protection, conservation and enhancement of natural capital should be among core requirements for any infrastructure projects.

Green infrastructure is a smart solution for today's needs and demands to achieving environmental, public health, social, and economic benefits. Sustainable projects can be developed both on brownfield and greenfield projects. Level of scope should be defined at the design and planning stage.

‘Building local, thinking global’ - to achieve these tagline, a structural plan should be designed. Focusing on placemaking where people are in heart of the process development and implementation.

A basic checklist can be incorporated into some infrastructure projects on the city level:

- preservation of open space and green areas;
- development of green areas and recreation zones;
- building mixed-use developments with a strong sense of place (place branding);
- carless streets, conversion into walking and biking streets;
- promotion and state regulation for green building practices (BREEAM, ISO certification, UNGC, CDP, Carbon Credits)

There is no “one fits all” approach, however a starting point for such projects should include not only top-bottom approach only, but promoted across communities and local residents where the prime goal achieving resilience of natural systems and the built environment. Additionally digital infrastructure (ICT) has to play a vital role in the process and, adding practical value and efficiency to existing systems.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent? Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

To increase existing models and techniques, tech innovation can be applied. One of such technologies is distributed ledger technology / blockchain (Interbit, www.btl.co). It does not replace existing audit or financial practices, however it adds a number of advantages. Interbit enables institutions to issue and transfer assets over a network, which uses smart contracts and blockchain technology to automate processes and reduce cost.

Why Mutual ledger means there is no way for the parties to fall out of sync

with each other.

Audit costs are reduced and regulatory reports are automated as the blockchain provides a provable trail of all recorded events in your platform. Blockchain is a digital “assurance” instrument that provides necessary transparency being independent and ‘unhackable’. Interbit is designed from the ground up with a key focus around privacy and scalability, meeting the needs of the most demanding enterprise business use cases. Built on proven technology, Interbit implements unique design patterns to develop a powerful, yet lightweight, DTL platform, which enables:

- Effortless scalability across multiple networks
- True siloing of data for industry grade privacy
- Flexible redundancy across permissioned nodes
- HSM (Hardware Security Module) compatibility for transaction signing

Interbit empowers businesses to accelerate their digital strategy, and find increased efficiency, reduced cost and a high level of automation, by leveraging DLT.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

To effectively provide the water management solutions, firstly it is important to continuously measure and analyse the water demand. Alternatively, it would be useful to measure wastewater, which accounts for higher costs and greater environmental impact. In addition, use of smart technologies such as sensors that would transmit real-time information into country Water Hub (Smart 4.0 www.smart4.tech), (potential integration with energy and carbon), an engaging digital water community, an interactive water map and a marketplace platform for innovative solutions and services. It may also act as a unified platform for billing and transactions for service payments (B2B and B2C level) secured by smart contracts. Water Hub will also provide Secured Personalised Accounts for government, businesses, and customers with customised analytical reports and data on water consumption and relevant statistics.

Secondly, it would potentially useful to introduce compulsory reporting – Water Disclosure where set rules, limits and norms would be outlined (i.e.

CDP, <http://www.cdp.net>) with integrated set norms for Energy and Carbon.

Thirdly, it would be helpful to introduce water credits system (i.e. Smart 4.0, www.smart4.tech) that would be tradable and exchangeable with other. Hence, creating 360 resilience and smart communities. Alternatively to Brooklyn microgrid, water provision along with a

Development of green finance instruments: water mini-bonds, where individuals can invest into local “water project” and innovation of the sector.

Decentralised Water Supply Systems to complement centralised water services. Innovation and interconnectivity: using alternative water sources, water saving devices for corporate and domestic levels, water re-utilisation opportunities.

National promo communications campaign integrated with all measures above, creating 360 strategy and tactics aimed to change behavioural patterns with proactive call to action and facilitation means to provide active response (i.e. combining efforts of numerous actors, Government, NGOs, Enterprises, Start-Ups, R&D sector, Smart 4.0 and local communities).

Collaboration via market liberalisation with the final goal of creating Water Trade Exchange, that would be interconnected with 5 other ones (Chile, Australia, US and others).

Similarly to water supply management, application of decentralised water supply (drainage and sewerage can be applied) in order to localise the processes and downsize the water supply chain cycle where possible.

Additionally, wastewater credits can be introduced (Smart 4.0).

Submission to National Infrastructure Assessment Call for Evidence 2017/18

Context: Transport Q15: “What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?”

Contact: [Name redacted], [email address redacted], [telephone number redacted]

Date: 10 February 2017

Overview

We would like to propose three junctions on the Strategic Road Network for consideration as high value transport investments (see map on following page):

- A14-M11-A428 (Girton Interchange)
- M11-A11 (Junction 9)
- A14-A11 (Junction 36)

We make the case that building additional connections at these junctions would improve regional connectivity and increase resilience of the key strategic freight route between Felixstowe and the Midlands.

The A428 does not connect directly to the M11. This is where the Oxford–Cambridge and London–Stansted–Cambridge corridors should connect. The A428 also does not connect with A1307. If it did, it would provide strong support for a business case to build a Park & Ride site at the Girton Interchange.

The M11, A14 and A11 form a triangle around Cambridge. This has the potential to be a continuously-dualled outer orbital route if connections were added between the A11 and the M11 north, and between the A11 and the A14 west. It would then be possible for traffic to bypass a closure of any one side of the triangle without using local roads.

Road delays owing to road works, collisions and other incidents reduce the productivity of businesses that use the strategic road network, most obviously those involved in moving freight. Diverting this traffic onto local roads causes severe congestion and reduces the productivity of local businesses.

As we shift to considering transport needs in terms of *mobility*, we must recognise that *resilience* and *capacity* are both critical components of an efficient network.

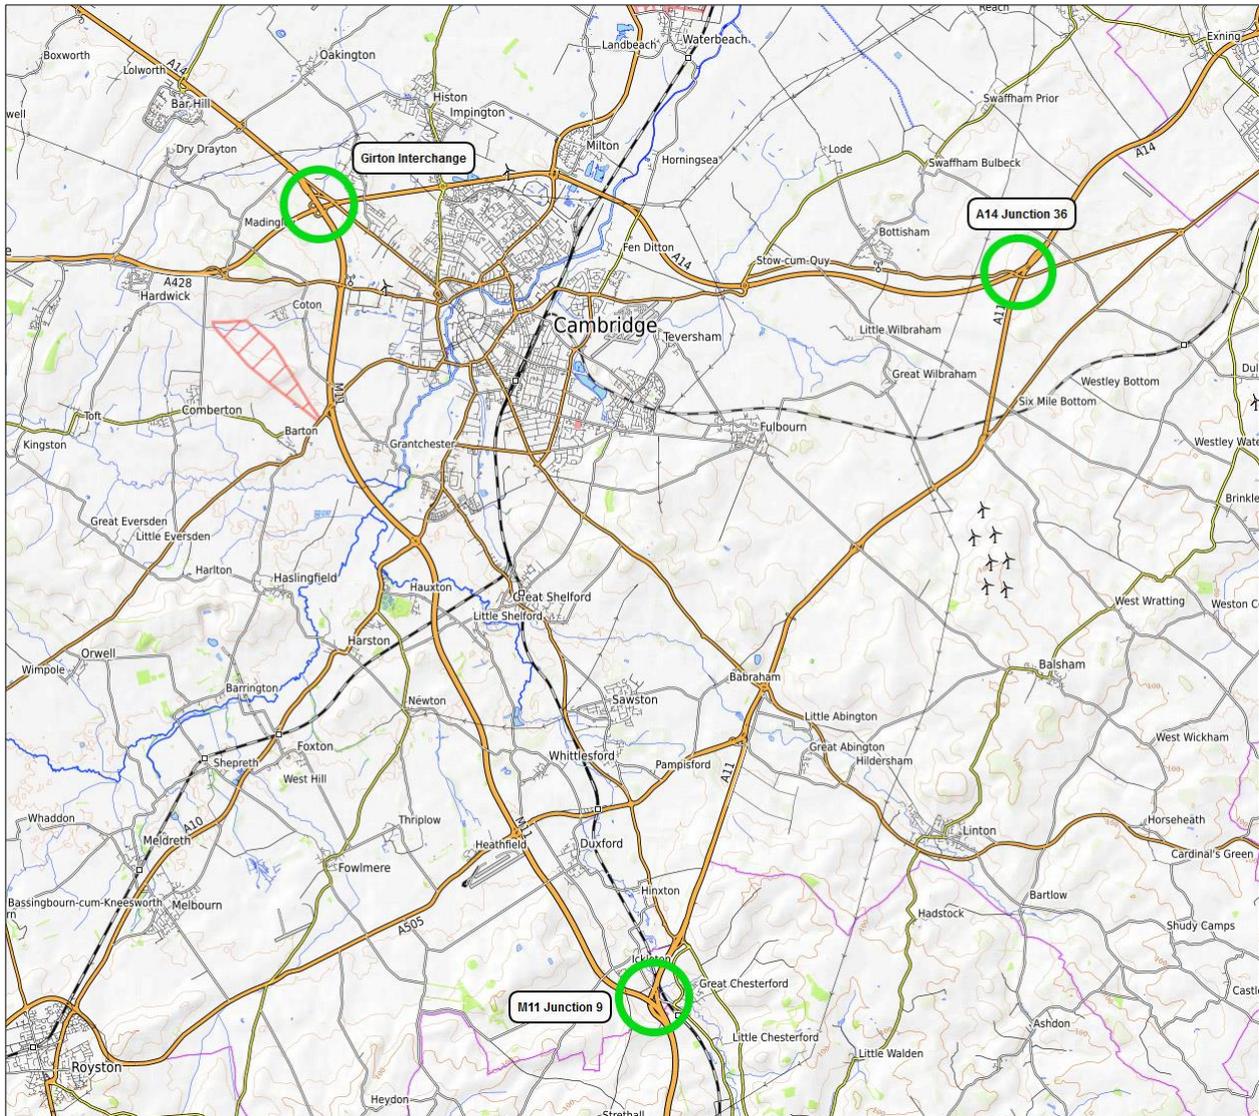

Figure 1: Junctions proposed for investment

Girton Interchange

The Girton Interchange already features in the National Infrastructure Commission's study for the Oxford-Cambridge Expressway. We want to make sure that its potential strategic role, regionally and locally, is fully appreciated.

Even after the [A14 Improvement Scheme](#) is completed, connections at the Girton Interchange will be limited. Traffic moving between the A428 and M11 will still have to use a congested single-carriage local road (A1303). Cambridge city centre is not the only destination: traffic arriving on the A428 from Cambourne, St Neots, Bedford, Milton Keynes, Oxford, etc is also aiming for the Cambridge Biomedical Campus, the science parks south of Cambridge (Genome Campus, Babraham Research Campus, Granta Park, Chesterford Research Park), and Stansted Airport.

In other words the Oxford-Cambridge corridor needs to connect seamlessly with the London-Stansted-Cambridge corridor. This requires the Girton Interchange to be reconfigured as the critical road connector.

But there is a local need for this too: a Park & Ride at this interchange (off the A1307) could intercept traffic from the north and west of Cambridge. At the moment the choice is between driving into the city and parking (possibly for free on a residential street) or detouring 6km (to Milton) to reach the nearest Park & Ride.

A Park & Ride here also has strong potential to be a hub for a rapid transit (e.g. light rail) line connecting the Girton Interchange, Cambridge city centre, Cambridge rail station, the Biomedical Campus, and Trumpington Park & Ride. It is likely that such a line would quickly attract a ridership in excess of 10 million passenger-journeys a year. This is based on some headline figures: each year the city already welcomes 5 million tourists, 5 million arrivals at the railway station (including tourists), and over 1.5 million Park & Ride users. The Biomedical Campus is expected to see 10 million arrivals per year within fifteen years.

Design ideas for the Girton Interchange are appended.

M11 Junction 9

In theory, the A505 provides the missing link between the M11 north and A11, but this is almost entirely single-carriageway (4.3km), already heavily congested, and an important local road. It serves a number of villages (Duxford, Whittlesford, Sawston, and Pampisford) with a combined population in excess of 10,000; employment centres around the A505 and in Sawston are growing; and it is the main access route to Whittlesford Parkway rail station, with an annual footfall of 493,004 passengers (2015/16), and services to London, Stansted and Cambridge.

There is a great need for a high capacity alternative route for A14 traffic when there is an incident or road works. In the two years 2015–16, there were 24 [collision incidents](#) recorded on

the section of the A14 between the M11 and A11. There were also delays owing to road works. If there were an alternative, fast route via the A11 and M11, the impact of such disruption would be greatly reduced, increasing productivity and hence GDP.

The next junction south on the M11 (Junction 8) is 22.5km away at Stansted Airport, so not a practical diversion.

The choice therefore is between bringing the A505 into the Strategic Road Network, dualling it and adding grade-separated junctions; or adding connections at the M11-A11 junction. The latter would create more extra capacity (in effect three lanes in each direction: A505 plus M11–A11) and greater resilience (two routes instead of one). The investment cost would also be lower.

A14 Junction 36

The lack of a connection between the A11 and A14 west does mean that traffic must use local roads, but the main benefit of adding a connection here would be to add resilience to the strategic road network. Closure of the northern part of the M11 (perhaps as part of future road widening) would have a greatly reduced impact if traffic could travel via the A14 and A11.

Design ideas for the Girton Interchange

Extract of paper as published on 30 Jan 2017 at smartertransport.uk/a14-girton-interchange

Since the new design for the Girton Interchange is now fixed, we have updated our proposal to fit around what will be built over the next few years. The two key objectives for us are:

1. Connect the A428 directly to the M11 in both directions, taking traffic off the heavily congested A1303 (Madingley Hill).
2. Provide a new Park & Ride site at the Girton Interchange, serving traffic arriving from the west on the A428 and from the north-west on the A14.

This [rough sketch](#) (which should not be taken to be geographically or technically precise) shows how these objectives could be met with the minimum of land take, and preserving or enhancing cycle/bridleways ([view map interactively](#)):

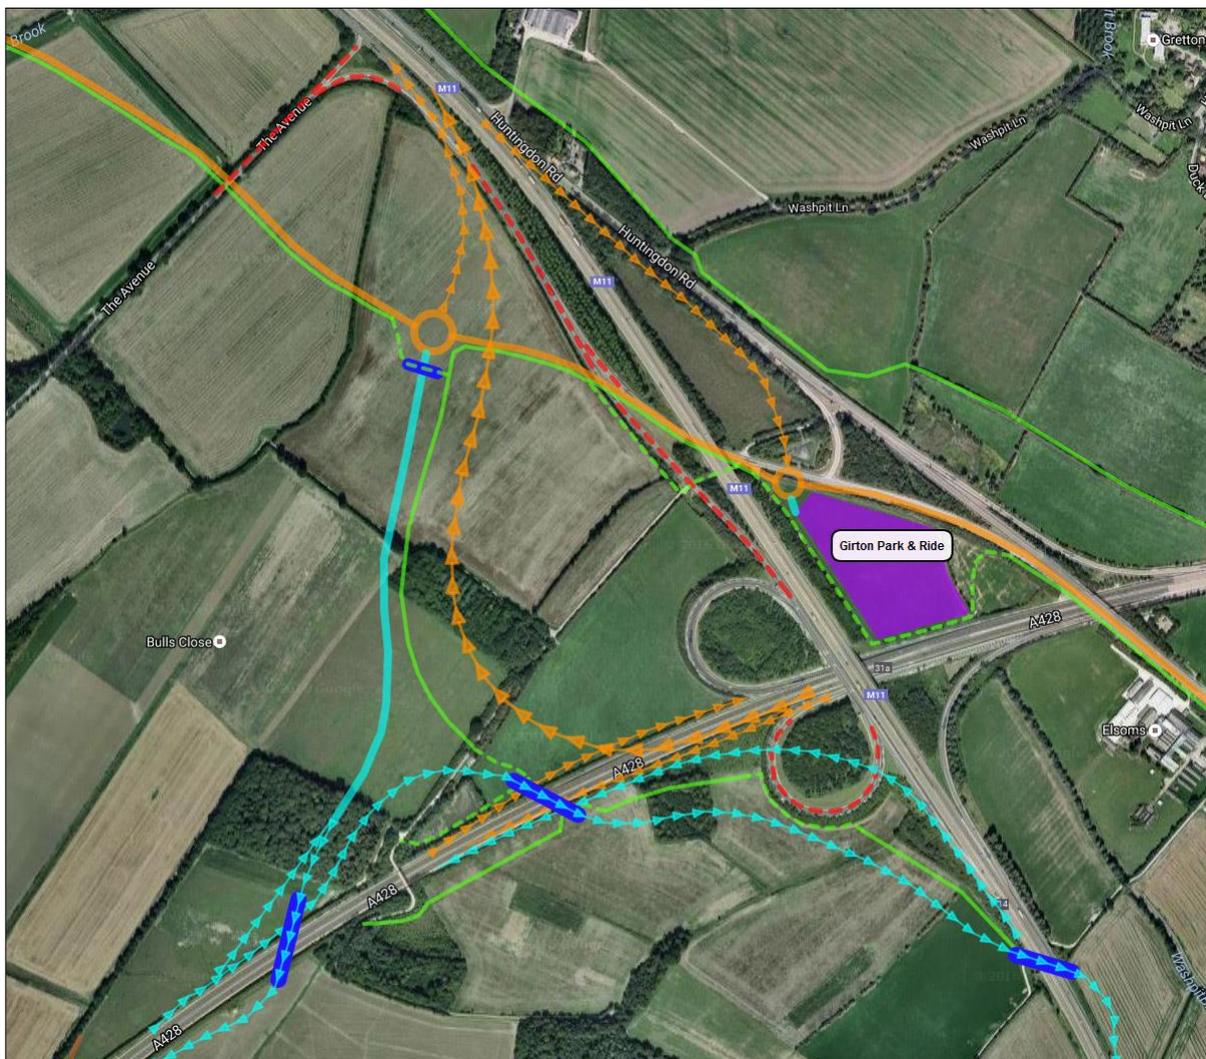

Figure 2: Smarter Cambridge Transport's sketch showing connections that could be added to the remodelled interchange.

Orange indicates roads to be built and red dashes mark roads to be closed as part of the [A14 Improvement Scheme](#), now underway. Cyan indicates additional roads proposed by Smarter Cambridge Transport. Green indicates cycle/bridleways (existing or to be created as part of the A14 Improvement Scheme), with dashed sections being amendments that we're proposing. Dark blue indicates a new bridge. The brown line indicates where a new farm access road and bridge might be needed.

Design notes

1. The roundabouts on the A1307 (Huntingdon Rd) either side of the M11 should employ elements of '[turbo](#)' design to maximise throughput and safety.
2. The eastern roundabout, connecting to the Park & Ride site, should integrate the bus stops so as to minimise bus journey times.
3. The bus station for the Girton P&R should be designed into the roundabout to minimise bus turnaround time.
4. We have shown the cycleway using the existing M11 underpass, officially a bridleway (rather than following the A1307 under the M11, as planned by Highways England).
5. The proposed P&R site is 3 hectares, which compares with 4 hectares for the existing Madingley Rd site. The site should be designed to be multi-level, enabling future expansion as demand grows. A compact, multi-level design minimises the land take and environmental impact (including rainwater run-off), and reduces the distance people must walk from their car to the bus station.

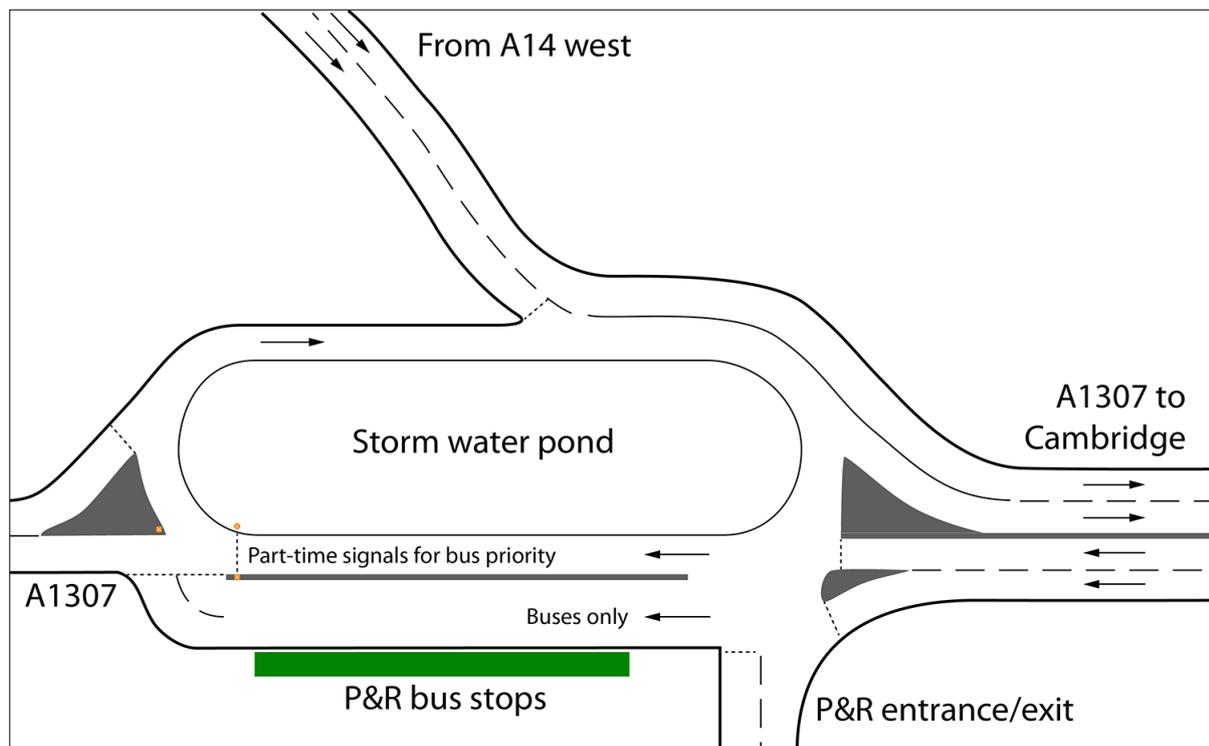

Figure 3: Detail of Girton Park & Ride junction

All-ways junction

There is a strong case for making this an all-ways junction. The lack of a connection between the A14 east and the A1307 (Huntingdon Rd) means that traffic heading for north-west Cambridge must leave the A14 at the Histon interchange and travel along Histon Rd and via the congested Victoria Rd junction, or rat-run via Windsor Rd and Oxford Rd. There are a few ways in which an all-ways junction might be achieved, one of which we have sketched here:

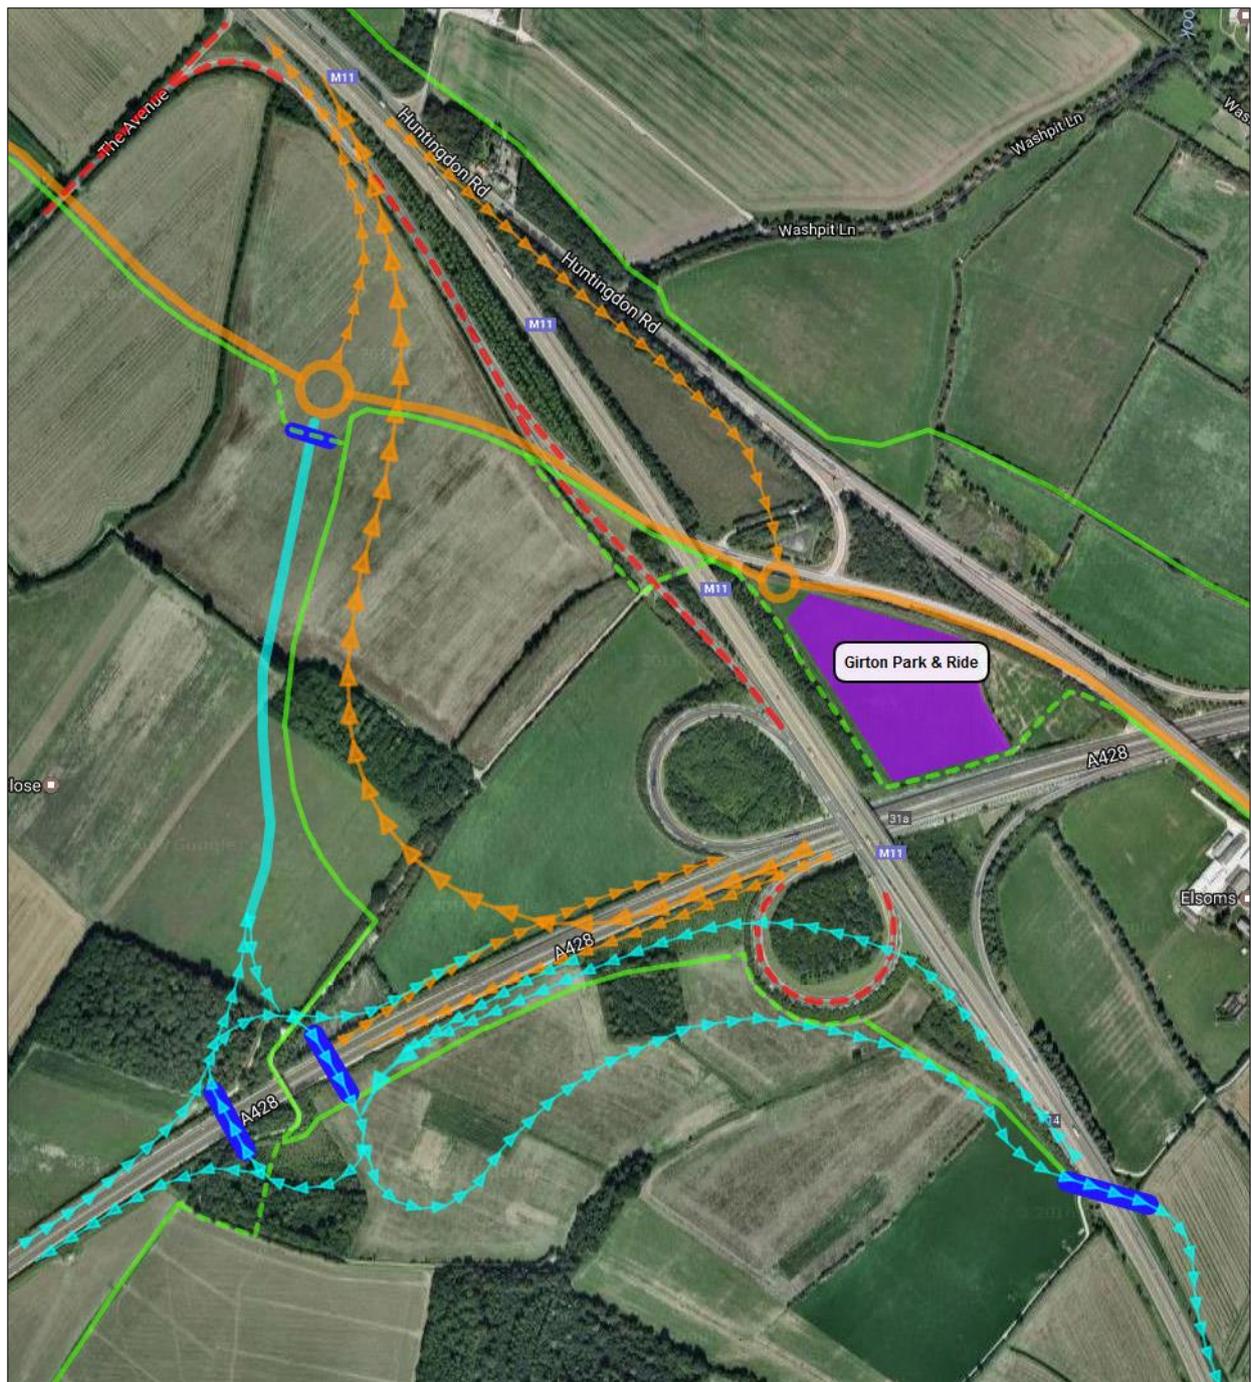

Figure 4: A possible design for an all-ways junction at the Girton Interchange ([view map interactively](#))

A14 Improvement Scheme

Highways England is going ahead with a major [upgrade](#) to the A14 between Cambridge and Huntingdon. It concluded a [public consultation](#) in 2014. The plans have been examined by the [Planning Inspectorate](#) and the Secretary of State gave his consent to the Development Consent Order. Construction is expected to finish in 2020.

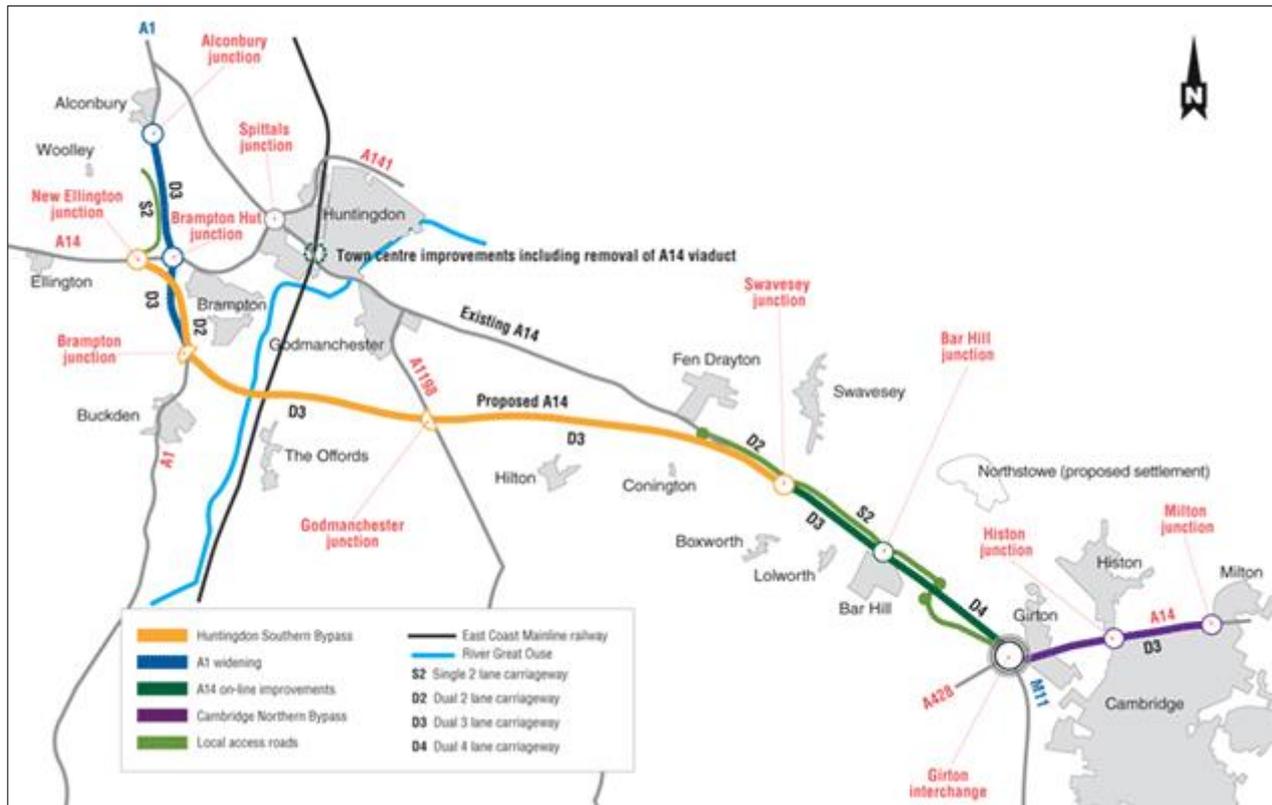

Figure 5: Highways England's proposed A14 Cambridge to Huntingdon Improvement Scheme

The principal improvements Highways England will make to the Girton Interchange are:

1. The tight loop in the A14 westbound is replaced by a gentle curve.
2. A new local access road connects Huntingdon Rd to Fen Drayton (and provides a new access to the crematorium).
3. Access to Huntingdon Road from the A14 west is via a new roundabout on what will become the local access road.

Figure 6: Draft plan of Highways England's remodelling of the Girton Interchange ([download as a PDF](#))

Principal concerns

1. It adds no new connections (in fact it removes a connection from the M11), even though it is acknowledged by the County Council and City Deal Board that a high capacity connection between the A428 and the M11 is essential for the viability of planned developments at [Cambourne West](#), [Bourn Airfield](#) and [St Neots](#); and also for the realisation of the planned [Oxford–Cambridge Expressway](#).
2. Access to the M11 from the A428 will continue to be via the A1303 (Madingley Road), which is already severely congested.
3. Access to the A14 east from Huntingdon Road or from the [North West Cambridge](#) development will be via a 5.5 mile detour to Junction 29 (Bar Hill) and back (as the Oakington Road junction is to be closed) or, as now, via congested city roads (either Histon Road to Junction 32, or Victoria Avenue and Milton Road to Junction 33).
4. The effectiveness of a park-and-ride site at this location will depend on good connections, for cars and buses.

-
5. Whilst addressing the safety concern over the tight loop that currently carries A14 westbound traffic, the safety of the similarly tight loop joining the M11 to the A14 eastbound is not addressed.
 6. Building a massive embankment and flyover to carry the A14 westbound lanes is unnecessarily expensive.
 7. Construction will have a huge environmental impact, including obliterating 2 hectares (5 acres) of woodland.
 8. Elevating the carriageway will amplify traffic noise for residents of Girton, Madingley, Dry Drayton and north-west Cambridge.

National Infrastructure Assessment Call For Evidence 2016-17

Response on behalf of the Solar Trade Association

About us

We are a not-for-profit trade association representing both the solar heat and solar power sectors in the UK. We are funded entirely by our membership, which includes installers, manufacturers, distributors, large-scale developers, investors and law firms.

Answers to Consultation questions

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

Solar is now the lowest cost, lowest carbon energy source which if effectively invested in now, along with the accompanying smart power infrastructure, would allow an accelerated growth through 2030 to 2050.

This would meet the Governments stated objective on energy policy which is:

“To ensure that the country has secure energy supplies that are reliable, affordable and clean”

Solar power combined with a smart energy policy can meet all of those elements. Solar is:

- **Secure:** solar energy uses an unlimited, free source of energy with a lifespan 25-40 years. There is no reliance on overseas feedstocks with volatile pricing from politically unstable regions. In 2014, over 60% of the fuel used to generate electricity in the UK was purchased from overseas. The Committee on Climate Change’s ‘High Renewables’ scenario proposed 40GW of solar and 45GW of wind by 2030, which would meet 55% of UK electricity demand. Investing in UK solar generation would reduce imports, which would greatly reduce the balance of payments deficit while significantly enhancing our security of supply.
- **Reliable:** Variable generation from solar and wind packaged together with battery storage and flexible capacity from CCGT, peaking power and demand-side response converts variable generation into predictable and reliable generation throughout the year, which far better matches consumer and industrial demand.
- **Affordable:** Even allowing for the cost of intermittency, the cost of solar is plummeting. But factor in smart power, in particular the potential to deploy 8GW of battery storage by 2030, and that apparent cost becomes a net financial benefit to the system as presented by the [Aurora Energy Research report](#). This also complements the evidence from the NIC’s £8bn savings by 2030.
- **Clean:** like wind, solar is a free source of clean energy.

2. How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Energy is a key part of economic infrastructure, as identified in this consultation and by Government in the recent Green Paper on *Building our Industrial Strategy* ([HM Government, 2017](#)). Solar can provide sustainable growth in the form of cheap, low-carbon and zero air pollution energy generation, high-quality jobs and export possibilities.

Lower energy costs

Government analysis forecasts large-scale solar photovoltaics (PV) could be the cheapest form of new electricity generation, alongside onshore wind, within the next five years ([BEIS, 2016](#)). By 2030 the cost advantage of solar compared to all other technologies bar onshore wind is forecast to be significant – potentially £45/MWh cheaper than combined-cycle gas. As ageing generation capacity is decommissioned and power demand rises with electric vehicles and the electrification of heat, it is in the interest of consumers we meet this gap with the cheapest generation available. It is important the UK is positioned to deploy solar as these cost reductions are realised, and that there is sufficient strength in the UK solar industry that the value is not entirely captured by overseas installers and investors.

As well as low-cost, low-carbon power, localised ‘behind the meter’ generation (e.g. a PV installation on a factory roof) reduces pressure on the electricity grid, reducing overall demand and the need for costly transmission network reinforcements (which ultimately must be paid for by the consumer). For example, Bentley’s rooftop solar installation provides up to [40% of energy](#) requirements at peak times, while also providing certainty on a proportion of the business’s future energy costs, enhancing competitiveness.

Considered in this light, solar power becomes cheaper still than other energy sources, which require costly grid re-enforcement.

Employment

Solar is the most job-rich energy technology in terms of jobs provided per generation output. At its peak in 2014 the UK solar industry employed 35,000 people. The sector has developed a workforce built on highly valued, transferable skills while providing opportunities across the UK ([Solar Trade Association, 2015](#)), though research has shown that one third of these jobs were lost following changes to the subsidy regime ([PwC and Solar Trade Association, 2016](#)). A strong solar industry will boost employment and help to retain and develop a skilled labour economy ([Centre for Economics and Business Research, 2014](#)).

Exports

Globally, 2016 will see solar attract more investment and employ more people than any other renewable power source ([IRENA, 2016](#)). The IEA expects renewables to absorb two-thirds of all power investment to 2020 ([IEA, 2015](#)), with solar set to attract \$3.7 trillion or a third of *all* power technology investments to 2040 ([BNEF, 2015](#)). The question is how can the UK benefit from this trend?

It is a widely-held misconception that because the majority of solar cells and modules are manufactured in Asia, that there is no value in solar for the UK economy. In fact the UK has developed significant installation expertise across a number of companies. Similarly, the UK investment and legal sectors have both flourished. Over 60% of the capital cost of installing solar remains in the UK as part of the balance of systems, labour and overheads.

The UK benefits from being an early mover, currently the sixth largest solar market globally by capacity deployed ([Bloomberg, 2016](#)). Already our members are investigating the possibility of bidding into tenders for solar power provision in Saudi Arabia, while also looking at investment opportunities in India. But tapping these external markets requires a strong UK solar base, something which current policies do not support.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Incorporating solar power into new-build homes is an easy way to meet many of the Government's stated goals such as reducing carbon emissions and making the electricity network 'smarter'. London and Scotland have both adopted new-build energy efficiency requirements (which can be met in part with rooftop solar panels) above that of the national average, without any impact on the number of new homes under construction.

Similarly, minimum efficiency standards for new commercial buildings would increase the number of rooftop solar installations. Certainty over new building regulations in both the residential and commercial sectors would encourage the uptake of solar in the UK and also preserve and create jobs in the UK solar industry.

With Government targets of building 250,000 homes per year, if even half were appropriate homes with roofs to install solar that would allow nearly 400MW of generating capacity. As storage continues to drop in price, most of these installations will add storage, smart meters and electric vehicle charging points and will be close to self-sufficient with their electrical energy needs.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Solar power offers the greatest scope for demand management when combined with storage systems such as battery storage. At the domestic level, a house-scale battery can hold 15kWh (see [example](#)) of electricity, which represents roughly the daily electricity consumption of an average UK household. Solar panels can charge the battery during the day, which households can then consume in the evening, reducing stress on the grid at what is typically the peak time for demand.

Rebound effects are inherently hard to quantify, but there is no evidence that the installation of rooftop solar leads to increased electricity consumption. At the domestic level, the combination of smart meters and time-of-use tariffs means solar and battery combinations are more likely to time-shift consumption than increase it. Once storage becomes widely and economically available, the incentives will be in place to ensure most new build homes can be self-sufficient on electricity as ‘prosumers’.

On the utility scale, the majority of (non-hydro) storage at this stage is focused on frequency-response rather than demand management. However as storage becomes cheaper we can expect a similar time-shifting of demand as batteries are charged during peak solar output during the day, with electricity consumed later during the demand peak.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

At current wholesale power price levels, it does not make financial sense to construct new utility-scale power generation of [any type](#). Solar cannot access capacity market auctions, the Renewables Obligation scheme has closed and feed-in-tariffs have been cut to near-negligible levels for larger plants (once capping provisions are considered). Barring a total redesign of the electricity market, the logical way to fund utility-scale solar in the short term is to hold a Pot 1 contract for difference (CfD) auction. The government is averse to CfD rounds because of the limitations to the Levy Control Framework budget as well as their manifesto pledge on stopping further subsidies for onshore wind. However, the upshot of this policy is to shut off new large-scale solar power from the market altogether. This therefore needs to be addressed.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system

Localised solar power (whether at the residential or commercial level) generation improves system resilience – consumers are less dependent on single large generation plants for supply, particularly as

batteries are introduced. On-site solar supply also reduces pressure on the grid, freeing up capacity for more distant generation (e.g. offshore wind).

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

There are two aspects to this question: the impact on the wider environment (in terms of air pollution and climate change) and also the local environment. Solar installations can be placed on the rooftops of [industrial sites](#) and [railway bridges](#) with minimal visual impact, while sheep grazing can be maintained in and around utility-scale solar farms. Indeed, one of the conditions of planning for ground-mounted solar sites is dual-purpose usage which ensures that if sheep grazing isn't appropriate, other measures such as enhancing biodiversity are required, contributing to the natural environment.

On the climate change front, the UK is committed to reducing carbon emissions by 80% from 1990 levels by 2050. The Committee on Climate Change says electrifying our heat and transport network is necessary to meet this challenge, with consequent increases expected in electricity demand ([Committee on Climate Change, 2015](#)).

Solar is among the lowest carbon-output forms of electricity generation, with utility-scale solar accounting for around [48g of CO₂ /kWh](#) (based on the CO₂ associated with construction – after construction emissions are essentially zero), compared with [820g of CO₂ /kWh](#) for coal-fired plants and [490 CO₂ /kWh](#) for efficient gas plants. Replacing existing coal and gas-fired infrastructure with solar power is therefore an obvious way to reduce carbon emissions cheaply.

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

There are two strands to our response: solar thermal in domestic, commercial and industrial heating; and electrifying heat.

Electrifying heat

We do not have specific comments on the method by which heating should be electrified, other than to echo our earlier comments that electrification of heat will naturally lead to increased power demand in coming years, and the best way to meet much of this new electricity demand will be a combination of domestic and utility-scale solar power. We support the roll out of both air and ground-source heat pumps and comment that additional flexible generation such as wind and solar is available to meet that demand.

It should also be noted that a Kingspan study stated the technical potential of south-facing commercial rooftops was 2,500km², or the equivalent of 380GW. To date we have only installed solar on 0.1% of that. We anticipate that from around 2018-2020 a subsidy will not be required and the majority of this potential can be installed without a generation tariff. But a strong UK market is needed now to ensure we can achieve that potential.

Solar Thermal

By both European and international standards the UK has a historically low deployment of renewable heat technologies, including solar thermal. In 2015 renewable sources provided only 5.6% of the UK's heat, which puts the UK well behind its own target of 12% renewable heat by 2020 ([DECC, 2016](#)). It is widely understood that a step change is needed in renewable heat deployment across Europe given the dominance of heating in energy use and the consequent implications for energy security (particularly in relation to gas security) and carbon emissions.

The scope for solar thermal to displace fossil heating is significant in both the domestic and non-domestic market. At the household level its potential contribution to energy savings through hot water heating increases as regulations increasingly tighten the thermal performance of buildings. Solar thermal also ensures the widest possible number of homes, including smaller, urban and less-able-to-pay homes, will be able to benefit from the Renewable Heat Incentive, helping improve fairness and inclusivity in public funding. Solar thermal is also unique in not presenting ongoing fuel cost risk, which is particularly important for the future, especially for more vulnerable households.

Technologically solar thermal continues to develop internationally and it offers tremendous potential in industrial process heating, as well as growing complementarity with other heat technologies, both through the development of combi-systems and increasing the overall performance of other renewable heat technologies such as heat pumps. Analysis by [IRENA](#) shows that:

- In developed countries solar thermal technologies could technically provide nearly half of heat demand in the industrial sector. Process heating accounts for two-thirds of total energy consumption in industry and half of this is for medium to low temperature processes, much of which can be met by existing solar thermal technologies.
- IRENA estimates that thermal technologies have the potential to supply 10% of industrial energy demand by 2030.
- However, while the technical potential is extremely high, deployment remains low, with low levels of awareness recognised as a particular problem.
- IRENA recommend that governments work to grow awareness of solar thermal potential in the industrial sector and the STA is keen to work with the NIC and other departments to do this.

Despite all this, rates of solar thermal deployment in the UK have fallen in both the domestic and non-domestic sectors since 2010, as a result of several factors:

- Space heating and solar thermal combined with PV technology are both excluded from the Renewable Heat Incentive (RHI), discouraging deployment.
- There is an absence of regulatory support for including solar thermal on new-build domestic properties.
- The non-domestic RHI has an upper installation size limit of 200kW, which limits economies of scale and discourages those with large roofs from deploying solar thermal technology.

Remedying each of these factors is likely to see a significant increase in the number of solar thermal installations.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

What the 2050 power sector will look like

According to the [IEA](#), solar power costs will fall another 40%-70% on today's numbers by 2040. Wind costs are also projected to fall significantly. With these falling costs, in the future solar power is likely to represent a significant share of total electricity generation, possibly even the majority. The efficiency of solar panels is also likely to increase as developments in inverter and panel technology take hold. Total power generation requirements will be far higher as the majority of heat generation has been electrified and road transport is increasingly the domain of electric vehicles.

This means integrating solar power's variable output into the electricity system. New research shows that the system cost of integrating variable renewables is modest at the levels of penetration needed to meet our 2030 carbon commitments; costs are still lower than those of traditional generation, even accounting for the costs associated with variability ([Aurora Energy Research, 2016](#)). Research by Imperial College for the National Infrastructure Commission shows combining renewables with greater system flexibility can bring [huge net economic gains](#) while also retaining security of supply.

As we move through the first half of the 21st century battery costs will continue to fall, while the proliferation of electric vehicles will also provide additional storage which can potentially be integrated with the grid. The greater the incidence of batteries in the system, the easier it will be to match the supply from solar power to demand.

How could this be achieved?

Much of solar's march to grid dominance will be driven by ever-falling costs, which will happen as a natural function of global markets and technological advances. However there are a number of policies which must be altered to ensure solar has market access, which we have set out earlier in this document.

In addition, the grid needs to be 'smartened'. The National Infrastructure Commission, Ofgem and Government have identified the direction of travel in the UK energy system towards a smarter, more flexible energy system ([National Infrastructure Commission, 2016](#)) ([BEIS and Ofgem, 2016](#)). A smarter system in future will require greater demand and supply flexibility to maintain the system balance, using synergies across a portfolio of different technologies and appliances. It will empower consumers, as well as new market entrants and distributed generation and provide more localised price signals. The technical and financial characteristics of solar have stimulated much of the recent innovation in the power sector so it sits naturally at the heart of this transition. 'Baseload' has already become an outdated term in energy supply ([National Grid, 2015](#)), as solar and other renewables with zero marginal costs dispatch first and are complemented by flexible generation and demand.

Companies offering solutions adjusting demand to meet supply need to be given greater access to markets, and District Network Operators (DNOs) need to be incentivised to procure their services. Currently DNOs are resistant to flexible generation and lack the incentives to improve grid flexibility.

On a general level, the UK cannot wake up in 2049 and decide that solar should be an integral part of the power-generation system. There needs to be a clear policy roadmap over the next thirty years, based on the areas set out in this response.

10th February 2017

Dear Sir / Madam,

Re: Solent LEP Response to the National Infrastructure Assessment Call for Evidence

The Solent LEP is the key interface and lead for economic development in the Solent. It is a partnership organisation between the business community, the Further Education and Higher Education sector, three unitary authorities, eight district councils and one county council, all of whom are actively working together to secure a more prosperous and sustainable future for the Solent area. Meeting our growth aspirations requires the area to attract investment and create jobs that support growth in the business sector and create jobs, while also ensuring that we have the infrastructure through facilitating the growth of innovation and research and development in the Solent area that will support our economic growth.

Call for Evidence
by panel, this
in, the
on an
S. att

A. Executive Summary

The Solent is an interconnected city region with two major economic centres in Portsmouth and Southampton, connected by the M27 corridor. The area as a whole has a complex socio-economic geography that is influenced by its 290 miles of coastline, high levels of urbanisation and population density, and skills and sectoral profiles that are contributing to a significant underperformance in productivity.

The Solent economy is positioned as the "Southern Gateway," shaped by the three ports which are high performing economic assets of national significance (Port of Southampton, Portsmouth Naval Base, and Southampton International Airport). Clearly they are not only hugely important to the Solent area, but they also need to be positioned in terms of the wider contribution they make to the growth and prosperity of the UK economy as a whole. The Southern Gateway performs a vital role in delivering access to global markets supporting the UK industry and specifically the automotive sector, whilst having a key defence cluster of international significance as well as being the home for the Royal Navy. Alongside this, the Solent has three universities which are also major economic assets, providing the region with a world class research, innovation and science base as well as a strengthening skills base.

The economy of the M27 corridor, incorporating the two cities, is growing rapidly, driven by an emerging tech sector, further expansion of marine and maritime sectors, higher levels of consumer spending and population increases. This growth is now stalling and is constrained. There are already clear signs that it is underperforming as evidenced by the growing productivity gap. This sees the Solent lagging behind the south east average GVA by 9% and the UK average by just under half a per cent. This disparity is widening and is typically characterised by a lack of resilience in existing transport infrastructure on both road and rail, longer journey times and excessive congestion, poor air quality, significant unmet housing need, a lack of commercial space to support the expanding tech sector, breaches in flood defence, and challenges in energy supply.

Yet the intense growth of the area, in population terms, and of the two cities, its research, innovation and science base and its international gateways has not been matched by the provision of the modern infrastructure required to accommodate and fuel this growth, and this is holding back the economic potential of the Solent and its contribution to the wider UK economy.

On this basis it is vitally important that the National Infrastructure Assessment prioritises the following:

- **Support for the key Solent gateways** that underpin UK trading on both an import and export basis. This is vitally important as the UK establishes a new trading relationship with the world and it is critical that new infrastructure investment is targeted at road and rail in the Solent to upgrade and improve logistics connectivity and freight capacity to support our successful exporting sectors such as automotive.

- **Improving connectivity across the Solent and from the Solent to London** will lead to a greater pool of skills and talent being available, greater connections between businesses and supply chains and higher productivity in the area. Improving connections between our two cities and from the cities to London will drive growth, by improving economic proximity. Lowering travel times by rail to 30 minutes between Portsmouth and Southampton, and improving links between the Isle of Wight and the

mainland will lift productivity in the Solent by 10%. Significant gains can also be achieved by improving local transport links and reducing congestion.

- **Addressing unmet housing demand in the Solent** as the growing population and an acute shortage of housing impacts on affordability and consequently the recruitment of talent to support a shift to a more productive, high growth economy. There are increasing pressures on existing infrastructure (energy, wastewater, transport), which, when coupled with a legacy of underinvestment, challenges the viability of many developments and this has resulted in an infrastructure deficit.
- **Affordable Energy and clean growth including** energy security to support growth, and optimising the renewable energy potential of the Solent including the offshore wind manufacturing base on the Isle of Wight.
- **Ensuring that the Solent's digital infrastructure is prepared for the challenges of tomorrow** is pivotal to productivity. The Solent is home to an expanding tech sector which has grown by 33% in the past five years, outpacing the UK average of 29%. Southampton had digital turnover growth of 180% between 2010 and 2014, faster than any other UK city. The University of Southampton plays a key role in this with the Web Science Institute, and there is also a strong marine intelligence systems presence in Portsmouth. However significant investment in digital infrastructure to secure total superfast broadband coverage and 4G and, in the future, 5G networks, is necessary if we are to retain this capability.
- **Support for our key cities of Portsmouth and Southampton**, which require over £140 million investment in Flood defence to safeguard existing development as well as unlock new employment and residential land.

This consultation response has been shaped by engagement with the private and public sectors and is underpinned by a detailed published evidence base as set out in the following documents:

- [Solent Strategic Economic Plan](#)
- [Solent Productivity and Growth Strategy Update 2017](#)
- [Solent Strategic Transport Investment Plan](#)
- [Transforming Solent: Marine and Maritime Supplement](#)

In addition, the LEP is currently developing an Island Infrastructure Investment Plan, which will set out the key infrastructure priorities to support the specific economic challenges of the Isle of Wight - themselves influenced by its island geography. This is expected to be published in the summer of 2018 and will be forwarded to the DfID to support their work

...applied to the economy... economic... this... and incl... key... profit... the... Part... connected...

The Port of Southampton is strategically positioned in relation to the UK automotive industry based in the Midlands Engine and Northern Powerhouse, and is just 20 nautical miles from the key Shanghai to Rotterdam shipping superhighway. It is the UK's prime export port, and is strategically placed to support the changing flows of international trade. It alone handles exports worth more than £40 billion, with 90% of exports going to destinations outside of the EU. The Port of Portsmouth (including the Commercial Port and Naval Base) provide the anchor points for our globally leading marine and maritime sector, contributing 20.5% of our GVA, 5% of our private sector jobs and 7% of all manufacturing in the area. The Naval Base will see the first of two new QE Class Aircraft Carriers this year, which will be the largest and most complex warships in the history of the Navy. These are significant strategic national assets, and will require reliable and upgraded infrastructure, and notably transport and energy). Their arrival will result in associated peaks and troughs in infrastructure demand

Gateways of the area.

Whilst this complex economic geography gives the area its unique character, it also provides both opportunities and challenges with regard to local economic growth. Overlaid on this complex economic geography are the three major economic assets; the International

the current and forecast demands of a highly urbanized and growing economy. left the Solent in a position where the historic supply of infrastructure is unable to cater for cities but also the emergence of an increasingly polycentric settlement structure, which has 8,000 people each year. The long term growth trajectory has seen the not only growth of our residents, a total increase of 20%, or 0.6% annually, which is equivalent to adding around the population across all 12 local authority areas of the Solent has grown by 264,000 connectivity, transport, flood defences and provision of utilities. Between 1981 and 2014 islands and two peninsulas, present unique infrastructure challenges around digital London. This, coupled with 290 miles of coastline, habits of international significance three and the mainland part of the Solent is the most urbanised area in southern England outside The Solent has two large, growing, densely populated cities (Portsmouth and Southampton),

The Solent economy has a population of over 1.3 million, 50,000 businesses, local GVA of £27 billion. It has a range of assets that are globally renowned, a strong SME and skills base, and a thriving research community through its universities and research institutions. The coastal location and marine business base provide us with immense strengths on which we can build, taking advantage of global growth in maritime trade, the rapid expansion of the cruise sector and automotive exports, rising demand for leisure marine and specialist vessels, expansion in marine renewables and in technology-led industries.

B. Solent LEP Economic Profile

- Improved rail journey time to London from Portsmouth.
- Improved highway and rail access to / from the Port of Southampton;
- Improved Highway access to support major housing developments adjacent to the M27 Corridor and also on the M275 to improve access to the centre of the City of Portsmouth
- Flood defence to safeguard residential and business properties and unlock development opportunities in Portsmouth and Southampton;
- Future-proofing digital connectivity; and
- Providing energy security to support growth, and optimising the renewable energy potential of the Solent.

and draw on a pool of skilled labour that will be nationwide - requiring strong connectivity to the Solent.

Southampton International Airport plays an important complementary role in the south east's aviation offer, and has significant capacity for growth, which would free up capacity at other airports in the south east. In 2017, the airport is expected to surpass 2 million passengers, and plans for Southampton becoming an aerotropolis. Southampton Airport's Masterplan highlights plans to increase capacity at the airport on a phased basis to meet increasing passenger demand initially up to 3 million passengers per annum, and ultimately up to 6 million passengers. All three international gateways play an important role in the national infrastructure provision and, therefore, are national infrastructure assets.

As a result, the Solent is widely regarded as the Southern Gateway economy, with strengths across a range of industries in the private sector. As a consequence of these economic assets, the three Solent "ports" and their respective cities contain important clustered sectors and concentrations of economic activity and smart specialisation, most notably in the marine and maritime sector, and also in defence, logistics, and advanced manufacturing (including advanced materials and photonics), aerospace, digital (creative and cyber security) and tourism. These are some of the principal industries which benefit from the unique and beneficial economic environment in the Solent.

Despite our existing strengths and opportunities, the Solent economy is yet to reach its potential and productivity remains a major challenge. Measured by GVA, the area is lagging behind the south east average by 9% and the UK average by just under half a percent. Strong polycentric population growth combined with clustered economic development means that infrastructure will play a critical function in:

- providing satisfactory links between homes and jobs and key economic centres; and
- maintaining the critical artery for the automotive industry in the Midlands and the North and the Port of Southampton in the South.

A growing population and an acute shortage of housing, which impacts on affordability and consequently the recruitment of talent to support a shift to a more productive, high growth economy, mean that there are increasing pressures on existing infrastructure, which, when coupled with a legacy of underinvestment result in an infrastructure deficit. Ease or difficulty of commuting, and thus quality of the transport and digital network, is frequently highlighted as a key factor in our economic competitiveness whilst also being important to the locational decisions of high skilled and highly mobile labour in the Solent.

In an era of global competition, economic assets are only ever relative and require continued investment in order to maintain their international attractiveness. Efficient and effective infrastructure is an essential component in the success and survival of economic clusters and the Solent must continue to act to strengthen its comparative advantages across its key sectors to realise economic value.

As a result, the Solent's infrastructure (defined by government as transport, energy, water, waste, digital services and digital) are areas that are of significant importance to the Solent economy.

The Solent's infrastructure challenges to connect / changes, which are in part, influenced by the growth of the area, population growth and the presence of major economic hubs within the Solent, which contribute to the growth of the Solent.

rail connectivity is slow (45 - 60 minutes for a 20 mile journey) and infrequent, as is rail connectivity to Southampton airport from the east, when compared to other dual city areas such as Nottingham - Derby and Newcastle - Sunderland (both 15 miles apart with rail journey times of circa 20 minutes). This results in the parallel M27 being the default option, resulting in chronic peak period congestion. Rail access between Portsmouth and London is also unacceptably slow (between 96 minutes and 129 minutes). This erodes the geographic proximity of Portsmouth to Southampton Airport and on a wider basis to London, which is becoming even more pronounced as rail access to London from other towns and cities is enhanced.

Our response has been drafted within the context of the Building Our Industrial Strategy Green Paper and its focus on the role of infrastructure in unlocking place-based growth through increases in productivity and competitiveness, and within the changing landscape of international trade as a consequence of the decision of the UK to leave the European Union.

It is clear that the provision and performance of economic infrastructure in the Solent area does impose challenges to business growth and productivity and that future investment in economic infrastructure provides significant opportunities to support sustainable economic growth; improve competitiveness; and improve quality of life. It will therefore be important that the outputs from the NIA support the Solent to:

- Build on our strengths and extend excellence into the future;
- Close the gap in productive between the Solent and the wider south east and the UK; and
- Ensures that the Solent plays its full role in making the UK one of the most competitive places in the world to start or grow a business.

Our response considers the following thematic areas:

- Cross-Cutting Issues
- Transport
- Digital Communications
- Energy
- Flood Risk Management

We provide links to evidence documents, as requested, which support our position.

C. Cross-Cutting Issues

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

The highest value public infrastructure investments that would support long term sustainable growth in the Solent and contribute to broader growth in the UK are:

- Improved rail connectivity within and to/from the Solent, focussed on:
 - Delivery of an integrated high frequency Solent Metro service transforming journey time between Portsmouth and Southampton (including Southampton Airport) and better connecting our polycentric settlement structure and improved rail journey time to London from Portsmouth.
- Improved highway and rail access to / from the Port of Southampton; Improved Highway access to support major housing developments adjacent to the M27 Corridor and also on the M275 to improve access to the centre of the City of Portsmouth

- Flood defence to safeguard residential and business properties and unlock development opportunities in Portsmouth and Southampton;
- Future-proofing digital connectivity; and
- Providing energy security to support growth, and optimising the renewable energy potential of the Solent.

Solent Metro

Solent LEP very strongly contend that government should increase investment in the commuter rail network and other public transport in the Solent to ensure the economic development of our cities and urban centres is not constrained by overcrowding and congestion. Currently road congestion in our area severely delays commuting and other economic activity, and the city of Southampton is currently in breach of air pollution limits. This is exacerbated by an under-provision of public transport in our area and as a result the Solent area now needs to take the bold decision to focus on the development of an integrated and expanded public transport network - Solent Metro.

A Solent Metro network spanning the Solent would support the delivery of new housing and employment development opportunities along the M27 Corridor and in our two cities. Solent Metro will transform the Solent economy through: improving labour mobility; broadening the labour pool available to employers; supporting growth at our nationally important international gateways; improving productivity and competitiveness; improving agglomeration and economic interaction between Portsmouth and Southampton; improving connectivity of the Solent with London, the wider UK and international markets to enable the Solent to maximise its proximity advantage; and improving the attractiveness of the area to new investment, including foreign direct investment.

This is in line with the Solent Strategic Transport Investment Plan (STIP) published in 2016.

The STIP focuses on the more economically transformative and longer term investments necessary to support and unlock the Solent's growth potential over the next 30 to 40 years and ensure that the Solent's economic assets continue to play a key role in the wider UK supply chain. Over this timescale an additional 300,000 to 400,000 residents could make the Solent an area of 2 million people – equivalent to dual cities such as Nottingham/Derby and Newcastle/Sunderland. In order to accommodate this growth and to strengthen the role of our economic assets such as the Port of Southampton, there will be a requirement to address the transport deficit and invest in a modern metro-style transport network, to relive pressure on our highway network.

The STIP concludes that in the long term the Solent LEP's business-led transport strategy should aim to “increase economic proximity” through the following elements:

- Increase dual city (Portsmouth to Southampton) linkages around public transport and business critical movements to integrate labour and consumer markets.
- Support clustering and agglomeration around key local strengths and competitive advantages that other areas do not replicate (e.g. port functions).
- Develop a corridor of development nodes based around an improved public transport offering between the cities and across the urban network to 2040
- Optimise and integrate the transport network (ticketing, information and operation) using demand load that can be spread to improve resilience and especially in more constrained cities with pinch points.

The M3/A34/M40 spine is a critical artery in the UK supply chain, providing access to the UKs growing automotive industry to global markets. Investment is planned at the M3 Junction 9 / A34 interchange, which is key bottleneck along this route - but the scheme is not expected to commence until the end of the decade. Whilst funding was identified for the project in 2015, the pace of progress, is frustratingly slow, and is failing to build on the back of over £150m private sector investment to enable the UK to accommodate the world's

of Southampton. reflects the scale and pace of growth in these sectors and the market preference for the Port set out that within the period to 2035 it will need to expand to accommodate growth. This Master Plan forecasts for 2020 for Cruise Passengers and for 2030 for automobiles and has a context of increasing mode share for rail. The Port has already surpassed its 2009 Port forecast growth is such that additional highway and rail capacity will be required, even within going to non-EU destinations. Whilst 40% of freight traffic is transported by rail, the scale of passengers per annum and is the UKs second busiest container port, with 90% of exports the UK automotive supply chain. It is also the UKs premier cruise port, handling 1.77m Southampton in the UKs international automotive hub and therefore performs a key role in automotive supply chain. Handling 1m vehicles per annum (the vast majority for export), Southampton. The Port of Southampton plays an increasingly important role in the UK Our response to question 2, below, sets out the national strategic importance of the Port

and construction of new infrastructure. efficient maintenance and upgrade of existing infrastructure and the cost-effective design the effects of climate change and the increasing demands on the network, through the major focuses will be on rail transport, to meet challenges such as improving resilience to Southampton, which is presently building the National Infrastructure Laboratory. One of the In relation to this, there is an opportunity for the NIC to draw on the work of the University of

primary road and rail networks. The NIA should identify priority routes for capacity improvement on the strategic road,

Improved Highway and Rail Access to the Port of Southampton

Feasibility work on the initial phase of Solent Metro is being taken forward by the LEP and is focused on a route connecting Southampton Central Railway Station with Eastleigh Town Centre, via Town Quay, development sites along the River Itchen, and Southampton Airport. This will help optimise private sector investment in the area and will support the delivery of new housing and employment developments such as Itchen Riverside, Southampton Waterfront, Southampton Airport Economic Gateway, the former Ford site (now Mountpark), and respond to increasing congestion and air quality issues in the Southampton / Eastleigh area. This will provide a catalyst for the delivery of the future phases of the wider Solent Metro network.

- Secure improved strategic connections to London, the south east (airport passenger market), the UK (especially for port freight) and internationally for airport leisure and business market and "European" inward investment
- A greater focus on Transport Orientated Developments (TODs). Increase residential densities around new and underutilised transport nodes to accommodate additional housing development while protecting natural assets and addressing affordability with the same land take.

largest cargo and cruise ships through the DP World operation, which has a capacity for 35,500 containers.

Conversion from DC to AC of the freight route between Southampton and Basingstoke, as part of the route to the Midlands was planned as part of the Network Rail Control Period (CP) 5 Enhancements Programme, but will now be considered within CP6 (2019-24). This would have enabled faster and more efficient rolling stock to operate the route. Opportunities for decking container trains should be considered, to make best use of finite rail pathways.

Whilst investment in the Strategic Road Network (SRN) is critical to support access to the Port of Southampton, it is the final leg of the highway journey that can take a disproportionate amount of total journey time. This is the case in Southampton; congestion on the M27 and M271, as well as the A33 Redbridge Road / Millbrook Road (which is a local road) form the local access to the Port of Southampton, but are also used by commuters, businesses and visitors, which add significant delays to journey time and contribute to significant air quality issues experienced on the western approach to Southampton. Consideration of highway access to international gateways should reflect the whole route, not just the SRN.

Flood defence

There is an ongoing need to analyse flood risk at the scale of catchment and coastal cells such as the Solent. Resources should be allocated so as to minimise the economic risk of flooding and there is a very strong case to invest in flood defence in the Solent as it is clearly cost beneficial to do so.

Two schemes are of particular significance in the Solent: along the western bank of the River Itchen in Southampton, adjacent to the city centre, and at Southsea in Portsmouth. The former reduces flood risk to 1,157 properties and 679 businesses, whilst the later reduces flood risk to £649m of assets, 8,013 existing homes, and 1,035 businesses. In addition, the Itchen scheme enables over 2,000 new homes, and the Southsea scheme enables 1,000 new homes.

Energy

Ensuring secure, affordable and low carbon energy supplies requires a range of actions to manage energy demand and provide new energy generation capacity. Uncertainty over energy policy has dis-incentivised investment. In the Solent area, population increases, the growth of the economy, and increasing demand from the defence sector provide upward pressure on energy demand. As part of the NIA, there should be a commitment to set out alternative strategies for energy security post 2030 and this should include the use of technologies such as carbon capture and storage, electricity storage and low carbon generation.

In relation to the Solent, powerful ships such as the new QE Class Aircraft Carriers that will be base-ported in Portsmouth need strong power supplies and work is underway to create a new high voltage substation at Portsmouth Naval Base to support the energy requirements of the ships whilst in port. Each ship will host an independent distribution network capable of managing up to 200MW of power for 100 family homes. It is unknown if this upgrade will be sufficient to support the power demands when both Aircraft Carriers will be in Port at the

The Port of Southampton is a major private sector contributor to the Solent economy, and plays a critical role in UK trade - which is expected to become more pronounced following the decision of the UK to leave the EU, with Southampton in close proximity to the major shipping lanes linking Europe to the rest of the world, and in particular the key Shanghai to Rotterdam route. The Solent benefits from the natural advantage of a double high tide and sheltered berthing and is a sought after location for shipping.

The Port of Southampton is a major private sector contributor to the Solent economy, and plays a critical role in UK trade - which is expected to become more pronounced following the decision of the UK to leave the EU, with Southampton in close proximity to the major shipping lanes linking Europe to the rest of the world, and in particular the key Shanghai to Rotterdam route. The Solent benefits from the natural advantage of a double high tide and sheltered berthing and is a sought after location for shipping.

It is clear that the nature of the UK's trading relationship with Europe and the wider world will change. However, this is within a context of changing trade patterns brought about by globalisation.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

There is an opportunity to provide the private sector with incentives to roll-out ultra-fast broadband and the NIA should fully explore the digital communication requirement of new and emerging infrastructure systems and ensure that enabling digital technologies are put in place at the same time.

There is a need for significantly enhanced digital connectivity (both fibre and 4G/5G) to ensure that all areas of economy can access opportunities for growth. Yet, like many areas, and in particular rural areas, we have so called internet "hot spots" and areas where the market size make delivery unviable. This disadvantages some businesses and holds back growth. Furthermore, digital connectivity along key rail routes - including to London - is unacceptably poor, with large sections offering no connectivity. This reduces productivity.

Technological innovation provides an opportunity to use new and existing infrastructure capability more productively and efficiently and the Solent area would strongly support an infrastructure policy which combines and increase in capacity with optimisation of existing infrastructure through technological innovation. Some of the greatest opportunities for innovation are in people's homes and work places and ultra-fast digital connectivity would reduce and/or remove the need to travel as well as encourage smarter use of energy and storage as well as utilise sensor technology to deliver significant cost-savings in new construction and the ongoing management and maintenance of infrastructure.

Digital Connectivity and Technological Innovation

The Solent has immense potential with regards to marine renewables, and in particular tidal stream technology. The UK currently has a competitive advantage in the development of this emerging technology, as significant research and development capacity has taken place. However, the increased costs of developing such new technology result in more mature renewables being more cost effective, and there is a danger that the expertise the UK has in relation to marine renewables could be lost to international competitors. As such, there is a need to nurture this competitive advantage to scale-up and realise its potential.

outside of the EU. The Port performs a critical role within the UK supply chain, handling 900,000 vehicles in 2015, including around 520,000 for export, making Southampton the leading UK Port for car exports.

The significant role of the Port of Southampton in relation UK trade is clear and the combination of geographic location and the markets the Port is engaged in it is strategically positioned to perform an increasingly important role for the UK economy within a new international trade landscape.

The container trade is a key facilitator of UK exports and the Container Terminal in Southampton has been a leader in the UK in terms of productivity and customer service, which in turn has led to significant volume growth over the recent years. Substantial investment in the rail infrastructure has allowed close to 40% of containers to be transported to and from the port by rail, however the remaining 60% still depends on transport by road and is suffering from a road infrastructure which is heavily used and often congested.

ABP has invested significantly in Port infrastructure and this has both underpinned its rapid growth as well as the growth experienced by its customers. Investment has enabled the Port (and the UK) to accommodate the largest container vessels and cruise liners in the world, within the context of increasing length and tonnage of vessels operating in both markets. More generally, the Port plans to invest a further £200m of private sector investment over the next five years, including £50m in vehicle handling facilities to support the continued growth of UK automotive exports through Southampton.

Outline planned growth forecasts for the port show that further growth is forecast across all markets, further placing demand on the SRN, Local Highway, and rail infrastructure. The Port is of the view that significant port expansion will be required, opposite the existing port estate, in this timeframe, which may well require upgrades to the existing highways and rail network to optimise this potential.

The National Policy Statement for Ports states that Government policy is to encourage sustainable port development to cater for long-term forecast growth in volumes of imports and exports by sea with a competitive and efficient port industry capable of meeting the needs of importers and exporters cost effectively and in a timely manner. It is also noted that there is a compelling need for substantial additional port capacity over the next 20 to 30 years. Within this context it will be imperative that transport infrastructure continues to be invested in to support the important role of the Ports of Portsmouth and Southampton.

Portsmouth International Port is the second largest cross channel ferry port providing a gateway for over 2 million passengers and up to 1 million cars and freight vehicles to France, Spain and the Channel Islands. In addition Portsmouth Naval Base is a strategic national asset, and is at the heart of the sub-regional defence cluster providing, directly and indirectly, 20,000 jobs across the sub-region and contributing over £1.6bn GVA of output. The Naval Base is the base port for half the Royal Navy surface fleet and there is a strong maritime services function offering: integrated ship support; complex software engineering and advanced manufacturing solutions; equipment management; training; and estates and logistics service. It encompasses: the Naval Base; associated Naval establishments; the defence industrial base and other dependent firms.

The first of two new Queen Elizabeth Class Aircraft Carriers will arrive in Portsmouth in 2017. The carriers have a 50 year life span and at 260m long, 30m wide, 56,000 tonnes and 100,000 sq m of deck area are the largest surface warships in the Royal Navy. With

crews of 733 each, 500 support staff and others, the ships will require around 2,000 personnel providing links into the local economy and wider supply chains. There are good multiplier effects with every £1 million spent by the base triggering £0.75 million of additional spend locally, and every 100 jobs support up to 66 jobs elsewhere.

Southampton International Airport serves up to 49 short-haul UK and European destinations for business and leisure travellers (e.g. Glasgow, Manchester, Amsterdam, Jersey and Mallorca). About 1.4 million people live within 30 minutes of the airport and 3.5 million within an hour. The airport has one of the closest rail stations to a terminal in the UK and is adjacent to the M27, yet a number of transport constraints affect the economic performance of this asset:

- The airport runway length is shorter than many other regional airports limiting the range of aircraft that the airport can handle.
- Despite quick and direct rail connections to Southampton Central (7 min) and Winchester (10 min), there is no direct rail connection between the airport and Portsmouth (the journey time is 55-67 minutes for a journey of 20 miles) and eastwards along the South Coast.
- Locally the road network around the airport and surrounding development sites (including a major development opportunity at the former Ford manufacturing site) is comparatively constrained with a number of narrow and/or old bridges.

Despite this the airport is set to surpass 2m annual passengers in 2017. With plans for a high-tech development cluster centred on the airport, excellent transport connections (just 63 minutes to London Waterloo) and good links to local Universities, there is potential for Southampton becoming a future aerropolis - a combination of airport, city, shipping and business hub.

The airport was built for 1.5m annual passengers, and currently handles 1.77m (30% of which are business travellers) and aspires to grow to 3m annual passengers through increasing connections through Southampton for onward destinations.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The availability and affordability of housing poses a major challenge to the Solent area. Demand for housing is projected to grow and the planned increase in housing supply is unsurprisingly increasing demand across all sectors in the Solent including transport, energy, digital, flood defence and energy. Much of the Solent's infrastructure such as sewage systems, rail networks, highway links water based connections and housing stock have been serving the area much longer than originally designed for. Many of these assets need replacement or investment to extend their lives and given current fiscal constraints a strategic asset management approach is required to provide clear prioritisation and better performance. On this basis the Solent would encourage the development of an infrastructure pipeline to support economic assets of national significance. This should be managed by the Infrastructure Projects Authority and should provide the private sector and investors in general with a forward view of upcoming infrastructure programmes and projects. A long term programme approach to infrastructure development is needed to address stop start investor concerns and it will be particularly important to the Solent given that our international gateways including the Port of Southampton and Southampton Airport are developing new Master Plans for the next 50 years. Part of the approach to national

infrastructure investment should be inclusion of a whole life assessment to infrastructure investment.

It is recognised that there is a national imperative to build new homes. This imperative is particularly pronounced in the Solent with an assessed housing need for the Solent, published in June 2016, identifying a need to deliver 121,500 homes over the period 2011-2036. Given the limited geographic scale of the Solent, the existing densely populated geography, the large amount of MoD land, areas of flood risk, and our coastal location, this is a considerable challenge, yet critical to ensure the pipeline of employment to fuel economic growth and attract the talent to this area.

Infrastructure is often required to unlock and/or mitigate the impact of new housing development. This can significantly increase costs and reduce viability, or make projects uncommercial. However, the Solent does suffer an acute housing shortage, and the new funds announced as part of the Autumn Statement 2016 to accelerate housing delivery are welcomed and new opportunities to accelerate house building through up-front infrastructure funding are encouraged.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Solent LEP has identified that the nature and scale of demand will be driven by long term changes in population, economic growth, technological change and the environment. In the Solent area demand will be influenced by population growth as already acknowledged, forecast increased in economic activity in our key centres and economic assets, and technology and digital communication.

The Solent is becoming increasingly polycentric and therefore there is already a demand to improve the proximity of our two cities as well as the urban centres along the M27 corridor and linkages from the Island to the mainland.

A key priority for the area is smart motorways, which offers potential to better manage current and forecast demand on our motorway network. Highways England have committed to delivery Smart Motorways along the M27, and parts of the M3 this will contribute to mitigating existing levels of chronic congestion.

There is also potential for demand management in the energy sector to ensure that best use is being made of a finite supply and that people and businesses are incentivised to draw energy in a way that does not compromise supply.

Technology advances have the potential to dramatically improve connections from isolated communities to urbanised areas and markets. This is particularly relevant for the Isle of Wight, where it is recognised that digital communication could play an important role in shaping work habits and supporting high quality connection through fixed and mobile digital networks.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Capital investment in new infrastructure as well as revenue for the maintenance of existing infrastructure is equally important. Capital investments in new infrastructure can only deliver value if they are supported by the maintenance of existing infrastructure.

There can be a need for forward funding, to accelerate or unlock private sector investment, where cash-flow may be a blockage. This can be particularly relevant in relation to new employment and housing developments, which may require new or upgraded transport infrastructure. Locally, in the Solent, flood defence infrastructure can also be an essential

8. Are there circumstances where projects that can be funded will not be financed?

In addition, in funding policy terms currently it is recognised that a mix of private and public investment pays for infrastructure programmes and projects. Regulated sectors enjoy a high level of private investment as they benefit from a high level of certainty. As previously advised, providing a forward view of upcoming infrastructure programmes and projects across all sectors would improve investor confidence, particularly for locally based infrastructure investment. This would complement the current approach to programme planning that we see in certain areas of government such as DfT / Highways England through the Roads Investment Strategy.

Please see response to question 6, above.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Opportunities for collaboration should also be encouraged, in particular where this will deliver efficiencies and better value for money. An example would be the way in which rail and strategic road infrastructure are delivered in the UK, as highlighted above. In many instances, investment in one will influence demand on the other - yet the investment plans of Network Rail and Highways England are created separately and on differing timescales. Within the Solent context, rail and SRN infrastructure between Portsmouth and Southampton run, broadly, parallel. The supply of one influences the demand for the other, and locally the inadequacy of rail infrastructure and services is a contributory factor to chronic peak congestion on the M27. There is a broader need for the integration of investment and planning in rail and SRN infrastructure, which is something the LEP would encourage Highways England and Network Rail to pursue.

Competition should be encouraged to support innovation and value for money. Regulation should be light touch to encourage private sector investment and new entrants, but ensure fairness and customer responsiveness.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

The adoption of advanced materials and intelligent infrastructure provides an opportunity for reduced through-life costs, which will enable maintenance to be more targeted, and informed by real-time information.

We would encourage a fresh approach to capital investment in new infrastructure and maintenance that considers infrastructure in the round. For example, investment in rail that encourages mode shift from the car / HGV can reduce highways maintenance costs, which could be offset against the rail capital investment. However, presently, strategic rail and strategic road investment plans are developed in isolation and on differing timescales, and are not able to factor in reduced costs on other infrastructure within their value for money assessments.

up-front capital requirement to unlock a site for development in advance of a cash-flow being realised. In addition, many brownfield sites can require decontamination and up front funding to de-risk such sites can ensure that sites become more commercially attractive for new development.

Locally, the Solent has a range of MoD sites which no longer form part of strategic defence requirements, and are expected to become available for commercial development. Typically, such sites can require significant investment to de-risk them to make them commercially viable. As public estates, there is a key role for public funding to unlock these opportunities to regenerate areas.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Infrastructure in the Solent lacks resilience. This is most acutely felt in relation to highways infrastructure. The M27 suffers chronic peak hour congestion, but there have also been a number of instances when whole sections of the M27 have been closed recently, which, given the geography of the Solent, has brought the area to a standstill and impacted on Port Access.. This lack of resilience has the potential to present significant problems for the automotive sector, as the lead time for vehicle manufacture to export is just one week.

The current approach to infrastructure investment does not always recognise the interdependence between different types of infrastructure and it is widely felt that there should be a stronger commitment to integrated infrastructure investment planning across modes of transport, such as road and rail. In the Solent, poor rail connectivity between Portsmouth and Southampton has resulted in severe congestion on the M27 and investments on both networks are considered independently. The establishment of a single funding pot to improve connectivity across city-regions would undoubtedly improve the overall infrastructure system in the Solent, reduce the over-reliance on one mode of transport (i.e. the Motorway), and improve overall resilience.

We would also suggest that the NIC should consider the opportunities for using new technology to improve information and network management, giving users the information they need, when they need it.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

As noted above, the pace of infrastructure delivery both by the private and public sectors can be frustrated by the planning process. This can result in delays to benefits being realised, and a failure to optimise and build on investment. Feedback from business, in particular, is that the current spatial planning framework can work against market demand, and so stifle growth opportunities.

In relation to the growth of strategic national assets we would encourage the introduction of a long-term approach to infrastructure provision for such assets and the NIA should identify priority routes for capacity improvements on the strategic road, primary road and rail networks. At a national level, the government should increase investment in the commuter network, as well as public transport, to ensure that the economic development of our key growth areas and cities is not constrained by overcrowding and congestion. Alongside this,

substantive funding for transport and housing should be devolved to local areas to allow them to invest in the growth of their economies.

The Local Growth Deal has been an important and welcome introduction in this regard. We would also strongly support closer working and the development of new delivery models between key agencies such as Network Rail, Highways England and the HCA, working with Local Authorities to deliver new housing on sites around stations or adjacent to the SRN. This would facilitate the development of housing in areas supported by appropriate economic infrastructure. This is particularly important in the Solent, where we have seen extensive residential development along the M27 corridor encounter delays due to the need to introduce significant new junction improvements to ensure that infrastructure is in place to support housing growth.

On the assumption that economic assets such as ports and airports are considered nationally important infrastructure, we would recommend that the planning systems provides greater certainty and more responsive consideration of planning applications, recognising that the growth of such assets needs to be supported by the delivery of up-front enabling infrastructure to accommodate forecast growth and that arrangements for the financing of this investment will need to be put in place. This means that the lead in time for delivery of infrastructure ahead of forecast growth can be considerable, and that delays or indecision, does create a hiatus and planning blight. This can result in uncertainty in both UK markets and on a broader basis, global markets.

Greater autonomy for local areas in terms of funding and decision-making for smaller scale (or local infrastructure) projects is encouraged, to support planning decision-making and land allocations on a basis that reflects the economic geography of areas. The LEP also supports, consideration of sub-national architecture to enable local economic areas come together to plan for infrastructure that is of mutual benefits - for example the role out of 5G, or the planning or key sub-national transport infrastructure.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

A balanced approach should be taken to protection and enhancement of the natural environment. Economic growth should be allowed to come forward in a way that is not overly stifled or slowed by environmental considerations.

In the Solent, through the Solent Growth Deal, we have supported a green infrastructure project, which has enabled the purchase and upgrade of green assets to enable and mitigate the impact of new housing. Collectively the five projects have enabled Natural England to agree to these as mitigation for 10,000 new houses.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

We agree that infrastructure analysis techniques should be credible, tractable and transparent. Whilst value for money is important, it is clear that the government is seeking to rebalance the economy spatially, but it is not clear how this is captured in cost-benefit analysis. This needs to be more transparent and apply to all areas of the country that underperform relative to more successful areas. We have described, above, how the Solent, despite being part of the south east economy, does underperform in productivity terms.

Current cost benefit analysis techniques are focussed on evidencing unmet demand and do not seem to be able to return favourable assessments for projects that seek to transform or generate demand. Within the Solent, our two cities do not interact economically as other dual city regions, despite being just 20 miles apart, and as a consequence city to city movements are limited. This is, in part, a function of the infrastructure deficit that exists in the Solent - particularly in relation to rail. The delivery of Solent Metro - a high quality, high frequency, reliable public transport - would transform agglomeration and deepen labour markets and enable our two cities to collectively contribute more to UK growth.

Any cost benefit analysis should focus on value for money, but this is not always the case. For example DfT WebTAG prioritises transport benefits, but, in our view, should capture and account for the wider economic growth benefits that the transport project will unlock. Equally, cost benefit assessment of flood defence projects focusses on safeguarding properties, but should also factor in the benefits of flood defence projects in unlocking new development opportunities. We have also seen that the provision of superfast broadband can also provide the catalyst for tech-led development. Presently, it is the view of the LEP that current methods of cost benefit appraisal are too narrow, and that approaches should be broadened to prioritise the impact of an infrastructure project on productivity and competitiveness.

D. Transport

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Autonomy, artificial intelligence (AI) and robotics, along with increased use of the internet will change travel patterns over the next 30 years. Autonomous vehicles are already being trialled, and can be expected to be omnipresent over this timescale, for both personal and freight journeys. This in turn should result in optimum use of networks and increase system resilience.

Increase penetration of the internet and technologies can also be expected to influence the demand for travel, with increased use of artificial intelligence to undertake roles currently performed by humans. In addition, the internet of things, for example, within intelligent infrastructure will reduce the need for surveys and site visits.

In planning infrastructure for the future, it is clear that technological change is enabling, and will continue to enable new ways of working, which will impact on demand for infrastructure. People will increasingly be able to live and work in the same place, thus negating the need for travel, and resulting in the unlocking of capacity and reduced journey times - but this should not be an excuse for not upgrading infrastructure in the short to medium term.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

We have identified the role that a Solent Metro service and Smart Motorways can play within the Solent and the economic benefits that this can bring in our responses to questions 1 and 4 respectively. Both interventions will free up highway capacity for the increasing volumes of port traffic that are forecast.

It will be important that the UK stays at the forefront of digital connectivity and only attract inward investment, but to enable the talent and assets that reside in the UK is already leading on the development of 5G technology, and within Southampton's world leading Optoelectronics Research Centre, a Photonics Highway Programme is developing the next generation of optical fibres that will be 100 times faster and 1000 times more advanced than the fibres that are currently in use.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Whilst it is recognised that laying fibre is a costly process, and, as a consequence, there are some locations where it is not commercial, as noted above, digital connectivity is essential for connecting people and businesses and enabling all parts of the UK to be actively engaged in the 4th Industrial Revolution and its pace of technological change. As such, there is a role for government to ensure blanket roll out of fibre.

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

E. Digital

A shift away from personally owned modes of transportation and towards mobility solutions that are consumed as a service could be supported through the delivery of high quality, affordable, high frequency public transport infrastructure and services. This may negate any requirements for road-user charging as it would be expected to free-up highway capacity.

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

In addition, within our answer to question 1 we set out the need for digital connectivity to better connect people and businesses and to allow flows of knowledge.

We have identified the role that a Solent Metro service and Smart Motorways can play within the Solent and the economic benefits that this can bring in our responses to questions 1 and 4 respectively. Both interventions will free up highway capacity for the increasing volumes of port traffic that are forecast.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

The increased use of e-commerce is resulting in increased customer expectations on deliveries. This is resulting in a number of smaller van deliveries, with limited coordination across urban areas and associated diesel emissions. Break-bulk distribution centres on the periphery of urban areas supported by electric-powered vans could provide greater coordination across distributors, with resulting benefits in terms of reduced vehicle miles and improved air quality.

F. Energy

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

No response.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

The UK has significant potential for renewables. Locally, in the Solent, there are opportunities for tidal stream power as an important (and predictable) part of the UK's future energy mix. Whilst the government has nominated a strike price of £300/MWh for tidal stream energy, which reflects the true current cost of energy, in order to ensure that the short to medium term consumer prices are kept to a minimum they have also announced that they would not ring-fence (minima) any of the £290m budget for tidal stream energy in the Contract for Difference (CfD) auction (Round 2) in April 2017.

The price for energy at the auction will therefore reduce to the market value of the mature renewable industries (around £70-100/MWh for offshore wind). This is an unexpected change of policy from the initial elevated prices offered to develop wind and solar energy, which successfully reduced the cost of energy. The consequence is that the UK may not be able to commercialise their geographic (15% global/50% Europe capacity) and technical advantages and shovel ready projects until other countries have deployed sufficient capacity elsewhere, to bring down the cost of tidal stream energy. This may delay the introduction of continuous, totally predictable tidal stream energy in the UK and effectively reduce the UK to a customer only status surrendering our global lead in this technology.

A regime that enables new technologies to come forward and compete commercially to move the UK towards a zero carbon power sector.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The electrification of transport (vehicles and rail) as well as other modes of transport such as ships is placing a strain on the energy distribution network. Significant upgrades are required to support the arrival of the new QE Class Aircraft Carriers. It is unknown if this upgrade will be sufficient to provide for the rare occasions when both Aircraft Carriers will be in Port at the same time.

Increasing electricity requirements from transport should be considered alongside increased energy demands that will result from the internet of things, which combined will place significant strains on energy distribution networks in the UK, and therefore have the potential to frustrate the uptake of, participation in and creation of new technologies.

The increased use of e-commerce is resulting in increased customer expectations for deliveries. This is resulting in a proliferation of smaller van deliveries, with limited coordination across urban areas and associated emissions. Break-bulk distribution centres on the periphery of urban areas supported by electric-powered vans could provide greater coordination and efficiency, resulting in benefits in terms of reduced vehicle miles and emissions.

G. Flood Risk Management

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

Investment in flood defence should prioritise those areas that pose the greatest economic risk and that have the greatest opportunity to generate GVA. The Environment Agency's approach is focussed on safeguarding existing properties. Whilst we agree that this is critical, the opportunities for flood defence to unlock economic growth should also unlock flood defence funding.

With 290 miles of coastline and a highly urbanised geography, the role of flood defence in safeguarding existing properties and unlocking new development potential is significant in the Solent. Two schemes are of particular significance: along the western bank of the River Itchen in Southampton, adjacent to the city centre, and at Southsea in Portsmouth. The former reduces flood risk to 1,157 properties and 679 businesses, whilst the later reduces flood risk to £649m of assets, 8,013 existing homes, and 1,035 businesses. In addition, the Itchen scheme enables over 2,000 new homes, and the Southsea scheme enables 1,000 new homes.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

No response.

I hope that this response is helpful as the NIC finalises its Vision and Priorities document for publication in summer 2017. Should you have any questions in relation to this response, please contact [redacted]

PARTNERSHIP**

Meeting: Business Roundtable on the National Infrastructure Assessment Call for Evidence

Date: 24th January 2017

Time: 0830 - 1030

Venue: Spitfire Meeting Room, Southampton Airport

Attendees: Dave Lees (Solent LEP / Southampton Airport) Chair
Gary Jeffries (Solent LEP / Hughes Ellard)
Brian Johnson (Solent LEP / BAE Systems)
Stuart Baker (Solent LEP)
Robin Dickens (Lambert Smith Hampton)
Richard Peckham (Airbus Defence)
Jan Edrich (Eastleigh College)
Alex Howison (Scottish and Southern Electricity Networks)
Kevin George (Red Funnel)
Elwyn Dop (Wightlink)
Peter Goodship (Portsmouth Naval Base Property Trust)
Stewart Dunn (Hampshire Chamber of Commerce)
Veronika Krcalova (South West Trains)
Clare Little (Land Securities)
Sue Simmonite (Associated British Ports)
Commodore Jeremy Rigby (Portsmouth Naval Base)
Don Spalinger (University of Southampton)
Sean Sweeney (Land Securities)
Adrian Went (Griffon Hoverwork)
Jonathan Williams (Williams Shipping)

NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE

RESPONSE FROM SOMERSET COUNTY COUNCIL

Cross-Cutting Issues

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

High value investment programmes supporting growth in Somerset (and in some cases the wider South West Peninsula) include:

- **Hinkley Point C development.** EDF Energy's planned development of two new nuclear reactors at Hinkley Point in Somerset will meet 7% of the UK's energy needs and directly create 5,600 jobs at peak construction. Longer term the renaissance of the nuclear sector in the UK through the proposed programme of new build provides an opportunity to re-establish the sector as an important part of the UK economy as recognised in the consultation draft of the Government's industrial strategy. Hinkley Point C (and other nuclear investment in the South West, estimated at a value of £50 million over the next 20 years in a 2015 study commissioned by Heart of the South West and West of England LEPs), provides an opportunity to establish Somerset and the South West as a leader in this sector in the UK. Sustained investment is required to ensure that the right infrastructure is in place to enable connectivity, facilitate skills development and support research, development and innovation to enable business growth, investment and the development of supply chains
- **Tidal Power generation in the Bristol Channel.** A range of options have been promoted by different organisations to meet future energy use through the tidal power generation in the Bristol Channel and Severn Estuary. These include barrage options and the development of tidal lagoons and are estimated as being capable of generating up to 5% of UK future energy needs, with significant regional economic impact through their construction. Government has previously considered aspects of this through the Severn Tidal Power Feasibility Study –see link for further information. http://webarchive.nationalarchives.gov.uk/20121217150421/http://decc.gov.uk/en/content/cms/meeting_energy/wave_tidal/severn_tidal_power/severn_tidal_power.aspx. Detailed assessment of the environmental, economic and community impacts of any proposed developments would be necessary.
- **A303/A358/A30 corridor improvement programme.** An economic assessment (<http://www.somerset.gov.uk/policies-and-plans/schemes-and-initiatives/a30-a303-a358-improvement-project/>) demonstrates that an end-to-end improvement of the A303/A358 to dual carriageway and smaller scale improvements on the A30 to Exeter would deliver 21,000 jobs and £41.6bn GVA increase through improved productivity of existing businesses; £21.2bn of taxation, welfare savings, disposable income and tourism benefits; and £1.9bn transport benefits. It is essential that Government allocates sufficient funds in the next road investment strategy to honour a commitment

(<https://www.gov.uk/government/publications/a303-a358-and-a30-corridor-feasibility-study-technical-report>) to complete the end-to-end improvements despite recent cost increases. The full economic potential of the corridor improvements will only be realised if the whole corridor is improved.

- **The South West Peninsula 20 year rail strategy.** This proposes a long-term programme of investment in rail links between London and the South West which would unlock a host of benefits, generating an additional £7.2bn of GVA and £1.8bn of transport benefits. The strategy also suggests productivity benefits from simple improvements such as high quality/uninterrupted wifi connectivity enabling productive use of the travel time. Both improvement programmes also tackle an inherent lack of resilience in the south west transport networks which are increasingly vulnerable to extreme weather events. Further background available at <https://peninsularailtaskforce.co.uk/closing-the-gap-the-south-west-peninsula-strategic-rail-blueprint/>
- **Digital - The Connecting Devon and Somerset Programme** has made good progress in driving the delivery of digital connectivity and Next Generation Access broadband infrastructure will require high levels of investment which are secured by very long term returns of around 20 years. CDS' recent experience suggested a good appetite in the market for investment in NGA networks with significant private investment being made. However further commitment to gap funding is needed in areas which are not commercially viable.
- **Flood and Water Management** – Following the severe flooding in 2013/14 a multi-partner Flood Action Plan was produced in Somerset and this includes significant infrastructure works which increases resilience against flooding but also supports longer term economic growth and development. The largest proposal is a tidal barrier for the River Parrett, which will make use of funding from a range of sources including Section 106 and Community infrastructure Levy funding. There is also a flood alleviation scheme in the Upper Tone area above Taunton, providing protection to the county town. A post-flood economic study undertaken has demonstrated that up to £147.5m worth of damage was created by the flood event, strengthening the need to make investment decisions to improve resilience and infrastructure against future floods. The Flood Action Plan has also resulted in the creation of the Somerset Rivers Authority (SRA), a body whose role is to provide an enhanced level of flood protection in the county. The SRA is the vehicle to administer funding for a range of flood-related works, including the funding of major infrastructure works.
- **Somerset University** – Somerset is the only shire county in England without a dedicated University and, while growing amounts of NVQ level 4 and above provision is delivered through our Further Education Colleges under franchised arrangements with external Universities, the absence of a Higher Education institution in the county is a barrier to economic growth. The extent of Higher Education “coldspots” in the county is reflected in HEFCE’s published evidence base, with significant parts of the county experiencing

deprivation of access to Higher Education. This results in the relatively low levels of NVQ 4 and above qualifications in the workforce and the low levels of innovation and research and development engagement with Universities by Somerset businesses. The absence of a University also has implications for the ageing demographic balance of Somerset's working age and overall populations. Given these factors the ambition to establish a University of Somerset forms a key ambition in Somerset County Council's County Plan Vision for Somerset (2016).

- **Infrastructure for raising economic productivity.** Productivity in Somerset (measured on a GVA per capita basis) is circa 80% of the national average and this performance gap has remained consistent over a long period of time. This gap is a reflection of a number of factors including Somerset's geography (the county's dispersed economic geography limits the agglomeration effects which promote critical mass, competition and higher value business activity) and our economic structure (which includes a high representation of lower value business sectors including agriculture, tourism and care). A key economic priority for Somerset County Council, the Heart of the South West LEP and our partners is to address and improve this productivity performance. As part of our approach to this we aim to facilitate innovation and growth in our key opportunity business sectors of aerospace and advanced engineering, nuclear and low carbon energy and agri-food. Infrastructure investment priorities include the development of the Somerset energy innovation centre in Bridgwater (to act as hub for a nuclear cluster centred in Somerset) an iAero centre in Yeovil (to promote innovation linked to high value design, with a particular focus on rotorblade technology) and an agri-food centre.

In addition the main growth hubs in Somerset also require infrastructure investment to accommodate planned growth and development, given a significant funding gap between what development can afford (viability challenges) and the infrastructure needed to ensure transport networks continue to function effectively in the future. Infrastructure improvements are needed on the M5 corridor particularly at junctions 22, 23 and 25 in Somerset which are the gateways to planned growth areas, and on the local highway, bus, walking and cycling networks in our main towns.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

No response provided.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Whilst the need to provide appropriate infrastructure to facilitate other development, and the need to provide better places to live and work, is obvious, care should be taken when it comes providing infrastructure that could help to alleviate flood risk.

Sustainable urban drainage systems should be seen as both a way to mitigate flood risk and of enhancing developments, thus providing critical infrastructure but also as a means of natural enhancement. It goes without saying that housing estate layouts should where possible incorporate green spaces; however, using these spaces for drainage/flood mitigation should also be an important part of their design and use.

The planning process should also be wary about using the introduction of new infrastructure as a way of freeing up land for development without proper and sound flood risk assessment.

Developments should also ensure waste management is incorporated within them and this should be done in innovative and attractive ways wherever possible.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

There is considerable potential for demand management on the highway network. With one or two exceptions outside London there is currently unrestrained access to the network resulting in significant congestion at peak time.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The use of cost-benefit analysis and ensuring there is a strong business case in place are critical when making investment decisions and local expertise should be used to assess whether it is more efficient use of funding to repair and maintain infrastructure or to replace it with modern infrastructure. Regular repair and maintenance will avoid capital outlay for replacement structures and local government should ensure risk management authorities have sufficient funds to conduct their responsibilities effectively and to ensure flood risk is well managed.

Sufficient resource should be provided to all Local Authorities as a basic need annually to keep local networks in a steady-state prior to considering allocation of any improvement funds nationally. Current allocations of maintenance funding for basic need are insufficient and there is an over-reliance on ad-hoc 'top-up' grants and challenge funds to secure sufficient funds locally. Assets created over the last 30-40 years (traffic signals and lighting columns etc) are now becoming life-expired and a national replacement strategy should be considered to complement carriageway maintenance programmes and enable implementation of new smarter technologies which will deliver operational efficiencies.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Somerset is a good example of where risk management authorities (in the case of flood management) and waste disposal and collection authorities (waste) have come together in partnership to provide an improved and coordinated service. Both are good examples of collaboration; the Somerset Rivers Authority includes local government, Environment Agency, internal Drainage Boards and is progressing to

becoming a precepting organisation; this process should be as quick and efficient as possible to help similar processes in other areas of the country.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The current policy of 'funding competition' to allocate large tranches of resources to local highways and transport projects is extremely time consuming and costly to local authorities. Significant sums and scarce officer time are often invested in preparing bids which may be unsuccessful, and assessing the bids must also be resource-hungry. The reasoning behind the choice of which bids to fund is often not transparent, often simply noting 'oversubscribed funds'. Successful authorities can build a resource pool to win more bids resulting in funding opportunities often going to the same pool of authorities, leaving some authorities with little resource to create future successes. Authorities are developing schemes 'at risk' until capital funding is secured and risk the sunk costs reverting to (scarce) revenue pressures if bids are unsuccessful. Efficiency could be improved through agreeing a long-term investment plan for each area covering a defined funding period with funding allocations made at the outset.

Funding for flood risk management is a complex area and the current cost benefit ratio applied by the Environment Agency is not fit for purpose for delivering smaller schemes. These currently have to be funded locally and funds are reducing for this work. Simplifying and clarifying the whole landscape when it comes to funding for flood and water management would be an improvement.

Funding reductions to local government have meant finding more innovative ways of waste collection/disposal. Whilst this in itself is a positive development it is important that sufficient funding is made available, based on a formula that meets the needs of all areas of the country (specifically, both rural and urban areas).

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

No response provided.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? *Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.*

One crucial factor relates to the skills shortages and distortions in the market created by the demand for specialised skills in competing areas. Particular examples in the Heart of the South West relate to the requirement for construction skills which are already in high demand and short supply across the area, and with the imminent

significant potential for Hinkley C to draw on the labour pool. The risks around skills shortages need to be better understood and planned for.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The planning system in two-tier authorities can result in conflicting priorities and lack of clarity about the delivery plan for the infrastructure (including for highways and transport and flood and water management) required to support development. The two-tier system can also introduce a political element into the choice of where to invest scarce resources, rather than having one agreed list of priorities for an area. There can be a tendency to attempt to share resources thinly across a wide area rather than focusing on a smaller number of essential infrastructure investments. Similarly the introduction of the LEP as a further upper-tier of decision making and choice about infrastructure investment has led to a complex patchwork of routes for investment in critical infrastructure (Planning authorities have infrastructure delivery plans, highway authorities have LTP implementation plans and the LEP has an investment programme). Simplification to enable one infrastructure plan and delivery body per-area would be helpful in prioritising investments and managing spend in a more coherent way.

Phasing of development with essential infrastructure still needs to be improved. In addition there has to be an appropriate balance on what is asked of developers, and making sure the development process within a two tier system reflects the true priorities (rather than political decisions made by one tier possibly favouring the requirements of that tier instead of taking the most balanced view possible.)

The whole viability assessment process is also not currently fit for purpose. Local authorities are ill-equipped to challenge developers' claims that delivery of infrastructure is not viable. In addition, CIL rates and developer contributions are based on excessive assumptions on land values, minimising the adopted CIL rates and section 106 contributions. These issues cause significant difficulty in securing sufficient funding to deliver the infrastructure required, meaning development impact is often not appropriately mitigated. To avoid this, the planning system needs to be better equipped to either control or capture land value uplift.

Another issue associated with the operation of CIL is the lack of control over phasing, at present development can get ahead of the delivery of critical infrastructure. One option to address this could be some form of Grampian type control to ensure infrastructure is in place to support sustainable development. As we have already pointed out, the reason why new communities such as Cranbrook have been a success is because infrastructure funding is front loaded.

Regulation 60 of the Community Infrastructure Levy (CIL) Regulations makes provision for a percentage of CIL receipts to be used to pay borrowing costs. Currently however the percentage of CIL that can be used to pay back loans, as

prescribed within the Regulations is set to zero. There is also provision for the Secretary of State to change this and allow repayments, specifying the percentage that could be applied.

Generally, infrastructure needs to be provided up front to enable growth. Not being able to apply the CIL funds in this way is an impediment to growth. Therefore, there should be a change to the Regulations to allow repayments on loans.

In our Devolution Prospectus, we advised Government of our strong track record of delivery in partnership with residents and businesses. We believe that scaling up our governance arrangements will deliver greater efficiency and accelerated delivery. This would come through the sharing of resources and collective leadership on commonly agreed goals. The effective delivery of new infrastructure investments would be a beneficiary of these new arrangements.

In order to facilitate this Government would need to allow local areas to control investment, for example by lifting pooling restrictions for those areas that wish to enter into new arrangements for the use of CIL, Section 106 and other capital investments.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The current legislative framework is very effective at protecting and enhancing the natural environment and (Brexit issues aside) is fit for purpose.

Sustainable transport schemes are increasingly important in managing urban growth yet there is no routine allocation of infrastructure for bus networks or walking and cycling networks; or 'behaviour change' revenue funds. Local Authorities have the flexibility to use existing capital grants for these networks, but in reality there is little left once maintenance need is covered. Occasional competitive funding opportunities result in some ad-hoc investment for some authorities. Specific funding need for these networks should become part of routine national funding allocations.

Having the correct flood and water management infrastructure is essential for building the resilience of communities, and whilst environmental protection regulations can slow down delivery it is accepted that it is important that all factors are properly taken into account in the development process.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

It would be helpful to have a greater ability to base decisions on the wider economic growth and productivity benefits of schemes rather than a narrow reliance on the Benefit/ Cost ratio. In transport schemes (e.g. A303 above) the wider economic benefits far outweigh the transport benefits but decisions are often based on the narrower transport benefits. Some standardisation of approach in this respect would

also be useful as business cases are currently being prepared using a variety of approaches making it difficult to compare competing investments.

The funding of an enhanced level of flood management through the initial delivery of the 20 year plan for the Somerset Levels and Moors and establishment of the Somerset Rivers Authority demonstrates how an area can adapt to locally important issues. The cost benefit ratio typically employed by the Treasury would stifle a lot of the improvements in this case; employing our own method of raising funding and scheme prioritisation in the county has shown that alternatives are possible. Either sufficient resourcing from government or guidance on ways to address locally important issues would be useful.

Transport

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

The CIHT has produced a useful 'futures' report (<http://www.ciht.org.uk/en/knowledge/futures/index.cfm>) which starts to consider these issues and manage the difficulty in predicting future travel behaviour and adoption of technologies. Government should enable the market to come up with technology solutions and then form appropriate frameworks for managing new technologies as they mature. A flexible and agile approach is needed to enable rapid response to change as it will be impossible to predict what the technologies and impacts will be. It makes sense to plan ahead in relatively short periods (say 15-20 years) so that sensible investments can be made for the medium term allowing change to happen in the longer term. It is clear that autonomous vehicles and smart cities technologies will have a radical impact over a relatively short time period and a useful report by WSPPB/ Farrells explores the implications (<http://www.google.co.uk/url?sa=t&rct=j&q=&esrc=s&source=web&cd=&cad=rja&uact=8&ved=0ahUKEwjVj5nd4d3RAhXEWhoKHbHcBlSQFggaMAA&url=http%3A%2F%2Fwww.wsp-pb.com%2FGlobaln%2FUK%2FWSPPB-Farrells-AV-whitepaper.pdf&usq=AFQjCNGNV3ITUVZt7PCHn8ETIPsYls418w>)

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

This is likely to be very specific to the place, and most major urban areas should have well developed plans to identify appropriate investments. In the medium term, the required investments are likely to continue to include a mix of road and rail, bus, walking, cycling and parking projects. Smart technologies will become an increasingly important area of investment to facilitate efficient movement into and around urban areas. As new technologies mature and vehicles become increasingly autonomous it should be possible to re-allocate more of the road-space and parking space and dedicate it to other modes.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Strategic road and rail investments are likely to continue to be required. (See answer to question 1).

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Most people are currently used to buying a car and paying road tax, with the associated expectation of a subsequent right to use the road as much as they like without further charge. Mobility as a service (Uber etc) is already starting to get people used to the concept of paying for a car journey as a service and if their travel needs are being met effectively in this way then this is likely to get more popular. Once people are used to paying for mobility as a service then the introduction of a charge to use the road (which would simply become an additional element of the bill for the journey) should be more acceptable particularly if that funding provides improved infrastructure which keeps the journey cost down through managing congestion levels and ensuring good levels of service. Managing demand for travel then becomes easier by increasing charges at peak times.

Mobility as a service (in conjunction with increased automation) would appear to create significant further opportunities to reduce car ownership, reduce road space, reduce land dedicated to car parking in urban areas and reduce investment needs for highway assets (currently required to support and manage human driving) and make more efficient use of the available road space.

Digital Communications

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends? When would decisions need to be made?

A Full Fibre infrastructure network providing symmetrical and ultrafast connectivity across the country is currently acknowledged as the way forward for fixed Broadband infrastructure.

Existing programmes achieved significant uplift in the numbers of premises receiving SF broadband (24 mbps) in a relatively short time, largely by utilising and upgrading existing infrastructure. However a number of these premises will have to be revisited to achieve Next Generation Access (NGA) (30 mbps) speeds. Dated copper networks are being superseded by fibre technology and are unlikely to merit significant or long term maintenance investment.

Investment needs to be made as soon as possible as demand increases rapidly and feeds economic growth.

Government should encourage commercial providers to provide this infrastructure. However gap funded or public/ private collaborations should be considered for areas which are not yet commercially viable.

Continual technical developments should mean that most areas will become commercially viable. This is illustrated by the recent Connecting Devon and Somerset (CDS) experience. In December 2016 CDS awarded 4 contracts for the delivery of NGA Full Fibre services on a gap funded basis. These contracts will deliver symmetrical Full Fibre networks providing speeds of up to 1 GB. The value of the network is £62.25 M including a £43.75 M private sector investment. In addition the contractor is also undertaking commercial build. A number of providers participated in the procurement providing a competitive environment. This resulted in a good proposal for a joint public/ private collaboration and with a significant private sector funding contribution which greatly exceeded the public sector subsidy.

NGA broadband infrastructure requires high levels of investment which are secured by very long term returns of around 20 years. This may point to a different investment model using equity investment. CDS recent experience suggested a good appetite in the market for investment in NGA networks with significant private investment being made. The CDS procurement tested the market on a gap funded basis. The continued market dominance of a single commercial provider causes imbalance in the telecommunications market and appears to frustrate competition. A competitive environment accelerates delivery of Full Fibre networks and provides additional resilience for important infrastructure.

The CDS procurement also highlighted that some deeply rural areas will remain outside the current long term economic limit for Full Fibre networks. This means that other technologies and existing technologies will need to be supported for the next 5-10 years on a “stop gap” basis so that more remote areas are not left behind.

Full Fibre Broadband infrastructure should be included in all new build or a suitable alternative for single premises/ remote sites.

18. Is the existing digital communications regime going to deliver what is needed when it is needed in the areas that require it if digital connectivity is becoming a utility? If not how can we facilitate this?

At present no. Whilst there is increasing investment in fixed connectivity which can be supplemented by mobile connectivity in more remote/ difficult to reach areas, the timescales for roll out of comprehensive full fibre networks are not within the next 3-5 years. That timescale may be changing as the dominant provider appears to be contemplating further investment in fibre to maintain its position.

Mobile connectivity whilst better than nothing is not available universally and provides comparatively low speeds and at comparatively higher cost.

Interim solutions such as fixed wireless access do appear able to provide a useful speed increase, whilst not having the full flexibility of a Full Fibre network.

Fixed connectivity

In addition to testing markets and taking a gap funding/ public/private collaboration approach the following should be considered;

- Supporting commercial providers to innovate new techniques resulting in a reduction in costs.
- Promoting effective competition and seeking to achieve a more balanced market rather than continued market dominance by a single provider.
- Pump-priming more remote communities or co-investment models using public funds
- Availability of long term low cost finance whether by loan or equity investment.
- Use of “interim” solutions pending a Full Fibre solution. E.g. CDS has awarded a fixed wireless contract to cover parts of Dartmoor and Exmoor; a particularly challenging location to deliver broadband infrastructure.
- Local Body/ Local community solutions – no “one size fits all” approach. Previous experience of a nationally driven solution has not worked particularly well for more rural areas. Greater flexibility could be achieved by devolving funds in sympathy with the devolution proposals.

Mobile Connectivity

O2 has a licence obligation through the 2013 4G spectrum auction to provide 98% indoor coverage by the end of 2017 however this is only at 2Mbps and is a national target. EE is investing around £1Billion to achieve 98% of the UK population as soon as possible and 95 % of the UK landmass by 2020. However national targets mask under delivery in rural areas. It is anticipated that there will be a shortfall of between 6-10 % indoor 4G mobile coverage in Devon and Somerset and a shortfall of around 1 % outdoor coverage for the area. These are significant shortfalls when compared to the national targets.

On an interim basis it may be possible to improve indoor mobile signals using Femtocell and VoWiFi. These solutions are reliable and comparatively cost effective ways to improve mobile signals but less well known. Mobile solutions still tend to be comparatively more expensive.

The Mobile Infrastructure Project (MIP) was intended to improve 4G “not-spots” by provision of additional mobile sites. The project was not as successful as hoped with around 8-10 sites becoming operational out of a projected 43 sites which were expected to be needed across Devon and Somerset. Locations had to be set aside due to location, planning or other problems. It may be appropriate to re-launch the MIP whilst incorporating the lessons learned from the last phase including;

- more consultation (not imposing large lattice masts on communities where smaller less obtrusive masts would be appropriate),
- being flexible - inconsistencies in mapping between operators needs to be considered,

- reflecting the costs that the market can sustain when compared to annual revenues. As remote masts have a limited market these will not sustain high annual rental fees in addition to power costs.
- Mobile operators should be encouraged to use the experience gained from 3G small cell deployments in rural areas and apply that to 4G rural not-spots. Costs may require community engagement.

Other ways in which mobile infrastructure might be facilitated include;

- Amendments to planning and permitted development rights for small cell sites
- Business rate relief for small masts

It would be worthwhile having a reliable source for information about “stop-gap” technologies which could be used pending a universal Full Fibre solution. This could be promoted in areas which are unlikely to have early Full Fibre networks.

It may also be appropriate to offer some form of subsidy for more costly connectivity pending a universal Full Fibre network.

Energy

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

No response.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Somerset already has a thriving low carbon power sector in the form of nuclear. The construction and operation of Hinkley Point C will bring jobs, skills, training, and investment, and give huge opportunities for a supply chain that stretches across Somerset and the South West and the wider UK. There are £50billion worth of opportunities in the nuclear industry within 75 miles of the South West. We are leading a global renaissance in nuclear power. Getting it right in the South West will demonstrate the UK’s pre-eminence in the global nuclear marketplace. But this needs to be supported through appropriate and ongoing investment in the region’s infrastructure system, including transport (including roads, rail and air), communications and the electricity distribution system.

A zero carbon power sector in 2050 undoubtedly needs to harness the opportunity that renewable energy production presents. Given that the Severn Estuary has the second largest tidal range in the world, the South West is well placed to support renewable energy production through the development of water based technologies.

Through the Bristol Channel & Severn Estuary Energy Group (Energy Group), support has been expressed for exploring a balanced technology approach to the

regions energy assets, advocating that water based projects and technologies are deployed in a way which contribute significant energy and economic benefits in balance with the environment, other marine users and all relevant stakeholders in the region. In summary this would involve

- Treating the Bristol Channel as a holistic, energy system including tidal stream, wind, floating wind, wave as well as tidal range.
- Considering the various energy technologies in combination to understand their impacts and interdependencies, as each converts energy from the system.
- At all times considering the balance of economic and energy benefit of project development in the estuary against the environmental, ecological and other impacts.
- A time based strategy to develop and deploy a portfolio of technologies allowing new technology to be developed and brought on stream when proven, their risks and costs understood and managed.
- Supporting technologies which can be built out incrementally, with continuous monitoring and evaluation so that individual and cumulative impacts and risks can be understood and mitigated.

In conjunction with the tremendous opportunity presented for energy generation, tidal lagoons and other marine based technologies present a huge opportunity for UK companies to deliver significant supply chain content. The marine based elements and civil engineering elements of schemes, particularly lagoons, are largely compatible with other large scale infrastructure projects. These opportunities are very important and weigh significantly in favour of tidal lagoons forming part of the UK energy mix.

Recent publication of the Government review, led by Charles Hendry, into the feasibility and practicality of tidal lagoon energy in the UK is therefore a positive step forward confirming “that tidal lagoons would help deliver security of supply; they would assist in delivering our decarbonisation commitments; and they would bring real and substantial opportunities for the UK supply chain”.

The success of large scale energy schemes in the Bristol Channel must however be based on a strong consensus and secure support from communities on both Welsh and English sides of the channel. To date, prospective development of the regions' energy resources has been left in large part to individual project developers and consortia to evolve piecemeal. Whilst private sector engagement is essential, without participation and agreement between relevant authorities it would not deliver the necessary balance with the environmental and economic interests required and further requires project developers to take on burden of planning risks.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

No response

Water and wastewater (drainage and sewerage)

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

No response

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Close working between local planning authorities, statutory drainage consultees (utilities and the lead local flood authority) is important. Adopted development plan policies will ensure embedding the issue in the planning process; these have to be informed by water companies and housing/development projections.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Partnership working and appropriate funding is critical to the success of a whole catchment approach. Catchment Partnerships may be a mechanism for enhancing the approach taken however their success at present is patchy and requires a) more time and b) more funding (currently funding is only guaranteed until March 2017).

Flood risk management

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

Put simply, the UK has to take a pragmatic and realistic approach to flood management and aim to provide as high a level of resilience as possible with the funding available. Evidence has to be used to inform the level of resilience provided, and this is likely to mean difficult decisions will have to be made in the future about the allocation of funding and the level of protection afforded to certain areas. Primarily in this areas changes to our climate has to be a key issue to inform policy and spend in the future.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Natural flood management schemes tend to be less expensive, less intrusive and have a range of potential benefits including environmental ones (biodiversity benefits, water quality, carbon storage, recreational access to nature). They can be more aesthetically more pleasing too. These schemes can mean engagement with landowners who can feel they are helping their communities through implementing

natural flood risk management schemes. “Innovative technologies” can actually mean relatively simple activities, which can improve the potential for them to be delivered. Accessing funding for these worthwhile schemes is not sufficiently straightforward; there is still also a lack of evidence from existing work that gives a rigorous scientific base and as such it is sometimes difficult to justify the investment. Collecting evidence can be expensive, with proper monitoring sometimes difficult to finance.

Solid Waste

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

There is still some way to go to provide sufficient incentives to ensure that waste is treated in the correct way and that there is sufficient treatment capacity. The discord between reducing funding and the ability of waste collection/disposal authorities to manage waste effectively needs to be reviewed. The planning process is a key facilitator of this capacity and waste planning authorities need to work closely with operators, and cooperate with other waste planning authorities, to ensure sufficient and coordinated capacity.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

No response provided.

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London
EC3M 8UD

t: 020 8541 7555
e: admin@secouncils.gov.uk

Sent to: NIAEvidence@nic.gsi.gov.uk

10 February 2017

Submission to the National Infrastructure Assessment – call for evidence

Together SEEC and SESL promote the views and interests of all tiers of local government across the South East, representing over 60 local authorities and over 9.1 million residents – the largest population in the UK.

We are pleased to have the opportunity to respond to your call for evidence, developing further some of the issues raised at the National Infrastructure Commission's stakeholder event in Winchester on 20 January. The South East plays a key national economic role and needs transport and infrastructure investment to continue delivering this success. The South East is the engine room of the UK economy, generating £249bn GVA in 2015. The South East is also a global transport gateway for businesses and travellers UK-wide, by air, sea and rail. Both roles are at risk from major infrastructure deficits which, if not urgently addressed, will undermine future long-term national economic success and the South East's ability to facilitate further housing and economic growth.

We have grouped our response to your call for evidence by question themes, and provide more detailed answers to questions in Appendices 1, 2 and 3.

Cross-cutting issues: Questions 1, 2, 3, 7, 10, 12– see appendix 1 for further detail

The South East offers the highest return on public investment in England, contributing a net profit of £80bn to the Treasury between 2002-12, some £6bn more than 2nd place London, profit the Government reinvests across the country. However the South East's economic success and role as a major funder of public spending nationwide are at risk from under-investment in transport and infrastructure that is essential for local and national economic growth. National criteria for investment should be updated to take better account of GVA uplift that infrastructure schemes will deliver. A transparent, accountable approach to investing an agreed proportion of national funds in schemes that deliver this uplift – in the South East and elsewhere – will ensure that both the economy grows and that the Government achieves the best returns on public funding.

We draw your attention to the LG Futures (LGF) table (in Appendix 1) which shows the £15.4bn infrastructure investment funding gap in the SEEC area over the next 15 years. This will restrict economic growth, impact on the viability of new home-building and risks harming public services if not addressed.

Whilst local authority Leaders recognise that there is no new money on offer from Government, we believe that reallocating existing funding and providing councils with financial freedoms and flexibilities could help address this growing infrastructure gap. Clearly schemes with a national impact need an allocation of national funding, but there are also changes that could release more investment from councils for local priorities – for example creating more infrastructure funds, reviewing proposed changes to the New Homes Bonus, retaining first time sale Stamp Duty for infrastructure funding and greater local decision-making over income streams such as business rates. These would all give councils greater certainty to support borrowing for infrastructure investment. This would pay tremendous dividends in helping to enable local authorities to provide some of the infrastructure needed to support housing and business growth.

Not only is the South East's economic success/return on investment critical to spending nationwide, but the South East is a key global transport gateway vital for businesses UK-wide. This access to international markets underpins the UK's global competitiveness and inward investment now and post-Brexit. Without significant infrastructure investment, businesses face increased congestion and operational costs, not only in the South East but across the UK. This includes addressing South East impacts of Heathrow Airport

expansion in light of the Government's recommendation. This will have significant impacts on the South East, placing extra demand and needs on transport, housing, infrastructure and risks to the environment and air quality, which all require significant investment to address.

Infrastructure is also critical to unlock development sites for housing and economic growth, but existing deficits in investment hinder this across the South East. Councils know where major infrastructure is needed to support and unlock development but currently lack the funding to take forward projects on the scale required to meet national needs. Utility companies also need to play their part in planning infrastructure to better match housing delivery. We have provided more detail on this in Appendix 1.

Transport: Questions 13, 14, 15, – see Appendix 2 for further detail

As we highlight above, the impact of South East infrastructure is national, not just local. Companies UK-wide rely on our transport gateways to reach international markets, now and post-Brexit. However these links are increasingly congested, harming businesses, commuters, residents and the environment – reducing UK attractiveness for global investment. Without action now, these problems will continue to get worse - and Heathrow Airport expansion risks further exacerbating them without significant new infrastructure investment.

Also as set out above, the South East is an economic powerhouse in its own right. Over 1.2 million residents commute within the South East's boundaries, roughly 750,000 more than commute into London. Improvements to orbital routes will support and strengthen the South East economy and national network – not simply those commuting into London - and complement radial links to and from London.

There are a number of critical strategic transport routes in the South East, as highlighted in SESL and SEEC's recent Missing Links [report](#), which, if delivered, would unlock significant economic and housing potential. We ask for the NIC's support in moving these schemes forward and to consider undertaking a study on the economic benefits of improving surface access to international gateways. The schemes identified in the report – listed in Appendix 2 - represent strategic cross-boundary transport needs and opportunities across the South East. Investing in these strategic transport corridors, international gateways and wider transport networks would benefit job creation, the reliability of imports and exports, and the delivery of homes.

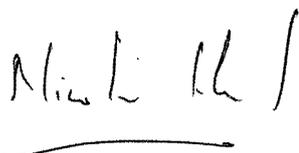

Digital: Questions 17, 18 – see Appendix 3 for further detail

Across the South East many rural homes and businesses do not have access to the broadband they need, which is detrimental to the area's economic potential and the profits of UK plc. Improving broadband speeds, access and delivery will boost productivity across many industries, opening up more markets without the need to travel. This will allow all businesses, regardless of location, to access customers and suppliers creating a bigger and more competitive marketplace.

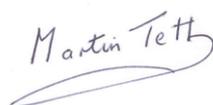

All utility companies, including broadband companies, should be required to engage in the planning process at the earliest stages.

We would be pleased to discuss these points further with you.

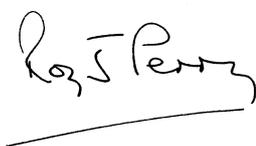

Yours sincerely,

Cllr Nicolas Heslop
Chairman, South East England Councils
Leader, Tonbridge & Malling Borough Council

Cllr Martin Tett
Chairman, South East Strategic Leaders
Leader, Buckinghamshire County Council

Cllr Roy Perry
Deputy Chairman, South East England Councils
Leader, Hampshire County Council

Cllr David Renard
Vice Chairman, South East Strategic Leaders
Leader, Swindon Borough Council

Appendix 1: Cross-cutting issues

Questions 1 and 2: What are the highest value infrastructure investments that would support long term sustainable growth in your city or region? How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

The South East is the engine room of the UK economy, and offers the best return on investment in England. The South East made a net contribution of £80bn to the Treasury in 2002-12 - supporting public spending across the whole country. Its GVA (£249bn in 2015) is greater than all 8 English core cities combined (£169bn). Investing in infrastructure to support this high performing economy, maintaining growth in jobs and productivity, and unlocking housing, is vital for the whole UK now and post-Brexit.

Research for SEEC and SESL by local government finance experts LG Futures (LGF) estimates the South East has an infrastructure funding gap of £15.4bn by 2030 in the SEEC area. Additional data from Essex, Central Beds and Swindon further increases this gap. The scale of the infrastructure funding gap across the South East, broken down by type, can be seen in the table below. Taking account of expected population growth, providing transport, education, health, community and green space infrastructure for South East residents, plus flood protection, utilities and emergency services, the total infrastructure cost is calculated at £38.3bn for the SEEC area. Current funding streams are expected to cover around £22.9bn of this, leaving a gap of £15.4bn for the SEEC area.

Table 1 - South East (SEEC) region estimated infrastructure cost (over 15 years)

	Estimated Cost	Expected Funding	Gap	Estimated cost per head
	£m	£m	£m	£
Transport	17,822	8,154	9,668	1,796
Education	4,634	2,699	1,935	467
Health and social care	6,145	5,375	770	619
Community	1,675	928	747	169
Green infrastructure	399	106	293	40
Utilities	5,088	4,606	481	513
Flood protection	2,387	912	1,475	241
Emergency services	127	93	34	13
TOTAL	38,275	22,873	15,402	3,858
Current population	8,919,600			
Growth in population to 2030	1,002,100			
Population estimate in 2030	9,921,700			

SEEC and SESL's recent Missing Links [report](#) highlights some of the most important vital strategic transport investments that would help alleviate pressures across the South East, creating better productivity and fewer delays to freight transport. Without South East infrastructure investment, companies across the UK who rely on our transport gateways to reach international markets now and post-Brexit may choose to move to alternative EU locations where infrastructure is better equipped to handle demand. As road and rail routes to and through the South East become increasingly congested, overcrowded and inefficient they damage business profitability and inward investment to the UK.

Heathrow Airport is one of the UK's most important international gateways, and proposals for expansion would have a significant impact on South East. Accommodating the additional runway and achieving its full economic potential are dependent upon maintaining and improving access to the expanded Airport. Although not in the South East, Heathrow's position close to the London/ South East border means much of the airport traffic needs to travel via the South East. It is also inevitable that many of the approximately 48,000 new homes needed to support Heathrow expansion would be in the South East, further adding to congestion. Without investment in infrastructure, the expansion of Heathrow Airport will have significant impacts on transport links across the South East and to the rest of the UK. While access to Heathrow Airport is important, there is also a need to invest in improving transport links to other major air and sea ports, and commercial centres across the country. This is an opportunity to invest in the South East's existing and new road and rail infrastructure to maintain and improve access to all gateways so that it is able to reach its full economic potential and support UK plc's success.

As highlighted in our covering letter, there needs to be clear, accountable criteria to underpin allocation of national funding for infrastructure projects with significant national/ global economic significance.

Questions 3 and 10: How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this? What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The South East has England's largest population and largest growth in homes, with an increase of 34,900 across the South East in 2015-16 (SEEC area). This was 4,500 more homes than London delivered in the same period. SESL members in Essex, Central Bedfordshire and Swindon saw completion of 8,060 homes in the same period. SEEC's Unlock the Housing Blockers [report](#) highlights that many areas suffer from an existing infrastructure deficit which can hinder development, and which new developments will add to. Congestion and pollution degrade the environment and impact on residents' quality of life, while poor road and rail links have a negative impact on commuting times and reliability of freight transport. These factors not only create local concerns about further new development – which can delay the delivery of planned housing - but also undermine our vital economic profitability to UK plc. Without the necessary investment in infrastructure, it cannot be assumed that the South East's economic powerhouse role and track record in supporting new homes will continue now and post-Brexit.

We fully support raising the economic performance of other parts of the country through infrastructure investment, but believe this must happen alongside continued national investment in the South East success – in terms of its vital contributions to housing delivery and economic growth. Alongside this, allowing councils to access a greater share of locally-generated business rates, retain Stamp Duty from first time property sales to reinvest in infrastructure, and to have greater freedoms to set tax rates locally would help release funds that councils could contribute to the provision of essential local infrastructure thereby opening up housing sites and reducing the costs of congestion for businesses.

In addition, South East Councils would welcome better co-ordination to ensure infrastructure investment is well aligned with councils' housing and other economic/growth plans. This would allow for timely delivery, ahead of new housing and workplace developments, supporting sustainable growth and ensuring infrastructure is designed and delivered effectively and in the right places for new developments. There is a need to better balance national, regional and local investment priorities.

Encouraging utility companies, including energy, water and waste management companies, to better align their infrastructure investment in advance of planned housing growth would speed up the delivery of new housing developments. Requiring utility companies to fully engage in the earliest stage of the planning process would help support the delivery of more timely utilities for new developments. Allowing councils to negotiate high level development agreements with utilities, other infrastructure providers and developers on the timing of development would help agree approaches to infrastructure investment and avoid blocking sites.

Questions 7 & 12: What changes in funding policy could improve the efficiency with which infrastructure services are delivered? What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

SEEC and SESL members want to explore solutions to infrastructure funding to ensure that continued housing and economic growth does not become unsustainable by simply adding to existing congestion, overcrowding and existing pressures on services. Changes to how infrastructure is funded are needed because of the growing funding gap across the South East, made worse by a lack of council freedoms and flexibilities to raise their own funds for more local infrastructure needs. For example, giving the South East access to one or more infrastructure funds, similar to those operating in areas with devolution deals, would release significant capacity for investment at more local level. Other options to explore include reviewing the proposed changes to the New Homes Bonus, greater accountability over local income streams (such as business rates) for councils, giving councils greater confidence to borrow for infrastructure investment, and allocating first-time sale Stamp Duty on new South East homes for infrastructure investment. While these measures are not appropriate ways to fund national, strategic priorities, these measures would allow councils to make a much greater contribution to more local infrastructure needs.

Exploring the Stamp Duty example further, in 2014-15, 209,000 properties were sold in the South East, generating a total of £2.1bn in Stamp Duty. New homes were some 13.5% of the total sales. Allocating councils 13.5% of the total Stamp Duty receipts to spend on infrastructure would have generated £278m for South East authorities in 2014-15. Stamp Duty receipts can vary significantly each year but, if receipts were to continue at 2014-15 levels, the South East authorities could raise £4.1bn over 15 years (SEEC area).

Another example is allowing councils to maintain access to the New Homes Bonus (NHB) which could deliver £2.1bn funding for South East authorities over 15 years. The NHB initiative has been very popular with local authorities and residents alike. A review of the Government's planned changes to the NHB, which propose to reduce the pot and introduce a threshold before councils can qualify for payments, should be undertaken. We recognise the pressing need for care funding but know there is also a strong need for wider infrastructure. It is not a choice of either social care or infrastructure, the South East needs investment in both.

At national level, we urge the NIC to review the criteria currently used to allocate Government departments' infrastructure investments. For example:

- Our member councils have previously found that flood prevention funding failed to take adequate account of the economic impact of flooding.
- There are also concerns about outdated methodologies used in assessments such as the DfT green book appraisals, which should be refreshed to ensure assessments give more weighting to the GVA uplift to be delivered by transport investments.

SEEC and SESL believe that the NIC can play an important role in updating investment criteria to deliver an investment programme that is fit for the 21st century. Within such an updated system we believe there could then be transparent and accountable decisions made about the proportions of funding to be allocated to projects that offer strong GVA growth alongside those that offer lower growth but regeneration opportunities.

Appendix 2: Transport

Questions 13-15: How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas? What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

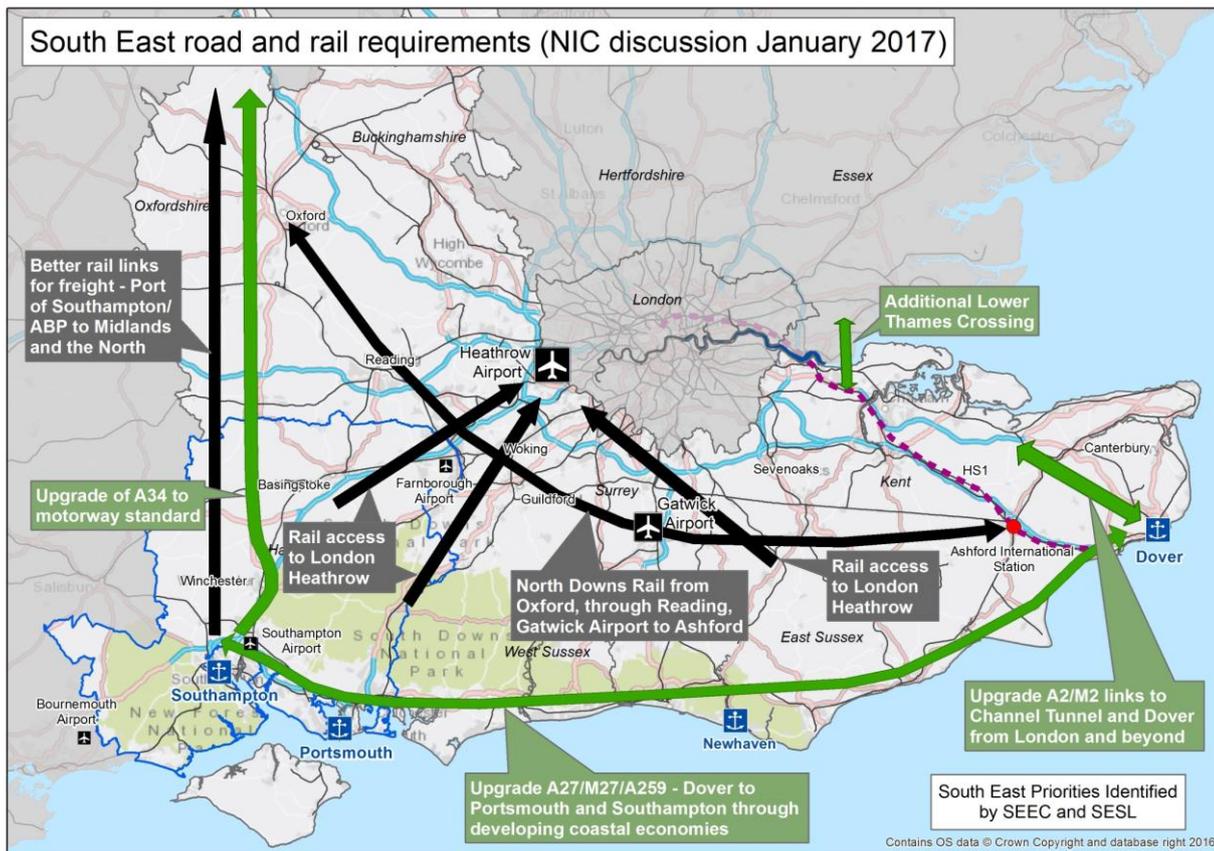

The South East has a dual role as the UK's most profitable economy (in terms of net profit to the Exchequer) and as a major international gateway used by businesses nationwide. Investment in improving the South East's strategic road and rail routes will provide significant dividends for the Treasury and for the country as a whole. SEEC and SESL's Missing Links [report](#) highlights some of the nationally important South East projects which are vital for future economic success and which cross multiple council and LEP boundaries. These strategic transport routes (Map 1) include major schemes which would also facilitate growth at Heathrow Airport, open up significant economic and housing potential across a much wider area and support housing and economic growth in other areas of the country. For example:

- Improving the A34/M3 and rail links to Southampton-Portsmouth from Oxford, the West Midlands and beyond;
- A2/M2 – links to the Channel Tunnel and Dover from London, East, the Midlands and beyond;
- A27/M27/A259 – from Dover to Southampton and Portsmouth, through developing coastal economies and university towns;
- North Downs Rail – from Oxford, through Reading and Gatwick Airport to Ashford in Kent will have major benefits for the local and national economy.

These projects include both radial and orbital routes. The value of radial routes is widely recognised, but the South East also sees significant benefits to improving orbital routes as a way of supporting the South East's own economy by linking key economic centres across the South East and beyond without the need to travel via central London. These orbital routes would relieve pressure on already heavily-congested routes, such as the M25 and rail routes into central London, by providing viable alternative travel options. Combining physical road and rail improvements with new transport technology and innovation would improve travel capacity, reduce congestion and support inward investment and business growth.

Without infrastructure investment businesses face increased congestion and increased operational costs, not only in the South East but across the UK. Figures from the Freight Transport Association, for example, put the cost of traffic congestion at £1 per minute for their members. Without South East infrastructure investment, companies across the UK may choose to move to alternative global locations where infrastructure is better equipped to handle demand.

Map 1 – South East road and rail requirements

Appendix 3: Digital

Questions 17 and 18: What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made? Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Access to superfast broadband is critical for continuing the economic success of the South East and UK in the future. It supports economic growth and productivity across all sectors and provides access to international markets without the need to travel. Almost 5% of homes and businesses across the UK are still without access to superfast broadband. It is important to recognise that economic activity takes place across a range of locations, generating income for UK plc.

Delivering coverage for all homes and businesses should be a priority to boost the economic success of the South East. Superfast broadband gives homes and businesses access to services, customers, markets and suppliers regardless of location, allowing all areas to compete on equal terms locally, nationally and globally. For example, in rural Hampshire where the council have paid for the installation of infrastructure, over 75% of households have taken up superfast services. Without it, rural areas are not able to participate on the digital community or economy.

In future to avoid creating a digital deficit for newly built homes or employment sites, broadband companies, should be required to engage in the planning process at the earliest stages.

Commission Secretariat
NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London
EC3M 8UD

By email: NIAEvidence@nic.gsi.gov.uk

Dear Sir,

THE NATIONAL INFRASTRUCTURE ASSESSMENT: CALL FOR EVIDENCE

We welcome the opportunity to respond to the National Infrastructure Commissions Call for Evidence, and have provided detailed answers to the questions in the Appendix to this letter.

South West Water Limited (SWW) provides water and sewerage services to a population of approximately 1.7 million in Devon and Cornwall and parts of Dorset and Somerset. Pennon Group Plc (our parent company) acquired Bournemouth Water in April 2015 and has now integrated the company into South West Water. Bournemouth Water provides water services to a population of approximately 0.4 million people in the Bournemouth and Christchurch region.

Pennon has strong links with both the National Infrastructure Commission and the Institution of Civil Engineers. Pennon is also currently working with the Treasury on the National Infrastructure Plan for Skills and UK Infrastructure Delivery. Pennon is investing, innovating and working to deliver the infrastructure networks and services the UK needs.

We have sought to outline our responses using experience from our business. You are welcome to acknowledge South West Water in the final report and to use and publish evidence submitted with our consent. We would also be very willing to participate in any further consultations and to offer any members of our Executive Management Team to speak to you in further detail on any of the topics in this report.

If you should require any further information please do not hesitate to contact me.

Yours faithfully,

(signature redacted)

(name redacted)
(job title redacted)
(phone number redacted)
(email address redacted)

APPENDIX

Cross-cutting issues:

1. *What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?*

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline

The economic structure of the South West reflects its geographical location at some distance from major markets and centres of commerce. It continues to have a high reliance on traditional land based and extractive industries, together with tourism all of which are a function of its natural environment.

The overwhelming majority of businesses in the South West are small, with 75% having no employees. There has been an increase of 118,000 businesses in the past 5 years, and this is almost entirely down to the start-up of micro businesses with fewer than 5 employees.

The South West Peninsula has a smaller share of exports than almost every other part of the UK and low levels of foreign direct investment. These are key indicators of the fact that the South West Peninsula is one of the most cut off areas of the UK.

The view that emerges of the South West Peninsula is an area with skilled workers, innovative businesses and resilient productivity, but one in which not all business opportunities are captured and which is poorly related to other communities in the area and to national and international markets.

The South West is considered by some to be an unattractive place to do business because of poor access, prolonged journeys, increased cost of transport leading to uncompetitive pricing or reduced margins, disruption due to lack of resilience in communications networks and difficulties in recruiting key personnel because of extended travel. If these communications deficiencies can be addressed then the productive energy of the South West Peninsula can be released. As a result of the above we consider that infrastructure investment in road, rail, air and broadband are essential to the productivity of the region.

2. *How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?*

Businesses in the South West have the best prospects of trading internationally if they are well connected to key gateways, particularly major airports such as Heathrow, Gatwick and Manchester. Direct services by rail and good highway connectivity to international gateways will be increasingly important in maintaining the UK's competitiveness.

SWW is therefore supportive of the Western Rail Access to Heathrow as well as the role of regional airports which should be supported, not just for outbound travel to international

destinations, but also for inbound travel – particularly to areas such as the South West which attract significant tourist numbers. Enhanced surface access to regional airports such as Exeter Airport is therefore a priority for attracting inbound visitors.

SWW is currently discussing with Defra the delivery of water and sewerage services for the Isles of Scilly. The continued maintenance and enhancement of transport link to the Isle of Scilly is therefore essential to maintain the efficient delivery of these services. It is therefore important that plane and sea transfers to the islands are maintained and improve in terms of both frequency and reductions in cost. We are supportive of the currently proposed helicopter services to the islands.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Significant growth is being experienced in the South West, with new housing coming on stream as employment rises. The South West also faces housing pressures because it is a popular area for retirement and tourism, and in some parts of the region the ratio of house price to income is among the highest outside London.

Sustainable new communities, at Cranbrook (Exeter) and Sherford (Plymouth) are being delivered in the South West as a result of strategic land use planning decisions taken 20 years ago and they highlight the need for housing to be planned in conjunction with key supporting infrastructure such as transport, education and training, energy and water. Similar commitment to support early infrastructure delivery will be needed to successfully deliver the new garden town at Taunton, and the garden village at Culm in Mid Devon.

We continue to support an integrated approach which we consider will deliver the broadest range of gains with active attention to opportunities to enhance natural capital as an integral part of infrastructure planning. We continue to consider that water companies should be engaged in the planning process and should be a statutory consultee on all planning applications.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Within the water industry the biggest contribution towards more effective demand management is increased levels of metering. Both SWW and Bourne mouth Water have reached relatively high levels of customer metering. This is not yet compulsory, so may yet reach a maximum. The potential for further savings resulting from new meter optants is therefore limited. This high level of metering could however result in greater customer engagement and incentives through gamification with demand management initiatives, as reductions in consumption can be promoted as a way of cutting bills.

Recent decades have seen an increase in the frequency of personal washing, with a daily shower now normal, particularly among younger generations. This behaviour may lead to increased average demand in the future. Future population growth for the Devon, Cornwall and Bournemouth regions show a increase in population within the >60 age band as these regions continue to be a retirement destination. Over time this will result in more single person households within the regions with an increased per capita consumption. This increase in per capita consumption has been countered somewhat by improved efficiency in water using fixtures and fittings, for example lower flush volume toilets and more efficient washing machines. Potential for future reductions in consumption from improved efficiency fixtures and fittings is limited, but savings through influencing customer behaviour could be delivered in the medium to long-term.

SWMW has run successful behavioural change campaigns such as Love your Loo and Think Sink, which aim to reduce sewer blockages. Lessons learnt from these campaigns are being used to design campaigns aimed at reducing water consumption, for example through encouraging more efficient garden watering strategies.

SWMW also targets customer behaviour by offering free water saving devices and advice to customers on conserving water. SWMW offers home visits to its most vulnerable customers with a focus on reducing bill costs through water conservation. More could be done to engage customers, e.g. through offering home visits out to more all customers.

Consultancy packages are offered to business customers, offering leak detection, water efficiency advice, devices and rainwater harvesting.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Infrastructure investment should be planned from cradle to grave with clear accountabilities in place for the maintenance of the system of assets which deliver the services to customers and the environment. Within the regulatory period from 2015-20, water companies are incentivised to move to a tolex based approach through the application of whole life costing and efficient asset management. These incentives should be sustained to ensure that incremental improvements in asset management continue to deliver economic and efficient delivery resulting in greater value for customers and the environment.

Some aspects of asset management are hampered by customer behaviour; we have a throwaway culture across the developed world, with products no longer designed for re-use with quick, simple solutions which fit easily into our daily routines. Changes around personal hygiene are also driving a continuing increase in the use of wet wipes which are being inappropriately disposed in the toilet causing a massive problem for water companies, with wipes and non-sewer products being responsible for around 75% of all sewer blockages.

Campaigns such as our Love your Loo and Think Sink are very efficient methods to target customer behaviours, informing the optimum opex vs capex balance to attain the best system reliability without resorting to constructing expensive new assets.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Competition and collaboration are key roles within the delivery of economic and efficient infrastructure services, particularly as most of the infrastructure services are delivered by discreet service providers with separate regulation or governance arrangements. At times these operational and regulatory boundaries can lead to inefficient delivery or perceived lack of co-ordination.

Competition is already occurring within the water sector with Open Water, the non-household water retail market opens in April 2017; shadow operation is now well underway across the sector. One of the key requirements in the market will be that the wholesaler maintains a level playing field, in that it treats all retailers exactly the same.

Collaboration across utilities and with local authorities is also key to delivering services across our operational areas. Through our Upstream Thinking (UST) and Downstream Thinking (DST) programmes of work we have been working collaboratively with external organisations to deliver long term sustainable solutions to issues. These collaboration initiatives could be more comprehensive and better supported by the UK Government through incentivisation and stronger regulation for catchment polluters. Legislation and support for ecosystem service payments and natural capital accounting can play a significant role alongside more accessible regional or national co-funding for catchment management.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

Many would consider that the privatisation of infrastructure services such as water, sewerage, electricity, gas and telecoms has been successful at raising private finance and investing to improve our asset infrastructure over the last 25-30 years. We consider that these mechanisms have been very successful and should continue but greater emphasis should be placed on co-ordination across these regulatory regimes to ensure that common outcomes are delivered at least cost.

These could include:

- improving the delivery of infrastructure projects and how access to infrastructure corridors can be improved and co-ordinated
- incentivisation for developers – the requisition process is changing to a roof tax (yet to be confirmed but is likely to be Spring 2018) which should balance who pays for infrastructure services
- FDGIA funding is driven by risk to life and properties at risk i.e. residential dwellings. This does not give much weight to commercial property and does not consider the impact on the economy/tourism by not providing flood defence
- The Countryside Stewardship funding for water quality on farms could be better distributed by water and sewerage companies (WasCS) through for example UST so this should be changed

- public funded bodies could also be incentivised through totex regimes to align with the funding processes within the regulated utilities.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

There are a number of these projects within the South West region where infrastructure projects can deliver benefits for the region, however the funding streams are across multiple parties each of whom have different objectives, constraints and timing of funding. Infrastructure projects require medium to long term commitments to funding. Many local government bodies are dependent upon support from either central government or European structural funds for infrastructure investment. The future of these investment funds is uncertain post Brexit, creating project uncertainty.

Commitments to long term funding over five to six years for Government bodies alongside an alignment to risk based outcomes and totex incentives should encourage greater collaboration across infrastructure providers.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

Holistic total system resilience assessments will be the key to the effective delivery of these resilience outcomes. These should be common risk assessments across power, water, telecoms and transport based upon shared hazards. This approach should build on the foundation of the good work that has gone into flooding to wider infrastructure and should encourage the establishment of better links between service industries with more collaboration.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Schedule 3 of the FWMMA should be enacted and WaSCS should be made statutory consultees in the planning process. The right to connect should also be removed. Enacting Schedule 3 would also resolve the outstanding issues of ownership and maintenance of SUDs.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The local environment in the South West region is a distinctive and unique natural asset. For example according to the Great Britain Tourism Survey 2010 – 2012¹ the area attracts approximately 26.7 million visitors per annum. Therefore, infrastructure developments that promote access but that are sensitive to preserving, protecting and enhancing it are very important.

An integrated approach to catchment management and the natural environment will deliver the broadest range of gains with active attention to opportunities to enhance biodiversity and other natural capital as an integral part of infrastructure planning. Ideally, local regions would be charged with providing and maintaining information on the location of the most valuable natural and cultural capital and opportunities to enhance these alongside future development. For example, establish natural flood management approaches to protect infrastructure at risk from flooding.

Regulatory regimes should be aligned and should promote this long term thinking with robust Natural Capital Assessments included within evaluations and regulatory decisions.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

Cost benefit techniques should be focussed on real world outcomes that are measurable and deliverable. The techniques should reflect the needs of the end user and of the wider environment as well as the costs of asset ownership and management.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

With increasing prosperity demand for travel is likely to grow. However, there is also likely to be a greater tendency for flexibility in terms of journey time and destination such that demand for travel may reach more of a continuum across the hours of the day with less pronounced peak periods.

¹ https://www.visitbritain.org/sites/default/files/vb-corporate/Documents-Library/documents/England-documents/gjb_tourist_-_30-08-2013_-_lv_lcm30-38527.pdf

The widespread deployment of autonomous vehicles could lead to an increase in the demand for highway capacity, as personal travel may be available to those who are not able currently to drive cars.

It is reasonable to assume that there will be a further erosion of public transport in rural areas, but that this decline may be offset by the availability of autonomous vehicles and widespread use of information systems to match drivers with potential passengers.

The continued adoption of new and alternative technologies may lead to a reduction in the number of business trips taken, as road congestion continues to worsen and broadband and communications channels such as video conferencing become more attractive.

The spread of Ultra Low Emissions Zones (ULEZs) across the country and road charging may mean that only absolutely critical meetings occur face to face. Freight may see a shift in delivery patterns as more delivery activity occurs over night when the roads are quieter.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

Highway space in our urban areas is going to remain at a premium, with effective capacity potentially declining as the size of the vehicles increases while the available width of the highway network is constrained by adjoining development. Therefore the highest value transport investments are likely to be those which overcome such constraints, for example greater use of the urban rail networks, together with off road cycle and pedestrian routes.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

The increasing size of heavy goods vehicles and more access restrictions make this an interesting issue. Coupled to ever decreasing levels of public transport is 'forcing' a modal shift from public transport to private. Rural transport infrastructure should be enhanced utilising public funding and incentivising developers away from developing industrial activity in sparsely served areas.

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Road charging will inevitably spread further, particularly from a commercial perspective, although this will place additional pressure on the cost of goods and services and would ultimately impact on the cost base of companies. Obviously this would be an undesirable position.

Digital Communications:

17. What are the highest value infrastructure investment to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

The water industry relies on reliable low bandwidth communication and high bandwidth communication to operate its assets. While the rise of superfast digital communications has enabled us to deploy advanced technologies in the field, we continue to see the withdrawal of low bandwidth services with no equivalent services being made available. The CSDN network was retired in 2008, in three years time analogue private circuits and TDM digital private services will be withdrawn from service. In the longer term the future of ISDN and even analogue PSTN is uncertain.

If superfast is the only future solution, it must have the coverage and reliability that low bandwidth services have provided and the costs to install business grade services significantly reduced. To date, affordable products have relied on consumer orientated broadband and mobile products which, compared to low bandwidth services, are complex, have poor coverage, are unreliable and have poor service levels. Fibre to the premises provides the reliability and service level required but infrastructure needs to be put in place, in rural areas, so that installation costs are not an insurmountable hurdle. Rental costs of fibre services are far too high compared to the low bandwidth services currently in use. If charging is to continue to be based on distance from ethernet points of presence then more ethernet POPs need to be established closer to customer sites.

We need a new universal service offering with fibre as a core component.

Low bandwidth services

The water industry's machine to machine communication requirement has changed little over the past several decades, requiring reliable low bandwidth services.

We believe there is a place for low bandwidth services alongside superfast services. A reliable low bandwidth copper delivered service with the reach of analogue exchange lines sitting along side a pervasive low bandwidth radio service would provide for most of our critical communications needs.

It is rather too late to make decisions to build infrastructure to cope with the withdrawal of analogue private circuits; even if radio technologies such as Lower Power Wide Area Network and TV Whitespace were immediately made available it will take some time before manufactures develop products to work with the technology. There is time left to pre-empt the retirement of analogue exchange lines and plans to retire traditional, modem friendly services, should be accompanied by products that will provide at least as reliable service with the same reach.

Mobile communications

Water utilities also require good mobile communications to operate their large field teams. To date, the rollout of 3G and 4G has largely passed by the rural areas where we operate our assets. Decisions should be made now to attach conditions to new licenses to get coverage to places where people go as well as where they live. Conditions based on national coverage rates continue to exclude rural areas.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing “regime” refers to the current market, competition and planning frameworks. “Digital communications” includes both fixed and mobile connectivity.

The regulatory regime for telecoms appears focussed on making the market work and does not drive investment in infrastructure. Regimes in the water and rail promote large investment driven by central policy rather than market forces; sometimes with public money. Communications providers, both fixed and mobile, appear to meet regulatory targets by picking off low hanging fruit – like superfast broadband to cities, or rural areas that are easy to reach with fibre. As the number of customers using older services dwindle (typically to those in rural areas), we see these essential services withdrawn because they are no longer popular or are uneconomic to sustain. Regulation needs to be more focussed on ensuring infrastructure is built and services delivered in all areas to ensure essential services remain available.

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

The highest value option would be to extract heat benefit from power generating equipment as in combined heat and power (CHP) to achieve a much higher overall operational efficiency. New communities and housing estates should have distributed heating systems installed as part of their initial construction. Decisions need to be made at the design and planning stages.

The water sector uses many CHP engines to generate electricity from biogas produced within anaerobic digestion processes.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

Zero carbon should specifically relate to the generation of energy and there should be clear product differentiation and carbon labelling, thus supporting consumer choice.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Low carbon vehicles include electric hybrids, plug-in hybrids or pure electric vehicles. Plug-in vehicles will create extra demand on the supplying infrastructure introducing additional peak demand periods. There is a rising need for rapid charging facilities which will require new, specific infrastructure to service. The need for and technological capability to create large battery storage systems could smooth these demands but these systems bring further additional costs

Water and wastewater (drainage and sewerage):

22. What are the most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Water companies have statutory duties to manage and maintain water and sewerage systems to deliver water and sewerage services to their customers. The costs of maintaining and enhancing these services are regulated by Ofwat with the companies presenting five year plans to the regulator through the price review process.

There are a number of projects testing approaches to catchment management, including: Defra Pioneer projects developed under the Government's 25 Year Environment Plan. Recently, the Environment Agency has been working with local communities to set out how to manage flood risk across their catchments.

Defra's 'Catchment Based Approach' (2013)² advocates community participation in decision making, and improving the water environment. Alongside this, the Environment Agency can now better consider ecosystem services³ across catchments and make more joined up decisions about development and infrastructure in a way that can take better account of environmental hazards, including floods and drought. Whilst many of the catchment partners are willing to work together on this catchment based approach, one key challenge to note is around the leadership of a catchment based approach, as current legislation and policy does not determine the lead (who's catchment is it anyway?).

Water supply and water quality concerns often cross local authority boundaries and are best considered on a catchment basis. Liaison between local planning authorities, the Environment Agency, catchment partnerships⁴ and water and sewerage companies from the outset (at the plan scoping and evidence gathering stages of plan-making) will help to identify water supply and quality issues, the need for new water and wastewater infrastructure to fully account for proposed growth and other relevant issues such as flood risk.

One of the challenges of a holistic approach to flood drainage is that the duties of drainage are split across many parties whether water and sewerage companies, highways authorities, lead local flood authorities, the Environment Agency or riparian land owners. Simplification of these duties should be considered to enable clarity to be given to customers affected by flooding and to ensure that an appropriate lead can be determined for action. Water companies could well be an appropriate vehicle to manage and maintain all drainage matters within a catchment, with the Environment Agency managing rivers and maintaining flood and coastal defences.

² <https://www.gov.uk/government/publications/catchment-based-approach-improving-the-quality-of-our-water-environment>

³ <https://www.gov.uk/guidance/ecosystems-services>

⁴ <https://www.gov.uk/guidance/water-supply-wastewater-and-water-quality#catchment-based-approach>

The river basin management plan⁵ prepared by the Environment Agency is the key over-arching source of information on the water environment including the condition of water bodies and measures to help meet Water Framework Directive⁶ objectives.

Resilience of water and sewerage services is important to ensure that these key public services are maintained and continuous during extreme events. Continuous water supply is essential to maintain public health and should be protected to resilience hazards. Maintaining resilient wastewater services is essential to the environment and should be considered to reduce pollutions and ensure that recovery following major events is swift in order to protect any permanent damage to the environment.

Water and sewerage services should be considered as part of the development of the circular economy through the use and promotion of grey water reuse, the generation of energy from sewerage sludge and the recycling of biosolids to land as a natural fertiliser. The South West is a key region for the circular economy as it has such a rich and diverse natural capital landscape which can take advantage of the benefits of the circular economy to improve efficiency and economy of our region.

2.3. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

In the water and sewerage industry, Water UK has led a sector wide initiative in this area, 21st Century Drainage. A key workshop underway within the programme is that of drainage capacity management. This aims to better understand the linkage between current and future pressures on available hydraulic capacity and in turn on outcomes, to facilitate the development of optimal long term interventions.

Our sewer network is in most places a 'combined system', taking both surface water and foul flows. This network is increasingly being inundated by storm water from the catchment. SWW believe that long-term planning and collaboration are key to meeting future demand. As an example, SWW's Downstream Thinking Programme is an ambitious long-term approach, to achieve both the best outcomes for customers in the short term and support our longer term goals by applying the principles of holistic catchment management with the removal of surface water from the combined sewer network.

Sewer flooding is a blight on society, an extremely distressing experience for householders, a health hazard and can be harmful to river ecology. Some traditional solutions, such as massive storm storage tanks or upsizing pipes, might resolve the sewer flooding for a time but unless the whole issue of surface water in the area is tackled, homeowners and businesses will continue to suffer from flooding. This requires partnership collaboration to provide long-term resilience to the network.

⁵ <https://www.gov.uk/guidance/water-supply-wastewater-and-water-quality/#river-basin-management-plan>
⁶ <http://eur-lex.europa.eu/legal-content/EN/ALL/?uri=CELEX:32000L0060>

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Integrated catchment management solutions can be applied to whole catchments to protect and enhance raw water supplies (resilience and quality). The techniques and evidence for successful catchment management are now well documented from multiple practitioners and projects in the UK. The future approach should be whole catchment management and the application of natural capital solutions to risks and challenges that affect all parts of the raw water supply (rivers, reservoirs and aquifers), the treated water networks and waste water/drainage systems. Issues such as raw water quality, low base flows, peak flow excesses and whole catchment nutrient budgets can be addressed successfully through whole catchment management.

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing cost, development pressure and the long-term risks posed by climate change?

The National Flood Resilience Review has looked at how we:

- understand the risks of river and coastal flooding from extreme weather over the next 10 years
- assess the resilience of key local infrastructure (such as energy, water, transport and communications), and identify ways to protect it better
- improve how we respond to flood incidents, including through new temporary flood defences

Even though, the Environment Agency are now designing for exceedance i.e. understanding where water will go when defences are beaten etc. and ensuring it doesn't go towards properties, there will always be a residual risk and this also needs to be explained and understood so members of the public can be prepared and take effective action during a flood event.

As identified in CIRIA Report C688, flood resilience measures should be adopted as an integral part of individual organisation's business continuity management processes, whole life management plans, and climate change adaptation strategies. Critical infrastructure owners need to develop long term strategic investment approaches that allow for optimised investment optimised investment decision making. The economic regulators should aim to provide a framework to achieve this objective.

Through the development of the Water 2020 framework, water companies are working with Defra, Ofwat and the Environment Agency around the development of resilience metrics for water and sewerage services, to measure and incentivise effective decision making for resilient services.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

Following the National Flood Resilience Review, the Government is launching four new trailblazing projects to develop, test and accelerate new ways of managing the environment; this will include a

project in Cumbria, which focuses on natural flood management strategies and up-to-date modelling and data tools. While these tools will undoubtedly deliver benefits in the long term, many of these will take many years to deliver and as a result there remains a need to invest in the short to medium term in order to reduce flood risk.

Solid waste:

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Although we have landfill tax that has discouraged the use of landfill, greater incentives are required to support the installation of new treatment capacity such as anaerobic digestion. Further incentive mechanisms for embedded generation would also be beneficial.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

SWW consider that we already operate in a circular economy in the fact that we currently recycle the vast majority of our treated biosolids to agricultural land in line with the ADAS Safe Sludge Matrix and the recently introduced Biosolids Assurance Scheme.

Incentives to recycle more waste materials in both operational and construction activities would

National Infrastructure Commission - Call for Evidence Southampton City Council response

Southampton City Council welcomes the opportunity to respond to this call for evidence. Southampton has maintained strong economic growth in recent years having weathered the recession relatively successfully – PWC's Good Growth for Cities Index places Southampton in the top 4 fastest growing cities for the 4th year in a row. No single factor can account for this success, but a major feature has been the development of the City Centre Master Plan that provides the basis for £3bn of investment in housing, business space, retail and leisure attractions. More than £1.6bn of development has been completed or has entered the development pipeline since 2010. The City Council through its Master Plan has provided the property industry with a clear vision of what the City Council is seeking to achieve and this has created the confidence for their substantial investment. Confidence is critical in driving investment, and this relates equally well to certainty about the infrastructure that will support all stakeholders making development decisions. The NIC should seek to ensure all parts of the infrastructure jigsaw plan effectively, communicate well, and remain open to adjusting schemes so that they can deliver shared benefit for all investors.

Cross-Cutting Issues

The public transport network in the City, and beyond, is in need of significant additional investment, having suffered from a long period of poor levels of resourcing. In particular, the connection between Southampton and Portsmouth is very poor, limiting the opportunities for people and goods to move effectively. The development of a Solent Metro integrated public transport system is widely supported across sectors and administrative boundaries. The implementation of this scheme, in particular the first phase linking Southampton Airport and Port of Southampton, would assist in improving labour mobility, reducing road congestion, and make a major contribution to productivity.

The Port of Southampton contributes in a significant manner to the local and national economy. It is a key component in the automotive sector's export success and is acknowledged as the largest home port for cruise liners in Northern Europe, joining up the varied infrastructure requirements that support key gateways such as the port is vital – different parts of the system (rail, road, public transport, air, utilities) need to consider improvements in a cohesive manner and developed shared work programmes to deliver improvements that will underpin further growth. Investment in existing infrastructure assets, often designed to deal with far lower densities of housing, movements and business operations, should be considered carefully. Improvements to these assets can assist in engaging with local communities, as opposed to new schemes which often take more valuable land. Ensuring the digital capacity of existing infrastructure to link different elements and ensuring that this enables capacity improvements is vital to taking advantage of demand management opportunities. Public transport usage can be significantly enhanced by quick, accurate and easily received communication about availability, delays and arrival times.

As a coastal City, flood resilience remains a major consideration. Securing flood defences along the River Itchen to protect over 1,000 homes and 650 businesses, but also secure large tracts of development opportunity (up to 2,000 homes) is vital.

The planning cycles of the infrastructure providers need to be better synchronised, be able to respond to regional priorities and be flexible and commercial enough to participate in development opportunities. As land values rise following infrastructure implementation, a commercial concordat of public sector and infrastructure agencies should be in a position to drive development and benefit from rising land values.

Transport

Perhaps the most fundamental change in the next 30 years will be electric and autonomous vehicles. This may allow for much greater utilisation of the road network and modelling should take account of this. It seems quite possible that autonomous vehicles could lead to a wider ability to share vehicles and potentially reduce use at peak times, with a positive impact on congestion. A potential disadvantage of this may be that parking income for local authorities may fall – a key source of funding for highway and transport projects. Charging points for electric vehicles via charging could present commercial opportunities to replace this revenue challenge.

As previously mentioned, the development of the Solent Metro is a key transport initiative required to address the productivity challenge in the City and region. In addition, the development of rail and road infrastructure on the west side of Southampton Water will be critical to enabling the use of the strategic land reserve held by the Port of Southampton, enabling its ongoing expansion, a vital part of the regional economy, and reducing congestion.

Digital Communications

Extending and increasing the speed of the fibre-optic network is critical to enabling the potential of digital technology to be realised and increasing productivity. Ensuring that major infrastructure projects, such a rail and road, make provision for this in implementation seems an important element for developing the grid. Government will need to find a way to ensure the market agrees how to support this approach.

Energy

Energy generation is clearly important – waste to energy plants should be considered an important part of the UK's energy infrastructure, given the other considerable environmental benefits they provide.

At the same time, reducing energy consumption needs appropriate attention – not least the ability to drive up standards of housing and commercial properties. Modern methods of construction are important and need to be supported in this regard.

Flood Risk Management

As already mentioned, flood risk management is vital to the continued growth of the City. A key issue to address is the current stance of the Environment Agency which provides support for schemes that protect existing property (largely housing) with no consideration as to how that funding may unlock development sites, such as the significant potential in Southampton.

National Infrastructure Assessment Call for Evidence Southern Water's Response

February 2017

Introduction

We are grateful for the opportunity to contribute to the National Infrastructure Commission's work to develop a body of evidence for the National Infrastructure Assessment.

The recognition of interdependencies between sectors is critical in meeting infrastructure challenges. The challenges posed by climate change, population and housing growth, and their impact on vital infrastructure, cannot be addressed in isolation. The Institution of Civil Engineers' National Needs Assessment¹ found almost 30% of all licenced abstractions are used for cooling water used in power generation – constituting 5% of all freshwater resources in the UK. The Committee on Climate Change Adaptation Sub-Committee warned the amount of water needed for energy generation could “markedly increase” if there is greater reliance on biofuel production, fracking or carbon capture and storage². This is just one example of where future infrastructure policy must take into account the impact sectors have on each other and the critical role the water sector plays in supporting others.

Likewise, the water sector is reliant on constant, uninterrupted sources of power to provide vital services for households, businesses and integral public services such as schools, prisons and hospitals. We are taking steps to generate more of our own power, and in 2015/16 17.3 per cent of our energy was self-generated – largely through Combined Heat and Power plants on our sites. In total, we generated 77 gigawatt hours and exported 13 gigawatt hours back to the national grid. We have investment plans in place to grow the amount of energy we self-generate, but we will still rely on external sources of power for most of our sites.

Much of the water sector's infrastructure investment has been driven by EU legislation, and Britain's exit from the union provides an opportunity to re-design legislation in a smarter, more effective way. It could also allow greater alignment of planning cycles – such as water companies' price reviews, Water Resource Management Plans (WRMP) and River Basin Management Plans (RBMP). There is also an opportunity to examine potential wider benefits from agricultural subsidies, delivered through the replacement to the Common Agricultural Policy – particularly a closer alignment of land management practices and water quality.

We remain heartened by the NIC's proactive approach to engaging with stakeholders. We attended the South East event, hosted by Hampshire County Council, and found it to be thought-provoking. When developing its assessments and recommendations, we would welcome clarity on where the burden of funding is likely to fall – whether on government, the private sector or a combination of both.

This is a wide-ranging response, so we would like to outline our six key points. They are:

- Infrastructure should be planned using techniques which consider what could happen, rather than basing analysis on the historical record. This is especially important in water resources planning
- Greater integration and collaboration within and across sectors is critical in meeting the challenges of the future and ensuring the resilience of our service is enhanced
- Demand reduction can play a vital role in securing supplies and in ensuring there is sufficiency capacity for growth in existing networks – for both water supply and wastewater services
- Water infrastructure should be recognised as key to supporting economic growth and the “value added” to the region taken into account, rather than just considering impact of failure

¹ [National Needs Assessment](#) – Institute of Civil Engineers

² [Is the UK preparing for flooding and water scarcity?](#) – Committee on Climate Change Adaptation Sub Committee

- Investing in innovation and new technology will be critical in ensuring infrastructure is provided in a cost effective way in the future
- Effectively valuing the natural capital associated with our infrastructure and operations will be critical in developing sustainable and resilient solutions for the future.

We will be responding separately to the Department for Business, Energy and Industrial Strategies' consultation on future industrial strategy but hope that the work of the NIC is closely aligned with any new strategy. As both documents recognise, it is critical that government agencies and delivery bodies are aligned when planning new infrastructure.

We have responded to the areas which are most relevant / topics in which we have direct experience. We would be happy to further discuss any of the points made below.

Cross-cutting issues

What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

The highest value infrastructure investments – both in terms of their capital cost and the growth they are supporting – would be any potential new wastewater treatment works and associated networks to support large developments such as the proposed garden cities in Ebbsfleet and Otterpool, Kent. Due to the size of the developments, it may not be possible to connect to existing assets if there is insufficient existing capacity. We are working closely with the Ebbsfleet Development Corporation (EDC) and local authorities to determine the scale and pace of growth and will develop appropriate solutions as part of the master planning process.

In terms of water resources, the highest value planned investments are two planned water reuse schemes – one each in Kent and West Sussex planned for 2022 and 2026 respectively. These combined will have a benefit of around 40 ml/d across the catchments – at a (currently estimated) combined cost of £107.7 million. Future high-value investments are anticipated to include a desalination plant – the size and timing of which is not yet determined.

We are in the early stages of our next water resources management plan (WRMP) and business plan processes, so will have a clearer idea of costs the further we progress through our plans. While indirect water reuse is currently an expensive option, we predict, due to future tightening of wastewater treatment processes combined with improved technology, the marginal costs of reuse will fall. It also offers greater resilience, particularly at times of drought and potential three dry winter scenarios, where a prolonged lack of winter rainfall will mean groundwater sources, which make up 70% of our water resources will see limited recharge and low river flows will limit our ability to fill our reservoirs.

While there are some specific, high-value investments which will support long-term economic growth, there are many more, smaller projects across our region which will support economic growth by providing essential water and wastewater services. We are glad government continues to recognise the important role of the services we provide by including upgrading water infrastructure in the ten pillars supporting its industrial strategy³.

We make the point below about the importance of improving water resilience to protect against economic damage, but we believe water infrastructure should also be considered as a driver for economic growth, rather than purely a guard against economic damage. Water infrastructure can deliver wider benefits through maintaining or increasing amenity value of the natural environment and plays an important role in protecting species and habitats.

³ [Building Our Industrial Strategy](#) – The Department for Business, Energy and Industrial Strategy

Water infrastructure also plays a vital role in driving growth in certain industrial sectors. We are working with farmers, growers and other abstractors in the Medway catchment on a trading pilot linked to our water reuse scheme to support sustainable growth in their sector. Tourism is another large sector in the south east and our infrastructure – both water and wastewater – plays a vital role in supporting it.

How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

New infrastructure and significant new developments need to be designed holistically, recognising the interdependencies between, and impacts on, housing, water and wastewater services, energy and flood defences. The designs for new infrastructure are likely to be influenced by the needs and location of the development, and new developments should take the needs of infrastructure into account when being designed. For example, new homes in a water stressed area should be water efficient and new developments in areas liable to flooding should have mitigation measures. Water efficiency standards in new affordable and social homes would also have a positive impact on the overall cost of the home for customers by minimising running costs.

By planning new infrastructure alongside new developments, authorities and infrastructure providers can work together to ensure issues such as surface water management can be properly addressed. This could include sustainable drainage systems (SuDS) or including plans for meadows or attenuation ponds to assist drainage and provide valuable green spaces, increasing the natural capital of an area.

It is important to consider existing assets when planning new infrastructure – including housing. We are working with developers, local authorities and our regulators to trial a variable infrastructure charge for a development of around 1200 homes in Hampshire. This will see us waive all or part of our connection fees if a developer proves they have installed water efficiency devices. We hope this will incentivise water efficient development and if this pilot is successful, we will look to extend this approach across our region.

Beyond the design stage, the delivery of new housing and supporting infrastructure needs to be aligned. We are working closely with the EDC to develop a strategic solution for the area, including understanding the certainty and pace of growth, capacity in our networks and considering the need for a new wastewater treatment works. This approach will mean that new homes are built alongside their supporting infrastructure – meaning the 15,000 houses are delivered as timely and cost-effectively as possible.

What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

We are the first water company in the UK to undertake a universal metering programme (UMP). The programme saw us install more than 450,000 meters over five years and means more than 90 per cent of our customers are now metered.

A study by the University of Southampton⁴ found metering reduced household consumption by 16.5 per cent. The study found customers reduced their consumption as a result of the meter being installed – rather than waiting until they would see a financial benefit from using less water.

Customers were not placed onto a measured tariff as soon as meter was installed. There was a three month period where customers' charges were still based on the rateable value of their property.

⁴ [The Effect of Metering on Water Consumption](#), University of Southampton

Three months after this switch, we wrote to customers with an estimated bill based on their consumption since the meter was installed.

The study found customers started to reduce their consumption in the first three months after a meter was installed – before they would receive any financial benefit from doing so. The study also found there was very little rebound from metering, with the average 16.5 per cent reduction in consumption continuing after customers moved to fully metered bills.

Metering customers gave us access to a vast amount of data on customers' consumption habits – meaning we can continue to target water efficiency support in areas with higher consumption. Our programme of water efficiency visits – including retrofitting water efficient devices and encouraging behaviour change – has shown an additional sustained reduction of 10 per cent. It is worth mentioning the Isle of Wight was metered in 1989 and now has a per capita consumption of less than 120 litres per person per day – demonstrating metering drives long-term behavioural change.

On average, Southern Water customers are now using 130 litres per person per day, meaning we have achieved the government's aspirational target for per capita consumption (PCC) of 130 litres by 2030, 13 years early. We believe this demonstrates water efficiency is achievable, effective and there is potential for it to go further and be more widespread. However, the platform of metering is integral to this.

A Green Alliance report⁵ estimated that ambitious water efficiency programmes could save customers almost £80 per year through reduced water and energy bill –, with up to £20 of this coming from reduced energy consumption. The concept of linking lower water consumption with reduced energy bills helped inform our water efficiency messaging – save water, energy and money and it again demonstrates important links between the sectors.

Demand reduction could also help reduce bills by reducing the need for, or deferring, capital investment. The same Green Alliance report uses the example of Barrie, Ontario when faced with a \$68 million bill to meet new demands on its water and wastewater networks, city planners chose to implement a demand management incentive scheme, costing \$4.7 million. This reduced consumption by 1.78 megalitres per day (ml/d) and wastewater entering sewers by 55 litres per household. This resulted in a net saving to the city of \$17.1 million by deferring capital investment of \$21.8 million.

The national long-term water resources framework (see below) advocates enhanced demand reduction measures, including behaviour change and leakage reduction, to reduce per capita consumption (PCC). The report predicts under “business as usual” demand management, PCC could fall to an average 130 litres per day. Enhanced demand management – including large scale mains replacement to address leakage, all new homes being water efficient to 105 litres per head and extensive retrofitting – could see savings of 5,000 ml/d⁶.

As part of our future planning, and building on our metering programme, we are starting to think about possible different tariff options. These could be reflective of the cost of supplying water in each area, the level of investment required to maintain services or to achieve certain environmental objectives. Tariffs could also be reflective of the amount of water a customer uses – either “reward” tariffs for those who use less, or higher tariffs for those who use more. Using data from our meters, they could also be dependent on the time of day water is used to reflect the increased costs during peak times.

At this stage, this is just indicative of our thinking and is not company policy. If we were to follow this thinking, we would undertake detailed studies and engage with customers, stakeholders and our

⁵ [Cutting the cost of water](#), Green Alliance

⁶ [Long-term water resource framework](#) – page 102 – 106 – Water UK

regulators. With any potential tariff options, we would consider the impact on affordability and customers in vulnerable circumstances.

What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Greater collaboration between local authorities, developers and infrastructure providers is integral to ensuring large developments are built as timely and cost-efficiently as possible. We are working closely with EDC to ensure the garden city development is a success and that, where possible, infrastructure construction can be done in a co-ordinated and efficient way through the use of utility corridors.

As mentioned above, there is a strong link between water and energy efficiency – with benefits both to consumers and infrastructure providers. Greater coordination and shared messaging between different utility sectors could have a significant impact on demand for relatively low cost. The Green Alliance report calls for water and energy efficiency programmes to be integrated, lowering their cost and reaching a wider audience. This was originally recommended in the Walker Review in 2009⁷, saying “hot water efficient fittings should be included in any energy efficiency retrofitting scheme”.

Catchment management will only be successful through collaboration with key stakeholders – ranging from small landowners and farmers, to local authorities and organisations such as the National Farmers’ Union. Whether this is through joint funding of Catchment Sensitive Farming Officers – which we are doing with Natural England – or new ways of working such as water trading and funding models which would need support from government and stakeholders⁸.

The variable infrastructure charge pilot, mentioned above, is an example of multiple sectors working together to minimise the impact on existing infrastructure, provide a financial benefit for consumers and lay the groundwork for an approach which could be mirrored elsewhere.

Water Resources in the South East (WRSE)⁹ is a group comprising of the six South East water companies along with our regulatory bodies – Defra, the EA, Ofwat, CCWater and Natural England – with the purpose of developing long-term plans for securing water supplies and identifying strategic solutions. The aim is to develop a regional water resources strategy with the most appropriate long-term solutions for customers and the environment. This collaboration is particularly valuable in the south east, given the crossover between companies and potential for shared benefits from catchment management and inter-company transfers. We do, however, recognise greater integration between companies will be required so at a regional level the plans offer the highest level of resilience and the best value for customers.

There is also opportunity for it to be extended to capture the needs of industry and agriculture to ensure the water needs of other key users are planned in a more holistic way. Further work will be needed to consider how multi-sector funding arrangements could be put in place. A study commissioned by Anglian Water considered a number of possible funding arrangements, each with strengths and weaknesses, which could be supported by multiple parties to bring wider benefits such as alignment of water resource planning¹⁰.

Competition can play an important role in driving innovation and efficiency in the delivery of services and infrastructure. For example, we anticipate the non-household retail market will drive innovation in demand management by incentivising retailers to help their customers save water and money.

⁷ [The Independent Review of Charging for Household Water and Sewerage Services](#) – Anna Walker

⁸ [New markets for land and nature](#) – Green Alliance

⁹ [Water Resources in the South East](#)

¹⁰ [Financing Multi-Sector Water Supply Assets](#) – FTI Consulting

However, the role of markets in delivering services can be overstated and markets alone should not be relied on to deliver an optimal level of resilience. As in our response to the NIC's consultation on the methodology for its National Infrastructure Assessment, we feel it is important there is a clear policy framework with decisions taken about what is delivered reached collaboratively, while harnessing competition to drive innovation in how it is delivered.

What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Much of our investment in infrastructure is in response to demand – either environmental protection or to meet the needs of growth. Environmental protections can be factored into our long-term planning, but growth needs can arise outside of our usual five-year funding periods – despite the work we do to understand local planning expectations. If we are unable to raise or recover funds needed to provide necessary infrastructure, this could delay a development. A mechanism could be put in place for infrastructure providers to raise or recover funds partway through a regulatory period if necessary to fund significant infrastructure projects.

The switch to a total expenditure (totex) approach in the water industry has encouraged water companies to consider demand reduction measures alongside new sources by removing the “implicit financial incentive to favour” capital assets over water efficiency programmes¹¹. It is also supporting the industry to try more catchment-based solutions to address issues such as water quality, rather than relying on more expensive end of pipe solutions. However, there are still limits on the certainty of success of such schemes and the timeframe required to see benefits, which poses a challenge under our current regulatory and financing structure.

Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Investment in infrastructure is by its nature long term and investors will require some surety over being able to make a return on their investment. Within regulated sectors the Regulatory Asset Value was created to provide this degree of surety and ensure investment can be financed at reasonable cost. As regulators seek to open up markets in infrastructure services they naturally will wish to consider the extent to which such long-term guarantees are compatible with a market.

This creates a risk that necessary, long term investment is unable to be financed and will not be provided at the right level. It will be important that, if RAV-protection is not provided for new investment, then an alternative mechanism exists to ensure that investors are able to earn a reasonable return on their investments. This could be through a government guarantee, but will more likely be better effected through the creation of long-term contracts (either real or deemed) which ensure that over the life of an asset, the investment can be recouped.

How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

In the National Flood Resilience Review, government said it was proactively working with utility companies to establish “a national infrastructure resilience council or forum”. This, when it is established, should provide a way of enhancing collaboration and coordination between infrastructure providers. In addition to addressing short-term resilience to flooding, the council/forum should be asked to consider longer-term resilience challenges such as reducing the risks of future flooding and water resources challenges.

¹¹ Cutting the cost of Water – Green Alliance

The National Infrastructure Commission must ensure it uses its position and remit to share best practice and highlight areas of concern between sectors to ensure they can be addressed. It must push, as much as possible, for holistic solutions to infrastructure challenges and encourage collaboration, cooperation and communication across sectors. It could consider creating a database of planned infrastructure projects and their likely demands on infrastructure, such as water and power. This would give greater sight of the demands future infrastructure will have on other key infrastructure and allow for informed planning, possible identification of interdependencies and opportunities for collaboration between infrastructure providers.

This could also highlight how reliable sources are, and the expected recovery times to bring them back online after a shock. This would assist with planning against high-impact, low-likelihood events and what level of resilience providers should consider to be as cost-effective as possible. This would be particularly critical for the interdependency between water and power companies. For example, a wastewater pumping station could be reliant on a particular electricity sub-station. We would benefit from understanding the probability it could be taken offline by flooding and how long it would take to become operational again. This way we could plan for appropriate levels of back-up power supplies or arrange for additional fuel for on-site generators.

Local groups will play an incredibly important role in improving the resilience of our infrastructure systems. Local authorities are responsible for surface water management, and local groups – such as local resilience forums – have a wealth of knowledge that can help identify potential resilience gaps. These groups are important in bringing groups of stakeholders together to address short and long-term challenges in specific areas and their significance should not be overlooked.

Moving towards a circular economy approach will also help reduce some interdependencies. In 2015-16 Southern Water generated 17.3% of our energy from renewable sources – largely from the 16 combined heat and power plants (CHPs) on our sites, powered using biogas from sludge – a by-product of the treatment process. These generated 77 gigawatt hours over the year. This reduces our reliance and demand on local power infrastructure and, in some cases, can support it. Of the 77 gigawatt hours we generated, 13 were exported to the national grid.

We are increasing the amount of generating capacity we have to 14.1 megawatt hours by improving CHP engines at a number of sites. Our largest wastewater treatment works will become around 95% self-sufficient, with another, smaller site becoming totally self-sufficient.

What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

As mentioned above, for the most part we build new infrastructure in response to a demand – either meeting environmental or housing growth requirements. When planning and designing the required infrastructure, we work to ensure as little disruption to the local environment and customers as possible.

When infrastructure is considered as necessary for economic growth, some of the planning hurdles could be lowered – or removed – and greater priority could be given to it to ensure planning permission is granted in sufficient time for the infrastructure to be built. We would welcome a review of planning guidance regarding economically significant infrastructure to see if it can be simplified or streamlined.

How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Infrastructure providers would benefit from a fuller understanding of the natural capital of an area as this would give us a better appreciation of the impact of our assets.

For water companies, natural infrastructure such as groundwater sources and rivers are a critical part of our wider networks. Being able to better value these assets, and incorporate this into our decision making, will enable us to choose solutions which provide greater environmental benefit and enhance the resilience of the natural infrastructure we rely on. We previously developed a shadow pricing approach which took water scarcity into account when considering the cost of water abstraction. This approach promoted alternative solutions to those in our previous WRMP¹² and have encouraged Ofwat, the EA and Defra to consider how this method could be used to complement the Abstraction Incentive Mechanism approach. We welcome the work of the natural capital committee, and look forward to understanding how the NIC will incorporate natural capital accounting into its plans.

A better understanding of natural capital could, for example, mean we find it would be beneficial to divert an outlet from a wastewater treatment works upstream of a wetlands, rather than releasing treated effluent into a river. It would also give all water users in a catchment a better understanding of the impact of abstractions, support licence trading and could lead to innovation in areas of water storage and reuse, as alternative, less detrimental sources are required.¹³

It is important to consider soft infrastructure solutions as well as “hard” capital investment. Moving towards greater integration in catchments, and more applications of natural flood management and SuDS, will also enhance the natural environment in an area. Catchment management methods such as, for example, planting trees can have benefits to flood prevention and providing a habitat for wildlife. SuDS such as drainage ponds can provide valuable green spaces to otherwise urban areas.

What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

There is a strong argument to consider alternative cost-benefit measures when planning infrastructure and moving away from basing decisions on customer’ willingness to pay towards factors such as the cost to the economy. The impact on vital public services – schools, hospitals and the emergency services – should also be considered.

Within the water sector cost benefit analysis is typically based on customers’ willingness to pay for investment through their bills, as a benefit value. In general, this works well and helps to maintain the legitimacy of the water sector. However, there may be circumstances where these techniques will deliver a service that does not capture the wider benefits to society. For example, we know the cost to the wider economy of water restrictions is significantly in excess of customers’ willingness to pay to avoid such events. The National Water Resources Framework project estimated a cost of £1.3 billion per day to the wider economy if level 4 water restrictions were introduced. In areas such as London and the south east which make a significant contribution to GDP, this would be felt most acutely. We would welcome guidance on how these wider costs should be reflected in cost benefit analysis, while being mindful of the issues around legitimacy and affordability.

How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Where appropriate we will seek to repair, refurbish or maintain existing assets rather than build new ones. This is primarily due to the costs and disruption associated with putting new assets in place. In the future we will increasingly rely on new technologies to ensure we can still make the best use of our existing asset base.

¹² [Interconnection and Bulk Water Trade – Part 1: Modelling Scarcity](#) – Southern Water

¹³ [Water 2020: Water resources: proposed changes to enhance the scope for innovation and competition](#) – Southern Water

In our 2015-2020 business plan¹⁴ we outlined our plans to replace or refurbish around 310 kilometres of our water mains by 2020 – representing two per cent of our total network. This includes replacing around 30km of water main in Chatham, Kent to improve the supply of water to almost 13,000 customers. This is in addition to the nearly 50km previously replaced.

Also in our business plan, we will be replacing or refurbishing over 220km of sewers. Again, due to the high cost of replacing and renewing our sewers we are targeting this investment in the areas we know we can bring about the most benefit. This is part of a longer term approach to replacing and refurbishing sewers where their condition deteriorates, have insufficient capacity or become prone to flooding.

Making the economic case for large-scale replacement of pipes is difficult, and may not be necessary. Technological advances means it is easier, cheaper and more effective than before to repair and refurbish pipework against a variety of different challenges and in a number of environments. These advances, combined with consistently improving performance means large-scale replacement does not make economic sense. Our programme to find and fix leaks – including identifying leaks on customers' supply pipes – has been successful without the need for large scale renewal and replacement.

We have a large programme of repair and maintenance underway during this AMP. This will help improve site performance and efficiency, as well as extending the life of existing asset in a cost-effective way. It is important to strike a balance between ensuring our services are resilient while keeping customers' bills affordable.

Taking a modular approach to design is another way of reducing the need for new infrastructure, by ensuring our assets can be modified at a later date with additional capacity or treatment facilities as needed. This can improve the resilience of a site as well as reduce, delay or negate the need for otherwise expensive capital investment.

Water and wastewater

What are the most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Universal metering

Water companies' Water Resources Management Plans (WRMPs) are a valuable source of evidence. They are produced every five years, and outline how companies will meet their water resource needs to a 25-year horizon. They take local factors into account, such as predicted growth and the geology and geography of a region.

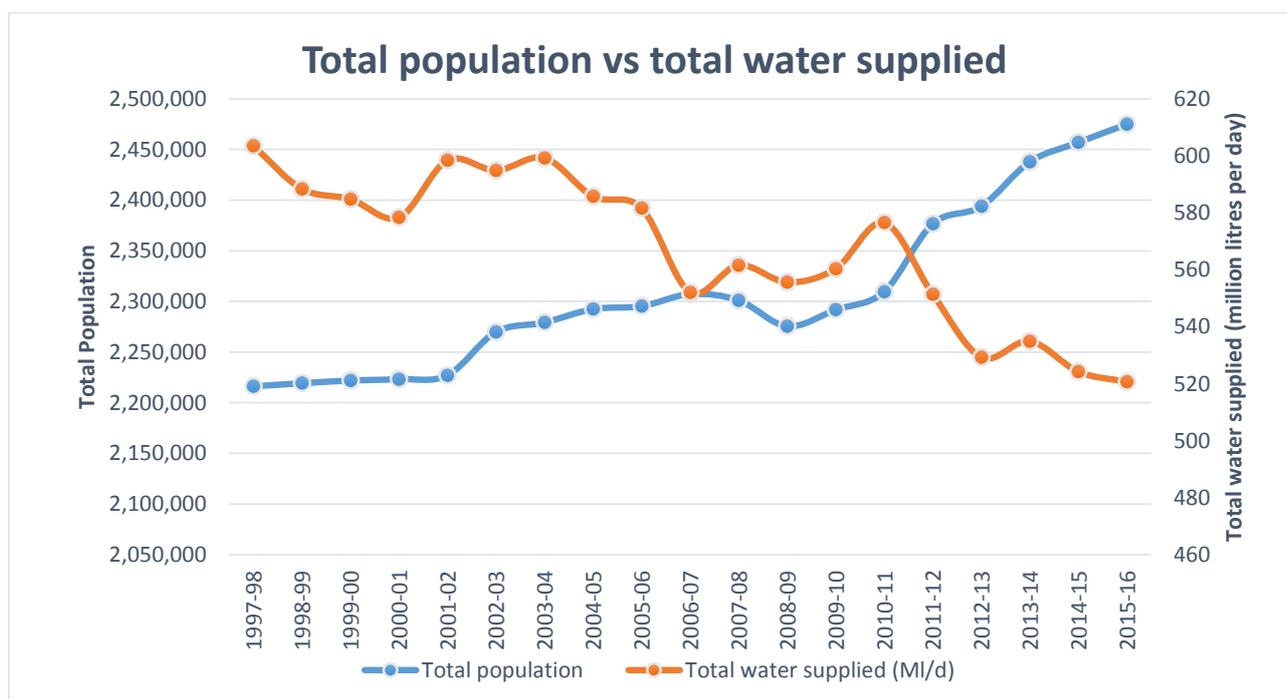

¹⁴ [Five-year Business Plan 2015 to 2020](#) – Southern Water

As mentioned above, our UMP reduced household consumption by an average of 16.5% with little evidence of a rebound effect. This, combined with demand reduction measures such as large-scale leakage reduction and water efficiency programmes has seen our per capita consumption (PCC) fall

to 129.72 litres per person per day and means we are putting less water into supply now (521 ml/d) than during drought restrictions in 1976 (550 ml/d). The graph above shows how the amount of water we put into supply has fallen over time.

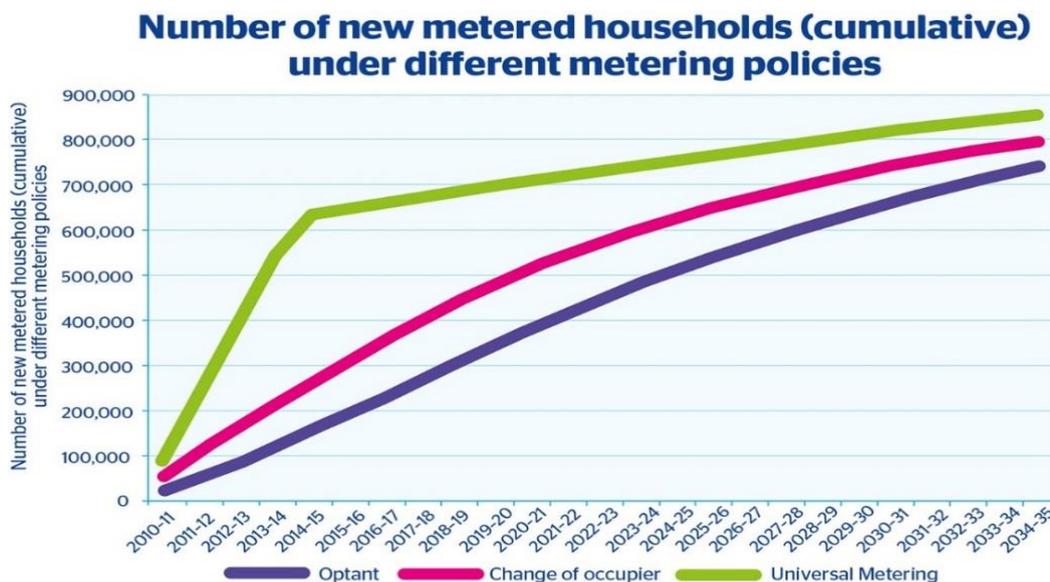

The next graph shows the contrast in population growth in our water supply areas with the amount of water put into supply. For reference, UMP started in 2010. It clearly shows the downwards trend in water put into supply against a continued increase in population – with notable differences from 2009-10 onwards.

In our WRMP 2010 – 2035¹⁵, we examined three different metering policies – optant, change of occupier and universal metering. Based on using “intelligent” meters read using a drive-by facility, and factoring in reduced operating costs from a 10 per cent drop in demand, universal metering was

¹⁵ [Water Resources Management Plan – 2010 – 2035](#) – Southern Water

found to be the most cost-effective – more than £7 million cheaper than optant metering and almost £22 million cheaper than change of occupier metering. The graph below shows how effective universal metering was projected to be in contract to optant and change of occupier policies.

There is a case to consider allowing water companies to consider universal metering, whether or not they are in a water stressed area. Our experience demonstrates it is the most cost effective and efficient way of metering a customer base and can significantly reduce household consumption. We would be happy to share our experience of metering and have already worked with the Consumer Council for Water on research into how to improve the experience for customers¹⁶.

National long-term water resources planning framework

The national water resources long term planning framework¹⁷, developed by water companies in England and Wales and published by Water UK, provides the first detailed, long-term look at national water resources needs and is a valuable source of evidence. It found droughts of the future will be more severe and geographically widespread than previously thought and the potential economic impact of inaction could be as high as £1.3 billion per day during severe droughts. It advocates a number of interventions, both policy changes and capital investment. One of which is looking to a 50 year time horizon to fully understand the impacts of climate change and population growth on water resources. We encourage the NIC to extend its ability to examine future needs from a 30 year horizon to a 50 year horizon.

The most important intervention to take from the long-term framework is the use of new techniques to understand and plan against uncertainty. The framework uses stochastic modelling – a technique pioneered in the water industry by Southern Water – to examine a wide range of different possible weather scenarios. By changing the fundamentals of our approach to planning to what could happen, rather than what has happened, our infrastructure will be in a much better position to deal with the uncertainties of tomorrow.

This modelling approach will feed into new design standards based on a number of different factors and should be supported by decision making techniques which allow for uncertainty, such as Real Options. This approach allows plans to be developed which meet current demands and pressures, whilst still being resilient and adaptable to future scenarios – based on outputs from stochastic

¹⁶ [Beneath the Surface: Customers' Experiences of Universal Metering](#) – Southern Water and Consumer Council for Water

¹⁷ [National water resources long term planning framework](#) – Water UK

modelling. This modelling and decision making will determine which options are most appropriate for the “twin-track” approach, explained below.

The report makes a strong case for a national minimum standard of resilience, to ensure all customers receive the same level of resilient service, providing it is set at an appropriate level. This could be achieved for a relatively low cost of £4 per household. The most appropriate approach to achieve greater resilience is a “twin-track” of enhanced demand management and new resources – including inter-regional transfers between companies. More extensive demand reduction measures includes further work to reduce leakage, significant changes to consumers’ behaviour and increased efficiency of new homes.

Large scale transfers of water between companies potentially “offer some of the best value options” to address the supply and demand balance after demand reduction measures have been implemented. Despite possibly offering the best value solutions, transfers face a number of environmental, technical and commercial challenges which require detailed investigation before the benefits could be realised – including identifying which body would be the lead planning authority for nationally significant infrastructure which crosses multiple local authority boundaries.

The report makes the case for a national level adaptive plan which would support ongoing WRMPs and balances risks against opportunities to defer costs. This adaptive plan would identify key “trigger points”, which would determine which “investments and policy decisions would be needed for the 2040 and 2065 horizons” – dependant on how risks materialise. Southern Water has taken a step towards this by using a Real Options approach to determining which investments would be suitable for current needs – while still being suitable for a number of future scenarios.

It is increasingly important to support capital investment with catchment based programmes such as more effective land management or nitrates reductions. For example, we are investing in four nitrates removals plants in Sussex with supporting catchment management work to negate the need for the plants in the future. Across our region, we are spending around £700k to investigate 25 sites across to inform future catchment management work and around £2.5 million to mitigate the impact of pesticides.

We release around 860 ml/d of highly treated wastewater into rivers, estuaries and out to sea. We recognise the potential for this to become a resilient supply of water and are planning two indirect water reuse schemes – one in Aylesford, Kent and one near Ford, West Sussex. We will redirect highly treated final effluent upstream of abstraction points to augment flows and provide a combined 40 ml/d across the two catchments.

These are both being supported by trading pilots to ensure that the additional water is used effectively by abstractors that need it most, and the environment is protected from over-abstraction. Due to possible misconceptions about water reuse, these projects will be supported by customer and stakeholder engagement to allay concerns and ensure we get the greatest benefit from our investments. In the Medway catchment we are working closely with the agricultural sector

Other interventions

As with wastewater provision, we need certainty to effectively plan our water infrastructure. The work of the NIC is welcome in helping to determine future infrastructure needs and identifying interdependencies.

The 25-year plan for the environment should be published, consulted on, and finalised as soon as possible – while still undertaking a thorough development process. It needs to accept a range of possible future scenarios and have capacity to adapt to changing challenges from climate change and population growth. We welcome the suggestion by the Natural Capital Committee that the 25-

year plan is put on a statutory footing and encourage a regular review process to be adopted. This will allow the plan to be adaptive and reflect the most current research.

It would be beneficial to understand through the 25-year plan what future ecosystems will look like. This will help providers plan infrastructure more effectively as the levels of protections required for certain species may change. It will also help water companies better understand the possible impacts on raw water quality and if alternative sources need to be identified.

Continued innovation and investment in new technologies will be extremely beneficial – as will a focus on circular economy approaches. Demand management – leakage, metering and water efficiency – have all been effective. Likewise, storage reservoirs have been successful, but the space for new reservoirs is limited.

Continued investment in research and development will lead to new technology and techniques which will address these problems. We agree with government when it says “we must become a more innovative economy” and agree that investing in science, research and innovation is a key pillar to support its industrial strategy.

As part of our investment in research and development, we are looking into alternative methods of finding and fixing leaks. Our current echo correlation techniques for finding leaks are less effective with plastic pipes than metal ones. As a result, we are looking at methods such as ground-penetrating radar to find leaks. We will also be collecting more data, and making better use of it. We are looking into increasing the amount of data points on our networks and feeding this data into smart algorithms. These algorithms will help us to balance the pressure in our networks, reducing the likelihood of bursts and leaks.

More efficient technology for water reuse and desalination will be extremely beneficial. As mentioned above, more efficient technology combined with increased wastewater treatment standards will drive down the marginal costs of water reuse. Treating highly-treated final effluent as a resource rather than a waste product will make more water available in a catchment for public supply, businesses and the environment.

What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

One of the most effective interventions to ensure drainage and sewerage capacity is sufficient to meet future demand is removing surface water from the wastewater networks. To help achieve this, we would like to see the automatic right for developers to connect surface water systems to our networks end unless alternative methods have been given proper consideration.

We – alongside most of the water industry – asked our regional MPs to support the Lords amendment 110 to the Housing and Planning Bill which would have removed the automatic right to connect. Before connecting surface water systems to our networks, developers would have had to ensure they had properly considered SuDS as an alternative. We welcome the upcoming review of SuDS legislation and hope it is full, thorough and takes serious consideration of stakeholders’ views.

To give an example of the costs of removing surface water from wastewater networks, we invested around £20 million on a surface water separation scheme in Portsmouth. This scheme removes up to 6,400 litres per second of surface water from the wastewater network during rainfall, reducing the burden on the network and our pumping station by up to a third, thereby dramatically reducing the risk of flooding to Portsmouth, its critical infrastructure and nationally important naval base. Crucially, this also makes additional capacity available for new growth – without the necessity for additional infrastructure.

While investment may be needed to separate existing combined surface water and wastewater networks, there is no reason new developments should automatically have the right to connect surface water drainage to wastewater networks – unless other options such as separate surface water networks or SuDS have been properly considered.

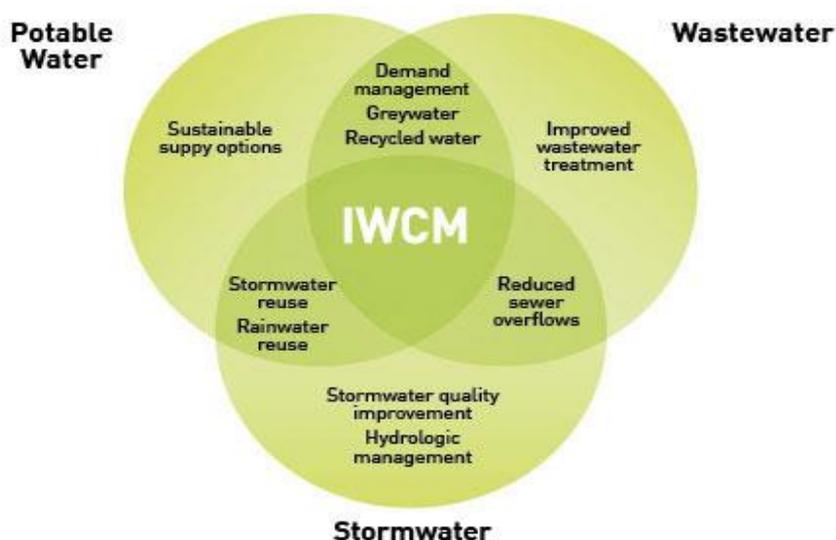

Encouraging a modular approach to asset design will help ensure assets have sufficiency capacity to meet future demand. By ensuring new sites have suitable technology and space to expand if necessary, it will make it easier for water companies to quickly adapt to changing growth patterns. This may need to be included in planning applications for new sites, so would benefit from supportive planning guidance.

An example of where we are taking a modular approach is our Tangmere wastewater treatment works near Chichester, West Sussex. We recognise the need to expand capacity to meet immediate growth, but also that Chichester is likely to experience growth in the future. This approach means we can be flexible and add additional treatment capacity, without the need for a new treatment works.

How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

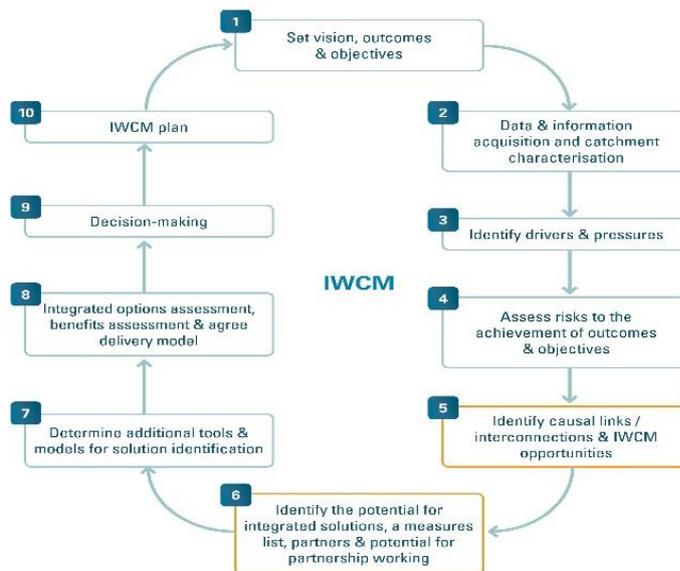

We believe greater integration and coordination is the most effective way of using a whole catchment approach. A single plan for water would be the best way to manage water, wastewater and flood management systems and we are very keen to see best practice and learning emerging from Defra's current Pioneer projects.

We are developing an Integrated Water Cycle Management¹⁸ (IWCM) approach to help us address multiple, complex issues at a catchment scale. We will work in collaboration with stakeholders to drive innovation and deliver the most effective solutions for our customers and the environment. This is an innovative approach and our ambition is to be operating a fully integrated water environment, across catchments, in a phased way, by 2040.

We recognise the issues and opportunities related to water management are complex and inter-related, but that there are significant benefits to be derived from an integrated approach. To start to understand what IWCM means in practice we have developed a 10 step approach (see below).

¹⁸ [Integrated Water Cycle Management](#) – Southern Water

To further develop our understanding we are focussing on two catchments, the River Medway catchment in Kent, and the Arun and Western Streams catchment, which takes in large areas of West Sussex and parts of east Hampshire. These catchments have been chosen due to their contrasting features. The Arun and Western Streams is relatively small and rural in nature while the Medway is the largest catchment in south east England and Wales and has considerable urban pressures.

We are developing an evidence base and a number of tools to help us understand where integrated catchment solutions could deliver the greatest benefits, and how we embed this way of working. As well as potential cost savings, IWCM offers an opportunity to deliver wider benefits for our customers and stakeholders and we are exploring how we might use natural capital accounting to capture this. We plan to develop a number of pilot catchment schemes for inclusion in our PR19 Business Plan in order to test and further refine our approach, although we will implement sooner if opportunities arise.

Collaboration with key partners across catchments is essential to ensure that we focus on the most cost beneficial opportunities and deliver multiple benefits for customers and for the environment, now and for future generations. We recognise that there are existing mechanisms such as catchment partnerships and strategic flood risk management groups who can help us develop and deliver our IWCM approach through collaborative working. Collaborative working includes the potential for securing partnership funding from stakeholders with associated risks.

Considering water in a catchment holistically is important to understand the opportunities and the risks associated with certain interventions. It is also critical to recognise that not all catchments are the same and so interventions need to be take regional characteristics into account. Research has been focussed on upland catchment management but lowland catchments, especially those with groundwater connections, are complex and less well understood in terms of effective interventions. We are planning to host a workshop with key stakeholders to share best practice on lowland catchment interventions and help inform our approach.

The benefits of some catchment interventions may not be seen for many years (e.g. reversing trends in nitrate levels in groundwater) and we welcome the Natural Capital Committee's recommendation that Ofwat gives water companies "sufficient scope" to develop catchment approaches. We hope this includes the ability to plan to deliver benefits outside of the usual five year regulatory timeframe.

We understand measuring natural capital can be challenging – particularly with regard to water. The Office of National Statistics found "data and methodology limitations" prevented it from fully valuing the natural capital of water in the environment and so only included domestic and non-domestic water supply in its 2014 calculations¹⁹. The Natural Capital Committee has called for Ofwat to "encourage" natural capital catchment based approaches for the next price review process and recognised water companies as "key player in influencing natural capital" in catchments²⁰. We are using natural capital as part of our IWCM benefits assessment work to start to understand how we might practically incorporate this into our business planning. To support this, case studies and best-practice guidance would be welcome – particularly if this was agreed and adopted by government and regulators.

As this field is still developing, we believe it is incredibly important all parties look to take best practice from across the UK and beyond. When developing IWCM, we have looked to Australia and North America for their experience of operating in more integrated catchments. We have found working with universities to be incredibly valuable. Working with academia has brought fresh, independent thinking to projects and switched our approach from focusing on what we can currently do, to what we could do. This is leading to the development of transferrable skills and knowledge giving us much more dynamic understandings of the catchments we work in.

Flood Risk Management

What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

Setting a national minimum level of resilience to flooding, particularly when needing to balance cost-effectiveness, is difficult. Companies could invest to achieve a certain level of protection at specified sites, but this investment may not be cost effective. It may be more effective to have regional levels of resilience, depending on risk and wider economic impact.

The level of resilience should not only reflect likelihood of disruption, but also the economic or societal significance of the area. For example, London is protected against 1 in 1000 year flooding events due to its economic importance. Our surface water separation scheme in Portsmouth increase the city's resilience to 1 in 76 year events – due to its specific topography and the nationally strategic importance of the naval base. Water companies usual plan against 1 in 30 year events.

It is important to consider recovery as well as protection as part of resilience. When considering flood protection schemes, a key part of the cost-benefit analysis, alongside the impact of disruption to service, is the relative cost of recovering from an event. Taken as a hypothetical example, it could cost £1 million to make a site resilient to a 1 in 100 year event, while the cost of recovering from that shock could be £300,000. In this instance, it may make better economic sense to have plans in place to recover from an event that may not happen than protect against it.

What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

We support the development of natural flood management schemes and practices such as enhanced land management in reducing flood risk. As above, we are undertaking significant research into the

¹⁹ [UK Natural Capital – Initial and Partial Monetary Estimates](#) – ONS

²⁰ [Improving Natural Capital – An assessment of progress](#) – Natural Capital Committee

efficacy of catchment management and will be hosting a workshop to enhance our understanding of how upland catchment management practices can be successfully adapted to the lower-lying terrain of our region.

One of the drivers behind the research and workshops is to determine a level of certainty about how successful natural flood management schemes are. We are heartened that schemes such as slowing the flow in Pickering have been successful, but need to understand how effective they will be in our area.

Another concern, is the issue of continued ownership and maintenance. For example, if a water company pays for a farmer to plant trees on their land to reduce the risk of flooding downstream, and the farmer then sells the land, would the ownership of the trees be with the water company or the new owners, and would they be under an obligation to keep and maintain the trees?

We believe there should be a balance of traditional “hard” infrastructure supported by natural flood management schemes. This would allow for surety on levels on protection and developing innovative, greener ways of managing flood waters.

NATIONAL INFRASTRUCTURE ASSESSMENT: SSE RESPONSE

About SSE

SSE is a UK-listed utility and the broadest based energy company operating in Great Britain and Ireland.

SSE's core purpose is to provide the energy people need in a reliable and sustainable way. We operate across the energy value chain in GB from generation and production, through to transmission and distribution, and finally supplying electricity and gas to households and businesses. SSE has operations across the UK and independent research by PWC found SSE made a £8.78bn contribution to UK GDP in 2015, indirectly supporting around 106,000 jobs.

SSE welcomes the opportunity to respond to the National Infrastructure Commission's (NIC) National Infrastructure Assessment (NIA) call for evidence. The NIA represents an ambitious and important undertaking and could help ensure risk is managed and opportunities are grasped.

Executive Summary

The UK requires significant infrastructure investment to 2050 to support and maximise the benefits of the changes occurring in key sectors including energy, transport and communications.

SSE looks forward to supporting the National Infrastructure Commission (NIC) with regards to their three objectives to (i) support sustainable economic growth across all regions of the UK, (ii) improve competitiveness and (iii) improve quality of life.

It is important that the regulatory and policy framework(s) are fit for purpose to enable efficient markets to develop whereby all providers, including customers, are able to compete. Energy related technology and infrastructure has significant long-term impacts on meeting the three objectives the NIC have set. Therefore the NIC can play a key role in balancing the short and long term requirements of the energy system and its users.

SSE strongly supports the UK Government's decarbonisation aims and targets. The National Infrastructure Assessment (NIA) presents an opportune moment to consider how the heat and transport sectors can play a greater role in transitioning the UK to a cost-effective, low-carbon economy. These sectors will be underpinned by the energy assets that are built over the next decade. Therefore clear policy direction is necessary for the UK's heat and transport sectors to be underpinned by a low carbon electricity system from 2030-2050.

The emergence and uptake of low carbon technologies, electrification of transport and decarbonisation of heat will provide significant challenges to the GB electricity networks. Innovative solutions will allow networks to provide better services at lower cost, whilst opening up new marketplaces for other industry participants. The NIA's recommendations should facilitate the objectives of ultimately providing lower cost and sustainable electricity supplies for consumers as well as the chance to contribute to the efficient functioning of the country's energy infrastructure.

Energy Networks

The NIA should explore how the Government can ensure the UK's electricity network is both resilient and able to maximise opportunities from innovation

- The UK has led the way in stable, robust and efficient price control mechanisms (RIIO) which have delivered significant investment due to 8-year regulatory stability, maximising value for customers' money.
- Evolution towards a smart, flexible energy system must prioritise the interests of the end consumer. SSE supports a consumer-centric approach that will thoroughly examine the risks to consumers as a priority.
- SSE believes that consumers' and the UK's interests are best protected by a transition of the Distribution Network Operator (DNO) to a more active Distribution System Operator (DSO).
- DNOs will need to transition to new roles and are best positioned to support the efficient connection and utilisation of new flexible and dispatchable resource below the Grid Supply Point (GSP).

Energy efficiency

SSE believes improving the energy efficiency of the UK's housing stock should be a national infrastructure priority

- SSE believes the NIA should consider how future funding of energy efficiency programmes, and strongly supports eschewing regressive models of funding.

- Two thirds of existing properties in the UK will still be in use in 2050. Ensuring these properties are as energy efficient as possible can help not only reduce carbon emissions, but also lower consumer energy bills.

Heat

The NIA should explore a ‘whole-systems’ approach to the decarbonisation of heat

- SSE envisages a whole systems approach can be delivered through a mix of district heating, repurposing of gas distribution networks, and reinforcement of electrical distribution networks.
- Long-term sustainable growth in the district heating sector will be dependent on the development of effective legal and commercial structures that encourage investment and attract private sector expertise.
- Technologies that use electricity to generate heat are well placed to become major low carbon heating technologies in the coming decades as a greater proportion of our electricity is generated from low carbon sources.
- SSE urges that national infrastructure decisions are driven by the best information available and in the case of decarbonising heat more should be done to acknowledge the reducing electricity emission factor.

Decarbonised Transport

Removing barriers toward the decarbonisation of transport whilst ensuring the infrastructure critical to delivery is supported and protected

- Electric Vehicles (EVs) have demonstrated significant demand side response potential, which is particularly important to utilise low carbon generation at traditionally low demand times.
- Without managed EV charging, customer education, and time of use tariffs there is a risk that the high cost (networks/supply) associated with their peak demand will prohibit their uptake.
- The NIA should explore the benefits of standardising EV charging through dialogue between industry stakeholders and government. This can help avoid a system hampered by multifarious systems and technology, incapable of communicating and facilitating managed EV charging.
- The NIA should consider the role of hydrogen in delivering the UK’s decarbonisation in the transport sector, and how to develop and support hydrogen refuelling stations that maximises fuel cell electric vehicles (FCEVs) uptake in the coming decade.

Digital Communications

The digital communications regime needs to develop comprehensive, independent and transparent market governance arrangements

- SSE strongly believes that retail market governance arrangements for the digital communications sector should be developed in order to support the consumer switching experience
- An effective digital communications regime will coordinate processes ‘behind the scenes’ in order to ensure that consumers experience a seamless switch of services between different retail providers.
- SSE therefore supports the NIA exploring how elements of a traditional utility regulatory and statutory framework could be developed in the digital communications regime.

Section 1: Cross-cutting issues

What are the highest value infrastructure investments that would support long term sustainable growth in your region?

Energy efficiency

The decarbonisation of heat in the UK is a pressing challenge that requires greater levels of focus if we are to meet our future climate change targets. Heat represents almost half of final energy consumption in the UK and is an essential element in meeting the UK's decarbonisation targets. Improving the energy efficiency of the UK's housing stock should be made a national infrastructure priority. Two thirds of existing properties will still be in use in 2050 and 65% of the housing stock in England could benefit from energy efficiency improvement. Therefore the NIA should consider what actions need to be taken now to reduce the UK's carbon emissions from heating.

SSE advocates the Government takes a 'fabric-first' approach that ensures that improvements to heating networks will be maximised for households today and into the future. The policy work already being undertaken to improve the efficiency of buildings should be built upon as well as implementing incentives for retrofit district heating networks which are relatively rare in the current market.

Certain energy efficiency measures have been delivered at scale, such as cavity wall insulation. Similar levels of solid wall insulation have not been achieved – only 8% of solid wall properties have been insulated compared to 69% of cavity wall properties. SSE recognises that solid wall insulation is one of the more expensive energy efficiency measures that can be installed, and that remaining cavity wall properties may be harder-to-treat, meaning that the costs of any policy or government mechanism to address this need to be properly assessed at the outset.

As well as certain property types, certain property tenures are also less likely to be well insulated and energy efficient. Under ECO, the private rented sector has traditionally been hard to reach due to the split incentive and an earlier lack of regulation. In addition, the Green Deal model did not prove an appealing proposition for the able-to-pay market to improve the energy efficiency of their property. As a result, there is now a policy vacuum in this area which SSE believes needs to be addressed to ensure that the existing housing infrastructure is able to realise the maximum benefits of the decarbonisation of heat.

SSE advocates the NIA considering how future energy efficiency programmes should be funded. Funding policies through gas and electricity bills can be regressive and mean that the most vulnerable consumers pay disproportionately more than others; ultimately this could undermine the policy as it risks pushing more people into fuel poverty by adding to energy prices. Long-term recommendations should aim to shift costs to means-tested taxation so that those least able to pay for such schemes are sheltered from the burden, including those living in rural off-gas grid areas.

Heat networks

For new build developments, a series of interconnected heat networks will allow the best opportunity to take advantage of lower and zero carbon technologies as they become financially viable. These would include large scale EfW (Energy from Waste) and Biomass based systems as well as heat pump and fuel cell technologies. This can then enable a significant number of energy users to be provided with even lower, or zero, carbon energy as it becomes available.

SSE has specific experience in this sector through our project at the Wyndford Estate in Glasgow, where over 1700 previously electrically heated properties have been connected to a new district heating network. SSE carried out a social, environmental and economic impact study three years after the scheme's completion and found significant energy, carbon and wider social benefits had been achieved by this ground breaking scheme.¹

Long-term sustainable growth in both the district heating and energy efficiency sectors will be dependent on the development of effective legal and commercial structures that encourage investment and attract private sector expertise, whilst giving public sector bodies, (which will be imperative to the increased deployment of heat networks) the control and investment returns that they require. Avoiding the stop-start nature of energy efficiency schemes with a relatively short life (and changes to rules midway through) is welcomed, as the current arrangements makes it difficult for them to be efficient.

The role of hydrogen in heat

SSE is supportive of the actions to upgrade the majority of the UK's distribution pipes to polyethylene which is suitable for transporting 100% hydrogen. This should continue and extend to transmission networks as well so that existing networks are ready to transport hydrogen.

What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

The Government's *2050 Pathways Analysis Report* set out an expectation that electricity demand in the UK will double by 2050.² Demand management and demand side response will have an important role in ensuring that the UK efficiently and effectively meets this increase. It is important therefore that the NIA considers how to maximise the benefits of demand management and demand side response within energy, particularly in regards to heat and transport.

Maximising the benefit from demand management for heat

SSE is collaborating with Community Energy Scotland, V-Charge (an aggregator) and the Mull and Iona Community Trust on a project called 'Assisting Communities to Connect to Electric Sustainable Sources' (ACCESS). This project aims to develop a smart, active local network that balances local renewable energy sources with new electric storage heaters. Managing electric heating in this way provides a virtual district heating network without as much disruption and cost as commissioning new underground heat networks.

Technologies that use electricity to generate heat are well placed to become major low carbon heating technologies in the coming decades as a greater proportion of our electricity is generated from low carbon sources. Electric storage heaters are often seen as an ineffective and costly method for heating a home, and have not been deployed significantly under the Energy Company Obligation (ECO). Whilst other technologies, such as heat pumps, are more appropriate in certain locations, storage heaters have coverage across all British properties, and have low installation/maintenance costs. Yet modern high heat retention storage heaters bring many benefits as they are able to provide efficient heating and produce cost savings of 20% on an annual household heating bill. There is the potential for new generation storage heaters to contribute to the management of peak

¹ The Wyndford Estate case study is available online: www.sseenterprise.co.uk/information-centre/case-studies/wyndford-estate-case-study

² HM Government, 2050 Pathways Report (2010), available online: www.gov.uk/government/uploads/system/uploads/attachment_data/file/42562/216-2050-pathways-analysis-report.pdf

demand, through demand side response capabilities; this has already been demonstrated in the Northern Isles New Energy Solutions (NINES) project, which has used flexible smart electric thermal storage load to balance over 100 MWh of local inflexible generation.

Maximising the benefit from demand management for transport

The potential benefits of using ULEVs for demand management in GB are substantial. A key advantage of ULEVs is that there is a blank canvas from which systems can be built that help meet the challenges we are currently facing in the move to a smarter, more flexible low carbon system. EVs have demonstrated their significant DSR potential, which is particularly important to utilise low carbon generation at traditionally low demand times. Without managed EV charging, customer engagement, and the utilisation of 'time-of-use' tariffs there is a risk that the high cost (networks/supply) associated with their peak demand will prohibit their uptake. Furthermore, the customer journey in terms of meeting their requirements i.e. EV range, cost and convenience is fundamental to managed EV charging.

Educating customers about the potential benefits of ULEV and EV ownership will have an important role to play in addressing the behavioural constraints of switching from ownership of traditional cars. Without customer education innovative solutions presented by ULEVs and demand management may have limited uptake.

Findings from innovation projects such as Scottish and Southern Electricity Network's (SSEN's) 'My Electric Avenue' project show clustering of EVs will cause issues long before market saturation (32% of all GB circuits will experience issues when EV uptake on a street exceeds 40% of households).³ This work investigated how technology can be used to manage EV charging, to not only protect networks, but also to facilitate the connection of more load such as EVs. It is therefore recommended that there is need for localised managed (either through control or shifting) EV charging during periods of peak demand on a network.

Taking into account views expressed by the Society of Motor Manufacturers and Traders (SMMT) SSE is keen that the energy system is not deemed to be unfairly targeting EVs as a means of managing network protection. Ideally in the future it will be possible to allow customers to determine via a smart hub/smart meter how they wish to manage the load at their property in response to a signal from a supplier or aggregator, as they may wish to prioritise their EV charging and instead shift their cooking/washing activities outside the peak demand period.

A potential barrier for any party seeking to implement managed EV charging could stem from the fact there is no standard agreed in the UK for managing communicating with, and managing the charging of, EV chargers. It is crucial, therefore, that standards are agreed between the energy, automotive and electric vehicle supply equipment (EVSE) industries to avoid there being a large number of different types of system and technology in the market and connected to the networks that are incapable of communicating and facilitating managed EV charging. Our Smart EV project is seeking to address this by informing an engineering recommendation (or similar standard) for the control of EV charging.

Whilst cost reflectivity and cost efficiency with regards to charging arrangements and affecting investment/and or behaviour decisions is welcome, this needs to be balanced with the benefits that the socialisation of costs brings. We believe this trade-off is for policymakers to determine, SSE would welcome guidance on what the Government's policy objective is as it will affect decisions taken by DNOs and investors in smart technology (suppliers, aggregators, tech companies).

³ Further information is available online: www.myelectricavenue.info/

SSE envisages that if DSR happens in clusters without DNO involvement this could lead to network related issues. Ideally DNOs should be a key facilitator and not a barrier, and this could be helped by greater visibility and engagement with aggregators e.g. obligations on aggregators and suppliers to provide visibility of their anticipated volumes, profiles and recruitment for defined areas. In order to engage with end users, simplicity will be crucial as experience shows that complexity is a barrier – ideally domestic customers will have one point of contact that will be licensed as the balancing responsible party for those customers’ site(s).

How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Unlike direct fuel use such as gas for heating and oil for transport, electricity networks require more sophisticated tools to maintain resilience. As heat and transport become electrified, and more devices become connected, in terms of being remotely controlled, the system operation of electricity networks will become more complex and potentially more vulnerable.

Risks associated with the removal of diversity

SSE is particularly concerned with the risk that ‘connected’ devices will have on the potential of removing electric load diversity from current end use. Load diversity is essential in terms of reducing the need for network reinforcement and additional capacity. The diversity of 10,000 households effectively means that less than 20% of the network is required than if each individual household had its own network. Diversity is caused by individual end users operating devices in a largely randomised way – albeit with general trends towards using more appliances at certain times of the day.

The rollout of smart and connected devices risks removing existing diversity as more appliances are controlled by agents or aggregators responding to price signals for set 30 minute (settlement) periods. This issue has already been dealt with when the transition to Radio-Teleswitching of electric heating occurred in the 1970s. A key learning from that process was that individual devices were required to have a random offset of +/- 3minutes to prevent large peaks and network capacity issues.

Guiding Principles

Insufficient regulation or coordination risks electricity imbalances and thermal or voltage issues being experienced on low voltage feeders. To prevent these issues DSOs will need greater authority to manage, from a physical perspective, aggregated load to ensure network resilience, whilst recognising that, in principle, where consumers are constrained as a result that they may expect to be appropriately compensated by the DSO. The NIA should consider the need for this greater authority to ensure these issues are avoided.

SSE believes network operators should work together with all stakeholders to ensure standardisation in this space, whilst recognising that developments in terms of the EU Network Codes may already address some aspects of this. One of the key issues is how data gets from a third party to network operators (and vice versa) and whether this is secure. It is likely that regulations will need to focus on ensuring all parties meet requirements on this as it will be these entities that are coming to market with innovative solutions and technologies.

Whilst there is an ongoing debate on how batteries are treated in regulations, the DSO will be principally concerned with how batteries behave in terms of importing electricity from, or exporting electricity to, the network and reactive power. This should be considered when any regulatory changes are being made, or recommended, especially as different batteries will behave in very

diverse ways in terms of power, efficiency and ramping up or down. Whilst a battery can help ease network constraints or help with network congestion, they also risk exasperating both of these issues when they operate in reverse; i.e. discharge to charge mode. Therefore careful consideration will be required in how to physically monitor and control batteries in order to secure the system, whilst recognising that, in principle, if a user is constrained by the network operator that appropriate compensation will be provided to them by that network operator.

Unintended Consequences

The regulation and specification of smart appliances is important. At low volumes the combined effect of smart appliances are relatively benign; however, when aggregated they can quickly create unintended effects on the system. This requires careful design and consideration of the “at scale” impact. A good example of this scenario can be seen in SSEN’s Northern Isles New Energy Solutions(NINES) project which illustrated that frequency responsive appliances can, if not properly regulated, add to system instability.⁴

⁴ SSEN’s NINES Project information available online: www.ssepd.co.uk/NINES

Section 2: Transport

How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

SSE welcomes the Government's bold ambitions for Ultra Low Emission Vehicles (ULEVs) and its desire for nearly all new cars and vans to be zero emission by 2040.

The application of financial support measures to support the increased uptake of ULEVs and a change in travel patterns will contribute to a significant shift away from internal combustion engines (ICE) vehicles to ULEVs.

SSE expects the use of plug-in hybrid vehicles (PHEVs) and battery electric vehicles (BEVs) to continue to increase steadily from 2017, with major leaps in uptake taking place from 2020-30 as more infrastructure is put in place. Manufacturers will release greater numbers of ULEVs, and legislation impacting both the sale and use of ICE vehicles, particularly diesel, will come into effect.

ULEVs could become competitive with ICE vehicles both in terms of costs and range, due to continued improvements in the capacity of batteries, the reduction of cost and increasing speeds of charging. These developments should increase both the frequency and distance of journeys undertaken by ULEVs.

SSE anticipates that the proposed support from the UK Government for the use of hydrogen in transport will ensure that hydrogen fuel cell electric vehicles (FCEVs) play a significant role in the personal and commercial travel markets, most likely during the late 2020s. The infrastructure required and range capabilities is likely to appeal to the commercial (notably freight) market initially, however it is envisaged that they will form a key part of the ULEV market as we move towards 2050.

The role of hydrogen in transport

Hydrogen produced from renewable sources such as wind through the process of water electrolysis is 100% renewable and produces zero greenhouse gases along the whole process from production to end consumption. Water is the only by-product emitted at the end of the process.

Hydrogen could dramatically reduce GB's reliance on diesel to propel its vehicles and tail pipe pollution. It has also the potential to replace carbon intensive fossil fuels in heating and cooling. It is an important and viable route for a country working towards decarbonisation of transport and heat, and could help achieve ambitious emissions reduction targets.

There is a need to develop a nationwide network of hydrogen refuelling stations that maximises fuel cell electric vehicles (FCEVs) uptake in the coming decade. SSE has been a partner in the Aberdeen hydrogen bus project, which has significant potential to scale up in the future.⁵

Managing the increased demand on networks

The increased adoption of ULEVs (including PHEVs, BEVs and FCEVs) will increase the demand placed on the electricity network. This will affect all levels, from generation to transmission and distribution, and will require significant generation and reinforcement or upgrade investment.

SSE recommends that the NIC liaises with the Office for Low Emission Vehicles (OLEV) to discuss the confidential analysis carried out by the Distribution Network Operator (DNO) community for the UK

⁵ Further information on the Aberdeen hydrogen bus project is available online: www.ukh2mobility.co.uk/the-project/refuelling-infrastructure/

Government ahead of their Autumn Statement, which contains forecasts of the anticipated increases in generation and reinforcement required to meet the demands placed by PHEVs and BEVs.

SSE has experience from its innovation projects (plus others undertaken by DNOs and research organisations) which have trialled ULEVs to determine the impacts to electricity networks and it is clear that in the early stages of uptake the clustering effect seen with early adoption of low carbon technologies (LCTs) will place significant demand on the networks due to periods of peak demand for ULEV charging coinciding with traditional domestic household peak demand periods.

SSE's research revealed that 32% of all GB distribution network circuits will experience issues when 40-70% customers charge an ULEV at home, which could equate to over £2.2bn in reinforcement required by 2050.

Supporting the changing nature of transport

Shared mobility is expected to increase substantially in the next 15 years (McKinsey predicts that one out of ten cars sold in 2030 could potentially be a shared vehicle⁶), which means government may have to consider the future role of public transport within the context of increased shared mobility. This might manifest in the Government's planning for the charging networks considering: shared and autonomous vehicles; coordinating of shared mobility and urban planning in order to avoid congestion around drop off points; and low public transport utilisation.

What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

SSE welcomed the Government's £80m commitment in the 2016 Autumn Statement to support ULEV charging infrastructure. Government support will be crucial for the commercial case for building ULEV infrastructure as the uptake of ULEVs increases concurrently. SSE would support the Government, and the NIA, considering further means to increase take-up of ULEVs through instruments such as Plug-in Car Grants as well as continued support for the infrastructure as announced in the aforementioned Autumn Statement.

A rapid-charging network for ULEVs, with appropriate numbers of PHEV/BEV charge points and FCEV well placed fuelling stations, will be crucial to facilitate movements between and via urban and rural areas as it will de-risk travelling using ULEVs and support the Government's ambitions.

⁶ McKinsey report available online: www.mckinsey.com/industries/high-tech/our-insights/disruptive-trends-that-will-transform-the-auto-industry

Section 3: Digital communications

Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

SSE believes that retail market governance arrangements for the digital communications sector should be developed to support the consumer experience in switching between the many different technologies and services available. A digital communications regime that effectively co-ordinates the 'behind the scenes' processes to deliver positive switching experiences will improve competition and deliver subsequent benefits to the customer.

In other utility industries, there is a clear and formal separation between the infrastructure providers and the suppliers of services using the infrastructure. There is generally long term regulated funding for dominant or 'legacy' infrastructure (not precluding competition for investment in 'new' network extensions) with incentives and standards on the required network performance characteristics such as repair time and high availability. Suppliers of services, on the other hand, are able to use the available infrastructures on a non-discriminatory basis and are exposed to market pressures to provide competitive, innovative product offerings and excellent, responsive customer service. This separation of roles facilitates the organisation of retail switching arrangements so that consumers can readily move between service offerings – whether they are connected to legacy networks or newly provided competing infrastructure.

Since the independent organisation of retail switching arrangements is such a key part of the regulatory framework for other utilities, SSE proposes the NIA consider how this could be developed in an appropriate manner for the parts of the electronic communications industry serving the 'mass market' of consumers.

In the energy industry, comprehensive, independent and transparent market governance arrangements exist to protect the consumer switching experience. In contrast, the retail communications markets have developed with no overall industry governance or coordination of this activity. Appropriate governance arrangements to define, maintain and develop industry processes that affect consumers do not emerge naturally in a market and need to be 'designed in' to market arrangements under the auspices of government and/or regulatory oversight, as is currently being seen in the preparations for the 2017 opening of the non-household water market in England and Wales.

Drawing on SSE's experience of the governed retail market switching in other industries, we believe that the following items need to be developed:

- An authoritative market body, owned and funded by relevant industry participants, whose remit is to ensure that retail switching is efficiently coordinated across market participants for the benefit of consumers; and
- Documentation of switching rules, processes and agreed procedures: these to be held centrally by the market body and subject to transparent change control to incorporate market developments and suggested improvements.

At present in the communications markets, there is no single body that represents all relevant parties involved in services to the 'mass market' of consumers. A market body that is set up to coordinate retail switching could provide such a focus and enable government or regulatory bodies

to instigate consideration of topics that need to be addressed by the consumer facing part of 'the industry'. SSE notes that the existence of this type of inclusive body in the energy industry has helped government and regulators to further the "faster switching" area of work in energy supply.

Currently, with the rate of technological change in the communications markets, new products and technologies develop relatively quickly and have led to fragmented, *ad-hoc* switching arrangements due to the lack of market oversight. SSE would support the NIA reviewing the regulatory and industry governance framework in the retail digital communications market.

Section 4: Energy

What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

District heating

The NIA should consider the existing barriers to increasing the uptake of affordable, secure and low carbon heat infrastructure. District heating can secure significant reduction in CO2 emissions using 'waste' energy from the industrial process. This removes the need for additional energy to be generated, allows for economies of scale and the integration of energy sources (meaning customers are not dependent on one supply source). District heating networks ensure greater reliability of service with the ability to balance the supply and generation of heat. CHPs used to power district heating networks are highly efficient, reaching efficiency ratings of about 80% compared to approximately 50% for gas power and 40% for coal-fired power.

SSE welcomed the Government's recent £320m commitment to the development of heat networks in the UK. If well targeted this money could provide the momentum for significant deployment of heat networks across urban areas in England and Wales.

The NIA provides a good opportunity to consider the role of district heating alongside others means of decarbonising heat. SSE advocates the NIA taking a 'whole energy system' approach, and believes that mass decarbonisation of heat is viable. SSE envisages this aim will be achieved through a mix of district heating, repurposing of gas distribution networks, and reinforcement of electrical distribution networks. Uncoordinated activity in the decarbonisation of heat risks stranded assets in future.

SSE is an investor and operator of district heating and cooling networks across the UK, and has experienced the issues associated with the successful development, implementation and operation of district heating sites. District heating schemes have had a far greater chance of successful implementation in situations where there is a strongly supportive planning policy in place that, in effect, obligates major developments and other relevant stakeholders to, where feasible, incorporate a connection to an existing scheme or develop a site wide CHP network of their own. This environment also provides investors such as SSE with additional confidence in achieving connected loads.

SSE believes preferential business rates and supportive building regulations can have an integral role in achieving a high value solution for decarbonising heat. The development of effective legal and commercial structures that encourage investment and attract private sector expertise, whilst giving public sector bodies (which will be imperative to the increased deployment of heat networks) the control and investment returns that they require. Capital guarantees are potentially critical as a long-term method for de-risking heat networks projects for investors. A low carbon heat incentive (including incentives to use waste as well as renewable heat as a low carbon) would be a positive step towards an achievable solution.

Early decision making is essential to provide planning for the long term decarbonisation of the heat sector given the long lead times in making infrastructure decisions.

Electric heating

Traditional electric storage heaters are often viewed as an ineffective and costly method for heating a home, and have not been deployed significantly under the Energy Company Obligation (ECO). Yet modern high heat retention storage heaters bring many benefits as they are able to provide efficient heating and generate cost savings of 20% or more on an annual household heating bill.

The NIA should consider how Ofgem and BEIS can drive the expansion of electric heating. SSE believes that the removal of policy costs on electricity bills and more reflective carbon emission factors on electricity use are sensible routes.

For the past decade supplier energy efficiency obligations relied on a market based approach to encourage measures that reduce carbon emissions at the lowest cost. The savings in carbon are estimated over the lifetime of the measure which can be a forty year period. The calculation of carbon savings requires a large number of inputs and assumptions, such as physical characteristics of a building, assumptions about the measure lifetime and assumptions about how a building be used. Although a significant amount of effort is made to try and ensure these calculations provide an accurate forecast of carbon savings, there is currently no recognition that electricity emission factors are reducing quite rapidly and are forecast to continue reducing until 2050. This means that any energy efficiency measures that involve the use of electricity are being assessed using historic (2012) carbon emission factors. Measures are being assessed on the basis of coal fired electricity generation continuing to play a significant role for the next 40 years, however we expect that by 2025 coal plant will have been phased out and replaced by low carbon generation sources.

SSE urges that national infrastructure decisions are driven by the best information available and in the case of decarbonising heat more should be done to acknowledge the reducing electricity emission factor.

Subject: CALL FOR EVIDENCE - NIA

The Staffordshire Chambers of Commerce works with 4,500 businesses across Stoke-on-Trent and Staffordshire. It's central location in the country's transport network makes the area an ideal base for successful manufacturing, exporting and the transport and logistics sector.

Our infrastructure investment priorities which we believe are of national significance are as follows:

- **HS2 connectivity:** To unlock housing and economic growth in the city of Stoke on Trent and the wider Northern Gateway Development Zone, there needs to be a minimum of two HS2 services per hour serving Stoke-on-Trent and Stafford, and existing road and public transport infrastructure must be fully integrated
- **M6 Capacity and Safety:** To improve journey times, increase capacity and reduce congestion on the M6 through Staffordshire, there must be investment in Smart Motorway technology between junctions 15 and 16. In addition, urgent safety improvements are needed at J15.
- **East-West Connectivity:** To boost trade and access to skills, there is a need for upgraded rolling stock and electronic signalling which would improve capacity and frequency of rail services between Crewe, Stoke and Derby.

For more information on any of these priorities, please contact me.

Kind regards

9th February 2017

Dear Philip

NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE

Thank you for giving Stagecoach Plc the opportunity to submit our thoughts on future infrastructure investment priorities. Our summarised response below addresses primarily the transport-related questions but also covers some of the cross-cutting questions posed.

I must stress that our submission is very much an executive summary of our thoughts on Infrastructure and as one of the largest providers of public transport in the UK we would welcome further dialogue on the matters we raised and can provide further data and substantiation behind any of our views if required.

How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

The key ingredient here will be population growth and how the development landscape accommodates it. Whilst we have seen an increasing shift to urbanisation in recent years, there is no doubt that there will continue to be dispersed development in greenbelt locations. A growing population will naturally lead to a greater demand for travel across all of the modes. Planning and funding policy will, to a degree influence the split of demand between the modes together with the transportation marketplace.

The other key variable is technological change and how this impacts on lifestyle. Whilst trends such as increased internet shopping and greater home working would be expected to burn off some degree of a demand for transportation, we do not consider this to be significant in the short to medium term although by 2050, we would have expected an evolution of town and city centres, perhaps with more leisure options. Urban centres are traditionally quite resilient and have battled with competition from out of town developments for years.

Employment will be a key determinant of travel. Our current demand is generally although not exclusively determined by the level of economic activity and this is supported by the passenger growth we have in areas which are economically healthy and have growing

populations such as Hampshire, Surrey and West Sussex whilst in other areas such as North East England and East Scotland, the picture is the reverse. One trend that we do believe will continue is that people will be willing to travel longer distances to work and this will result in greater inter-urban and inter-regional traffic over time.

We believe that with greater population densities likely over time, there will always be a natural agglomeration of more popular journeys and therefore the demand for mass transit will remain or more likely increase. There will of course remain an increasing demand for road space from private forms of transport leading to increased pressures on the road network.

The need for better management of available road-space is already crucial will become more acute as the population increases. The use of smart technology will become more prevalent and some of the smart technology may impact on choice of mode if real time demand data is made available to help inform travel choices.

What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas? Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

The highest value transport will be that which can move people to where they want to be as quickly, cost-effectively, conveniently and comfortably as possible. Often this amounts to private transport as the natural choice for many people but choices are also influenced by levels of congestion, pricing of mass transit options, the cost of motoring, particularly fuel costs and parking charges, and general comfort of all modes.

Rail-based mass transit is an attractive, fast and relatively unimpeded alternative to the car. However, the cost of providing heavy rail is relatively expensive both in terms of the infrastructure and the ongoing running costs. There are significant constraints to increasing rail capacity and this is unlikely to change. Light rail, similarly offers an attractive alternative to other modes with lower running costs compared to that of heavy rail but with high infrastructure costs and the same project delivery constraints and lengthy lead times as with heavy rail. However many key links will never justify the investment required for rail services.

Currently by far the most popular form of public transport in the UK, with nearly 5bn journeys per annum is the bus, which offers cost effective road-based mass transit. Such is the flexibility of routeing and ability to penetrate more population and employment due to a greater infrastructure available (the road network) and more frequent stops, the bus simply caters for the journey needs of many people and this is unlikely to change materially. The capital cost of vehicles is generally far less than other forms of public transport while staff costs are lower than that of rail. Pricing is generally good value, reflecting lower running costs, which are unlikely to change markedly in relative terms over the coming decades. A shift has already started from diesel towards more sustainable propulsion such as electric power but this too is not impacting on pricing to any significant degree.

Whilst the bus is often the most cost effective mode, its comparative attractiveness is constrained by traffic congestion. Current policy and funding does not really address this despite the significant numbers of people affected and the resultant 'lost time' and impact on the economy. Allocation of road space to buses is often seen as politically unpopular and some cities, such as London have actually allocated road space away from the bus in recent years with a resultant reduction in journey speeds and reduced demand for bus services. Such policies can result in increased journey times and congestion for all. Conversely, a well thought out bus priority scheme which may allocate some road space to the bus but also

looks at the overall design of the highway including the efficiency of junctions will improve journey times overall as evidenced by the 'Quality Bus Corridor' Programme in Greater Manchester, which successfully navigated the consultation process and was delivered on the back of reduced journey times and improved street environment for all.

As noted previously, the smarter use of road space will become more important but, given the constraints provided by rail, it is also clear that provision of bus-related highway infrastructure should become more attractive over time. This will make the bus more attractive a mode and, in turn assist with the efficient use of road space.

Current trends in terms of equipping public transport with technological features designed to improve the customer experience will likely continue. USB chargers and wifi are already widespread but further projection of multi-media entertainment to passengers at their seat will become more popular thus further enhancing the unique selling point of public transport.

Technology will play an even greater part in the retailing of public transport. The last decade has seen a growth in smart ticketing and it won't be long before contactless payment and mobile ticketing largely takes over from cash transactions. Internet retailing and information provision together with ticketing and payment mechanisms will nevertheless become far more intuitive, driven by the market and this will serve to unlock latent demand from those who currently see information and ticketing as a key barrier to using public transport, particularly the bus. Increasing retailing of mobility covering all the travel options, assisted by data from transport providers will become more prevalent and potentially, with real time demand data, facilitate smarter use of road space.

It is expected that driverless technology will play a role in public transport and the agglomeration of journeys but the extent of that role is not yet clear and will be dependent on the level and cost of development in the coming decades. Driverless technology does, however present the opportunity to redefine private transport and, at least for urban journeys, assist in the smart use of the highways network. Arguably, the highways network will need to be much smarter and smooth flowing in advance of the driverless technology being a credible option.

What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area? *Note: this includes travel in and between rural areas, as well as between urban areas and international travel.*

Provision of connectivity depends on the flexibility of transport available to the public. The car can take you anywhere at any time subject to congestion but provision of rail services is restricted to a limited and costly infrastructure.

Outside the urban area, agglomeration of journeys becomes more difficult and public transport less viable. Equally, congestion is often less prevalent although this is challenged by the increase of dispersed inter urban and interregional journeys.

Often the most credible form of mass transit for such journeys is, once again, the bus as it can be provided at minimal capital cost and relatively low unit cost. The ability of the bus to penetrate dispersed settlements and places of employment is way ahead of other public transport modes.

As the demand for interurban road space increases, we will see the opportunity for more agglomeration of journeys but this will be dependent on facilitating attractive journey times by public transport compared to the car.

A good example of catering for inter urban and inter-regional journey needs is the Oxford – Milton Keynes – Bedford – Cambridge 30 minute frequency X5 service provided with 17 high quality coaches by Stagecoach. Such is the success of the service in agglomerating interurban and inter-regional journeys, it is now considered feasible to build a railway line along much of the route and support a rail service. There are plans for significant residential and business development along the entire corridor, which the X5 is well placed to support and service also passes a number of bus and rail based P&R sites at Cambridge, Bicester and Oxford. The rail line meanwhile will be able to support development to a degree but it is limited in its ability to reach and penetrate those developments and this could restrict the positive impact of the investment. The X5 could assist the railway in providing the penetration needed. We would be very keen to provide a better frequency of 3 departures per hour with faster journey times, aided by good bus priority measures including the East-West Expressway. This would require an additional eight vehicles with a capital cost of only £1.6m per annum and we would anticipate revenue generation to be about £800k extra per annum after year one of the enhanced service. These figures are, of course a small fraction of what the rail solution would cost.

What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Pricing of mobility according to demand levels will serve to more smartly manage the road network by reducing demand at peak times and spreading traffic over a far greater time period. This will provide restraint via the marketplace in the same way that rail pricing does to a degree. Road pricing of this nature could then be used to fund initiatives that encourage further agglomeration of journeys onto public transport thus taking more pressure off the road network. Pricing in this way will also provide a more level playing field with public transport whose cost of supply at the peak time can be far more expensive due to congestion on both road and rail networks.

There are further health benefits to this approach through tackling AQMA's and also improving safety. Reduced congestion at peak times will not only improve air quality but will also allow transport providers to either provide more frequency with the resource available or remove resource and reduce price.

What are the highest value infrastructure investments that would support long term sustainable growth in your city or region? *Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.*

The St Ives to Cambridge and Leigh Salford busways are great examples of where car users have been attracted to local and inter-urban bus services for relatively low capital cost. The services are not restricted to the infrastructure but serve a variety of other areas at each ends of the infrastructure. Journey times have been reduced and patronage has consequently grown. In case of the Cambridge busway annual patronage on our services benefitting from the busway increased from 1.1m in 2010/11 to 3.5m in 2015/16, a 200% increase.

We passionately believe that provision of segregated alignments for buses generally yields far greater passenger benefits than the same investment in other public transport alignments such as rail due to the increased penetration and lower costs previously mentioned.

How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Over the next 20 years, more new homes are anticipated to be built than in the last 40. In parts of the UK where growth will be focused, many towns will see the most growth they have ever experienced, and several will more than double in size. It is especially important that this growth makes fullest possible use of the opportunities offered by public transport, by "designing in" those features that support the efficient delivery of the highest-quality bus services.

Where buses are properly considered at the outset, in development location, master planning and detailed design, high levels of service take-up are achievable. Indeed, across a very wide variety of scenarios, appropriate development can help catalyse improved bus services that achieve mode shift across a wider area. This can help to offset the residual car-borne traffic from a proposal. Where buses are properly harnessed in support of the best development proposals, they can provide wider public betterment.

We feel that urban design must respond to a number of important drivers, so Stagecoach has produced a document, which is intended to highlight the features that are needed to ensure that buses can best serve developments, and the possible role in delivering high-quality, attractive and sustainable places. In this document, we tackle infrastructure design including highway configuration, bus stops, and parking. Meanwhile we also discuss how Stagecoach can work with stakeholders within the planning process. The document will be complete within the next month. We will forward a copy to you and we would welcome the opportunity to discuss it with you in detail.

What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? *Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.*

The maximum potential for demand management obviously depends on the type and extent of measure(s) put in place. The London congestion charge has created a revenue stream and assisted in improving journey times within the central area for many years although demand has returned partly due to the growth of London. This has happened with little or no adverse economic impact. The charging mechanism could be far more sophisticated, however taking into account peak demand in greater detail although this may not be deliverable on the scale of London. There also needs to be some predictability to pricing and so pricing down to real time demand might have its constraints.

Congestion charging has been politically difficult to apply elsewhere in the country. Notably, Manchester's attempt saw millions spent on the proposal and little support gained from the general public. This should not deter authorities from pursuing it but the economic case will

probably become more marked in time as our cities become more choked. We definitely support congestion charging but it is best delivered alongside wholesale improvements to the public transport network.

Parking charging and control is another key restraint tool. Parking can occupy large areas of city centres and use of valuable land for parking could arguably be viewed as a lost opportunity when an alternative land use may have provided more contribution to the economy. People will be more likely to choose public transport to visit a place where parking charges are high.

Other ways of burning off peak demand could be delivered through influencing or controlling the active times of employers, schools or colleges. This form of demand management would also assist with the peak cost of road-based public transport provision.

Thank you once again for allowing us the opportunity to comment on future infrastructure priorities. We would be delighted to provide any further evidence in the form of reasoning, information or data should you require it. We see lots of opportunities ahead and would welcome the opportunity to discuss our vision with you in greater detail. If you are willing to meet with us then please let me know and I will make the necessary arrangements.

Yours sincerely

Statoil response to the National Infrastructure Assessment Call for Evidence

Statoil (U.K.) Ltd. welcomes the opportunity to respond to the Commission's call for evidence on the first National Infrastructure Assessment (NIA).

Statoil is building and investing in a secure and sustainable energy future for the UK, where our business encompasses a broad range of activities including upstream operations on the UK continental shelf (UKCS), the development of offshore wind projects, natural gas trading and crude oil sales.

On the UKCS we are the operator of the Mariner oil development, the largest investment on the shelf in a decade and which is due to start commercial operations in 2018. We are also partners in the Jupiter and Alba fields. Our belief in the potential of the UKCS has led us to take a significant position in the 28th UK licencing round, adding 12 new licences (nine as an operator) in the Central North Sea.

Natural gas is a key part of our partnership with the UK, where 4.1 million homes are fuelled by Statoil gas. We are committed to increasing that figure, and through the Langeled, Vesterled and Tampen links from the Norwegian continental shelf, we have the capacity to supply up to 25% of peak UK demand.

The UK has also been the springboard for our offshore wind projects which are part of Statoil's global strategy to gradually complement the oil and gas portfolio with profitable renewable energy and other low-carbon solutions. We hold a 40% share in the Sheringham Shoal wind farm, in production since 2012, a 35% operated share in Dudgeon and a 75% operated share in Hywind Scotland, the world's first floating wind farm. Both Dudgeon and Hywind Scotland will be completed later this year. Together with our partners we are developing an offshore wind portfolio with the capacity of providing over 1 million homes in Europe with renewable energy.

We would be pleased to continue to provide input to the Commission in developing the NIA. If any further information is required, or if we could be of further assistance, please do not hesitate to contact me.

Kind regards,

Responses to selected consultation questions

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

- The UK currently has one of the most efficient and liquid wholesale gas markets in the world. It adjusts volumes of gas to and from the UK via price signals, and this delivers the right volumes at the most efficient pricing to the end user. From a security of supply perspective and also an affordability one, it is very important that this market remains supervised as it is currently and allowed to continue to work efficiently.
- On offshore wind, there is currently a disconnect between the timing and regularity of Contract for Difference auctions (the first in 2015, the next in 2017 with the timing of subsequent rounds unclear) and the requirement in an offshore wind project's consent to commence construction within a certain time limit. There is a need for better alignment and adjustments.

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

- The challenge to decarbonise heat is recognised as one of the largest the UK must tackle so as to meet its targets under the Climate Change Act. It is also widely accepted that there is no single solution that can be deployed to effect change in a complex system where heating needs and provision currently vary greatly according to type of user (residential, commercial, industrial), location and time of year.
- Decisions taken on heating have a long-term impact since they necessitate changes which at the individual user level only happen once in a generation. And, as with other infrastructure challenges, energy investments require long-term planning and there is a risk of closing off options prematurely through policy decisions being delayed or taken without fully taking into account the full system costs.
- We believe the first step must be to improve building energy efficiency. Doing so can reduce carbon emissions, reduce energy bills and fuel poverty and therefore improve health, while also driving economic growth. The Committee on Climate Change (CCC) notes that reducing the level of energy demand through improve efficiency can greatly reduce the cost of meeting the 2050 emissions reduction target.
- 83% of homes in the UK are heated by natural gas, using an efficient transmission and distribution network. Even as new technologies emerge this level is unlikely to change significantly in the medium term. Natural gas will therefore continue to play a significant role at least in the short to medium term. The emissions impact can be lessened by installing high efficiency boilers in new homes and retrofits, and by "greening" gas through the use of biogas and to mix in hydrogen.
- Security of long-term natural gas supplies for the UK can be secured if there are sufficiently strong long-term signals on future levels of natural gas demand, when decisions on new upstream fields on the UK and Norwegian continental shelves need to be taken.
- A promising longer term route to cut significantly emissions from heat is to use natural gas to produce hydrogen for use in heating. Hydrogen is a zero carbon gas, and it holds the features of natural gas – i.e. the flexibility to

turn temperature up and down, to distribute the energy need intra-day, intra-week and even intra-season. The feasibility of converting the natural gas network to hydrogen is being tested by the H21 Leeds City Gate project and first results are promising. A recent assessment by Imperial College found that using hydrogen would result in the smallest disruption to the end-user compared with other options (electrification, heat networks) as very few changes would need to be made to households to convert from natural gas to hydrogen.

- The conversion of natural gas into hydrogen through steam methane reforming (SMR) is the most well-known short/medium term process to produce hydrogen in large enough quantities. Other methods of hydrogen production that are more efficient than SMR are currently under test and development. Common to all these industrial production processes is the requirement for the large scale Carbon Capture and Storage technology (CCS), where the CO₂ is injected into sub-surface reservoirs. Such CCS developments would not only benefit hydrogen value chains but also allow decarbonisation of industrial emissions and fossil fuel power generation. The UK has done extensive research on the storage potential on the UK continental shelf and ample storage capacity has been identified¹, especially on the eastern part. Hence storage capacity is not seen as a barrier. A transport and storage infrastructure development plan is required to access these assets in the most optimal way. In several cases existing infrastructure could be reused.
- The experience we have with CCS in industrial production indicates that the price of capturing, transporting and storing one tonne of CO₂ captured post production is currently well below USD 50 per tonne (2016). We would most likely see a significant drop in costs if this was done on a larger scale across a basin, but it is difficult to say how fast and by how much.
- Hydrogen can also be produced by electrolysis, but the cost is still very high. The technology is developing and, with increased use or and interest for hydrogen, the costs are likely come down.
- We support the assessment by Imperial College that heat networks are beneficial on efficiency and cost terms in certain locations around large sources of waste heat, and that electrification can be used for more remote locations and tied to other building upgrades and in high rise buildings. We note that a wider deployment of heat pumps or wider electric heating would require significant changes in each home and investments in national and local power networks to manage the seasonal swings in heating demand.
- The current gas system offers this flexibility to cope with uneven demand both intra-day but, more crucially, between seasons. While intra-day can increasingly be solved by smarter electricity systems and battery storage, the inter-seasonal difference cannot be handled in a cost-efficient manner.
- If the gas network is not used for green gas, the falling utilisation of the gas distribution network will increase the distribution cost per unit of gas and the maintenance of the system will become costly. It is likely the network will be forced to close long before it is totally empty, making the need for an alternative network more urgent. Alternatively, gas transmission and distribution system could - under the existing maintenance programmes - transport and distribute hydrogen by the early 2020s. The current system transports on average three times the energy of the current electricity system. Using the gas grid to develop a zero carbon energy system would mean that the cost of new supply infrastructure would be limited and this is key to keeping costs down.
- Hydrogen networks can also be leveraged for other uses. One is transport, and another is in power, with the possibility to retrofit Combined Cycle Gas Turbines (CCGTs) at low cost to run on hydrogen. If this happens, the

¹ CO₂ STORage Evaluation Database (CO₂ Stored). <http://www.sciencedirect.com/science/article/pii/S1876610214023558>

electricity system can retain flexibility and obtain another source of back-up to renewable generation, and new-build CCGTs that can be converted to hydrogen may even be incentivised now to strengthen the current system. A whole systems approach is therefore needed and projects to test the economics and practicalities of developing hydrogen networks must therefore be supported.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes

- The sector will need to be significantly larger than it is today as electricity will be used to contribute to the reduction in emissions from transport, heating and industry. We believe that CCS should play a significant role, with the former offering flexible low-carbon generation and being part of an emissions-free hydrogen production process. The Committee on Climate Change has estimated that the cost of meeting the UK’s 2050 emissions target would be up to twice as high without CCS deployment.
- In addition, we believe that offshore wind should play a large role. The total resource potential for offshore wind is, as the CCC notes, greater than the total UK’s total electricity demand in 2014. Offshore wind has shown substantial cost reductions in recent years and it is expected that costs will continue to decrease. This indicates that the potential for offshore wind after 2020 could be higher than the communicated 10 GW ambition level.
- To support growing generation from renewables, the electricity system will need to be more flexible with greater levels of back up generation. there will be a need for a responsive network with flexible demand and flexible generation. This system will need a much larger role being played by demand side response, plus large scale hydrogen storage and large scale batteries and other forms of electricity storage.
- We will be trialling a battery storage solution, Batwind, as part of our Hywind pilot park project. The ambition for Batwind is to investigate how the various value drivers (e.g. congestion management, time arbitrage, balancing, system services such as enhanced frequency response) may work in tandem to generate robust streams of revenues for investors. Furthermore, by placing the battery next to the wind farm, we will be able to evaluate the value from integrating generation with storage and test out value drivers that cannot be tested if the battery is connected directly to the grid: reduced balancing costs by smoothening the variability of intermittent generation (“self-balancing”) and management of grid constrictions on the wind farm.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

- Please see above answer to Q19. Converting the gas distribution to hydrogen would provide the infrastructure for the building of filling stations, at relatively low cost and complexity, to serve hydrogen-fuelled vehicles. Hydrogen could thus offer some relief from the need to expand the electricity system massively to cater for increasing levels of electric vehicles by providing an alternative zero CO2 emissions energy option.

National Infrastructure Assessment Call for Evidence

Response from SUEZ

Preamble

SUEZ R&R UK (SUEZ – formerly SITA UK) are pleased to respond to this call for evidence to provide input into the NIC’s National Infrastructure Assessment (NIA). SUEZ are one of the UK’s largest waste and resource management companies, providing services to the public and private sectors. A long-term vision and plan for this sector is critical to support and ensure the viability of the new business model our sector is developing, based on the principles of the circular economy. In moving from a disposal (predominantly landfill)-led business model to one that relies on end-markets for recyclates and recovered energy, capital investment in the order of £10-15 billion over the next 10-15 years will be needed across the sector, in order to construct the facilities necessary to recover value from waste in the form of secondary resources. This scale of investment will only materialise if a robust resources policy framework is in place, backed up with an assessment of national infrastructure requirements.

In our response to the NIC’s previous consultation and process and methodology, we noted with approval that the NIA will take account of the “long term objectives and strategy” of “moving towards a more circular economy”. We stated that while on a site-by-site basis our sector frequently falls below national infrastructure thresholds, when viewed as a source of supply of (secondary) raw materials and recovered energy supporting the UK’s industrial and domestic sectors, our sector in the aggregate assumes national strategic importance, and the sectoral NIA should be conducted with this in mind – as a provider of secondary materials and recirculated products to replace virgin raw material and energy supplies. We also noted that infrastructure development for the management of commercial/industrial (C&I) waste lagged behind that for municipal solid waste.

With these comments in mind, we present our response to the call for evidence.

Q1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

SUEZ prefers not to view waste and resource management infrastructure in this way. The sector as a whole requires a balanced portfolio of assets, in which landfills for residual non-recyclable and non-combustible waste are as important as processing plants for secondary resources (plastics, paper, metals, etc), as are energy-from-waste (EFW) facilities for food waste and combustible residual waste. At present the UK (England in particular) suffers from a shortage of landfills, with some parts of the country in danger of running out of void space within the next 5-10 years. For example, it is anticipated that by 2021 there will be no landfill space left in Kent.

Because landfill infrastructure is not being replenished, residual combustible waste is driven to the next available treatment option, EFW, of which the UK is also in severe deficit. This imbalance has driven over 3 million tonnes per annum of waste-derived fuel (the majority derived from residual C&I waste, for which virtually no dedicated UK treatment capacity exists) to European EFW facilities where power and heat are recovered and used locally.

In terms of linking waste management infrastructure with the wider economy, EFW and recycling infrastructure are “highest value” in the sense that they offer significant local and regional economic and environmental benefits. Thermal EFW generates electricity, and especially heat that can be used for district heating and for delivering heat to local industries. SUEZ supplies waste-derived fuel to cement manufacturer CEMEX, where it is used as a substitute for pet coke to reduce operating costs and greenhouse gas emissions. A number of thermal EFW facilities in the UK supply heat and power to surrounding communities and to adjacent industries and institutions – Coventry (district heating for Coventry City Centre), Nottingham (district heating network), LondonWaste (energy to the Eco Park), Lerwick (district heating network) and Sheffield (district heating network) being five examples. Biological processes such as anaerobic digestion convert food waste into biomethane that is also used locally or injected into the national gas grid. Sainsbury’s power their distribution centres and stores with biogas produced from waste food, the energy generated supplying 10% of Sainsbury’s entire national gas consumption for the year.

Recycling infrastructure serves as a source of secondary raw materials for local and regional enterprises – the supply of aluminium by Novelis to Jaguar Landrover for use in the latter’s REALCAR project being one example. In general, owing to a lack of demand-side measures that favour the use of secondary materials over primary raw materials over 50% of the recyclates collected and processed in the UK is exported. The recent announcement by Liberty House that it is to develop a UK business using domestically recycled steel has been welcomed by UK recyclers.

This issue is addressed further in our response to Question 4.

Q2. How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways in ensuring this?

At the same time as interest in industrial strategy has re-emerged, environmental imperatives and the expressed interest of much of industry have driven a significant change in the resources and waste management sector. As noted above, the sector’s business models have moved from being disposal-led to being value-led. This model is consistent with reducing primary resource use in the economy: in most cases, the use of secondary materials, and the preparation of goods for reuse also help to reduce global greenhouse gas (GHG) emissions.

The UK exports secondary materials to be reprocessed overseas, and then imports processed materials use in manufacturing. In 2014 imports of ferrous metals and of aluminium were more than three times and five times respectively, relative to the mass of secondary materials exported.

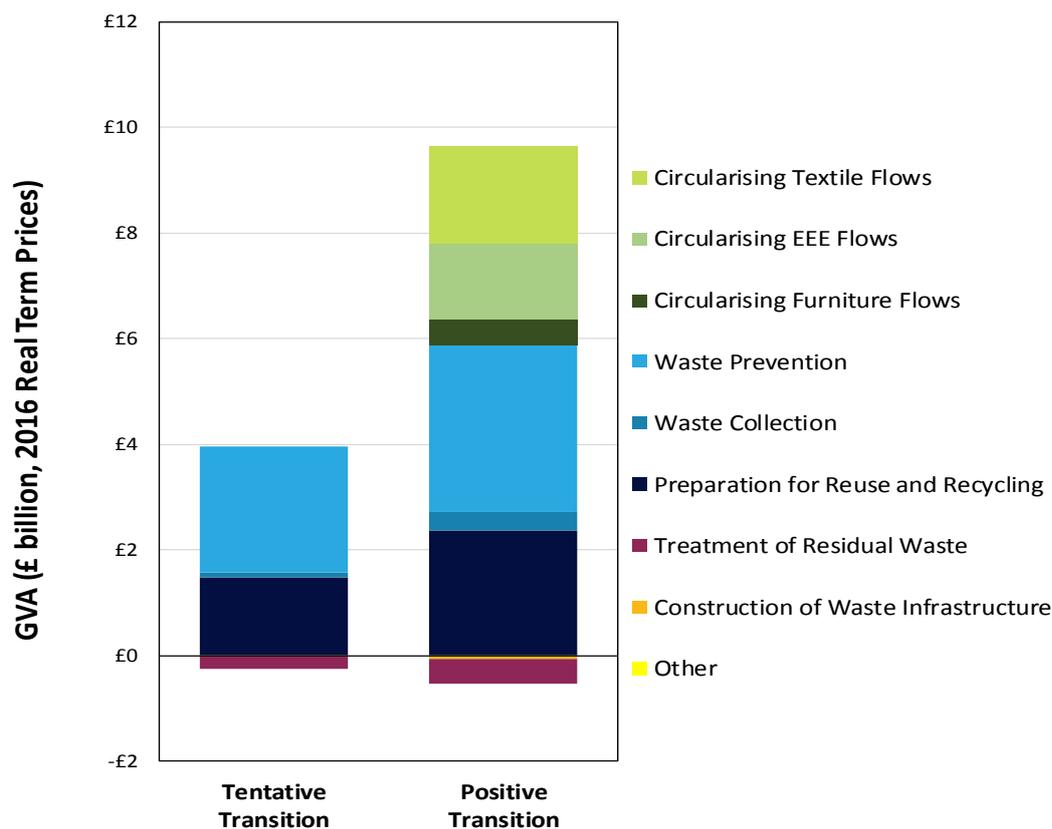

Analysis performed by consultants Eunomia on behalf of SUEZ suggests that re-shoring some of the materials that are currently exported for recycling could add significant value to the UK economy if they were processed locally, while boosting resource productivity and hence international competitiveness. In terms of Gross Value Added (GVA) as a result of changes in waste management and broader shifts in the consumption and use of furniture, electronic equipment, and textiles, the headline results indicate that significant additional gains result from measures which are more likely to result from embedding waste and resource management within a wider industrial strategy.

As shown in the figure below, of the two core scenarios modelled against the baseline ‘Business as Usual’ (BaU) scenario, the more ambitious ‘Positive Transition’ (to a more circular industrial strategy) scenario results in a total net gain in GVA of £9.1 billion in 2030. According to the ONS, the waste and resource management sector as a whole was responsible for generating an estimated £6.5

billion of GVA in 2014. The GVA uplift is considerable, with some of the modelled benefits in 2030 also being attributable to sectors other than waste management. It is estimated that the Net Present Value of the Positive Transition scenario (for the period 2016 to 2030) is £47 billion. This shows that there are substantial benefits to be gained over time under this ambitious scenario.

The Positive Transition scenario also generates savings in respect of GHG emissions. Improvement in waste management relative to the BaU scenario delivers reductions of around 4 million tonnes per annum by 2030, but the scenario also delivers substantial savings related to waste prevention. GHG savings are estimated to be 27 million tonnes by 2030.

Net Change in GVA Relative to BaU in 2030 (£ million, 2016 Real Term Prices)

The above analysis chimes with, for example, the London Infrastructure Plan 2050. An analysis of the waste infrastructure required for London showed the potential for £5 billion in cumulative resource efficiency and productivity savings to 2050 created by a more circular economy-style waste infrastructure focused on more repair, re-use and remanufacture.

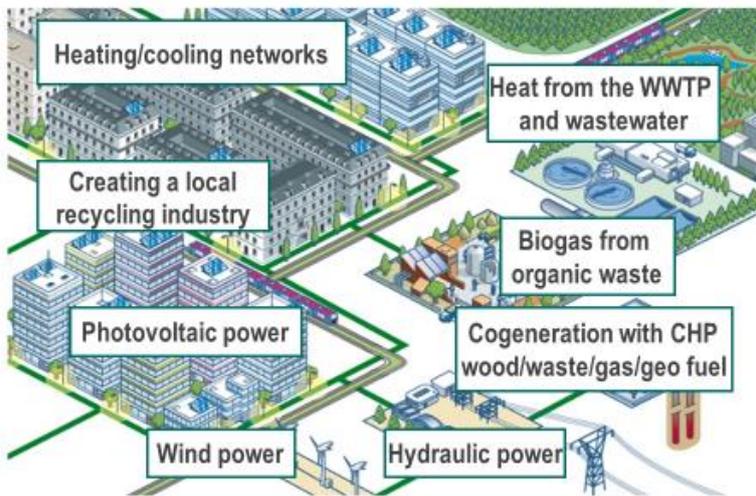

International gateways such as ports and their hinterland are well suited to the development of symbiotic industrial complexes, hubs and clusters, especially in the context of regional regeneration (for example, the ports within the Northern Powerhouse catchment), often zoned with special planning and tax concessions. The 2016 budget included a commitment to provide a further £1.8 billion of funding to Local Enterprise Partnerships during the course of 2016, on top of the £7.3 billion of Growth Deal funding that they had received by March 2016.

Rotterdam is an example of a successful integrated port-cum-industrial complex, which could be replicated in the UK.

Q3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated?

The “smart city” concept designs and integrates utilities with mobility, waste management, energy and other services into the urban infrastructure, as illustrated below.

The city of tomorrow – an integrated approach

Waste management services and infrastructure has not received as much attention as, say, transport and mobility, but there are considerable opportunities for innovation.

- Pneumatic waste collection infrastructure can be designed such that waste is transported through fixed aerial and underground conduits to central underground storage receptacles. Above-ground traffic movement is minimised because individual household collections are avoided, as is nuisance related to odour and littering.
- Drive-in waste collection centres can be linked to repair centres and sales outlets for recycled and refurbished goods.
- Waste-related vehicles can be fuelled by clean fuels such as biogas or waste-derived fuels. SUEZ produces vehicle fuel (LNG) from landfill gas, as well as diesel from waste plastics.
- The waste cycle can be integrated with the wastewater cycle to generate energy from waste. Electricity and heat generated can be used a source of decentralised power. Recovery of heat from the wastewater in pipes allows for less energy consumed for heating. Excess heat from wastewater treatment plants can be recycled to heat nearby neighborhoods. Sludge from these plants can be used as fuel outside of manure spreading periods for agriculture.
- Food waste can be combined with sewage sludge and digested to produce biomethane for heating. Digestate can be turned into a soil improver for local landscaping.
- Recycling facilities can provide secondary materials to support local businesses.

These innovations can best be implemented in new developments. The recent announcement of 14 new garden town and village developments in England provides an opportunity for architects and urban planners to integrate these considerations into their urban designs.

Q4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

“Demand management” as applied to the resources and waste management sector can take two meanings: firstly in terms of waste prevention, and secondly to create demand for secondary materials and recovered energy as a substitute for virgin raw materials and brown energy.

The waste management sector has undergone a huge transformation over the past 10-15 years. Traditionally disposal-led, the sector is now geared towards recovering value from waste, with ultimate disposal a last resort. Reusable products discarded by consumers are collected for repair and refurbishment, non-reusable products and materials are recovered in the form of recyclables, and value from residual non-recyclable waste is recovered in the form of energy. The estimated breakdown of the main value streams across the household and C&I sectors is as follows:

Value stream	Million Tonnes	Value
Material collected and processed for recycling	36	£10 Bn
Energy from waste (recovered in UK facilities)	6	£0.45 Bn
Energy from waste (in the form of waste derived fuel)	4	£0.4 Bn

The transformational technologies and processes have been constructed with the deployment of significant investment of £10-15 billion over the past 15 years.

However, as intimated in our response to Question 2, our sector is handicapped by a structurally dysfunctional market. Due to the almost complete absence of UK demand-led policies over supply-side measures such as recycling and landfill diversion targets, UK waste management companies rely heavily on overseas markets for the recyclates and waste-derived fuel our sector produces. Some 50% of recyclates and 90% of waste derived fuel is exported to overseas markets. This represents a direct annual loss of £6-8 billion to the UK economy and a drain on the UK’s balance of payments given that the UK is a net importer of primary raw materials and of energy.

Measures to reduce the production of waste focus on **influencing consumer behaviour** and include:

- Legislating to allow pay-as-you-throw schemes for household residual waste
- Alternatively, introducing targets to reduce residual household waste per inhabitant
- Broadening the scope of taxes on single use disposable products (beyond plastic bags)
- Introducing deposit refund schemes for beverage containers, as well as other items such as small waste electrical and electronic equipment.

Demand-side measures to promote secondary materials focus on **influencing industry**. Measures which could be used include:

- Mandated use of extended warranties for durable goods
- Requirements for products to be designed for repair and recycling

- Targeting a shift in Public Procurement so that 80% of spend is 'greened' by 2035
- Using agri-environmental payments to encourage use of compost and digestate
- Investing in collaborative research to support use of secondary materials
- Investigating the feasibility of a tax on raw materials, potentially linked to embodied carbon in materials.

The Government's industrial strategy and 25 Year Environment Plan provide the policy frameworks to pursue these and other demand-side policy measures.

Q5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Non-landfill assets typically have an operating life of 20-25 years, and over this period routine preventative repair and maintenance is carried out. Wholesale replacement of existing assets is not generally countenanced within the operating life of a facility except *in extremis* due to a fundamental design failure or change of law, since the return on capital employed is also factored over the same timescale, along with contract lengths for supply of waste. Technical modifications to existing infrastructure (such as improved sensing instruments) are routinely carried out.

New recycling and recovery assets are typically tied to municipal or commercial supply contracts, without which capital funding is difficult to source. Refer to our response to Questions 7 and 8 for further comments on financing.

Q6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Procurement of household waste collection services occurs under the procedure of Best Value, under which Competition is but one of the four Cs for reviewing service performance, alongside Challenge, Compare and Consult. Competitive tendering is now discretionary, so much so that according to the Audit Commission, "competition has been consistently the least applied of the four Cs in Best Value" (*Healthy Competition*, 2007). Studies conducted by the Office of Fair Trading in 2004 and 2006 raised similar concerns, recommending that when in-house providers were also tendering, local authorities should take care to ensure competition on a level playing field so that private suppliers were not discouraged from bidding.

In essence under Best Value, and invoking the exemption afforded to Teckal companies, Councils have increasingly taken service provision back into their Local Authority Trading Companies (LATCs) without first testing their service offer in fair and open competition. The intention expressed in the White Paper, that in the course of commissioning, commissioners should "seek and fully consider a minimum of three providers, from whichever sector, when they contract services", is unenforceable in the case of a Teckal company. This would also apply to the Right to Challenge under the Localism Act 2011 for services that pass the relevant control test.

Furthermore, individual collection contracts are often bundled together by partnering Councils, and are then taken in-house *in toto* without recourse to competitive tendering. If anything, the pace of transfer of waste collection services to in-house LATCs has accelerated over the past two years as Councils attempt to retain that revenue stream within their own organisations.

Arising out of our comments, we make three points:

- There is a discrepancy between the principles expressed in the White Paper *Open Public Services* (2011) regarding opening public services to competition, and the manner in which Best Value is being applied by Local Authorities when procuring waste services, especially in relation to the lack of competitive tendering, and transparency of Local Authority costs;
- Removal of ring-fencing of local government revenue grants from 2011/12 has given Local Authorities greater flexibility in moving costs between other budgets, which might obscure the "true" cost of waste collection to the Authority;
- Breaking up contracts into smaller lots is at odds with Government's call for joint working, and with the trend among Local Authorities to bundle-up collection contracts, while at the same time taking them in-house without recourse to competitive tendering.

It is noteworthy that waste management does not figure in any of the annual progress reports on Open Public Services published since 2011. Whereas Councils can track and monitor the performance of privately operated contracts through agreed performance indicators, it is virtually impossible for a private contractor to gain visibility of the service performance or costs of an in-house provider prior to the decision of a Council to retain a service. Costs shared across other public service sectors such as depreciation of shared assets, debt servicing and administrative overheads may not be fully isolated (or disclosed) when costing in-house waste management services.

Drawing on these general observations, some of the changes we would wish to see are:

- Waste contracts should be subject to (indeed, revert to) compulsory competitive tendering, backed up with robust and even-handed bid evaluation models that account for issues such as risk transfer.
- While Teckal companies will continue for the duration in line with the EU Procurement Directive 2014/24/EU, in the longer term, especially post-Brexit, we do not see why LATCs should retain or take in a service without recourse to competitive tender. This also applies to bundled contracts as part of a joint working agreement between local authorities.

Local Authorities should list well in advance their intention to transfer or take in-house a waste contract, including their reasoning behind that decision and their basic assumptions (including claimed savings), sufficient for interested parties to scrutinise the decision, exercise their Right to Challenge under the Localism Act 2011, or to launch other forms of legal challenge.

Q7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Q8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Ease of access to finance is dependent on security of feedstock supply, which in turn requires the company to secure supply contracts for the duration of the loan, or the ability to access new contracts over the period of the loan. SMEs are least able to fulfil these requirements, hence they are more reliant on venture capital and government support (for example through the Green Investment Bank or through WRAP), for infrastructure projects at the lower end of the scale.

In relation to funding of waste management infrastructure relating to obligated materials under Producer Responsibility legislation (such as packaging) the waste management sector has made a case for amending the present Packaging Recovery Note (PRN) system by requiring producers to bear the cost of downstream collection and waste management, in effect transferring these costs off Local Authority budgets. The move would draw more finance into the waste management system for funding new collection and processing infrastructure.

In terms of difficulties in attracting project funding, the overriding requirement is for regulatory certainty. For example the changes to feed-in tariffs for anaerobic digestion has resulted in a lack of confidence in the sector, which has affected access to funding. Lack of clarity in relation to the government's commitment to maintaining recycling targets has impacted adversely on investment for the upgrade of recycling facilities.

Q9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Actioning circular business models relies heavily on supply chain partnerships, in which the waste management sector is not merely a deliverer of end-of-pipe disposal services, but is also seen as a provider of secondary materials and recovered energy, along with the environmental and sustainability benefits that recycling and energy recovery offers. Collaboration across the supply chain is fundamental to the concept of the circular economy (Question 28) and for supporting the market-led business model and related infrastructure that is being adopted across the resources and waste management sector. The risk to the circular economy lies in individual actors not collaborating with or integrating their supply chain partners.

We have referred to some of the issues in our response to Questions 1 and 4. More detail is provided in our response to Questions 27 and 28.

Q10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The National Planning Policy for Waste (NPPW – October 2014) has been welcomed by SUEZ as a starting point for a “modern” strategy for waste and resources and related infrastructure. For example, the NPPW notes the ambition to deliver “sustainable development and resource efficiency”, the “positive contribution that waste management can make in the development of sustainable communities”, “ensuring the design and layout of new residential and commercial development and other infrastructure ... complements sustainable waste management”, and “looking for opportunities to co-locate waste management activities together and with complementary activities” – the last two harking back to Question 3 in the present Consultation. Some specific planning issues that merit comment are discussed below.

Planning for C&I waste management

Development plans should provide sufficient opportunities to meet the identified need for the management of *all* waste streams. As noted in the preamble, while capacity planning for waste under the responsibility and control of local authorities is adequately catered for, there remains a lacuna in relation to data for capacity planning in the management of C&I waste. The UK has historically relied on ad hoc campaigns to gather such data, which have been both costly and of

limited reliability. Data from such campaigns also rapidly lose their currency with shifting economic fortunes and the changing make-up of UK business.

With C&I waste tonnages exceeding that of municipal waste by a factor of 2 to 3, SUEZ advocates a more robust system of data capture delivering at least annual updates of waste arisings, which can be further analysed to discern sectoral trends. One such system would be the annual reporting by businesses of their waste arisings as part-fulfilment of their obligations under the duty of care, together with the mandatory use of the electronic reporting system EDOC.

Catchments and the proximity principle

While the NPPW enjoins local authorities to plan for new facilities “to serve catchment areas large enough to secure economic viability of the plant”, local authorities should be advised against restricting waste management developments within their boundaries to only deal with waste arisings in their areas. Catchment boundaries are not only anti-competitive and difficult to enforce, but fail to acknowledge that the business case for some waste facilities require a large catchment area extending beyond the planning authority’s administrative boundaries. Facilities with restricted catchments would be deemed a higher risk for investors, preventing the delivery of modern waste infrastructure. Defra publication *Energy from waste: a guide to the debate* (2014) notes:

“The ability to source waste from a range of locations/organisations helps ensure existing capacity is used effectively and efficiently, and importantly helps maintain local flexibility to increase recycling without resulting in local overcapacity”.

Strategic planning for resource management

While the NPPW stipulates that local planning strategies for sustainable waste management should be considered alongside other spatial planning concerns and integrate effectively with other strategies, planning bodies have little or no experience of producing integrated strategies of this type, or of linking waste and resource management strategies into the fabric of a broader, overarching economic development plan.

One exemplar of an integrated resource conservation and waste management strategy is the Material Resources Strategy (MRS) developed by Hampshire County Council. The publication *London: the circular economy capital* (London Waste & Recycling Board, 2015) applies these principles to the London Infrastructure Plan 2050, as does the Scottish government in its strategy *A Manufacturing Future for Scotland*, launched in February 2016.

Q11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Restoration of closed (mainly landfill) waste management sites has created a haven for flora and fauna. Under the Landfill Communities Fund (LCF) landfill operators have contributed a portion of their landfill tax liability towards community and environmental enhancement projects. Since the introduction of the scheme in 1996, the government reports that the LCF has provided £1.4 billion in total funds for over 52,500 community, biodiversity and environmental enhancement projects.

In addition to funding local environmental initiatives SUEZ’s Distributive Environmental Body SUEZ Trust has partnered with the RSPB to deliver biodiversity on a larger scale.

Q27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

The Association of Directors of Environment, Economy, Planning & Transport (ADEPT) warned Defra in July 2013 that a significant number of local authorities had experienced a reduction in recycling rates in 2012/13. With England's 2016 recycling rate at about 44% with the first signs of a downward trajectory, it is increasingly likely that the UK will default on its EU recycling target for household waste, of 50% by 2020.

The evidence suggests that the current suite of Defra policies has run its course, and that the target (or indeed higher recycling performance) will only be achieved by introducing a refreshed set of policies and policy instruments. These might have included, by way of example, an above-RPI increase in landfill tax, re-imposition of statutory recycling targets on local authorities, and an analysis of which particular waste streams should be targeted with landfill restrictions or with requirements for separate collection in order to accelerate recycling and diversion rates (for example, food waste). However, with just three years to 2020 it is now unlikely that policy fixes, even if expeditiously introduced, will have time to take effect.

Further uncertainty over the longer term has been introduced with the absence of signals from Defra, given the government's general reluctance to introduce "hard" regulation, as to whether the UK will honour or, in the event of a hard Brexit, mirror the higher recycling targets proposed in the EU's Circular Economy Package (65% of municipal waste by 2030). With no statutory targets, either for recycling or for landfill diversion, in the offing in England, investment in upgrading and replenishing the current stock of recycling infrastructure has been put on hold. The sector estimates that 15% of the UK's current recycling capacity will close by 2020.

In addition to the above, we have commented in our response to Question 4, some of the demand-side policy measures that are needed in the UK in order to drive a new generation of infrastructure growth in the resources and waste management sector as we transition from a traditional landfill/disposal-led strategy.

Q28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

We have largely addressed these issues in our response to Questions 2, 4, 10 and 27. Until virgin and secondary resource flows into and out of the economy are accounted for in economic terms (by Treasury) and integrated into other mainstream macroeconomic and sectoral fiscal flows, the bigger picture will continue to elude the UK government. A structured cost-benefit analysis can then be conducted by Defra, BEIS and Treasury – what monetised environmental and economic benefits accrue from substituting secondary materials for virgin (often imported) raw materials and from re-shoring exported secondary materials and energy-rich waste-derived fuel, what policy/government interventions are required to facilitate their achievement, how much would these interventions cost, and at what level should targets be pitched in order for the benefits to exceed the costs.

Businesses have a role in recycling and recovery, through the concept of Extended Producer Responsibility (EPR). In contrast to countries such as the Netherlands, the UK applies producer responsibility legislation to a relatively limited number of products and/or materials that end-up in municipal waste. The Packaging Recovery Note (PRN) system referred to in our response to

Questions 7 and 8 is an obvious example, though local authorities have commented that the distribution of PRN revenue is opaque, and relatively little revenue filters down to local authority level to support more and better collection systems.

10 February 2017

National Infrastructure Assessment Call for Evidence

Response from Suffolk County Council

This note supplements that provided by the Joint Suffolk Member Working Group which has already been sent on to you. Suffolk County Council is a party to that group and endorses the comments therein.

Cross cutting issues

1. What are the highest value infrastructure investments that would support long term growth in your city or region?

In Suffolk, we have produced a Strategic Planning and Infrastructure Framework that looks at the delivery of housing and jobs growth to 2050. This has identified key infrastructure requirements to help deliver this growth including,

- Improvements to the strategic road network to support our ambitious growth ambitions (as set out in the Joint Suffolk Member Working Group response).
- Improving the rail line from Felixstowe to Nuneaton and points north. This is not just about track but also about more efficient (digitised) signalling which allows for increased capacity using existing hardware.
- Improvements to the rail junctions at Ely which is a critical rail node for the whole region and is a significant constraint on growth.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Suffolk is home to the port of Felixstowe which handles 40% of the UK's container traffic and is the main container port for the Northern Powerhouse. We also have the largest grain exporting port in the country at Ipswich. Road and rail infrastructure to support these nationally significant assets is crucial. The new Industrial Strategy places a clear emphasis on the role of exporting in driving national growth so having a ports network with the right infrastructure for growth will be critical for the future economy of the UK

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

- 4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?**
- 5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?**

Simply maintaining and repairing assets will not support long-term growth. Our region has in the past done poorly compared to other regions for infrastructure investment – based on a repair and maintain policy. Despite this it has remained one of the three regions that are net contributors to UK plc. However, appropriate interventions at an earlier stage would not have led to the deficits identified at 1. above which are now acting as a brake on growth.

- 6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?**
- 7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?**
- 8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well- functioning markets?**
- 9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?**
- 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?**

Forward funding of infrastructure to ensure provision is in place before development would make growth more acceptable and deliverable. However it would require more intervention from the public sector at national and local level.

- 11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?**

We welcome the inclusion of this question in the NIC consultation, as it demonstrates Governments' commitment to being the first generation to leave the natural environment better than we found it.

First, we should not lose sight of the natural environment's intrinsic value, nor our moral obligation to protect it. However, notwithstanding this, the role that the natural environment plays, through providing immeasurable natural capital, on which society depends, is a key consideration for NIC. Use of the mitigation hierarchy in infrastructure development is a tried and tested mechanism that supports good decision-making, as is a collaborative approach that involves appropriate stakeholders. However, we need to think more broadly about the definition of the natural environment, widening it from the traditional approach of evaluating impacts on protected sites, species and landscapes (such as through EIA), aspects that are, unhelpfully, still widely seen as constraints on growth, to the role these and other natural environment features, such as those covered by the definitions of natural capital, play in the sustainable future of society.

Infrastructure development should take full account of natural capital accounting in decision-making to ensure that our natural capital (the world's stocks of natural assets which include geology, soil, air, water and all living things) is not unsustainably depleted. This should be a fundamental principle in infrastructure development. Society depends, and will continue to depend, on the health and wealth of our natural capital, so it is vital that this generation does not unsustainably deplete stocks as we grow the economy. Natural capital audits and accounting will be increasingly important in the future, such that conservation (and enhancement) of the natural environment and thereby its ability to support life on earth, is properly considered in decision-making.

A further, more specific, area that NIC should consider is the role that the natural environment (and its conservation & enhancement) plays in a circular economy and as part of this in our health & wellbeing. There is much evidence, for example in the UK National Ecosystem Assessment, to demonstrate the benefits of the natural environment to mental and physical health and quality of life, and thereby to a healthy workforce, to inward investment in an area where the natural environment remains a strong asset, and to economic prosperity itself. In 2015 a Suffolk wide poll demonstrated that the countryside & coast is seen by the vast majority of respondents as the best thing about living in Suffolk. Similarly, Visit Suffolk's market segmentation analysis in 2015, showed that natural and heritage attractions were by far the most visited. Both are simple, yet powerful, demonstrations of the importance of the natural environment to contemporary societal agendas. This demonstrates that we cannot and should not separate the natural environment from wider decision-making, and in fact that across society we should see the importance of natural environment as a key building block of our economic prosperity and health & well-being.

- 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?**

Transport

- 13. How will travel patterns change between now and 2050? What will be the impact of adoption of new technologies?**

High speed broadband availability across Suffolk will provide an increased opportunity for working from home for at least part of the week. This has the potential to reduce the level of commuting traffic to centres of employment, however the growth in population will still see an overall growth in traffic volume. It is also likely to increase the volume of local traffic (10-15 miles) with the opportunity for local shopping and socialising. The peak time commute is liable to spread over the day and the inter peak liable to grow in number levelling out the peaks across the day.

Local production of goods using 3D printing technology has the potential to provide a more distributed supply network. This has the potential to increase the demand on travel to the new local centres both for raw materials freight transport and customers visiting the sites.

Suffolk already has an above average older demographic and this is liable to increase. The short distance travel demand using new forms of mobility scooters and electric bicycles is expected to increase. Trips of 1-10 miles for retail and socialising will grow and place a demand on the infrastructure with new accessible purpose built "roads" being require to cater for this slower moving traffic.

Autonomous vehicles will provide the opportunity for higher volumes of vehicles travelling closer together and at consistent speeds. There is also the opportunity to reduce personal vehicle ownership with the related reduction in parking demand. The vehicles would also allow for greater usage of vehicles by those currently unable to drive due to infirmity or age (including under 17s), thereby increasing the numbers using the road network.

- 14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?**

On the assumption that economic growth will continue to develop in London, and the 3 major centres in the East i.e. Cambridge, Ipswich and Norwich investment is required in providing high speed and frequent transport between the centres. Improvements to the speed, reliable and frequent train links between the centres is key for both movement of both people and freight.

Pinch points on the trunk road require attention to improve the reliability of travel, this includes the provision of improvements at major junctions and interchange points on the network. These include the provision of new and enhancement of existing river crossings to increase the network capacity and to provide network resilience.

Within the urban areas sustainable transport improvements are essential to retain a working centre open for residential, commercial and leisure use. The provision of priority routes and areas for non- motorised and smaller sized/slower vehicles are key to achieving this.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

The continued growth of Felixstowe port as a centre for goods entering and leaving the UK requires investment in the connectivity of the port with the rest of the UK.

Short distance local travel in rural areas, needs to be improved, so that smaller sized and slower vehicle options are viewed as the normal means of getting around. The provision of routes segregated from the faster and larger vehicles is key to this goal.

With the potential for the growth of a more distributed network of local centres of production the transport network to these sites needs to be addressed. Improvements to the road and rail capacity and the requirement for improved maintenance as these routes become more heavily utilised.

16. What opportunities does “mobility as a service” create for road user charging? How would this affect road usage?

Mobility as a service is likely to drive down car ownership and with it parking demand. Associated with mobility as a service is the demand and requirement for full coverage and availability of real time on line data to ensure efficient movement.

In relation to road user charging this would need to be managed on a per mile basis which requires 100% accurate data coverage of vehicle movements to track, record and charge. Options to toll individual roads present a problem given the limited trunk road options and the potential impact from alternative routes through local roads and villages.

Management of the costs of travel could also be used to manage travel demand with peak time charging, emission charging and congestion zone charging. Freight road traffic to be managed along agreed corridors with penalties for non-compliance.

Digital communications

17. What are the highest value infrastructure investments to secure digital connectivity across the county (taking into consideration the inherent uncertainty in predicting long term technology trend)? When would decisions need to be made?

SCC believes that the UK requires both a breadth and depth of connectivity. There is no doubt that urban and business centres require to gigabit fixed fibre services to compete internationally, and likewise, the UK needs to be at the forefront of LTE and emerging 5G deployments for mobile connectivity. It is highly likely that the majority of this connectivity will be provided by the existing commercial marketplace, with all mobile operators currently signed up to 99% coverage of 4G by the end of 2017. SCC also believes however that policy needs to address the needs of the rural economy, and the platform for acceleration of the digital economy which can only be provided once ubiquitous broadband access is a reality. Therefore, given national broadband coverage will reach around 95% by 2019, our view is that we need to push on with the hardest to reach areas to ensure that full coverage is achieved as quickly as possible.

18. Is the existing digital communications regime going to deliver what is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Since the inception of state intervention to increase fibre broadband rollout beyond the half of the country which was addressed commercially, Suffolk has been fully supportive and adoptive of government policy, led by the BDUK unit in DCMS. We were extremely pleased to sign our initial contract under the BDUK framework in December 2011, and completed that scheme ahead of target, under budget, and with an over delivery in terms of premises covered. This took us to the then policy commitment of 85% superfast fibre coverage, a considerable step towards eradicating the digital divide in Suffolk, and providing ubiquitous internet access required to live, work, consume services, and enable a digital economy to grow and become default in the UK.

Acutely aware that this scheme still left around 15% of Suffolk, or over 50,000 premises in the county who are unable to access digital services which the vast majority of the country take for granted, we were the first county nationally to

proceed under the BDUK Superfast Extension Programme, and now have a contract which will see us reach 96% coverage by 2019.

This does leave Suffolk County Council with two key issues to address. Firstly, there is no policy commitment or funding made available to address the circa ten thousand Suffolk premises who will be left behind after existing policy interventions are delivered. Secondly, for those who have now waited from 2011, through to 2019, there was a very high degree of frustration and disillusion felt.

To date, the solution proposed by DCMS has been the “Universal Service Obligation”, providing 10Mbps by 2020. In Suffolk, we remain concerned about the inadequacies within this proposed approach.

Firstly, the USO cites a speed of 10Mbps in 2020, based on the Ofcom Annual Report of 2015. Whilst 10Mbps is sufficient today for the market to sell current broadband packages, as the market develops and the connection has to cope with multiple devices, HD/4K content, VPN and other applications it will be insufficient by the time the USO comes into force in 2020. Therefore, our view is that this policy condemns a proportion of Suffolk residents to a second class service. Technically, long reach VDSL using the copper network also neglects to bring fibre close enough to these properties to provide a clear upgrade path beyond ~10Mbps, creating the serious risk of a need to intervene again as bandwidth demands increase.

It is clear from this proposed policy that government believes that completing the rural broadband rollout does not represent value for money as you reach the final few percent. We would propose that, rather than looking at the cost of the first premise upgraded with state funding, or the last one to benefit, we should instead look at the average cost per premise within the entire intervention from 50% to 100% as a single strategic programme, rather than the cost of the final premise connected. Fibre can reach 99% of the UK without being overly costly per premise, and the average cost per premise across the entire intervention should be where we focus our minds when evaluating value for money and shaping government policy.

In terms of the current policy and market composition, and the announcement in the Autumn Statement 2016, our key concern is that lack of policy and funding commitments in place to provide ubiquitous, upgradable superfast access. Whilst we can see the merit in committing £400m of government funding to intervene in urban areas and increase speeds further, we are aware that these areas have already been subject to commercial and/or state funded upgrades, and for which a healthy commercial market exists to provide further upgrades (eg CityFibre, Hyperoptic, MNOs)

Instead, we believe that funding should be committed to ensuring broadband access for all – this could be in addition to the money for extending full fibre access. We believe that until ubiquitous access exists, the digital economy can never truly embed and excel, not least in counties such as Suffolk. We have strongly urged government to communicate a clear and equitable strategy for those left behind after the delivery of current policy.

The recent DCMS consultation on this subject discusses the desire to stimulate market activity in rural areas. In Suffolk, our view is that this is a difficult commercial proposition which we have discussed with many alternative providers. Having spent close to £1bn of public subsidy to reach the areas between 50% and 95% coverage due to market failure, we suggest that it is abundantly clear that the only realistic, viable option is to extend and build that scheme for the final few percent, rather than to seek to create a thriving infrastructure market in the very hardest to reach areas at this point in time.

The consultation also discussed public sector demand aggregation. Having tested this extensively in Suffolk, it is quite clear that this does not form a viable solution for rural broadband access. Prior to the state funded Openreach FTTC rollout, public sector bodies were driven to spend vast sums of money funding private connections to rural primary schools and offices; connections which due to legal, commercial and technical reasons could never be “opened up” to provide to consumers. However, as the DCMS/LA funded schemes with BT have rolled out, we have been able to utilise the open access OpenReach infrastructure to replace these privately funded connections, saving money and negating the need for vast, privately owned public networks which duplicated spend (between private WANs and state funded Openreach FTTX networks). This model will continue in the market, and only the CityFibre style infrastructure build schemes will be viable, and by definition, these will be in urban areas, overbuilding existing state funded Openreach networks, or privately funded Virgin Media networks.

Energy

- 19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?**
- 20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?**
- 21. What are the implications of low carbon vehicles for energy production?**

Water and wastewater (drainage and sewerage)

- 22. What are the most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?**

Suffolk is considered to be in a state of severe water stress, although water companies currently have plans in place to supply existing projected growth this is very likely to increase and when combined with the projected impacts of climate change the future cost of supply is likely to rise. Future domestic demand needs to be tackled in all new build developments with increased requirement for housebuilders to install measures that limit demand, this needs to go beyond low water use taps and toilet and include grey water systems that will reduce demand as well as positively impacting the management of surface water.

Another intervention that would enable more sustainable water supply would be greater flexibility to be applied to current water resources regulations. Competition for water in availability in Suffolk is high and agricultural irrigation is vital to maintain the local rural economy, the regulations for control of groundwater and fluvial extraction are outdated and do not fit with some of the more innovative solutions. For example in order to drain low lying coastal farm land fresh water has historically been pumped over defences to the sea/estuary, our data suggests that for the Suffolk coast this is equivalent to the amount of water currently used to irrigate in the local area. Therefore, twice the water currently used is available, however, to use this water abstraction licences would be required but are not forthcoming under current regulations (designed to retain current resources), this is clearly not conducive to solving the issue of supply. Flexibility to recognise, this water pumped to sea as “wasted resource” would facilitate opportunities for it to be used to supplement irrigation demand and public water supply

- 23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?**
- 24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?**

Flood risk management

- 25. What level of flood resilience should the UK aim to achieve, balancing cost, development pressure and the long-term risks posed by climate change?**

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Natural Flood Management will be a vital tool to manage pluvial and fluvial flood risk reduction in Suffolk, we have a number of projects exploring the practical delivery of this technique. The merits are well understood locally and can be modelled effectively, a key barrier/opportunity is the involvement of landowners. Their agreement to “sacrifice” land to make room for water is a vital agreement and the current structure and management of the agricultural subsidy system is not flexible enough to enable schemes to be delivered easily. The review of the post-Brexit agricultural subsidy package should look to embed incentives for landowners to become partners in delivering public good by reducing flood risk to property.

Solid waste

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste.

The current financial regime is effective in encouraging diversion from landfill. However, the lack of national policy direction on waste and appropriate financial mechanisms is widely acknowledged to be the cause of plateaued/falling recycling performance. The current producer responsibility regime for packaging fails to support the costs of material collection from households and legislation confuses accountability for recycling. Greater clarity of roles would be beneficial to all and stimulate investment. Producer responsibility should mean just that, with industry taking responsibility for funding the full costs of recycling and ensuring that markets exist for the secondary materials that they generate. Local authorities are excellently placed to be the collection agents for industry, due to their unique position in already having a customer interface and relationship with householders; much of the necessary infrastructure in place to deliver the collection service; and an obvious operational synergy between recycling collections and refuse collections. By clarifying responsibilities in this way and removing duplication and ambiguity, government could also enable a move to greater consistency in service provision to residents. Many of the major producers affected would recognise this model, it being how they are required to operate already in many other markets across Europe.

28. What are the barriers to achieving a more circular economy. What would the costs and benefits (private and social) be?

Enhanced producer responsibility is an essential pre-requisite to moving towards a circular economy. Such a move will also require a significant cultural shift away from owning products to buying services, in order to better incentivise and reward investment in improved durability and design for re-use and recycling. Examples such as the move from buying media to subscribing to streaming services demonstrate that such cultural shift is possible.

Submission to the National Infrastructure Commission – National Infrastructure Assessment

10th February 2017

Joint Suffolk Member Working Group on the Strategic Planning & Infrastructure Framework

Page | 1

Introduction

The National Infrastructure Commission (NIC) was formally established as an Executive Agency in January 2017. As part of its National Infrastructure Assessment (NIA), which will become a once per Parliament statement on UK infrastructure need, the Commission has called for evidence on the strategic, long term priorities for infrastructure investment across the UK.

Specifically, the Commission has invited local government (along with LEPs and other organisations) to *share plans that are relevant to nationally strategic infrastructure, to help inform the evidence base for the NIA.*

This paper has been prepared by the joint Suffolk local authority member working group (MWG)¹ that is progressing work on developing a Suffolk wide strategic planning and infrastructure framework (the framework). Following the East Anglia / NIC session, held in Ipswich on 1st February and attended by a number of Suffolk members and officers, the MWG and officer team has prepared this high level overview of the process for developing Suffolk's framework and the authorities' approach to planning for strategic infrastructure investment over the longer term.

Suffolk's Strategic Planning & Infrastructure Framework

Suffolk local authorities, district, borough and county, are working together to develop an innovative approach to delivering long term growth and development across the region. Looking to 2050 we are preparing a joint framework that will deliver the region's economic vision, building rapidly on our position as a net contributor to the UK economy. Suffolk is an area with a reputation for delivery, as demonstrated by the unanimous support for Devolution, and we are well able to drive large scale regional growth – an '*East Anglian Energiser*'. The London–Ipswich–Norwich–Cambridge diamond encompasses seven airports and the two largest ports in Europe. Suffolk is, and will continue to:

- provide the largest gateway for UK plc trade through national and internationally significant ports;
- lead the UK in energy technology, delivering both significant generation from existing and new sources and innovative solutions to long term energy demand through renewables development;
- deliver world leading research, development and implementation of ICT solutions building on the success of BT and the existing cluster at Adastral Park.

¹ The Suffolk SPIF Member Working Group (MWG) includes representatives from Babergh District Council, Forest Heath District Council, Ipswich Borough Council, Mid Suffolk District Council, St Edmundsbury Borough Council, Suffolk Coastal District Council, Suffolk County Council & Waveney District Council.

The framework will set the direction of housing and employment growth over the coming decades and crucially, it will identify the infrastructure that is required to deliver and support this growth. Suffolk requires investment in its infrastructure to deliver on its own and Government's ambitions for growth. We are well placed to ensure the return on this investment is achieved through our partnership approach and joint prioritisation of needs. With support we can ensure Suffolk:

- operates an integrated transport network through investment in strategic and local roads and passenger / freight rail services leading to industrial and business growth, reduced journey times and housing development;
- has a highly skilled and flexible resident workforce that can adapt to changing technologies, working practices and production approaches; and
- ensures land for commercial, industrial and housing is "unlocked" due to sufficient investment in enabling infrastructure (transport, water, power, flood defences, digital communications) giving confidence to the development sector that Suffolk can deliver;

The public sector partners recognise that this framework for growth cannot be delivered in isolation. Extensive work with both the area's LEPs (NALEP & GCGP) is underpinning this framework and engagement to identify the types of infrastructure and development required by the business community is on-going with the support of Suffolk Chamber of Commerce.

Crucially, the Framework is not simply looking at Suffolk's growth and development need. We are working with neighbouring authorities in Norfolk, Cambridgeshire and Essex to ensure we understand the development priorities in these counties and the challenges they are facing to ensure that Suffolk's growth reflects these priorities and works in alignment with rather than competition to its neighbours. We are also responding to London's plans for growth and the opportunities and challenges this growth poses for the East.

The approach

The Suffolk authorities have initiated a review and collation of the evidence underpinning economic development and local authority land-use planning. Working with consultants we are developing a baseline that sets out the Suffolk demand for housing, employment and infrastructure provision over the coming decades.

The emerging Suffolk Framework identifies both enabling infrastructure, that is upfront infrastructure that needs to be in place in order to allow development to happen, and supporting infrastructure, the continued infrastructure that must be delivered and maintained to allow growth to be secured over the longer term. At a very basic level we have defined these as:

- Enabling: transport (road & rail), utilities (incl: water, energy), communications (digital & mobile), flood defences
- Supporting: educational & training, health & social care provision, amenity (green space), and waste treatment

Investment in enabling infrastructure will ensure that Suffolk will deliver on its ambitions to improve regional competitiveness and resident prosperity. By working with Government and securing increased levels of investment for infrastructure Suffolk can exceed its current levels of growth and compete on a level playing field with other UK regions.

In terms of identifying and planning these enabling infrastructure priorities Suffolk Authorities are working closely with partners (including the LEPs and infrastructure providers) to ensure common priorities are delivered. However, we do not simply want to develop a long list of infrastructure projects but rather Suffolk Authorities are committed to developing a step change in the approach taken to delivering growth and ensuring infrastructure investment unlocks housing and employment growth.

The framework is being developed to ensure it informs and reflects national and regional strategies and plans for growth and infrastructure delivery as they emerge and continues to present the concise, cohesive vision for Suffolk's growth. Alignment is and will continue to take place with:

- The recently published consultation *Building our Industrial Strategy*, the Green Paper, published January 2017 and setting out the Government's approach to improving the UK's economy, including through infrastructure investment.
- *Fixing Our Broken Housing Market*, Government's White Paper published 7th February 2017 setting out plans to increase the supply of new homes in England.
- New Anglia and Greater Cambridgeshire Greater Peterborough LEP strategies, 2017 onwards, due for completion summer / autumn 2017.
- Suffolk & Norfolk's Integrated Transport Strategy: currently in development.
- Regional infrastructure investment priorities as identified through regulated providers, such as Anglian Water, National Rail, Highways England, energy firms and BT.

The draft framework

Suffolk Authorities will deliver a draft framework for late Spring 2017. This framework will be taken to Suffolk Public Sector Leaders and following agreement will form the basis of a forward work programme that will be undertaken to provide further detail on key elements, such as a precise examination of the relationship between infrastructure investment and housing delivery and ensure continued alignment with regional / national priorities as they emerge.

The framework will be providing an assessment of different patterns of development across Suffolk and the extent to which these patterns enable greater benefit in terms of both "agglomeration" economies and, crucially, infrastructure investment.

Additional evidence

We have included the draft vision / mission / objectives of our framework and our emerging infrastructure priorities at the end of this submission.

Next steps

The Suffolk team will share the framework with NIC once it is in a draft format with indicative costings allocated to our priority infrastructure proposals and an assessment of the scale and timing of growth that can be enabled as a result of this investment.

The Suffolk framework team would like to work with the NIC as our framework develops and hopes that further discussions can take place over the coming months.

Appendix 1: Suffolk Framework DRAFT vision, mission & objectives

Vision

By 2050 Suffolk will be a premier location in which to invest, live, work and spend leisure time. People of every age will be attracted to and remain in the County because of its dynamic and connected urban, rural and coastal environment, and the education and employment opportunities available. In the words of Andy Wood former LEP Chair “It could be the powerhouse of Europe”.

Mission

SPIF articulates an ambitious, but sustainable growth agenda demonstrating a step change in Suffolk’s competitive position and the prosperity of its residents. It provides clarity on the scale and broad distribution of both housing and employment growth and prioritises the infrastructure investment required to deliver the growth ambition, including, in effect a ‘pan-regional superhighway’ that reflects the overall ambition of the region.

Objectives

By securing significant investment is enabling infrastructure Suffolk will:

- Deliver sufficient homes to meet both current need and future demand across Suffolk. (Targets: minimum of xxx by 2036, with a further xxx by 2050 – these will be set following finalisation of the evidence base)
- Achieve growth in key sectors and new / expanding industries, including significant new jobs, leading to increased productivity, higher wage levels and an increase in Suffolk’s contribution to UK plc (Targets: xxxx, to be set following finalisation of the evidence base)
- Prioritise investment in Suffolk’s strategic transport infrastructure leading to the delivery of the M14, the A12 trunk road, a northern Ipswich route and greater connectivity on the Felixstowe – Midlands rail route, via Ely.
- Work with neighbouring authorities, Cambridgeshire, Norfolk and Essex to ensure greater transport connectivity across the Eastern region is secured and complementary development priorities are delivered, e.g. cross border housing developments.
- Strengthen Ipswich and the surrounding area as the key economic driver of the County by investing to: support key growth sectors (ICT, financial services and education/knowledge economy); transform the cultural offer and quality of the town centre; and deliver ambitious housing growth within and around the town.
- Strengthen Suffolk’s role as the UK’s principal trading gateway to the rest of the world through continued growth of Felixstowe port and significant investment in the transport corridors (both road & rail) to facilitate access to the rest of the UK.
- Support sustainable levels of growth in the rural areas of the County, whilst protecting and enhancing the key environmental and landscape assets of these areas, and the important contribution that these make to Suffolk’s economy and quality of life.

- Support the coastal economy, including off-shore energy, nuclear energy, tourism and the sustainable use of marine resources through appropriate investment in infrastructure, housing and skills.

Appendix 2: Emerging infrastructure priorities for the Suffolk framework

Currently these infrastructure priorities are listed as a series of projects, however as stated above the aim of the framework is to ensure a step change in the approach to infrastructure delivery to ensure the investment unlocks further economic growth and housing delivery. As the framework is developed the relationship between funding infrastructure, in advance of development, and maintaining this investment to sustain growth will be explored with investment plans altered as required. This list of priorities is a starting point and is focused on unfunded schemes. It does not list projects that are currently in design / execution stages.

- Rail transport
 - o Haughley junction (on the Ipswich – Bury - Cambridge line) – doubling needed to improve both passenger and freight services across the County on East – West basis. This improvement is particularly important to deliver on the commitments in the East Anglia franchise.
 - o Ely area improvements to enable further development of Felixstowe line and increased freight traffic from Felixstowe Port onto the Midlands and the rest of the UK
- Road transport:
 - o Junction improvements on the A14, specifically junctions 37, 38, 43, 44, 55, 56, 57, 58
 - Junction 37: improvements to secure growth in Suffolk & Cambridgeshire and improve the interchange between the A11 & A14
 - Junction 43/44: improvements to unlock additional growth in Bury St Edmunds
 - Junction 55-58: junction improvements to deliver increased capacity for safer journeys across the south of Ipswich and provide resilience to the A14
 - o Improved radial / strategic routes to the North of Ipswich to improve traffic flow in Ipswich and provide resilience to the SRN, especially if the Orwell Bridge is closed
 - o Further A12 improvements to enable Sizewell C development, e.g. 4 villages bypass
 - o A11 technology corridor
 - Mildenhall Improvements – including the Fiveways Junction to enable a safer route with improved journey times and unlock growth in West Suffolk area
- Utilities: initial discussions have been held with Essex and Suffolk Water, Anglian Water and UK Power Networks to understand the existing infrastructure provision within Suffolk and the providers’ plans for the future.
 - o Water: Suffolk is an area of severe water stress and while supply and demand are currently in balance investment is needed deliver future growth.
 - o Power: current plans look to 2023 and we are currently working to identify where projected growth will impact significantly on the power generation and distribution network.

The strength of the local economy means that investment in Surrey has the potential to increase tax revenue to have an overall positive impact at the national level on Britain's Gross Value Added (GVA). Conversely lack of investment in Surrey is a main constraint to business growth and if it continues unchecked, it could have significant and wide ranging negative economic impacts.

Investment in Surrey's road and rail links is required to ensure that levels of growth in Surrey can continue to contribute to the local and national economy. Initiatives seeking to achieve sustainable travel patterns and modal shift have a key role to play in reducing congestion and the associated economic costs. In particular, improvements to the North Downs rail line are essential to achieving better connectivity across the county and beyond by providing an alternative mode of transport to the private car.

The county council has worked with borough and district councils to jointly commission a Surrey Infrastructure Study. This provides a comprehensive picture of the infrastructure needed to support planned growth in the county to 2030. The study found a significant funding deficit, particularly in relation to highways, rail and flood defence infrastructure. The evidence presented in the study provides the response to Question 1 of the consultation. The study can be downloaded via the following web page link:

<http://www.surreycc.gov.uk/environment-housing-and-planning/development-in-surrey/future/surrey-infrastructure-study>

We should be happy to respond to any queries on this response and look forward to responding to any future consultations.

Yours sincerely

Surrey County Council's response to the questions set out in the National Infrastructure Assessment Call for Evidence

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

The Surrey Infrastructure Study presents the anticipated infrastructure requirement for each element of infrastructure, including transport, schools, healthcare, social care, community facilities, green infrastructure, flood defences, waste, utilities and emergency services. It found that the cost of infrastructure to support planned growth is likely to be in excess of £5.37 billion and identified a gap of at least £3.2 billion in the funding required to meet these costs. A critical requirement is to ensure that fast broadband is provided and investment is urgently required in a fibre network across the area along with 5G connectivity

Surrey's top transport priorities are:

- The A3 improvements – there are areas of significant congestion on this strategic route and also on the adjoining network which impacts as a constraint to the deliverability of development in the borough of Guildford and potentially in the adjoining boroughs of Woking, Elmbridge and Waverley. It additionally has impacts for development in outer London boroughs.
- Woking Rail Junction – improvements here will have positive impacts on the capacity for this critical commuter rail link delivering an express service into and out of London as well as orbital services with links to the wider area of the South East region and beyond to the South West.
- North Downs Rail Line – investment is critically needed to improve orbital services across the county, particularly to Gatwick. This would be for additional services and also for the electrification of the North Downs Rail Line between Reading and Gatwick. This scheme could benefit from an East-West Rail delivery approach.
- River Thames Scheme – this is critical to reducing flood risk to 15,000 properties in communities both within and beyond the county and includes constructing a new flood channel, weir improvements and installation of property level protection.
- Southern Rail Access – even without the implementation of the Government supported proposal to expand Heathrow, the provision of direct rail access from Surrey to Heathrow is critical to reducing congestion in Surrey and around London and unlocking growth. Government should prioritise Southern Rail Access for Grip 1&2 completion.

• M25 and M30/M25/M11/M10 corridor – capacity or alternative north south corridor is important to accommodate wider growth in the region well

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Businesses located throughout the UK rely on connectivity to international gateways to reach international markets. Road and rail routes to Heathrow, Gatwick and the channel ports are congested, overcrowded and inefficient. This increases costs to UK business which impacts on profitability and therefore reduces the attractiveness of the UK as a location base for international business.

To maximise the potential of the international gateways, particularly the major airports at Gatwick and Heathrow, requires a level of national planning that is currently hard to discern. This should focus on high quality and reliable long-distance strategic routes. The NIC seems well placed to specify this work.

Specifically for Heathrow, in order to deliver the economic potential promised by airport expansion, there will be a need for significant additional transport investment over and above the Airport's immediate needs. This should be through a fully integrated approach to improving strategic infrastructure and the county council advocates a rail link to provide southern access to the airport. Otherwise, the investment at Heathrow Airport will fail to deliver on the potential to genuinely enhance the national economy.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Housing costs in Surrey indicate an acute and growing demand for new homes which is not being met. Residents are acutely aware that new housing development will add to existing pressures on already overstretched infrastructure. The timely and adequate delivery of infrastructure is therefore the fulcrum for making development more acceptable and deliverable. There are currently no formal mechanisms for achieving this across local planning authority boundaries although informal arrangements have been developed including local strategic statements. These are a step forward but it is doubtful that this informal approach will deliver the homes, employment and infrastructure required without greater and more formalised collaboration across wider areas.

In that context, the Government's Devolution Deals provide the opportunity to revitalise infrastructure planning. Whilst the National Infrastructure Commission has a leading role to play in assessing nationally significant infrastructure needs, at the regional scale the Government's Devolution Deals offer the opportunity to adopt a more integrated approach to the planning and delivery of infrastructure to achieve better outcomes for the people who live and work there. The Devolution Deals also offer the potential to accelerate and increase the scale of infrastructure development through new enhanced and pooled funding arrangements.

The twenty six councils in Surrey, West Sussex and East Sussex County Councils together with the three Local Enterprise Partnerships, East Sussex Fire Authority and the South Downs National Park Authority have joined forces as the Three Southern Counties (3SC) to prepare a bid to government for a Devolution Deal. Work is already underway on the development of an Infrastructure Strategy covering the 3SC area to promote the delivery of the transport, schools, healthcare and utility infrastructure required to support housing and employment growth that better meets local needs, in the context of national strategies. The Infrastructure Strategy will set out the overall scale and distribution of future housing and employment land requirements across the 3SC area and the infrastructure that will be required to facilitate this scale and pattern of development.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Demand management can be an effective mechanism for optimising constrained resources. The maximum potential is difficult to ascertain as this is a dynamic issue and impacts would vary with circumstance. Scenarios are therefore likely to offer the best approach.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The balance between new and old infrastructure needs to be managed in such a way to ensure that future generations do not carry a higher burden for investment overall and so that assets do not deteriorate in a way in which they cease to provide a service to future generations.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Many of the current procurement routes favour larger players offering infrastructure services. This is because of the assurances required to do business. This reduces both competition but also in some cases access to knowledge in SMEs who may be offering far more intelligent solutions with a lower overall cost. How infrastructure is designed and delivered has a very great bearing on cost.

The Secretary of State for Transport announced a delivery model for East West Rail, whereby one organisation will deliver the design, construction and operation of the missing railway link between Oxford and Cambridge. This new approach is intended to accelerate delivery of the whole scheme from Oxford to Cambridge, as well as the Milton Keynes Aylesbury line. An East West Rail Consortium, established by local authorities and strategic partners, have committed to make a contribution towards the cost of the scheme and continue working alongside Government and the National Infrastructure Commission to ensure its delivery.

If successful, this model could be applied to other projects, for example, to advance investment in the North Downs Line. The county council has undertaken an assessment which sets out why investment is needed and what it will deliver in the way of employment opportunities, new housing, increase in GDP and other benefits.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: "funding", the Commission means who pays for infrastructure services and how they are financed in general terms.

Director of Infrastructure and Planning
Director of Economic Development and Regeneration

existing infrastructure. At present those that have a duty in many cases have to access funding from others to fulfill their obligations which is both time consuming and in many cases inefficient.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that "can be funded" but "will not be financed" refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

Current mechanisms do not encourage risk to be taken even when long-term returns can be shown. Revolving infrastructure funds operated on a devolved basis as have been proposed for a number of Devolution Deals may offer some scope to address this issue provided that they are of sufficient scale and operated in respect of a clearly defined infrastructure strategy for the relevant area.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

We have no comments to make in response to this question.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

This question and response relates closely to Question 3. The processes for funding and delivering infrastructure need to be better synchronised with the mechanisms for delivering development. It should also be recognised that lack of certainty about funding for investment in strategic infrastructure is a critical risk factor which can determine whether a strategically important development is delivered.

The strengthening of decision making processes at a strategic level for forward planning of development and the delivery of infrastructure is key to achieving greater efficiency in integrating the delivery of infrastructure to meet the needs of growth. A strategic planning approach would provide efficiencies in:

- Linking growth initiatives to wider strategies for infrastructure and housing provision; facilitating efficient decision-making and policy making on cross boundary matters relating to housing and infrastructure delivery;
- Enabling cost effectiveness in sharing resources to develop the evidence base for decision making;
- Providing a vehicle for engagement and cooperation with national, regional and local infrastructure delivery bodies such as Highways England, health authorities and education providers.

As set out in the response to Question 3, the Government's Devolution Deals provide the opportunity to revitalise infrastructure planning. Through the Devolution Deal, governance arrangements would be put in place to ensure clear democratic accountability and assurance at the local level for the delivery of the additional functions and responsibilities that underpin the devolution proposal, including the delivery of new infrastructure.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

It is appropriate here to refer to three of the core principles set out in the NPPF which relate to the natural environment. These principles are required to underpin both plan making and decision taking as follows:

- Contribute to conserving and enhancing the natural environment and reducing pollution. Allocations of land for development should prefer land of lesser environmental value, where consistent with other policies in this framework.
- Encourage the effective use of land by reusing land that has been previously developed (brownfield land), provided that it is not of high environmental value.
- Promote mixed use developments, and encourage multiple benefits from the use of land in urban and rural areas, recognising that some open land can perform many functions (such as for wildlife, recreation, flood risk mitigation, carbon storage, or food production).

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: "credible" improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. "Tractable" improvements are those that can generate usable quantitative outputs. "Transparent" improvements are those that do not rely on 'black box' modelling and assumptions.

We would reference an assessment of the potential economic benefits of investment in various strategic transport corridors commissioned by Coast to Capital, Enterprise M3, Solent and Thames Valley Berkshire Local Enterprise Partnerships (LEPs), along with partner local authorities.

The focus of the study was on the wider economic impacts of the strategic corridors and specifically, how these can help boost connectivity and productivity in the region. These corridors address the lack of orbital connectivity around London and the need to link better to ports and airports.

The methodology used in the study included the following features:

- The "building blocks" of the analysis use recognised guidance based on Treasury Green Book principles (i.e. DfT's WebTAG approach covering Wider Impacts is itself based on Green Book guidance);
- Although founded on WebTAG principles, several add-on economic impacts and metrics are derived (such as the impacts improved productivity has on regional GVA, employment and taxation revenues);
- The impacts were calculated in two ways: 1) firstly, as a "snapshot" of current impacts (i.e. what is the economic impact if the change took place now?) and 2) what is the "longer term" (or forecast) impact over time? – this is explained in more detail below;
- The approach is used at a high level to identify and prioritise corridors before more detailed analysis takes place for shortlisted corridors (i.e. to include proposed residential developments etc.); and
- The approach is designed to be flexible enough to be able to test several different strategic options.

This method was found to have several advantages:

- It is based on recognised methods and can be calculated relatively quickly given the information already available;
- It is flexible and can be used to assess different types and lengths of corridors (featuring different modes);
- Once the productivity impacts have been calculated, these can be applied to the latest ONS GVA data to give a regional and national impact; and
- There is sufficient flexibility in the input assumptions for each corridor so that these can be adjusted for sensitivity testing.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

We have no comments to make in response to this question.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

We have no comments to make in response to this question

13. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

We have no comments to make in response to this question

14. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

We have no comments to make in response to this question

Digital communications:

17. What are the highest value infrastructure investments to secure across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

There are a significant number of communities across Surrey that are difficult to reach into the more remote or hard to reach areas of the county, in particular in terms of broadband and financial services rollout.

support from the Government Better Broadband Scheme. However there is a clear need to extend the Better Broadband scheme beyond the planned closure at the end of 2017 and to provide a fibre network with 5G connectivity across the area to enable many more communities to take advantage of direct funding from central government.

18. **Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?**

Note: the existing "regime" refers to the current market, competition and planning frameworks. "Digital communications" includes both fixed and mobile connectivity.

See our response to 17 above.

Energy:

19. **What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?**

There are a wider variety of options for decarbonising heat, each with differing merits and feasibilities in different situations. Clearly efficiency improvements are key, including continued opportunity and need for retrofitting domestic properties with insulation (loft, cavity wall and solid wall). This requires further stable and long term funding, not a short term and On/Off approach which is the current case with funding in this sector, which is difficult (not efficient) for either the supply chain or the consumer.

In terms of decarbonising the residual heat demand, options include: electrification of heat (e.g. heat pumps) powered by an increasingly decarbonised grid; biomass including woodfuel, energy crops and Energy from Waste (which could be CHP or heat only boilers) and passive solar heating (i.e. building design considering orientation and glazing etc).

20. **What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.**

We have no comments to make in response to this question

21. **What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?**

We have no comments to make in response to this question

Water and wastewater (drainage and sewerage):

22. **What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?**

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

We have no comments to make in response to this question

23. **What are the most effective interventions to ensure that drainage and sewerage capacity is maintained and enhanced?**

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

Local Plans outlining future development must align with Flood Risk Management Strategies and Water Companies long term investment strategies. That way, investment in drainage and sewerage can be better matched with locations earmarked for future development. It is also essential that water companies are made statutory consultees.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

A whole catchment approach should be employed but the key parties must also be involved in a holistic approach to delivering solutions and managing current risks. The bodies involved among many are actively improving their joint working but commercial pressures (including LLFAs, Local Planning authorities, water and utility companies and the Environment Agency corporate sensitivity of data, OFWAT limitations), other planning pressures, the differing time scales for large scale planning (AMP periods vs Local Plans vs National & local FRM strategies) and the sheer number of parties involved mean that a truly holistic catchment approach is near impossible to achieve currently. A simple first start would be to make water & utility companies statutory consultees.

Catchment level boards could work and indeed the WFD approach of catchment partnerships for water quality should be seen as a model to joint pooling and coordination of resources, future planning and provision of joint innovative solutions.

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

The current levels of risk set out by the modelled flood maps for flooding from rivers and the sea and from surface water do not currently take into account the increase in risks due to climate change. Additional mapping should be produced to show these future risks. This would clearly demonstrate the likelihood of these risk to developers, planners and the general public and help decision making with respect to current and future development and protection of infrastructure. Similarly statistical analysis of the return periods used in flood modelling should be updated to ensure recent changes in our climate (and flood events) are being taken into account when flood risk models for new infrastructure development and flood risk management schemes are being planned.

The current focus is on building defences to reduce the level of risk. In areas of high flood risk the management of impacts can also be effective. Managing impacts through increasing community awareness is an approach which forms the foundation of Surrey's Flood Risk Management Strategy. This sets out the process undertaken by the flood authority of maintaining the existing systems and involves working with the community to build their resilience through awareness of responsibilities and local action and identifying opportunities to mitigate the residual risk once the local measures have been achieved. Through this approach we have been able to reduce the risk to a level which is tolerable to the community and infrastructure users whilst minimising the cost all round.

It is considered that infrastructure should be functioning within 24 hours of an incident being over and properties should be habitable within 6 months of an incident.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

There are distinct merits in using all available approaches to managing flood risk; especially as the requirement to understand the risk and live with water (using resilience and holistic management approaches) will become prevalent with climate change, an increasing maintenance burden and financial pressures.

Natural flood management has its place but due to the limited land available in key high risk areas (plus increases in demand for housing, agriculture etc), the variable topography and the limited impact these practices can achieve in the worst rainfall or storm events they should not be considered a panacea to the problem. A holistic catchment approach using innovative techniques, catchment scale planning (both for flood risk management and for new development), traditional engineering, property level protection and community resilience needs to be employed.

The Catchment Partnership Boards set up to deliver Water Framework Directive actions are a good example of how this can work. In Surrey we work with the Wey and Mole Catchment Partnerships to deliver flood risk management outcomes alongside habitat improvements.

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet land fill and recycling objectives and to assign responsibility for waste?

The largest barrier for developing waste infrastructure in Surrey remains the difficulty in finding suitable sites and obtaining planning consent. There is no easy fix to this but the national policy emphasis on housing must continue to emphasise the importance of waste management facilities as supporting infrastructure and the need to safeguard suitable sites for waste use. Competition for land in Surrey means that sites identified for waste use are often lost to higher value uses such as residential. Landfill tax has been the single most influential financial incentive to help drive the management of waste up the waste hierarchy. It is important that it is retained and continues to be increased, at the very least, in accordance with the retail price index.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A "circular economy" is an alternative to a traditional 'linear economy' (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

Producer responsibility has been shown to drive innovation in the industry to develop products that are more recyclable and to develop recycling infrastructure. A good example of this is with regard to Waste Electrical and Electronic Products – where the industry bears the cost of recycling and has developed infrastructure and processes to recycle this waste. Waste streams such as soft furnishings, carpets and mattresses continue to end up in landfill as they are problematic or not cost effective to recycle – Assigning responsibility to producers to pay for and deal with recycling of this waste would enable innovative processes to be developed for these materials.

Sustainable Energy Association

National Infrastructure Commission – Call for Evidence

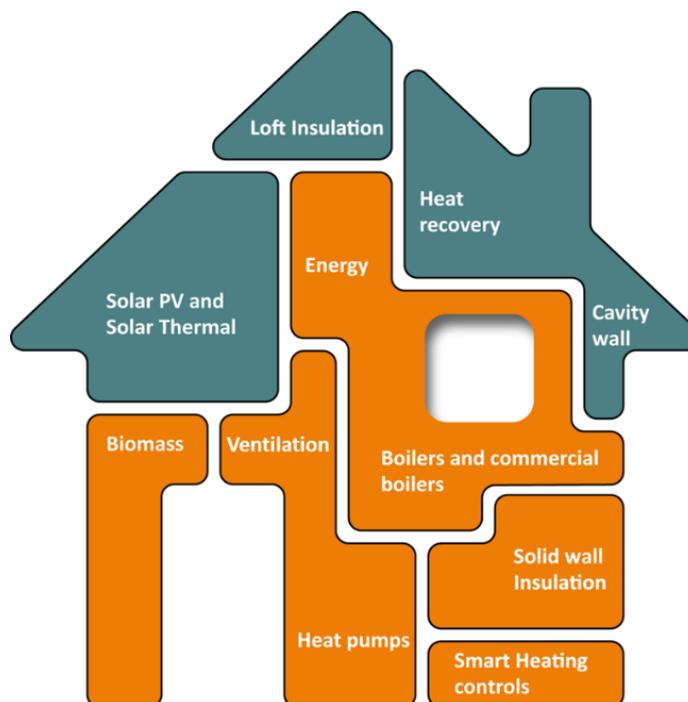

Date: 10th February 2017

Response submitted by: Sustainable Energy Association

For more information please contact: [name redacted]
[email redacted]

About the Sustainable Energy Association

The Sustainable Energy Association is a member based industry body. We are technology agnostic, taking a whole house and whole heating system approach which does not favour one technology over another but rather focuses on the right solution. We promote holistic approaches to developing heat policy ‘wrap then heat’ in line with our wide-ranging membership which covers energy efficiency as well as renewable technologies and non-renewable heating technologies such as gas boilers. Our members manufacture, retail or regulate a range of technologies including ones shown below:

Key Message

Improving our building stock, which is one of the least efficient in Europe, needs to be a priority. Our buildings are a significant physical asset and as such the Government should place buildings at the heart of delivering the United Kingdom’s energy policy goals. The delivery of energy efficiency including the deployment of low carbon energy sources is one of the most valuable, long term infrastructure investments that the Government could support. Investments of this kind, provide long term benefits to the economy and to society. Ensuring that our buildings are well-insulated, future proofed and able to accommodate low carbon heat sources is essential if the UK is to meet its carbon targets, address fuel poverty and improve consumer health and wellbeing.

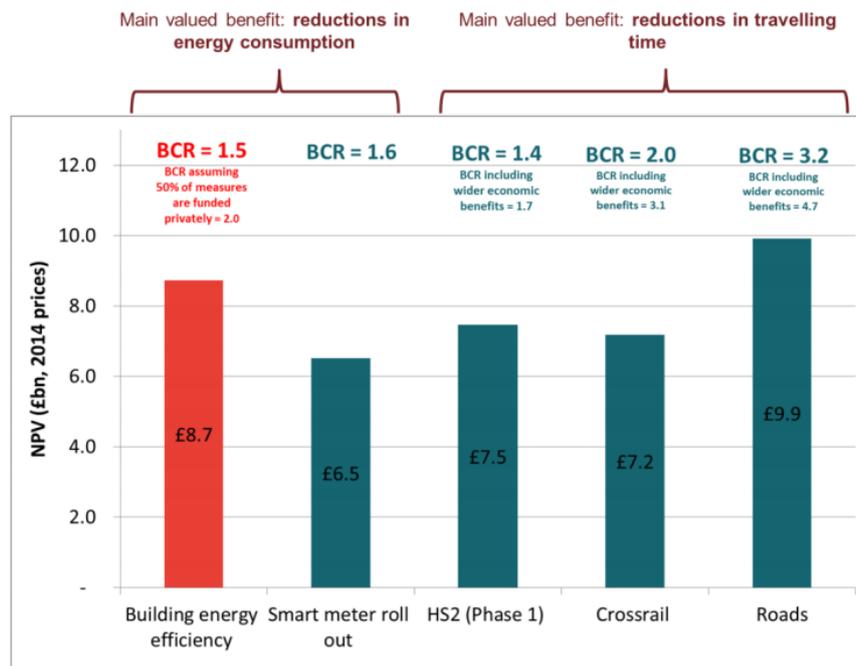

Cross-cutting issues

Q. 1. What are the highest value infrastructure investments that would support longterm sustainable growth in your city or region?

The SEA consider that the delivery of energy efficiency including the deployment of low carbon energy sources, is one of the most valuable, long term infrastructure investments that the Government could support. Investments of this kind, provide long term benefits to the economy and to society. Research produced by Cambridge Econometrics and Verco found that for every £1 invested in energy efficiency there is a £3.20 return to the Economy.

Figure 1 details this graphically, and shows that an energy efficiency infrastructure delivery scheme compares favourably with many other supported infrastructure projects when considered on a narrow cost/benefit perspective – without monetising the substantial health benefits that can be achieved. Here a major energy efficiency infrastructure scheme could deliver a net benefit of £8.7bn (2014 prices) to the UK economy¹. In addition such a project would reduce some of the £1.36 billion the NHS in England pays out to treat sufferers of ailments associated with cold homes.

¹ Frontier Economics (2015) Energy Efficiency: An infrastructure priority

Source: Frontier Economics, based on sources detailed Box 1 on page 17. The NPV is the present value of the difference between the stream of costs and benefits of each scheme. The BCRs represent the ratio of societal benefits to Government costs (In line with Webtag guidance). The NPV figures do not include wider economic benefits. The base year for the present values varies between 2010 and 2013.

Figure 1 - Estimated NPV of different infrastructure schemes (Frontier Economics, 2015)

Inefficient homes are expensive to heat and can have negative health implications with the risk of cardiovascular and respiratory illnesses being heightened by living cold and/or damp conditions. This means that poorly performing buildings are a drain on the NHS and on the economy as a whole. It is estimated that insulating all the solid wall homes in the UK could bring about health benefits worth £3.5bn - £5bn.²

Government should therefore make energy efficiency improvements a National Infrastructure Priority, and – where cost effective – move all homes up to EPC Band C. Such improvements will deliver significant environmental benefits and fuel bill savings and can have a transformative impact on those that live in fuel poverty – lowering NHS costs, improving social mobility (improving education and job prospects) and increasing wellbeing.

Improving energy efficiency increases productivity, reduces costs and provides jobs. The Scottish Government has declared energy efficiency a National Infrastructure Priority and as part of their Energy Efficiency Programme, the Government has estimated that for every £100 million spent on energy efficiency improvements in 2017, approximately 1,000 full-time equivalent jobs are

² UKGBC (2014) [A housing stock fit for the future: Making home energy efficiency a national infrastructure priority](#)

supported³. The Think Tank Bright Blue also highlights the job creation potential of energy efficiency, stating that “the sector of the UK low-carbon economy which creates the highest number of jobs is energy efficiency, employing 155,000 people in 2014” and that improving the energy performance of all homes to EPC band C would create 108,000 net jobs per annum between 2020 and 2030.⁴ It is important to note that job creation through energy efficiency is not area specific as the installation of energy efficiency measures requires local labour. The wide geographic spread of demand for energy efficiency measures means that the supply chains and manufacturers that support the energy efficiency industry are likely to be located outside wealthy areas and provide sustainable jobs across the country. No other investment can stimulate economic growth and create jobs in every UK constituency whilst helping struggling households and reduce the cost of decarbonisation⁵.

In off-gas grid areas/regions in particular, with limited heating options available for consumers, energy bills are typically higher than the on-grid average. Here the development of renewable heating infrastructure can help supply low-carbon energy to consumers, at lower and less variable costs. Currently, a barrier to such energy supply is the high upfront cost, of which a proportion is derived from the cost of ancillary measures (see Figure 2 below). This includes ensuring systems are specified to be ‘heat pump ready’ today (e.g. ensuring heat emitters are sized to enable low return temperatures). Figure 2 illustrates the high proportion of installation costs attributed to ensuring that the property has appropriate heat emitters and piping to enable the efficient running of a low flow temperature renewable technology. Government has a role to play in developing this energy infrastructure. Building regulations should ensure that heating systems are specified with renewable-ready infrastructure today, to ensure that the costs associated with installing low flow temperatures systems are lowered in the future.

Q. 2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Whilst there are many infrastructure investments which can improve the UK's international competitiveness, reducing energy costs is particularly pertinent for high energy users, such as companies operating industrial processes. Improving building fabric and installing energy efficient heating systems will deliver substantive energy savings and provide an enduring solution to energy demand reduction. Energy efficiency is key to maintaining the UK's international competitiveness as it lowers running costs, increases productivity and reduces carbon emissions. Moreover, it is estimated that in 2011-12, exports from the UK's energy efficiency sector were worth over 1.85bn⁶. Making energy efficiency a National Infrastructure Priority would put the UK in an advantageous position, as it should provide the necessary policy stability and investor confidence to enable industry to further increase skills and knowledge, and develop products for the domestic and export markets.

Q. 3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Energy requirements are consistent among places we live and work in, and indeed the impacts of hazardous conditions created by the lack of adequate heating, could be felt in either situation. When making the business case for energy efficiency measures, the first argument is often to highlight the reduction in energy bills; but efficient buildings also provide much greater and wider reaching benefits to companies and to the public. Studies have shown that fuel poverty and poor heating are correlated

⁶ DECC (2013) [Energy Efficiency Strategy](#)

with poor physical and mental health, lower educational attainment⁷ and lower labour productivity. Ensuring that properties are adequately ventilated can reduce the transmission of airborne illnesses which means that the number of sick days within an organisation could be reduced and the recovery time of individuals could be improved by addressing the building fabric. The UK Green Building Council states that offices which are designed and constructed to be ‘green’ are healthier and more productive places to work. Energy efficient schools and workplaces provide healthy, high performance environments to stimulate staff and students thus improving productivity. Improvements to building regulations and minimum performance standards can help deliver spaces which are better to live and work in.

The SEA advocate a Wrap then Heat approach to heating. By addressing heat without addressing efficiency could lead to a sub-optimal outcome, therefore the Government should ensure that the whole system is considered.

The Government has recently consulted on amendments to the domestic Building Regulations. The SEA responded to this consultation and proposed that the Government should develop a regulation roadmap outlining how energy efficiency and heating system improvements can reduce consumer energy bills and carbon emissions whilst leaving a legacy of more efficiently heating homes and low carbon ready infrastructure. We would like to see the Government mandate that heating systems are required to operate more efficiently and at lower temperatures. The technology and expertise to design and specify such systems currently exists. Such efficiency improvements would lower fuel bills, improve the distribution of heat within a building, and potentially allow for an improved standard of living in homes and office spaces that were previously under-heated because of costs.

In relation to the incentives that can deliver better energy efficiency and potentially improved living conditions in the places we work, a mixture of tools are needed. Market intervention is necessary to stimulate the wide scale adoption of efficiency measures. Regulations such as improved building standards, levies or taxation relief can obligate or encourage entities that otherwise would have been unwilling to invest to improve their energy efficiency. However, the composition of the solution needs to be tailored to the circumstances of the individual property; age, location, use and tenure (including the relationship between the owners and the occupants).

Energy efficiency should be a National Infrastructure Priority, but some decisions should be made and delivered locally. Local authorities and local actors (such as doctor’s surgeries and healthcare centres) have a good knowledge of their area and the problems faced by the local people. It is therefore important that local actors are involved in the decision making and planning process as they can help to ensure that infrastructure developments are designed to provide the most benefit to the local area. Allowing local authorities to set their own sub-targets, which could be set over and above the minimum national standard, will permit customisable objectives that take into consideration the profile of buildings within their remit. This approach would enable the Government to set the overall

⁷ Liddell, C. (2008) Save the Children: [The Impact of Fuel Poverty on Children](#).

Building Regulations or energy efficiency targets at a national level to ensure that minimum standards are met nationwide.

Q. 4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

The deployment of energy efficiency measures, improving building fabric and installing efficient heating systems will deliver more substantive energy savings and be a more enduring solution than encouraging behavioural change. There is a risk of slippage in energy performance gains with energy management and energy use options; particularly where buildings are in flexible use and subject to change in occupancy. Unlike behavioural programmes, improving the thermal efficiency of a building offers a greater chance of creating a lasting reduction in demand, independent of the occupiers. Research has shown that a combination of education and investments in infrastructure can foster new values which can lead to sustained behavioural change and participation in energy management activities. However, a holistic programme which addresses individual and social factors as well as ensures the provision of technology or infrastructure is needed to foster lasting change.⁸

It is important to note that the deployment of energy efficiency measures can make it cheaper for households to heat their homes and therefore they could increase energy usage. Prior to improvement, the cost of heating for some homes is too high due to the property being leaky and therefore, households opt not to heat at all. For low-income homes, Cambridge Econometrics use a rebound effect figure of 40% (i.e. reduce possible savings by 40%) to take account of comfort taking.⁹ Although this rebound effect exists, savings can be made and household wellbeing can be significantly improved as a result of energy efficiency take up. Rebound effects are often due to occupiers setting the room thermostat higher, increasing the heating period or the number of rooms heated. Smart technologies can be installed to overcome some of the rebounds effects associated with improved efficiencies.

The performance gap between energy performance and design has been extensively researched in domestic buildings and quantified under the ‘rebound effect’, however research into this effect in non-domestic buildings is lacking especially in the UK. A German study by Grossmann et al. found that non-domestic buildings saw comparatively low rebound effects but high energy performance gaps between design and performance.¹⁰ A further study assessing rebound effects in German non-residential public buildings found little indication of higher post-retrofit energy consumption.¹¹ The research noted that non-domestic building users or occupants, consume energy more carelessly at work than at home, this may be linked to the individual workers not being responsible for energy

⁸ Scottish Government (2012) [The impact of workplace initiatives on low carbon behaviours](#)

⁹ Vero and Cambridge Econometrics (2014) [Building the Future: Economic and fiscal impacts of making homes energy efficient](#)

¹⁰ Grossmann et al. (2015) [A methodology for estimating rebound effects in non-residential public service buildings: Case study of four buildings in Germany](#)

¹¹ Weiß (2016) [Rebound effects in non-residential public service buildings](#)

costs. The study found that rebound effects were near to zero, however it highlighted a high potential to improve user behaviour.

In non-domestic buildings, a recent BEIS survey of the UK's building stock¹² suggests that 63 TWh of consumption per year could be reduced through energy management, lighting replacement, and other energy efficiency measures - a 39% reduction. As a significant portion of abatement potential can be achieved through the installation of better energy management systems. It could be argued that significant rebound effects may not be great as many of these controls work automatically and optimise supply based on existing energy demands and are therefore not subject to user interference. Therefore the likelihood of users increasing consumption as per the rebound effect could be reduced by installing automatic controls.

As highlighted above, a holistic approach to energy use in buildings needs to be taken. The thermal efficiency of the UK's housing stock needs to be improved and the public need to be better informed to incite behavioural change. Long term, wide ranging benefits can be achieved by increasing the energy performance of buildings through the deployment of energy efficiency measures and low carbon heating. Behavioural changes are harder to encourage and maintain. The SEA would therefore advocate that the NIA adopts a whole house, wrap then heat approach to energy demand management.

Q. 5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Typically, it is more costly to retrofit a property with a new heating system or efficiency measure, than it is to install the same measure when building the property. Therefore the construction of new assets should be done to a standard which removes the need to retrofit in the future. Regulations should require the installation of cost effective and future-proofed infrastructure, which promotes low-carbon, efficient energy provision, and removes the need for expensive retrofitting in the future. Building standards should be incrementally strengthened, the SEA call for a long term regulatory framework to drive up new build performance. It is also important that new builds are built to current building standards and do not require additional retrofit in the near future and that performance better matches design estimates. Efforts in regard to new build should be focused on ensuring that buildings are built to a high standard and that installation quality is high.

The majority of today's housing stock will still be in place in 2050, by which time - as formalised in the Climate Change Act - the UK will need to have reduced GHG emissions by 80% from 1990 levels. It is therefore paramount that the current housing stock is improved and retrofitted to a high future-proofed standard. The UK has some of the least efficient properties in Europe and as such the Government needs to put in place a long term plan to improve the existing stock. The SEA is calling for the Government to bring all homes up to EPC band C by 2020, in doing so, the Government will help to reduce the risk of fuel poverty, improve wellbeing and lower healthcare costs whilst also

¹² BEIS (2016) [The Building Energy Efficiency Survey 2014-2015](#)

reducing carbon emissions. Heating is a key part of this, and making improvements to existing assets will be key to the UK meeting its legally binding climate change targets.

The challenge to maintain, repair and improve the UK's existing building stock is great and a range of financial and regulatory measures may be needed to achieve the goal of bringing properties up to EPC band C. Targeting moments when systems breakdown and require maintenance or repair, increases consumer appetite to engage with the construction of new energy infrastructure. At the point of system breakdown and repair, the consumer already faces some disruption and therefore some of the barriers to technology deployment are reduced. Policy should aim to target these trigger points. We would like to see Government provide a policy framework which encourages individuals to view their heating systems as a whole and incentivises them to carry out infrastructure upgrades. Moreover, the Government should help homeowners and businesses overcome the barriers to deployment such as access to finance and information.

Q. 6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Encouraging collaboration between businesses can provide significant benefits to all parties as energy efficiency can be improved. Companies that collaborate across the supply chain are able to realise significant reductions in costs and improvements in the speed of delivery, service and customer satisfaction.

Local authorities should also be encouraged to collaborate. Devolving powers to local authorities and enabling them to set their own targets will encourage local authorities to collaborate and undertake joint projects which will reduce the costs of implementation. At the same time local authorities will be sharing knowledge and maximising benefits from economies of scale.

If the Government is to adopt a 'whole-house' approach to energy, it may be increasingly necessary for supply chain actors to collaborate to enable multiple improvements to be made at the same time.

Q. 7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The ESCo model has been particularly successful in the USA however 80% is contracted to the public building sector, however there is a need to find ways to extend ESCo model to the commercial sector. Increasing the size of the Green Investment Bank and/or extending the remit of organisations like Salix Finance to the commercial and domestic sectors could help crowd private investment into energy efficiency and heating infrastructure projects.

At our recent Social Housing Roundtable, attendees highlighted the difficulties faced when navigating the existing sources of finance and information. A central funding portal may help reduce the complexities faced by organisations when researching available funding. This may reduce the time

spent assessing the available funding options at the beginning of a project and therefore mean that projects are implemented quicker and at less cost.

Q. 8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

In the renewable heating sector, uncertainty caused by political changes and alterations of incentive rates has hampered investment. Investor confidence in the renewable heating and energy efficiency sectors has been significantly impacted by policy instability and the removal of performance targets for example the zero carbon homes standard. Government needs to set and stick to clear, decisive, long-term policy to instil confidence and drive investment.

Q. 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The Department for Communities and Local Government has recently published a paper¹³ focused on increasing the number of homes and improving the quality of those built. The paper highlights the need to ensure that homes are built quickly once planning permission is granted. This is something that our members feel needs to be addressed, builders should not be able to build to old building regulations thus delivering lower quality homes. If planning permission is granted, developers should be required to begin building straight away or within a reasonable timeframe to avoid land banking. The Government has proposed to plan for the right home in the right place, this is an approach that the SEA supports as we believe that there is a right solution for each home and there is not a silver bullet to improving housing quality - a range of solutions are needed to ensure that homes are fit for purpose, built to a high standard and are of enduring quality. These solutions are dependent on the local circumstances and therefore we would like to see the design of new homes incorporating local needs.

Q. 11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The installation of energy efficiency measures, is on average the most cost-effective way to deliver carbon emission savings, and protect the environment from dangerous climate change and air pollution. The SEA supports a ‘wrap then heat’ approach to low-carbon heating development. After energy efficiency, infrastructure investment should consider ways in which heating supply can be delivered with lower emissions. Here the most cost-effective areas to initially target are new-build properties and off-gas grid regions where heating alternatives include heavily polluting fossil fuels such as oil.

13

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/590463/Fixing_our_broken_housing_market_-_accessible_version.pdf

Q. 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

The cost-benefit analysis technique needs to capture the disproportionately large and positive utility/wellbeing impact that energy efficiency improvements can have on those in fuel poverty/low income, and should seek to quantify the many significant, unmonetised benefits – including health improvements. In doing so, the Government could justify investing more into delivering energy efficiency improvements.

In addition, when considering the benefits of investing in future-proofed heating system infrastructure, the appropriate lifetime of the benefit should be calculated and used. Installing future proof technologies now will reduce the cost of moving to low carbon systems in the future and as such these benefits need to be quantified in cost-benefit analysis.

Energy

Q. 19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Commercial and domestic consumers should adopt a ‘Wrap then Heat’ approach– investing in cost-effectively reducing energy demand before addressing the heating system. All heating systems perform better in well-insulated properties. The cheapest energy is the energy we don’t use, therefore efforts should be made to reduce energy consumption.

Efforts should be targeted off-grid areas and in new build properties as these are seen as ‘low hanging fruit’ for low carbon investment. Building regulations are key to driving the deployment of energy efficiency and efficient heating systems, and are highly effective at doing so. It’s vital that new build properties are built to a high standard, to prevent unnecessary and expensive retrofit at a later date. Equally those times of renovation provide an intervention opportunity which should be exploited. During renovations it is important that property improvements are conducted to standards which are in keeping with energy efficiency and carbon targets.

In off-grid areas heat pumps and biomass can provide great solutions for a diverse building stock. It is important that the technology utilised fits the property characteristics and demand profile, as such there is not one superior technology. The SEA promote a technology agnostic approach which can deliver running cost savings for commercial and domestic consumers against fossil fuel derived heating in off-grid areas. There is no ‘silver bullet’ in regard to low carbon heating, each technology is suited to a particular niche and these niches should be exploited. It is important to ensure that consumers are opting for the most appropriate technology for their needs as this will increase the likelihood of the technology performing optimally and the consumer receiving maximum benefit.

As highlighted in our response to question 5, decisions in regard to the heating system are often made when a system breaks down, requires repair or replacement. At these trigger points, consumers are more aware of their heating system and have greater appetite to engage with energy infrastructure.

At these points, the consumer already faces some disruption and therefore some of the barriers to technology deployment are reduced. A further trigger point would be at the point of rent or sale of a property. The SEA has carried out research into a range of able to pay regulatory nudges and financial mechanisms which could encourage the uptake of energy efficiency measures including low carbon heating at the point of occupant change. Again at this trigger point, the barriers to deployment are reduced for example the occupant may be carrying out refurbishment work which means that builders will already be onsite. Also at the property sale or rent, the buyer or tenant is engaged in the performance of their property and therefore this period may provide a significant opportunity to deploy low carbon efficient heating systems.

Q. 20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

The SEA fully supports the Government’s intention to achieve the UK’s carbon targets. The UK has ambitious carbon emission reduction goals – an 80% reduction by 2050 – which can only be achieved with a co-ordinated and cohesive response addressing heat, transport and electricity.

There is no single solution to decarbonising the power sector, however the power sector must be decarbonised. The UK power sector will face significant challenges in the coming decades if it is to meet its binding carbon targets. Meeting the long-term carbon emission reduction targets will require the widespread expansion of low carbon generation technologies. A key consideration in regard to the uptake of renewable and low carbon technologies is the unpredictable supply and how to cost-effectively integrate the technologies into the grid. The Committee on Climate Change has found that “it is feasible to manage a future GB power system that is deeply decarbonised with high levels of intermittent renewables”¹⁴. The Government needs to assess the costs and benefits of all available options including more innovative technologies.

In order to accommodate a significant increase in intermittent renewables, there is a need for increased grid flexibility and reduced peak demand, this means making grid upgrades and maintaining current infrastructure as well as developing new solutions. Grids will need to be reinforced and smart technologies may need to be considered.

Demand side management has the ability to offer benefits in terms of reduced peak power demand and therefore reduce the stress on the grid. The electrification of heat and use of thermal energy storage systems in homes, can help provide this grid flexibility and peak load shaving when aggregated together. There are many technologies available to enable consumers to store thermal energy, for example hot water cylinders can be used as a means of storing excess heat generated. These stores can be installed alongside renewables to store energy for use during peak time and it is possible for thermal stores to take inputs from a range of different technologies. Demand side management

¹⁴ Committee on Climate Change (2015) [Value of Flexibility in a Decarbonised Grid and System Externalities of Low-Carbon Generation Technologies](#)

capabilities allow energy to be time-shifted, reducing wastage and helping to support a renewable-powered electricity network.

Q. 21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Greater uptake of low carbon vehicles, means that homes will play an increasingly important role. The home will become a recharging point and therefore will become a hub for all energy needs; heating, cooking, transport, leisure etc. The Office for Low Emission Vehicles has suggested that recharging at home is a viable option for the majority of the UK housing stock with 65% of homes having off-street parking. However, it is important that plug-in vehicle infrastructure is widely available away from the home; in towns, in rural locations and at workplaces.

The majority of plug-in vehicles are charged overnight; this means that consumers utilise off-peak generation which has a lower carbon intensity. The avoidance of peak demand, lowers the risk of stress on the electricity distribution networks and could reduce the need for potential reinforcement of the local grid¹⁵. Moreover, if plug-in vehicles are charged in off-peak periods, the need to increase supply may be reduced. The introduction of smart technologies mean that plug-in vehicles could be able to deliver demand side response, utilising additional capacity for example when high levels of renewable energy is being generated. It is also possible that these vehicles could, in the future, be used as energy stores and used to power homes during peak periods.

For the attention of the National Infrastructure Commission,

Thank you for the opportunity to respond to your discussion paper on 'The Impact of Technological Change on Future Infrastructure Supply and Demand.'

You are probably aware that the Infrastructure Client Group (ICG) is preparing to publish its report on new delivery models for infrastructure, and Digital Transformation is one of the key themes from the report that will be developed over the coming year. Mark Enzer has been asked to lead this theme and techUK will play a key part in its Steering Group. We are providing this joint feedback in advance of the official launch of the ICG's report.

Overall, we found the paper to be informative and helpful on the ways in which changes in technology could affect the UK's infrastructure in the future. However, there are a number of areas that we feel deserve more attention in further work:

1. **Information Value** – *The NIC should directly address the subject of data and the value of 'information' and not just as an adjunct to technology. While the technology may be eye-catching, the real value is in the data that it produces and the better processes and decisions 'information' derived from it enables. This is core to the value proposition for Smart Infrastructure. Such an approach would recognise the value of information as a resource. This provides a unifying theme and underlying purpose for innovation and disruption.*
2. **Technology framework** – *The NIC should create a structure or framework to support a better understanding of the way different types of technology fit and work together to deliver improvements in infrastructure, and outcomes for customers. Technology is not one homogeneous whole (it makes sense to separate propulsion technology from information technology or drones from AI for example), so it is important to identify this when exploring opportunities. However, there is real value in setting out interconnected categories for the technologies that are most relevant to infrastructure. Such an approach would help towards identifying the right type of technology for the right outcome and allow technologies (like satellite) that have not previously been associated with infrastructure to be included across multiple vectors.*
3. **Integration** – *The NIC should develop a systems-based narrative for technology in infrastructure. Infrastructure networks, by their very nature, are interconnected and much of the value of Smart Infrastructure is derived from enabling greater integration of systems. We feel that a system-based view of infrastructure technology would*

make greater sense of the way those different technologies fit together and highlight any system-based outcomes that can be obtained in existing and future infrastructure.

4. **Security** – *The NIC should give more emphasis to security and privacy. It is clear that the issues of security and privacy are fundamental to the management of information in infrastructure, and the related technologies too. It therefore makes sense to consider both 'security technology' and the 'security of technologies'. Such an approach would help to focus the infrastructure industry on this key issue by design.*

We would be very keen to explore any of these issues with you further.

Best regards,

10 February 2017

National Infrastructure Commission
1 Horse Guards Road
London
SW1A 2HQ

Dear Lord Adonis,

National Infrastructure Commission call for evidence

Tees Valley Combined Authority welcomes the opportunity to respond to the National Infrastructure Commission's call for evidence.

The Tees Valley Combined Authority is one of a small number of devolution areas, taking greater responsibility for the leadership of the economic development of our area. As a distinctive industrial region, we face particular challenges and opportunities in infrastructure development; including our role in the national and northern transport network, with one of the UK's largest ports; in supporting the transition to a low carbon economy; and as a host of many globally significant industrial and innovation facilities. As a flagship area for the UK's emerging Industrial Strategy, we recognise the contribution we need to make to national infrastructure priorities, and have developed a number of specific propositions in the areas of interest to your Commission.

Our response to the questions posed by the Commission is attached. We would be interested to engage with you further on these issues, and to provide more detail to the Commission's staff as required.

Yours sincerely

[signature redacted]

[name redacted]

[job title redacted]

Tees Valley Combined Authority

About Tees Valley Combined Authority

Tees Valley Combined Authority (TVCA) was created in April 2016 to drive economic growth and job creation in the area. It harnesses the economy-boosting powers of Tees Valley's five local councils (Darlington, Hartlepool, Middlesbrough, Redcar and Cleveland and Stockton) and Tees Valley Local Enterprise Partnership (Tees Valley Unlimited) to elevate partnership working between the public and private sectors to a new level in order to create an even more effective approach to building a stronger Tees Valley.

Scope of the Inquiry

The Government has given the National Infrastructure Commission (NIC) the following objectives to:

- Foster long term and sustainable economic growth across all regions of the UK;
- Improve the UK's international competitiveness; and
- Improve the quality of life for those living in the UK

The following document is TVCA's response to the NIC's call for evidence. TVCA has responded to only those questions which are within our policy remit:

Questions:

1. **What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?**

Response:

There has been a historic lack of investment in transport infrastructure in the north of England. This has resulted in lengthy, infrequent and unreliable journey times between and also within our key economic centres, which is a constraint to productivity, jobs, and housing growth. In economic terms city regions in the north of England are performing well individually but they are not realising their full potential partly as a result of this poor pan-Northern connectivity and also to other key destinations nationally. Where investments are made, it should be the case that these are created as part of an integrated transport system. Users view the transport system as a whole, crossing multiple modes and boundaries, rather than separate sets and investments should reflect this.

In terms of transport infrastructure investments, these can be broadly split by mode:

Rail

The East Coast Mainline (ECML) is an extremely important rail route to TVCA and to the nation as a whole and we are full members of the East Coast Mainline Authorities group (ECMA). Investments to improve capacity on the ECML along the route, but particularly

north of York, have been identified as essential by Network Rail, local authorities, operating companies and Transport for the North (TfN). The current two-tracking north of Northallerton represents a constraint on both inter-city capacity (linking the North East to Leeds and Manchester city-regions in the North and to the economic centre of London) and intraregional capacity, restricting the ability to increase the quantum of regional services and limiting local labour markets.

Further, it is expected that there will be future restrictions on the ability to assign freight paths on the route due to high demand for passenger services operating at high speed. As a result the growth of freight and logistics within the region faces future constraints, and some freight may switch to the highway network, with attendant negative consequences.

A cost-effective and short-term measure would begin with provision of passing loops for freight services north of Northallerton, as identified in CP5 and the Hendy Review. However, this does not represent a long-term solution to match anticipated growth, which is estimated at 144% for passengers up to 2043 and 13.2% annually for key biomass traffic or 11.9% for domestic intermodal up to 2043. The best way to match both estimated growth and the ambitions for the corridor would entail four-tracking the route between Northallerton and Newcastle and investigating capacity enhancements on the line north of Newcastle up to the Scottish border.

Of particular importance to the Tees Valley in this regard is the major upgrade and remodelling of Darlington Station which is a major rail gateway to our region. There are major constraints at Darlington which impact on both North-South and East-West rail connectivity and which have major implications for national, pan-Northern, regional and local passenger services and for freight services. This has been recognised by Network Rail through its emerging East Coast Route Study and TVCA has developed a wider masterplan for Darlington which will see the station develop as a major growth hub to complement the required rail infrastructure improvements. A key part of the masterplan is to ensure that Darlington is HS2 and Northern Powerhouse Rail (NPR) 'ready' as well as being able to cater for the forecast short-term growth through the existing franchises. More detail on the proposals for Darlington can be provided.

Another key strategic rail route for Tees Valley is the line from Northallerton to Middlesbrough (and on to Teesport) which carries important passenger services such as TransPennine to York/Leeds/Manchester/Manchester Airport and Grand Central to London. These will soon be boosted by new East Coast services between Middlesbrough and London and yet line-speeds and journey times are well below the required standard for such a strategic route. By way of example the rail journey time between Middlesbrough and York is double that for the rail journey between Darlington and York, which is of equivalent distance. Urgent steps must therefore be taken to increase these line-speeds. The line is also a key freight route but at the present time it does not have the capability to cater for large containers which is the significant growth market from Teesport, a nationally recognised economic asset. The upgrade of the line between Northallerton and

Middlesbrough/Teesport must also include W12 Gauge Clearance as a matter of urgency. The final element of the upgrade should be electrification and TVCA believes that electrification to Middlesbrough should become a fundamental part of the TransPennine Electrification programme. Linked to these line improvements is the upgrade of Middlesbrough Station itself to provide adequate capacity to facilitate this growth. As with Darlington there is insufficient capacity, so a similar masterplan study funded by TVCA is now underway involving key industry partners.

In his recent report of June 2016 – *Tees Valley: Opportunity Unlimited* - to support innovative thinking to secure a strong and sustainable economic future for the Tees Valley, Lord Hestletine made the following recommendations in relation to major rail infrastructure:

“Network Rail and Transport for the North are encouraged to recognise the importance of Darlington Station as the key rail gateway for the Tees Valley - at the heart of a commercial regeneration scheme - and to investigate the need for the station redevelopment to be included in the Network Rail and Transport for the North programmes for the period 2019 – 2024, which Tees Valley propose will allow train services in HS2 and Northern Powerhouse Rail to operate, maximising the growth opportunity afforded by the transformational rail packages.”

“The Department for Transport are encouraged to seriously investigate the inclusion of the Northallerton to Teesport Electrification rail scheme as an extension of the Transpennine electrification scheme already committed, driven by the benefits of simultaneously delivering W12 gauge clearance, to ensure that the economic benefits of PD Ports’ planned investment in 2018/19 can be maximised.”

High Speed Rail

As highlighted above, improvements to the ECML corridor are essential to the economic well-being of the North East and its contribution to the national economy. However, these improvements are unlikely to be sufficient to cope with forecast demand, both passenger and freight, and deliver the growth we seek in the long-term (defined in the Call for Evidence as up to 2050). Therefore, if these long term travel requirements are to be met, the existing commitment to deliver High Speed 2 needs to be developed further.

Working as part of Northern Powerhouse Rail, with Rail North, we support a link from HS2 phase 2b to the East Coast Main Line. This is planned at Church Fenton, linking HS2 phase 2b from Leeds to the East Coast Main Line.

In 2016 HS2 Ltd published its report - *Broad options for upgraded and high speed railways to the north of England and Scotland* - which explored options to:

- improve journey times from Edinburgh and Glasgow to cities further south, including options that could reduce journey times to London to 3 hours or under

- provide additional passenger and freight capacity where it is projected that future demand will not otherwise be met

TVCA advocates an Eastern route for HS2 Scotland, whether by a completely new route or upgrades to the existing ECML. The Eastern Route is ideal as it connects large existing centres of population more effectively, with fewer environmental constraints.

When HS2 phase 2b is delivered, stations need to be ready for the demands placed upon them by this additional capacity. As discussed above, Darlington Station has been identified as a future pinch-point by Network Rail and there is a need to make it ready for HS2 services and increase capacity. In a further report produced by HS2 in 2016 – *Changing Britain: HS2 taking root* – very useful narrative and data was provided highlighting the value of Darlington to the Tees Valley economy and its role as a HS2 Growth Hub.

Highways

TVCA supports the delivery of schemes identified and committed to within the current Road Investment Strategy (RIS) to 2020 and beyond in the North East. These schemes are integral to managing growth on the Strategic Road Network in the future and to addressing current, longstanding congestion issues. It is important that where funding has been secured for works, such as improvements on the A19 between Norton and Wynyard, timely delivery is ensured to enable the benefits to be secured as early as possible.

TVCA remains committed to support the further upgrades to the A19 strategic corridor that are required if it is to fully achieve the desired 'Expressway' status as outlined in the RIS. The most pressing priority, following the widening between Norton and Wynyard, then becomes on the section immediately to the South where the A19 crosses the River Tees. The current Tees flyover is only two lanes wide in each direction yet carries more than 100,000 vehicles every day meaning that it is one of the busiest routes in the region, if not the North. The lack of alternatives means that there is a real issue of congestion and network resilience in this area that is threatening to stifle economic growth and as a result TVCA has now committed development funding and is working closely with Highways England to develop a business case for a new crossing.

It is also the ambition of TVCA to achieve an upgrade of the A1 to provide continuous dual carriageway standard between London and the Scottish Border and we believe this should be a priority as it addresses identified weaknesses in inter-regional connectivity. We welcome commitments made by the Government as part of the RIS, City Deals and through other mechanisms to address existing capacity issues.

In terms of our East-West connectivity, TVCA has consistently supported the case for investment in the A66 to improve links between this region and North-West England/South West Scotland. We therefore welcome the commitment announced in the Autumn Statement to complete the dualling of the A66 between the M6 and A1. However the A66 needs to be treated holistically as it is a key route through the Tees Valley linking many of our main

economic centres and running all the way to Teesport which is a key pan-Northern and national asset due to the volumes of freight it handles. TVCA welcomes the development funding that has been awarded to work up improvement options between A1 and Teesport, and we are now working in close partnership with Highways England on this, but we remain disappointed that this was not included as part of the wider A66 improvement works.

In his recent report, Lord Heseltine also made some key recommendations relating to major highways infrastructure for the Tees Valley:

“Highways England are encouraged to seriously investigate consider adding the scheme to provide a new strategic road Tees Crossing to the existing scope of the A19 Norton-Wynyard widening scheme already planned by Highways England. This will maximise efficiency and ensure that the benefits of the committed investment are enhanced, thereby encouraging additional growth, as a result of improved access to Enterprise Zone sites.”

“Highways England and Transport for the North are encouraged to take account of the emerging improvements to east-west connectivity on the A66 east of the A1(M) being developed by the Tees Valley Combined Authority, as part of the wider North Trans-Pennine Routes study. Also, to seriously investigate the preferred option(s) from the east-west connectivity work within the recommended programme for trans-Pennine improvements to provide a holistic solution for the A66 through to Teesport.”

While delivering the above improvements is essential, there will still likely be future capacity issues on our network. In particular, this applies to capacity across our major rivers. We are looking to work with partners, particularly Highways England, to explore this issue.

Where improvements to the Strategic Road Network are prioritised, this must be done with consideration of the impacts this will have on the associated local road network. The interface between the two must be considered holistically to ensure the greatest possible support of growth from any intervention. This should also be a consideration with regard to asset management as well as new infrastructure.

Bus

Buses are the most well used form of public transport in the Tees Valley. It is essential that the needs of buses are taken into account when developing highway and pedestrian infrastructure and that needs of buses are integral to the masterplanning exercises such as those currently underway at Darlington and Middlesbrough Rail Stations. As outlined below, with the correct infrastructure in place, new legislation will make it possible for us to make sure the Tees Valley has an affordable, efficient and high quality bus network.

Active Travel

Investment in active travel, including walking and cycling, is among the most cost-effective forms of infrastructure investment. The relative proximity of the Tees Valley's towns means cycling infrastructure is well placed to replace car journeys for shorter trips. By removing many car based local commuter journeys, particularly on the Strategic Road Network, cycling infrastructure supports the efficient functioning of highway infrastructure in general.

TVCA would expect investment in the strategic road network to include cycling infrastructure improvements, including cycle routes along road corridors as well as reducing severance at interchanges. This will complement investment at a local level through local resources and the Government's forthcoming Cycling and Walking Investment Strategy.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Response:

Two of the ways in which international competitiveness can be addressed are to improve access to and from international gateways (such as ports) but also to improve connectivity within the country for freight and passengers. TVCA believe that both aspects need to be tackled equally to improve competitiveness.

The Tees Valley has a well-developed freight and logistics industry serving the import and export market as well as domestic needs.

Road

- The DfT's annual Continuing Survey of Road Goods Transport suggests that the average length of haul in the UK for an HGV in 2015 was 92 kilometres, having increased moderately (6%) since 2004 when it was 87 kilometres. The figure for Tees Valley-based HGVs, however, is 129 kilometres. This reflects the area's position as both a major centre for process and manufacturing and home to one of the UK's major ports.
- In terms of goods moved (tonnes lifted x kilometres), there have been significant increases for the Tees Valley in the movement of food, drink and tobacco products, coke / petroleum and waste in the last 10 years while at the same time there has been a slight decline chemicals and a more significant reduction in free-flowing dry bulk.

Rail

- The Tees Valley is a major hub for the movement of rail freight (100 freight trains per week) and we retain a number of rail-connected freight facilities operating at Middlesbrough, South Bank, Teesport, Redcar, Lackenby Wilton, Boulby Mine, Skinningrove, Port Clarence and Hartlepool (Hartlepool 20" Pipe Mill and the Power Station). These are supported by large marshalling yards at Thornaby (Tees Yard) and Middlesbrough;
- Much of these rail flows are linked to international trade through the Tees or other major UK ports;
- The Tees is the only port in the North of England with existing intermodal rail services operating directly from quayside facilities. Rail services for shipping containers currently operates between Teesport and Felixstowe, Southampton and Scotland.
- Redcar Bulk Terminal - this is the deepest port facility on the East Coast of England and is part of a rail-connected site that covers in excess of 125 hectares and is immediately adjacent to the ex-SSI steel-making site which covers a further 800 acres. Although historically used for dry bulk imports, the facility is well-positioned to diversify into new trades.

Sea

- Tees Valley is home to two ports: Tees and Hartlepool. PD Ports is the statutory harbour authority for both ports and also operates its own cargo handling facilities at Hartlepool Dock and Teesport;
- In 2015, Tees & Hartlepool handled 7% of all cargo tonnes through UK ports. The Port has consistently been in the DfT's UK Top Five in terms of cargo tonnes since the 1970s, following significant growth in the area's petro-chemical industry at that time following major investment in land reclamation, capital dredging and major new terminals;
- Much of the volume today is still handled by large, specialist terminals and driven by the needs of local industry with crude oil, other liquid bulks and dry bulk products dominating tonnages. A number of smaller wharves handle a mix of cargoes or operate engineering and support services to the offshore and shipping sectors. Freight ferries and container vessels carrying unitised cargo are the only ships using Tees and Hartlepool that operate as common carriers on the basis of a published timetable; and
- Nationally, 63% of cargo through UK ports is inward. Tees & Hartlepool, however, is an 'export port' whose higher outward tonnages largely reflect the trading activities and diversity of major local shippers. This is in contrast to a port such as Felixstowe which primarily handles container imports fuelled by UK consumer demand rather than local manufacturing industry.

Air

- Durham Tees Valley Airport, has daily scheduled flights to Schipol via KLM and regular flights through the week to Aberdeen. There are some chartered services at other times but no direct long-haul flights. Most airfreight is carried as bellyhold cargo and carried in wide-body long-haul passenger jets and planes that cover the short-haul market have less capacity to carry freight. Tees Valley airfreight is now mostly taken by road to other airports.

It is essential that the importance of these facilities is recognised in the plan and that they continue to receive adequate financial and planning support to secure their position as key gateways to the UK economy.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Response:

TVCA supports the Government's wish to see new development centred on brownfield sites as these are likely to be close to existing town and city centres and current transport routes. Where new housing or business developments take place outside these locations, it is essential that these are permeable, encouraging rather than deterring sustainable travel modes, and that, by use of the Community Infrastructure Levy where applicable, they are underpinned by investment in suitable transport links, including bus services and infrastructure, cycling and walking routes.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Response:

Being able to guide people and influence behaviour change is a key aspect of addressing congestion in urban areas where there are feasible transport alternatives.

Demand management may not be appropriate for all areas and should be part of an overall package of integrated transport where appropriate.

5. How should the maintenance and repair of existing assets be most effectively balanced with construction of new assets?

Response:

Prizing capital investment at the expense of revenue could lead to perverse incentives for local authorities to build new infrastructure at the expense of maintaining their existing

assets. In order to better balance this, revenue funding made available to local authorities to provide activities such as maintenance and planning should be increased.

Recent work from the Urban Transport Group indicates that increasing maintenance funding could provide returns of £6.50 for every £1 invested and TRL suggested that cuts in road maintenance budgets could result in wider costs to the economy of between £1.50 and £2 for every £1 saved²⁸. This has been backed up by the National Audit Office, which has called for long-term certainty in funding of road maintenance.

This should also be backed by more balanced investment in maintenance between the strategic and local road networks. The Highways England Network has a spend of £111,000 per km per year, while Local Authority B, C and U roads only spend £7,000 per km per year. While these are different types of road, these gaps should be narrowed

6. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Response:

One of the primary barriers to efficient transport funding is a preponderance of competition-based funding. While this may have some merit in allowing a more flexible approach from central government in terms of project selection, on the ground at a local level it produces challenges in terms of project selection and delivery. This means that it is challenging to bring forward projects which fall outside traditional 5 year funding envelopes or are at a very early stage and there is a bias toward 'shovel ready' projects, which may not be the most optimal to achieve long-term benefits.

As noted under Question 5, the preponderance of capital funding over revenue based funding means that there are significant challenges for authorities to deliver infrastructure services efficiently. The lack of revenue funding can mean that longer term priorities are not addressed efficiently.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Response:

At present a number of regionally impacting projects are put on hold, as they do not meet the funding threshold for national programmes. However a number of these are of a scale, that if progressed would use up all locally available funds (i.e Local Growth Funds). More weighting must therefore be applied to the wider impact along with a lower funding threshold.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Response:

This response can be broadly split into two points, one on the devolution of existing powers and another on alterations to the planning and governance structure.

TVCA is supportive of devolution of powers, which if developed appropriately, will have significant benefits for delivery of areas such as transport and housing in all devolved areas. Devolution of powers would mean that a long term programme of activity can be planned, rather than dealing with schemes on an ad hoc basis, therefore enabling projects with transformational impacts to be properly planned, appraised and delivered.

Transport for the North (TfN) is establishing unique governance arrangements to enhance its role as the voice of the North on Transport, bringing together representatives for the whole of the North through Combined Authorities and Local Enterprise Partnerships with an independent chair.

An embedding of the governance of TfN in its constituent transport authorities provides for the ability to better align strategic priorities both inter and intra-regionally. When allied to long-term planning and appraisal this presents the most effective governance to deliver transformative infrastructure.

In terms of alterations to the planning and governance structure, TVCA is a transport authority rather than a highway authority and does not currently believe highway authority powers would be appropriate over the large spatial area of the region. However, there are potential alterations to the planning and governance structure which would help ensure that infrastructure is delivered efficiently.

TVCA believes in delivering not merely transformational infrastructure, but public transport service delivery in the North and has pursued innovative governance and management solutions to enhance long term planning and outcomes for stakeholders. In terms of rail, it is anticipated that the North East Rail Management Unit, involving Tees Valley, the North East Combined Authority, Tees Valley, Cumbria, and North Yorkshire, will be integral to our ambitions to deliver a step change in quality for rail users in the North and support this model of more localised service delivery. This partnership, which includes train operators, is the first of its kind and will be helping the authorities in the North East ensure that new franchises truly deliver their ambitious upgrades for the regions trains.

12. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Response:

TVCA anticipates the following changes in travel patterns between now and 2050, resulting from the impact of new technologies and other trends:

1. Continuation of the trend away from traditional “Monday to Friday 9 to 5” working patterns, with technology enabling more homeworking, flexible working, video conferencing, dispersed employment locations and part-time working;
2. A readiness among younger people, especially in urban areas, to consider alternatives to the car, where these are supported by an adequate public transport, cycling and walking network. This has led to a fall in mileage travelled by these people;
3. Increased online shopping and banking, with consequent rise in delivery van traffic and reduced off-peak home to city centre or retail development travel demand;
4. An increasingly older population, resulting in : fewer work-related trips ; much greater focus on travel to health facilities ; more leisure journeys ; higher expectations of independent mobility ; increased need for appropriately designed infrastructure and services including door-to-door transport provision;
5. Increased expectations of the quality of public transport in terms of speed, reliability punctuality, comfort, seamless ticketing and comprehensive technology-based information before, during and after a journey; and
6. The potential for new technologies, such as driverless cars, to change the way in which we approach car ownership, mobility and the user of our time while travelling.

13. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Response:

In response to this question it is appropriate to refer to TVCA's Strategic Transport Plan framework (see <https://teesvalley-ca.gov.uk/transport-infrastructure/tees-valley-strategic-transport-plan/>). This sets the context for the full Plan which is expected to be published in Autumn 2017 and contains relevant details on our major transport infrastructure priorities:

National Rail:

What are we trying to do?

- We want to improve rail links between Tees Valley and the rest of the country and to key Airports and Ports.

- We want to improve the East Coast Mainline, Transpennine, Durham Coast and Tees Valley rail networks to cater for future growth in both freight and passenger numbers across the North; and
- We want to ensure that our main rail stations at Darlington and Middlesbrough are ready for major projects such as the new Inter-City Express trains, High Speed Rail and Northern Powerhouse Rail. Together these projects will radically improve train travel between Tees Valley and other major cities including London, Manchester, Newcastle, Leeds, Edinburgh and Glasgow.

Why is this necessary?

- To date, investment in the UK's major stations has not been focussed on the Tees Valley. meaning station facilities at Darlington and Middlesbrough are not sufficient for a major gateway servicing a region the size of the Tees Valley. For example, the layout of tracks and platforms at Darlington needs to be changed so that it can properly accommodate new High Speed and Northern Powerhouse Rail services.
- The railway line between Northallerton and Middlesbrough/Teesport needs to be upgraded so that bigger freight trains can access Teesport. Doing this will free up space on the East Coast Mainline for more and faster passenger trains in the future.

What are the priorities?

- 'Darlington Station Growth Hub', which includes new platforms and buildings at Darlington rail station will permit more long distance and local rail services to stop at Darlington This proposal will see around £100 million of public and private investment to develop Darlington station as an essential part of the town's heart. It will support the development of 30,000 sq m of new business space and 1,500 potential new homes. The investment will help to better integrate the station with Central Park and the town centre; and
- A major upgrade of the rail line between Northallerton and Middlesbrough/Teesport so that it can be used by bigger freight trains. This supports the ongoing development of Teesport, as a truly international freight gateway for the north of England. Funding is already in place to more than double existing container capacity, creating up to 4,000 direct and indirect jobs. The upgrade will also allow more trains to stop at Darlington and will see Middlesbrough station improved so that it can also handle more trains, prior to future electrification of the line.

Major Roads:

What are we trying to do?

- We want to improve road links within the Tees Valley and to/from the rest of the country, including to key Airports and Ports to improve access to global markets;
- We want to provide and maintain a high quality major road network that delivers consistency in journey time reliability, safety and standards and meets the needs of Tees Valley residents and businesses, whilst providing the capacity for future economic and housing growth across the North.

Why is this necessary?

- The A19 has been identified as a new high quality strategic route – an “expressway” – by Highways England, yet there remains a pinch point at the Tees flyover, where delays regularly occur because there are too few ways to cross the Tees.. At the point where it currently crosses the Tees, the A19 carries 96,000 vehicles per day – in contrast, the parallel A1(M) only carries 43,000 vehicles at the same point, emphasising how important the route is to the Tees Valley in connecting it to the rest of the UK; and
- Access to the A1(M) from the A66 south of Darlington is restricted for travellers to/from the north. This requires high levels of traffic, including heavy goods vehicles, to gain access via unsuitable residential areas to the north of Darlington. Sections of the A66 are also single carriageway and key junctions on the route are heavily congested. The A66 is only classified as part of the national Strategic Road Network and managed by Highways England up to the A19. Beyond this the A66 becomes the responsibility of the relevant local authority, so onward access to key strategic locations such as Teesport and Wilton International is essentially via a local road. Access to Durham Tees Valley Airport, our key hub for international connectivity is via the A67, a single carriageway local road.

What are the priorities?

- Providing an additional major road crossing of the River Tees – this proposal will ensure that the A19 expressway will meet the “mile per minute” objective for the SRN, address current issues with journey times and delays, as well as allowing the local road network to be improved in order to help deliver a number of new employment and housing sites. It will also help realise the full benefit of the A19 Norton to Wynyard widening scheme, due for completion by Highways England in 2021.
- Improving the east-west A66 corridor from the A1(M) to provide a consistent standard of route all the way to the international gateway at Teesport. This could be provided by a new all moves junction at Junction 57 of the A1(M), a new route around the north of Darlington, capacity improvements along the A66 around Darlington and Stockton, and junction improvements along the local road section of the A66 to Teesport, including at the Cargo Fleet and Port access roundabouts.

Connecting Centres:

What are we trying to do?

Tees Valley Combined Authority, Cavendish House, Teesdale Business Park, Stockton-on-Tees, Tees Valley, TS17 6QY

Tel: 01642 524400

Web: www.teesvalley-ca.gov.uk

- We want to better connect our town centres, economic assets (such as Teesport, Durham Tees Valley Airport and our major development sites) and key health, employment, education and retail locations, by frequent and high quality public transport services and improved private transport networks.

Why is this necessary?

- In addition to connections to the rest of the UK and beyond, linking together our town centres, economic assets and key health, employment, education and retail locations is vital for the Tees Valley to function effectively. Better transport connections within the Tees Valley and into our main rail stations will also allow us to maximise the opportunities afforded by committed/planned investment in the national networks; and
- To support our economic growth aspirations, people need to be able to travel easily around the Tees Valley to access jobs and training opportunities right across the area.. This is particularly important for the significant proportion of the Tees Valley population who do not have access to a car.

What are the priorities?

- An upgrade of the rail line between Northallerton and Teesport would also include major improvements at Middlesbrough station, to allow more efficient use by local and long distance rail services, including new direct rail services between Middlesbrough and London by 2022, as recently confirmed by the Office of Road and Rail;
- Station improvements at Darlington and Middlesbrough will allow increased frequencies, more evenly spaced stopping patterns, new trains and new stops along the local rail network to be considered as part of the next Northern Rail franchise;
- Buses are the most well used form of public transport in the Tees Valley. New legislation will make it possible for us to make sure the Tees Valley has an affordable, efficient and high quality bus network that is both easy and attractive to use and fully meets local needs. This includes introducing an integrated and simplified ticketing system for public transport in the Tees Valley and the continued development of network branding; and
- The Tees Valley Authorities will continue to invest in the maintenance and improvement of the local road network, as we recognise that for some people, the private car will be an essential mode of travel. We will continue to promote activities such as car sharing and the take up of electric vehicles so as to reduce the impact of private car use on health and the environment.

Supporting Economic Growth:

What are we trying to do?

- We want to address specific problems on the major and local transport networks to cater for future economic and housing growth across the Tees Valley; and
- We want to ensure that people and goods can travel around the Tees Valley more easily so that economy can grow effectively and sustainably.

Why is this necessary?

- The Transport for the North Independent Economic Review identified four key sectors of the economy in the north of England – Advanced Manufacturing, Energy, Health innovation, and Digital – that are seen as vital in supporting the desire for increased economic growth across the North. These are supported by three other key sectors – Financial and Professional Services, Logistics, and Further and Higher Education; and
- As outlined in the Tees Valley Strategic Economic Plan, The Tees Valley economy contains a growing number of companies and organisations across all these sectors, and all need effective and reliable transport connections, wherever they are located. However, there are currently a number of constraints on our existing transport networks, principally the road network, that act as a barrier to this growth for existing businesses, that are also delaying the development and delivery of key employment and housing sites that we need to meet our economic growth aspirations.

What are the priorities?

- There are two Local Major Transport Schemes already in development – Middlehaven Dock Bridge and Portrack Relief Road, which will continue to be progressed to support the growth of our major development sites. We will continue to build a detailed database of all predicted future housing and employment developments across the Tees Valley, which will inform detailed transport impact modelling analysis to identify future congestion points on the transport network. This will help us to identify and prioritise transport projects which will overcome these barriers to growth and support the levels of development and economic and housing growth envisaged in the Strategic Economic Plan. This process is known as the Tees Valley Area Action Plan; and
- There will also be specific transport infrastructure and sustainable transport provision requirements associated with individual large scale planning applications, such as those for large scale housing developments at Wynyard, South Stockton, South Middlesbrough and in West Hartlepool. It is important that the provision of appropriate access/services for all transport users is fully addressed when housing and employment sites are being planned and developed.

Local Journeys:

What are we trying to do?

- We want to ensure that the needs of pedestrians, cyclists and bus users are fully considered so that all aspects of the journey experience from door to door are covered; and
- We want to develop bus, cycling and walking networks that improve links between our: residential areas; towns and villages; hospitals; shopping centres; schools/colleges; centres of employment; key transport hubs such as Darlington, Eaglescliffe, Hartlepool; Middlesbrough and Redcar Rail Stations; and other key destinations across the Tees Valley. We want infrastructure to allow integration between all modes providing seamless door to door journeys.

Why is this necessary?

- We need to continue our work on improving walking, cycling and bus services that link housing sites to key destinations across the Tees Valley including rail stations, bus stops, town centres, schools, colleges, employment sites, hospitals and shopping centres.. This is important because census data shows that our car ownership levels are still lower than the national average and walking, cycling and bus trips continue to make up a significant proportion of daily journeys to work across the Tees Valley. Active travel options such as walking and cycling also offer major health benefits to residents and if more journeys are made by bus, on foot or by bike then we will have less congestion on our road network and lower levels of air pollution.

What are the priorities?

- Tees Valley cycle network – We will continue to develop a cycle network across the Tees Valley that offers as many direct, complete and safe routes possible, away from the strategic road network. this also includes providing cycle facilities at all of our key local destinations;
- Tees Valley walking network – We will provide safe and direct pedestrian links in and around residential areas and key destinations across the Tees Valley;
- Tees Valley bus network – We will work with Tees Valley bus operators to ensure the bus network provides the vital links from residential areas into our town centres, key local destinations this includes providing services to more rural or isolated areas; and
- Marketing and Information – We will provide residents with the information they need to make informed decisions on how they travel including the promotion of increased levels of physical activity through walking and cycling.

14. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Response:

The response and detail in Q13 also covers this.

Energy

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decision need to be made?

Response:

The introduction of novel, integrated renewable energy generation, storage and demand management systems is required to meet the UK's decarbonisation targets. It is also essential to build on the existing gas and electricity infrastructure as sources for heat and enablers of large grid scale energy storage systems to allow expanded renewable energy exploitation as well as supporting the decarbonisation of transport.

A major value creating opportunity for the UK is to supply heat via hydrogen. Unlike natural gas, hydrogen does not produce carbon dioxide on combustion. Recent projects, such as the H21 Leeds City Gate project have identified the potential to use much of the existing natural gas pipelines to supply homes and businesses at an affordable cost compared to electrification. Hydrogen production coupled with Carbon Capture and Storage used to heat homes and industry provides very significant value adding economic opportunities for the UK supply chain in any transition to a low carbon economy. Areas such as Tees Valley, Humberside, and the North West could all benefit from economic growth and industrial development as a result of hydrogen production for heat.

Due to the inherent similarities between hydrogen and natural gas, heating with hydrogen would require less change for consumers than other approaches to decarbonisation of heat. Public acceptance would need to be addressed but with a long history of industrial use and the earlier use of Town Gas, this is achievable.

The benefit of large scale low carbon hydrogen use on air quality is an additional benefit as it can displace petrol and diesel fuels in road and rail transport.

As noted above, the transfer to hydrogen, as part of a low carbon future, is dependent on the timely roll out of large scale carbon capture and storage. To date Government has been reluctant to identify priority locations for CCS even though there has been a clear and objective direction provided by organisations such as Teesside Collective. However it has to be recognised that this takes time, large scale industrial and infrastructure growth can take 10 or more years to achieve, therefore empowering local areas to play an active role should start as soon as possible but should continue over the long term.

In addition, comparative economic advantage accrues to the early movers and in this area the UK is well positioned to build on existing assets, skills and capability, compared to competing economies (Germany/Japan) where this technology is also being explored. The

UK currently develops and deploys many of the hydrogen production techniques, by utilising hydrogen as a heating fuel UK technology and supply chains will be supported. In addition Tees Valley has already designed and costed a CCS network through Teesside Collective which has been shown to be a cost effective method of decarbonisation.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved? (Note the zero carbon power sector' includes the generation, transmission and distribution processes)

Response:

The most effective zero carbon power sector will balance issues of affordability, security of supply and decarbonisation. This implies different ways, rather than one prescriptive path, through which this balance can be achieved, including the expanded use of renewables and continued use of base load and dispatchable gas power stations with grid scale storage. Whilst small scale generation/storage will become much more widely adopted (assuming support mechanisms remain) the security of supply offered by a national electricity network and the need to decarbonise heat will require the existence of a large scale network. As noted above, decarbonisation and security of supply, whilst adding value to the UK economy, is best achieved through the enhanced use of hydrogen and carbon capture and storage. Carbon capture and storage can provide a strategic piece of infrastructure to decarbonise energy and industrial sectors.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Response:

There are two principal barriers related to the use of the circular economy: Asymmetric information (i.e. individuals and companies are unaware or are sceptical as to the benefits of the approach and need independent validation) and secondly a coordination error (i.e. due to the need for one process to utilise the by-product of another process there is a need for a coordinated approach. This is often outside the control of one company or even a sector. There is therefore a need for external coordination of what in essence is a new supply chain).

Tees Valley has long championed the case for low carbon approaches to production as a means of meeting carbon reduction targets and improving long term competitiveness. This approach has now been fully incorporated into UK policy on the circular economy as a means of mitigating wastage, ensuring local sourcing of materials and enhancing productivity.

As noted in Lord Heseltine's review of Tees Valley, the area is:

“an ideal location to pilot and demonstrate the benefits and opportunities of the circular economy. With one of Europe’s largest integrated industrial complexes and national and internationally operating centres of excellence in processing, materials and biologics this approach is promising and together with targeted investment could help maintain the future of existing industries and to develop new economic opportunities.”

Tees Valley is already mitigating the two market failures cited above by:

- **Foresight design:** Examining all aspect of production and then looking (and validating) related opportunities for the use and reuse of by-products, waste and heat; and
- **Coordination:** Circular economies are most effective when based on integrated industrial locations, where industries producing heat, by-products and waste, together with agricultural production, combine with communities to provide opportunities for other industrial processes and enterprises, co-located to maximise collaboration. Wilton in Redcar is one of only a limited number of super-integrated locations, capable of dealing with heavy production and managing the environmental issues.

In line with our existing Smart Specialisation Strategy, major producers and the Tees Valley Centres of Excellence are already working with strategic partners across the North and this work will increase as demonstrator and pilot projects introduce new processes and products. New and innovative production processes are at the heart of the circular economy and this work is increasingly being led by major companies working with their supply chains. While Tees Valley has a leading interest in chemical processing, the impact of the circular economy has relevance across every production sub-sector, including traditional and advanced manufacturing.

Tees Valley has the company base and expertise to play a leading role in the adoption of the circular economy by the Northern Powerhouse and provides the opportunity for Tees Valley to be the leading region in England in the application of the circular economy- the exemplar region.

National Infrastructure Assessment

February 2017

Digital Transport: Thales Contribution

Road travel is taking longer each year in the UK. This has been true for the last four years. Travel times have increased by 4% in the last two years¹. Applying the principle finding of the Eddington Report 2006², this change over the last two years will cost the UK economy an additional £2bn per year going forward even without further deterioration.

Fuel tax revenues are projected to fall in the next few years “we forecast fuel duty receipts to fall from 1.6 per cent of GDP in 2013-14 to 1.5 per cent of GDP by 2018-19 reflecting improvements in fuel”³, so there is an additional need to review fuel tax.

This paper outlines a Digital Transport programme to improve travel times, decrease emissions and at the same time increase safety and resilience to disruptions. It proposes a switch of fuel duty to road usage charging. It also proposes a comprehensive national data warehouse of transport information regardless of transport authority boundary. This programme will take advantage of new connected vehicle technology and smart phone GPS tracking. A return on investment of tens of billions of pounds of GDP growth can be achieved over a decade.

This contribution to the National Infrastructure Assessment will concentrate on transport as infrastructure with the following themes:

- The latest connected vehicle technology and GPS smart phone data will be exploited
- Network Rail’s Digital Railway Programme’s techniques will be applied to roads, namely capacity improvements, safety improvements and resilience to disruptions
- Travellers’ journeys will be influenced to load balance the transport network better, taking the total cost of journeys into account
- Road capacity will be maximised
- New collaborations between government departments will be needed in operations and operational support, in planning for disruptions and managing incidents
- A new collaboration between government and consumer-focussed commercial companies is proposed
- Transparency of the total cost of roads and the burden of taxation will be established in order to increase public satisfaction and catalyse traveller behaviour change
- Better transport data will be available for public transport planning, civil investments and maintenance decisions
- The Digital Transport Programme will reduce congestion and overcrowding, encourage transport modal switch, improve safety and improve resilience to transport disruptions.

¹ “Travel time measures for local ‘A’ roads, England: July 2015 to June 2016” Department for Transport 25 August 2016

² Key Finding 1 “The Eddington Transport Study” HM Treasury December 2006

³ Office of Budget Responsibility, Fiscal sustainability report, July 2014

These benefits will in turn reduce travel times and make journeys more reliable and more resilient to disruptions. This will improve competitiveness of the UK economy and will result in GDP growth of tens of billions of pounds which will provide a return on investment.

This contribution will first expand on the proposed Digital Transport Programme and then answer the specific transport questions of the National Infrastructure Commission.

1 Situation

The situation on UK's roads presents a number of challenges that seem to be getting worse:

1. Unreliable journeys: road travel times are gradually getting worse on average in the UK. Regarding Highways England's Strategic Road Network (SRN) the DfT report: "For the year ending June 2016, 68% of additional time needed to be left compared to free flow, on average, on individual road sections of the SRN to ensure on time arrival. This is 2 percentage points (pp) higher than the year ending March 2016.⁴" The story is worse on main roads off the SRN: "The average delay ... represents an increase of 3.8% compared to the previous year (year ending June 2015)... average weekday morning peak speeds have been falling steadily for the past 4 years.⁵" This gradual decline of road performance needs to be reversed
2. Increasing congestion: Due to the increasing congestion and reduced average speeds noted above, road vehicle engines are running for longer resulting in avoidable emissions and noise
3. Road congestion holding back economic growth: Since the Eddington Report of 2006, it has been established that economic growth is linked to transport. In particular, as Sir Ron Eddington says in his key finding "a 5 per cent reduction in travel time for all business and freight travel on the roads could generate around £2.5 billion of cost savings – some 0.2 per cent of GDP⁶". Eddington stresses that the best transport investments come by focussing on relieving congestion points "In mature economies such as the UK, with established transport networks, the benefits from improved transport are likely to be greatest when focusing on congestion and bottlenecks."⁷ The importance of improved transport for economic growth is reflected in the formation of Transport for the North by the northern English cities to enable the Northern Powerhouse and the formation of Midlands Connect as part of growth in the Midlands
4. Poor quality of road surfaces: The Transport Focus reports in July 2015 "Road Users' Priorities for Improvement" from car, van, motorbike and HGV drivers consistently report drivers as wanting "Improved quality of road surfaces" and "Safer design and upkeep of roads" as their highest priorities. A recent report suggested that maintenance funding should allocate "funding in proportion to the volume of cars, buses, lorries, pedestrians and cyclists travelling on local roads rather than just in relation to road length"⁸
5. Poor management of disruptions, planned and unplanned: The Transport Focus reports of July 2015, cited above, list "Better management of unplanned delays such as accidents or breakdowns" and "Better management of roadworks" and "Better information about unplanned disruptions such as accidents" as the drivers' next highest priorities
6. A plateau of road safety: Reported road casualties in Great Britain: main results 2015 concludes: "The evidence, points towards Britain being in a period when the fatality numbers are fairly stable and most of the changes relate random variation." A Digital Transport scheme should aim to move off the plateau of road safety
7. Lack of road usage data: Away from the Strategic Road Network (SRN) there is no national model for gathering road usage or speed statistics

Given the fact that most journeys are on the roads and even most non-road journeys start on roads, the poor state of the roads is dragging down the UK economy, holding back growth.

2 Goals

In order to solve the outlined national challenges, the goals of a new comprehensive Digital Transport solution should therefore be as follows:

1. More reliable journey times – not just reduced average travel times but also travel times with little variation
2. Reduce congestion, emissions, noise – reducing stop and start, tackling high emitting and loud vehicles
3. Aid economic growth – increase GDP by reducing transport costs traversing bottlenecks and reducing time spent in transit
4. Improving the road surface – better detection of pot-holes but also fairer and more transparent allocation of whole-life transport infrastructure costs
5. Coordinated disruptions and incidents – better planning for disruptions and recovering from disruptions, together with better reporting of information about disruptions
6. Improve safety – a step change reduction in accidents, with a knock-on reduction in insurance costs
7. Comprehensive transport statistics – information and tools to plan building investments

This document describes a Digital Transport scheme to achieve these goals. Please see the following cause and effect diagram whose columns, from right to left, will be used to structure the next few sections of this document:

3 Principles

The principles recommended for delivering a comprehensive digital road system are as follows:

- Driver cost neutrality
- Maximising usable capacity
- Maximising journey time reliability
- Minimising delay
- Improving transport safety
- Motivating journey shift
- Transparency of expenditure
- Improving transport statistics
- Maintaining privacy
- Working with industry; not against it

Driver cost neutrality: It is essential that drivers back a digital transport scheme and therefore a clear principle of tax revenue neutrality should be announced and demonstrably kept.

Maximising usable capacity: Since building new roads or widening old roads are both relatively expensive, we must maximise current road capacity by either motivating journey shift, as above, or marshalling the traffic as to maximise traffic flow. It has been accepted that road traffic flow is similar in behaviour to fluid flow through pipes. In this way, maximising usable road capacity can be compared to maintaining laminar flow.

Maximising journey time reliability: Travellers need to be able to rely on their expected time to arrive without large variances.

Minimising delay: As noted above, delays are gradually increasing year-on-year. A digital transport scheme should improve delays by (A) encouraging journey shift through usage charging, (B) detecting and resolving incidents faster and (C) actively marshalling congested traffic.

Improving transport safety: Given the widespread availability of communication with vehicles, we should aim to gather alerts from vehicles and then pass them to other approaching vehicles in time to avoid an accident.

Motivating journey shift: There are a number of ways of reducing demand on the road, and therefore congestion and emissions, by changing the driver's journey

- **Spatial shift** – use a different route
- **Temporal shift** – go at a different time or on a different day
- **Modal shift** – take a different mode of transport e.g. walk, cycle, public transport, shared vehicle

Transparency of Expenditure: We should adopt the recommendation of The Passenger Transport Executive Group to openly pay road owners according to their roads' usage rather than their length.

Improving transport statistics: We should aim to extend the comprehensive statistics available for Highway England's roads to all A roads and bus routes in the UK. These statistics should include speed, usage, delays, transport mode and vehicle occupancy.

Maintaining privacy: A digital transport scheme must win the backing of the general public who would prefer that the government does not track their movements. Ironically, this is despite most people offering their detailed movements to social media and telecommunications companies in return for mobile services.

Working with industry; not against it: In order to take advantage of GPS data obtained by tracking mobile phones, either a road owner tracks vehicles directly or a road owner obtains this data anonymised from a social media company. We recommend the latter approach on the grounds that it avoids the need for government to track individuals. Similarly, we recommend the collection of road usage charges via private companies.

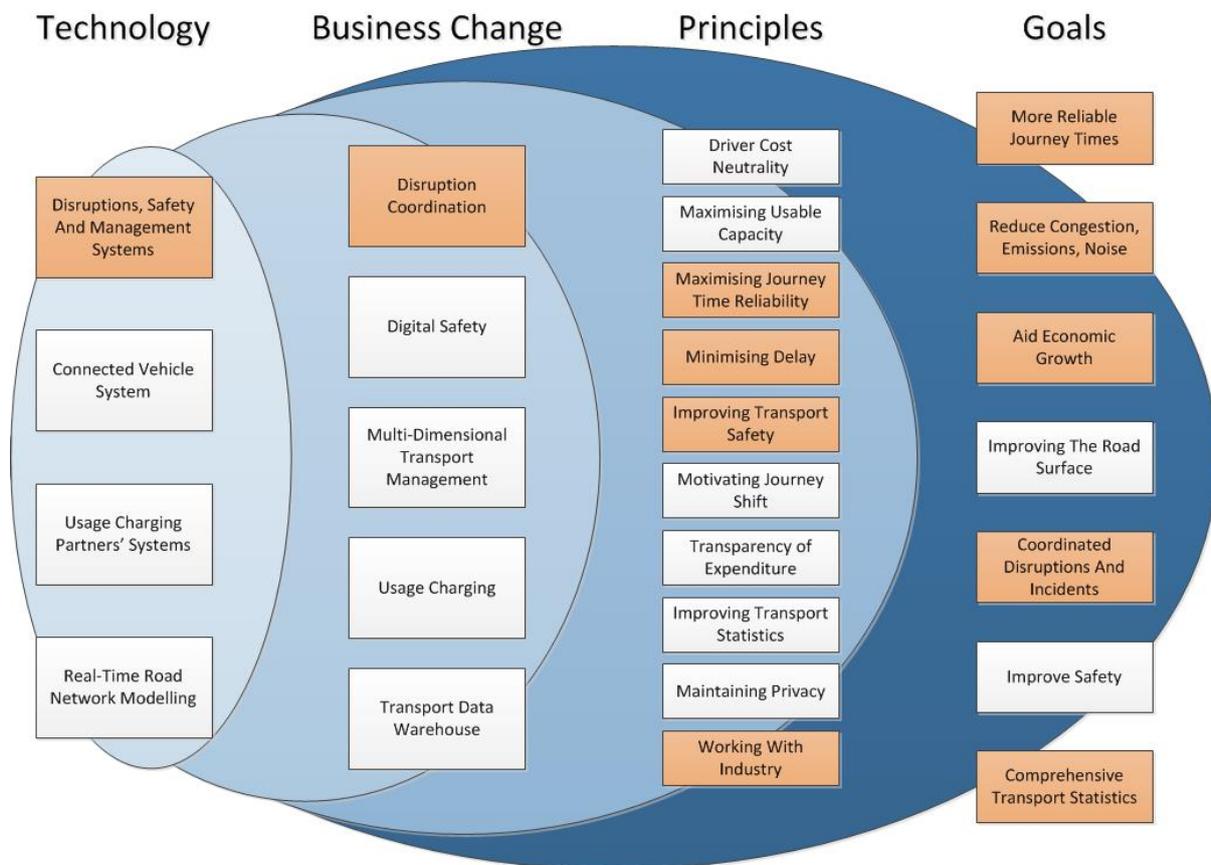

4 Business Change

4.1 Disruption Coordination

Disruptions, either planned (e.g. roadworks) or unplanned (e.g. accident) are a major source of delays and unreliable journeys. Also, disruptions to one mode of transport can affect other modes of transport as the demand changes when travellers look for alternative journeys.

To a traveller, accurate information about disruptions is hard to obtain and then harder to see & compare reasonable alternatives that provide backup journeys. Poor disruptions management adds to transport costs and is a blocker to improving a traveller's experience, also to mobility as a service.

Increased coordination between those involved in managing the disruptions must be established. Please see the diagram below highlighting the technology, principles and goals associated with the coordination of disruptions.

4.1.1 Coordination of Multiple Parties

Since all of the roads are connected, and many journeys cross more than one road owner, passing information between authorities allows more than one road authority to manage the impact of a disruption.

In addition, there are many types of road users, including public transport operators, taxi services and freight that also need an up-to-date view of disruptions. For example, an accident could block a road and therefore force a bus to divert from its planned route.

Unplanned disruption information is spread amongst emergency services, train operators, infrastructure maintainers, recovery services, highway authorities and their operational transport partners:

- Only police (and Traffic Officers on motorways) know when an accident will be cleared and when a section of road will open again after an incident
- Only police know when a police incident is resolved or when an accident investigation will be complete

- Only the fire and rescue services know when a vehicle is safe or a victim will be extracted
- Only the ambulance and air ambulance services know when the injured will leave the scene
- Only recovery services know when the broken vehicles will be cleared which are blocking a key road
- Only maintainers and utilities know when roadworks and trackworks will start and stop
- Only bus and train operators know when their faulty vehicles will be fixed

Therefore we propose a shared disruptions system for train operators, road owners, maintainers, emergency services and recovery services

- Disruptions knowledge can either be entered by hand by operators/dispatchers or can be transferred automatically from the organisations' command and control systems
- Each operational partner can see progress of partners' reactions to incidents (unplanned disruptions) and share their own progress
- Operational partners can plan together for major disruptions (roadworks, marathons, sporting events, political events) with coordinated responses or contingencies (e.g. major incident responses)
- Each operational partner must commit to manning this system, supplying their best information and taking into account other organisations' information e.g. additional buses and taxis can be deployed when a train line is disrupted or a when major public event is taking place

4.1.2 Public Sector Organisation Change and Commercial Partnership

Public and private sector involvement, both central and local, is essential in tracking disruptions: roadworks, accidents, police incidents, severe weather, and major public events.

Participation of road operators, emergency services, maintainers, utilities, transport operators and recovery services must be achieved by adding good disruption information flow to their organisational targets and contracts.

4.1.3 The Usefulness of Good Disruption Information

A shared disruption system can firstly detect incidents quicker, secondly coordinate incidents better, thirdly clear incidents quicker, and fourthly inform operational partners better. In this way, the transport system will be more resilient to disruptions. The results are that congestion due to disruptions will be reduced and average travel times will be reduced.

Accurate, up-to-date information should be given to travellers, so that they can take into account the current state of the transport network and avoid congested areas where possible. A driver may be able to take advantage of this information themselves, but also their SatNav will almost certainly be able to pick a revised optimal route given accurate disruption information. Good information about disruptions can not only increase traveller satisfaction per se, but can also provide resilience to their journey, allowing travellers to avoid disruptions. A further benefit is that informed travellers can load balance the network themselves.

Accurate historic disruption information can improve the disruption planning process and response plans.

There will be an increased cost of communication which will be rewarded by a significant reduction in travel times and a better resilience of the transport network, both of which bring increased UK competitiveness and increased GDP.

4.2 Digital Safety

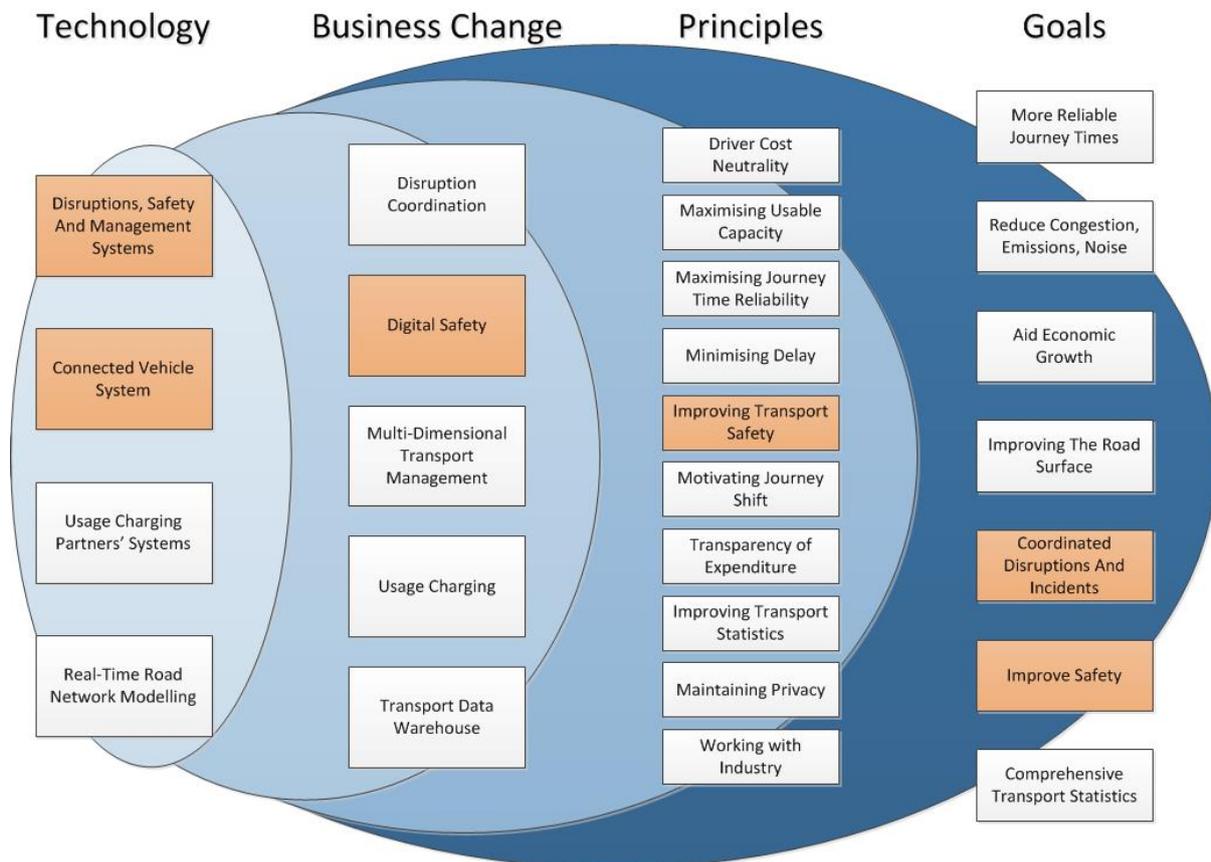

A new digital safety system can take best-practice motorway safety to smaller roads, without the need for expensive roadside equipment. MIDAS is the system which uses under-road loops and roadside variable message signs to warn motorists on many of England's motorways: "Queue Ahead Caution: 40mph".

The digital safety system is purely automatic and anonymous, taking advantage of the latest connected vehicle technology. A connected vehicle black box or smart phone app within a vehicle

can use the vehicle's telematics system (so called CAN Bus) to detect incidents. It can detect the vehicle being stationary, hitting debris or a pothole, breaking heavily, deploying its ABS or anti-skidding or air bag. The in-vehicle black box or app can alert a central system which will both send assistance and inform the black boxes of approaching vehicles. The in-vehicle black box or app can then alert the approaching driver with an audible message, e.g. "Debris ahead, lane 2". Please see the technology section below for further details.

The digital safety system achieves the following highlighted end goals while satisfying the highlighted principles:

The digital safety system can

- Alert drivers of approaching vehicles automatically in less than one second
- Bring additional safety to main roads without the need for roadside technology
- Bring additional precision to safety on motorways
- Provide early warning of incidents and immediate feedback on uneven road surfaces, such as pot-holes
- Pass key incident early warning information to drivers approaching from a greater distance e.g. "Accident after next junction, hard shoulder"
- A reduction in injuries and collisions will reduce in lower insurance costs, improving UK competitiveness and GDP growth

4.3 Multi-Dimensional Transport Management

Current best practice road management is single dimensional, taking a line of traffic and optimising its flow:

- Highways England's Smart Motorways is the combination of variable speeds and variable lane control, controlling lanes using signals above each lane

- SCOOT traffic light systems allow a line of multiple traffic light sequences to be optimised in one direction of travel so that flow is improved, for example into a city in the morning rush hour, and then switched to out-bound in the evening rush hour

These best practice systems can be replicated on smaller roads digitally; without the need for expensive roadside electronic equipment. In addition, by understanding wider route options, new multi-dimensional road management can be deployed to load balance the traffic in the light of current disruptions and congestion.

4.3.1 Widespread Capacity Improvements

Thanks to connected vehicle technology, control of variable speeds and lanes can be communicated to drivers using an in-vehicle black box or smart phone app which itself can take advantage of the vehicle's infotainment system. This means that variable speeds can be set without the need for roadside electronic equipment. Over time, more and more vehicles will support direct connections. Given sufficient percentage of connected vehicles, Smart Motorways' variable speed control could be extended to all major roads such as the North Circular Road.

4.3.2 Next Generation Smart Motorways

Given the current trend to increasing road use, and when the planned England Smart Motorways schemes have been completed, there will be a need for a next generation Smart Motorway scheme. Connected vehicle technology can provide this additional road capacity as follows:

- Certain of the busiest roads will be designated controllable by the road authority – a driver on these controllable roads agrees when joining such a road that the road authority can take control of the vehicles during congestion
- During congestion, the connected vehicle system takes control of the speed, lane and distance from the vehicle in front (so called "headway") for all vehicles
- The connected vehicle system will marshal the vehicles into optimal patterns, taking into account the road surface, weather conditions and types of vehicle
- Clearly, the road authority would be taking some of the driver's responsibilities under such a scheme, together with the legal and commercial responsibilities. Therefore, such a scheme should be investigated for use in the medium term
- Optimal patterns will need to balance safety and road capacity: the safest road would only have one vehicle on it! Therefore, there needs to be consensus on what level of risk of accident is acceptable given the economic need for many vehicles to use that road

4.3.3 Comparison to Network Rail's Digital Railway Programme

Road capacity improvements are complementary to the equivalent European Train Control System programme of Network Rail. Similarly, multi-dimensional responses to disruptions, described below, are complementary to Network Rail's Traffic Management System programme.

4.3.4 Multi-Dimensional Road Management

Multi-dimensional road management is a coordinated set of responses which may be pre-planned as contingencies or which may be ad hoc. Since the roads are all connected there is usually more than one alternative route available for drivers. Effective responses should take advantage of these multiple alternative routes.

Multi-dimensional road management takes advantage of the disruptions system which records the current road abnormalities, their impacts, and when they will clear. An expert system records responses in terms of appropriate processes for the various operational partners and a mixture of direct and indirect road management:

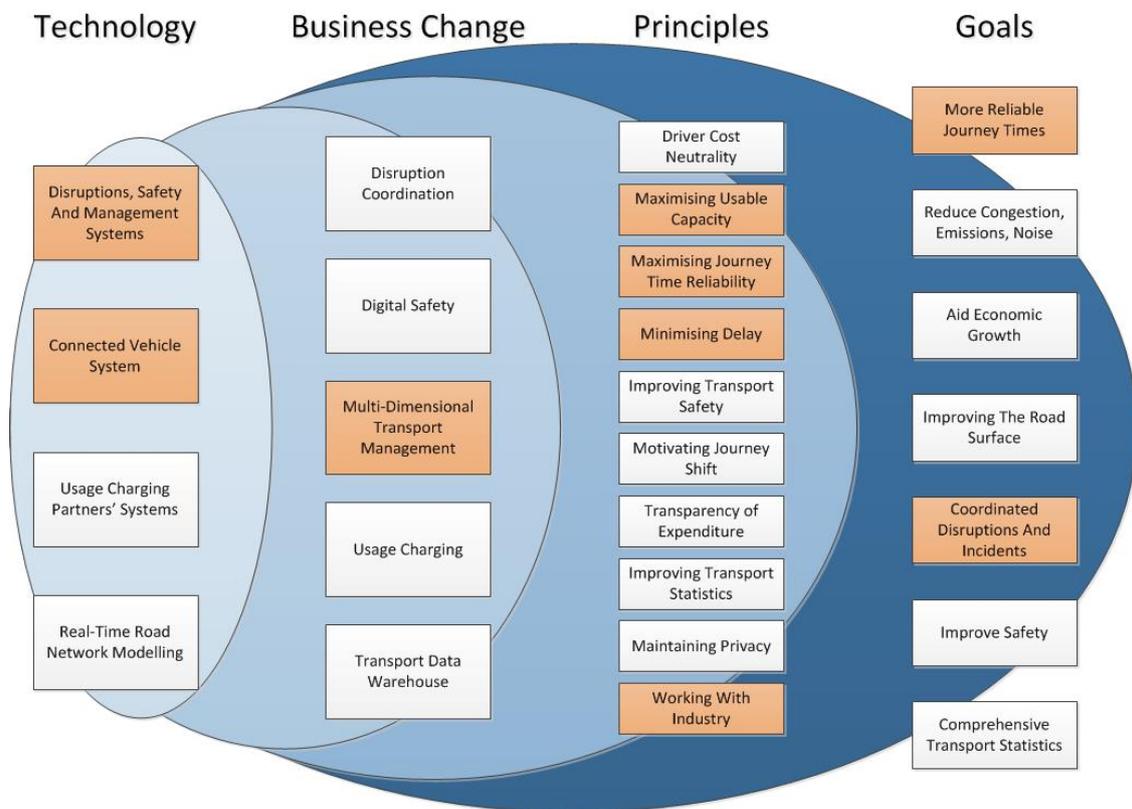

Direct Management: For the motorways and A roads, diversions can be chosen, displayed on variable message signs. Variable speeds can be set. For town and city centres, traffic light sequences can be changed to help traffic use diversions to go around the disruptions.

Indirect Management: The latest disruption information can also be sent to the SatNavs with the latest travel times, so that the SatNav can advise the driver. Note that only the driver and SatNav actually know where the vehicle is going, therefore indirect management is usually preferable to direct management.

4.3.5 Principles

Multi-dimensional road management can (please see the diagram below):

- Maximise the usable road capacity by varying the speed limit on roads, which has been proved successful in Smart Motorways, without the need for expensive roadside variable message signs and signals. In the medium term, use connect vehicle technology to take control of vehicles on the most busy stretches of road, marshalling them in patterns which minimise overall delay
- Maximise journey time reliability by informing drivers of their best way of avoiding current disruptions and congestion, through alternative routes
- Minimise delay by optimising centrally controlled traffic lights and Smart Motorways schemes to reduce the overall UK delay
- Effective road management responses should take advantage of more than one road authority and emergency services, but also coordinate industry partners such as maintainers and recovery services

4.4 Usage Charging

In order to motivate journey shift and transparency of taxation, usage charging should be introduced on major roads (A roads and motorways) and bus routes but not side roads. These usage charges should gradually replace fuel tax, so that the overall taxation on drivers is neutral. Tax neutrality must be clear to avoid drivers' sentiment that this might be "just another tax".

In the proposed usage charging scheme, each vehicle will report the sections of roads it uses to the driver's chosen Usage Charging Provider, a non-governmental company or commercial organisation. The Usage Charging Providers will, in turn, provide payment to the government and road owners. Fees should be collected according to a blend of a number of factors:

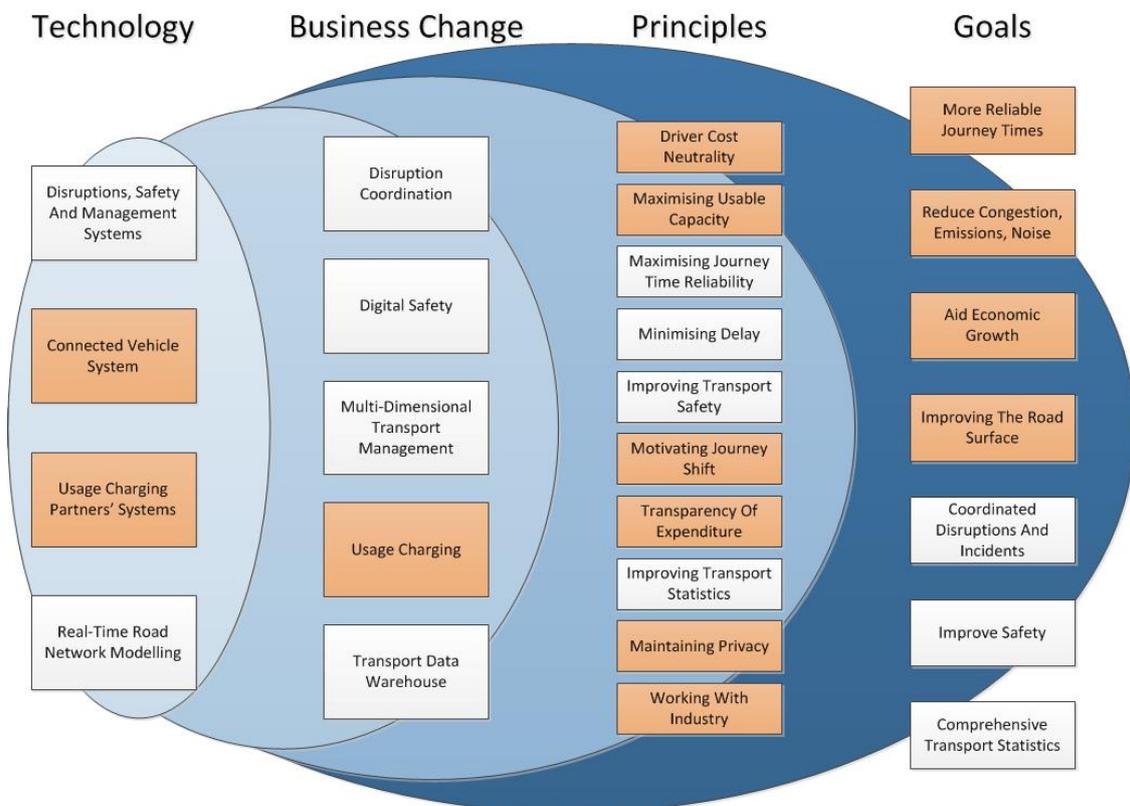

- **The section of road** – some roads are more heavily used than others, therefore apply a popularity premium which will encourage drivers to consider other roads which have lower fees – such a levy could be determined by the cost of maintaining that particular road (e.g. higher for bridges or tunnels)
- **The time of day or day of week** – all roads are more heavily used at certain times of the day, therefore apply a rush hour premium which will encourage drivers to consider travelling at different times of the day which have lower usage fees
- **The current laden weight of the vehicle** – the wear and tear on the road depends on the current laden weight of the vehicle which can now be measured real-time – the proportion of a usage charge which relates to current laden weight can be ear-marked wholly and transparently to road maintenance
- **The emissions of the vehicle** – this is currently levied by road tax through DVLA but could be levied partially or fully by a charge depending on the actual emissions as measured by the vehicle – this emissions charge could be higher when the vehicle is closer to areas of high population density
- **The noise of the vehicle** – this is not currently part of the formula for taxation but could be a factor in a future usage charging scheme – loud vehicles could be taxed when travelling through built up areas and when travelling at night
- **Current major planned events** – charges may be deliberately higher during major sporting events to discourage general traffic, as long as it is understood by the drivers

Note that this conforms largely to the recommendations of the 1964 report chaired by R. J. Smeed to the Department of Transport⁹ but is now practical through connected vehicle technology.

Connected vehicle technology is a key enabling part of usage charging, improved road safety and improved traffic management. The Government should ensure read-only access to the diagnostics of all new vehicles via USB connector. Please see the technology section below.

4.4.1 Principles Followed

Please see the highlighting in the diagram below:

⁹ "Road Pricing: The Economic and Technical Possibilities" HMSO 1964

- **Driver Cost Neutrality** – in order to help with acceptance by drivers, fuel tax should be gradually lowered; replaced by usage charges
- **Maximising Usable Capacity** – lower usage charges for less used roads and during less busy times of the day will encourage those roads to be used instead thus maximising the usable capacity
- **Motivating Journey Shift** – usage charges as above will motivate journey shift by avoiding that road, avoiding that time, sharing a vehicle, choosing alternative transport modes. A driver may also respond by changing job or moving house to avoid a regular commute triggering a usage charge. In order to help with the complexity of journey shift, each Usage Charging Provider should integrate with one or more SatNavs
- **Transparency of Expenditure** – billing by different attributes of the vehicle, its location and time could help win acceptance as people transparently see how their driving affects road and environmental costs: some road sections (e.g. tunnels and bridges) can be more expensive to maintain, some vehicles wear out the road more quickly than others. Therefore the road maintenance costs should be reflected in part of the usage charging fee. These maintenance costs can provide regular, sustainable finance to improve the road surface
- **Maintaining Privacy** – by using non-governmental usage charging providers, the drivers are not tracked by government, but rather tracked by their branded usage charges provider. All drivers connected to social media or using transport apps on smart phones will already be tracked by one or more trusted private companies. Only usage revenue and anonymised road usage statistics are passed to the government. This will win the backing of the general public who are worried by a “Big Brother” state

4.4.2 A Usage Charging Providers Market

In order to avoid unpopular tracking of vehicles by the government, it is proposed to create a new market of road Usage Charging Providers, paying to the government and selling to consumers and fleet owners – this market would be similar to that of electricity utilities or Internet service providers

- Each vehicle reports its road usage to the Usage Charging Providers who arrange billing
- Usage Charging Providers will aggregate the usage charges and could also mediate payments to multiple road authorities if necessary – they could also create simpler packages and services to drivers
- Such suppliers may come from the social media market, transport operators, taxi companies, utilities, telcos or any consumer brand e.g. Virgin
- Usage Charging Providers could finance their own road infrastructure at some point in the future

4.4.3 Enforcement and Adaptation

This system is dependent on accurate and truthful reporting of vehicle activity, emissions and weight. Therefore the in-vehicle app or black box should maintain a log of consistent telematics data by talking to the vehicle’s diagnostic system; it would know if the vehicle were up to date with payment and whether the box had itself been tampered with (e.g. shut down temporarily or disconnected). When refuelling, the app or black box will communicate with modified fuel pumps to prove the vehicle has paid usage charging. Tax-free fuel will be allowed to those who pass and fuel tax applied to those who cannot prove their payments.

This system is dependent on support fuel retailers. Each fuel retailers would need to deploy enforcement technologies at every service station. There will be additional cost and time to deploy such enforcement but it will be returned by shorter travel times leading to lower transportation costs and greater UK competitiveness and GDP growth.

Not all drivers will find it easy to adapt to the Digital Transport, therefore, the Digital Transport programme will proceed in phases

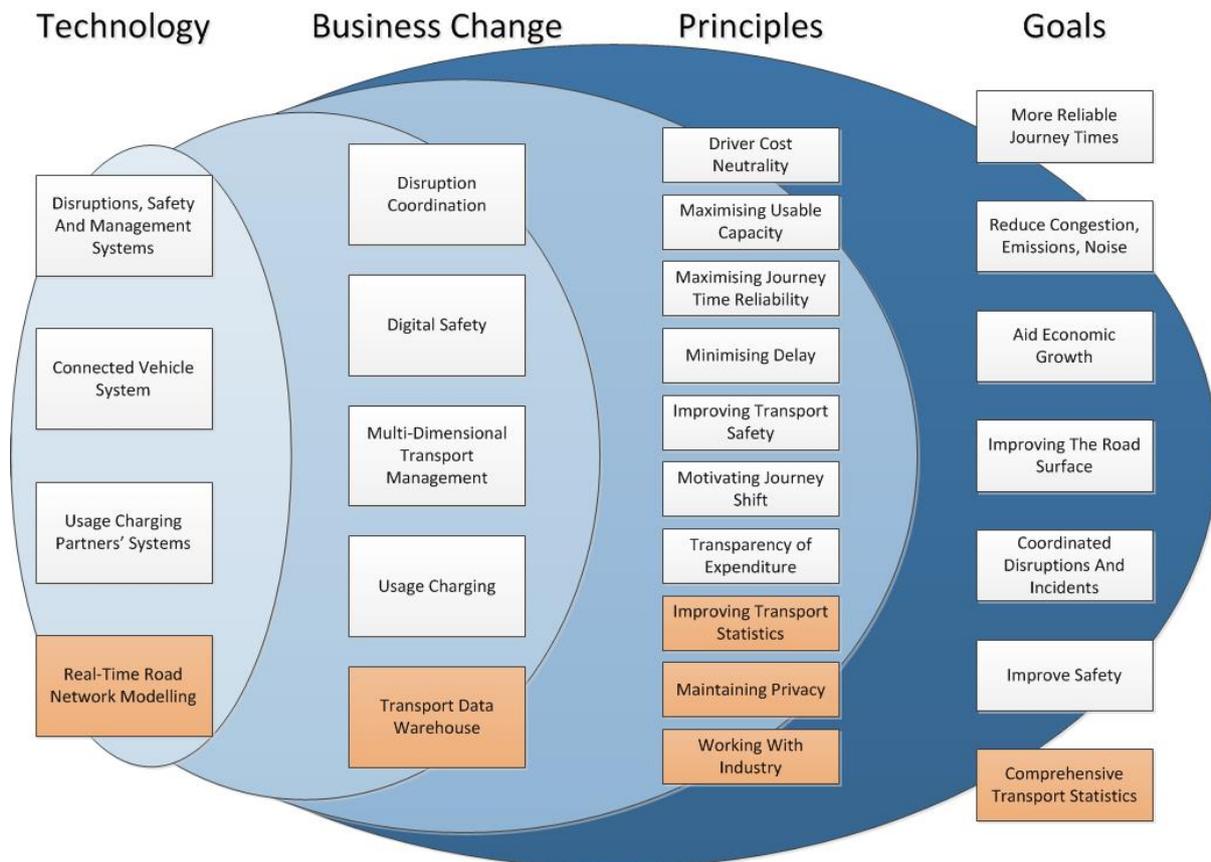

- Aim to connect all new vehicles and vehicles less than 10 years old initially
- In the initial phases the driver can continue to drive and buy fuel, but at rate including fuel duty. Later the price differential can be increased to ensure switch-over

4.5 Transport Data Warehouse

The importance of accurate, consistent transport usage and speed information is clear: business cases for road improvements and new roads need this information. Road data is needed about all motorways, A roads and bus routes, but is not needed for smaller roads.

The advent of GPS trackers in vehicles, whether gathered by fleet vehicle owners or gathered by social media companies from smart phones means that a national road data warehouse is now possible.

A national roads data warehouse will achieve the following highlighted end goals while satisfying the highlighted principles:

Since drivers are concerned about the UK Government tracking them, the Digital Transport programme recommends partnering with Usage Charging Providers who can provide aggregated and anonymised road statistics for each section of motorways, A roads and bus routes. It is feasible to gather this information every minute and only be a minute out-of-date.

Once gathered, real-time road behaviour can be deduced:

- Normal traffic travel times and road usage
- Vehicle occupancy
- Journey type e.g. commute, leisure, shopping, education, health
- Abnormal road usage and delays
- Incidents (unplanned disruptions) can be detected by looking for data abnormalities
- Predictions can be made
- Transport key performance indicators can be deduced automatically within hours
- Trends can be noted, and what if scenarios can be modelled, such as major sporting events, new housing investments, new roads, new bus routes

4.5.1 National Real-Time Road Network Modelling

A national road network model system should be established to provide definitive transport data:

- Maintain a list of all road sections and junctions for motorways, A roads and bus routes (note that not all roads will be modelled)
 - ◊ Geographical end points and a geographical polygon showing the road curvature and location
 - ◊ Each section of road has one or more names e.g. Oxford Street, A40
 - ◊ Each section has a unique direction of travel, therefore most road sections will be modelled by two sections, one for each direction
 - ◊ Number of lanes and speed restrictions are recorded
- Estimate each minute travel time and road usage for each section within the model
- Calculate daily profiles of normal travel times and usage for each day of the week and each time of day
- Calculate each minute the real-time delay from profile

Once such information is gathered then much useful information can be deduced

- Daily road usage data and road delay data, including trends
- Unusual congestion (worse travel time than profile) can provide early detection of an incident such as failed traffic lights or vehicle stopped reducing road capacity – unusual congestion should be passed to the disruptions system along with connected vehicle alerts to inform the operators using the disruption system
- Predictions can be made of future travel times and when travel times will return to normal

This will be a definitive national information asset, across road ownership boundaries, equally useful to planning, SatNavs, other modes of transport, and media: giving national road usage and road delay statistics.

4.5.2 Support from Road Owners and Ordnance Survey

This road network model must be supported by all road owners: updating road model data as road names, one-way streets and junctions are changed. Within Highways England a team with job title “Traffic Engineer” is already responsible for maintaining such a road model about Highways England’s Strategic Road Network (SRN). The Ordnance Survey should also be a partner in managing such a network model which could be based upon the OS-ITN data.

If all parties work together, it should be possible to have a road network model for UK’s roads which is completely up-to-date as new roads open, not just a few months out-of-date as at present. Such an up-to-date road model is essential in order to facilitate the Digital Safety, Usage Charging and Road Management services.

4.5.3 Usage Charging Providers are a Data Source

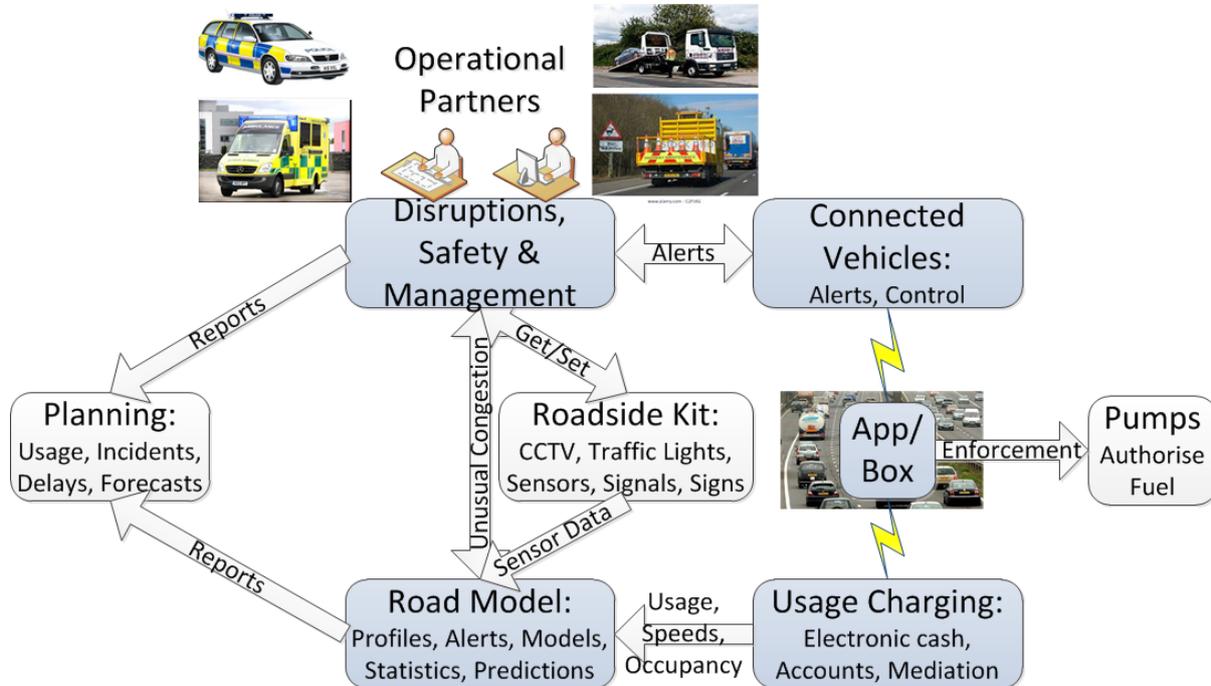

Aggregated, anonymised data should be received from all of the Usage Charging Providers. The data should be anonymised since the driver or passenger does not need to be identified. The data should be aggregated since statistics is all that is needed. In return for disruptions information, the Providers should supply within a minute:

- Average travel time per section of road
- Number of vehicles per section of road
- Number of each type of vehicle
- Average number of people in each vehicle
- Journey type
- Total laden weight of freight traffic

5 Digital Transport Technology

We describe our recommendations finally by focussing on enabling technology, which when added to organisational change, can deliver the Digital Transport.

Four connected central data systems, shown in the diagram below in grey, can take advantage of the two new discontinuous technologies to support this business transformation:

5.1 Discontinuous Technological Changes

There are two recent data technologies which offer help in creating a new national road infrastructure: connected vehicle technology and GPS tracking by social media companies.

5.1.1 Social media tracking and Personal Travel Assistants

Social media companies, mobile phone manufacturers, mobile phone operators and some travel applications currently track phones' locations using in-phone GPS technology. In return, services are provided:

- The various tracking companies mostly provide free services in return for permission to track, but can make their money by other means such as advertising
- Some of these suppliers use the data to inform their SatNav technology either real-time or historically
- Some of these suppliers sell on this data aggregated and anonymised
- This aggregated and anonymised data is of great benefit to government and infrastructure owners

5.1.2 Connected Vehicles Technology

New vehicles are being connected by wireless technology to the outside world for a number of commercial business reasons, such as remote diagnostics, insurance tracking, increased entertainment and information.

This connected vehicles technology offers new opportunities for improved safety, road management and usage charging:

- A new source of real-time big data
- Early incident detection: accidents, debris, flooding, black ice, pot holes
- Motorway safety and congestion management without costly motorway electronic infrastructure

Connected vehicles technology works without the need for roadside loop and message sign infrastructure; therefore it could be deployed economically on all motorways, A roads and bus routes.

5.2 Technology Needed within Vehicles

Real-time messages will be passed between vehicles and a central connected vehicles system:

- Read-only access to vehicle diagnostic information is essential. New vehicles are already supplied with standard CAN bus adapters, but there are variations about how diagnostic information can be accessed. A connected vehicle and usage charging app on a smart phone should preferably have USB read-only access to CAN bus statistics and the ability to pass messages to the vehicle's infotainment system. The Government should regulate to standardise this access to the vehicle over USB
- An in-vehicle black box or driver's phone app will connect the vehicle's diagnostic system, the CAN bus, so that it can receive the following alerts: air bag deployed, ABS deployed, traction control deployed, low temperature (less than 4 Celsius), debris hit, pot-hole hit
- The in-vehicle usage charging system will initially be an app on the driver's smart phone, but could later be a dedicated "black box" with the connectivity of a mobile phone (GPS, 4G, WiFi, USB, Bluetooth) – in the future a vehicle may be able to run the app if it could provide similar features to a smart phone
- In addition, the app or black box will regularly give the vehicle's rough location within an agreed grid – this is not to track the vehicle but rather to filter broadcast alerts only to nearby vehicles – a grid could be based on mobile phone cell or some larger geographical grid
- Upon receiving a broadcast alert from the national safety system, the app or black box will determine whether the vehicle is approaching the alert location – note that it is possible that the receiving vehicle is on a different road completely, the other carriageway or may have already passed the alert location
- The app will communicate with the infotainment system to raise an audible alert to the driver within 1 second
- The app (or black box) will keep track of location by using GPS and other phone location services to establish if the road being used is part of the usage charging – if so, which section of road the vehicle is currently on and in which direction it is travelling. The locations will be sent to the Usage Charging Partners' systems
- There will need to be an agreed list of sections of main roads, which is downloaded to the app from time to time. This is part of the national road model. The app would use the mobile phone's cellular technology to communicate a log of different sections of roads, timestamp, weight and possibly other telematics data

5.3 Central Technology

- Alerts from vehicles, together with section of road, distance along the section & lane will be sent to the Digital Safety System, passed to the Disruptions System and made available for road operators on a geographic map: ice, flood, pot hole, debris, sharp breaking, side wind, air bag. For example, pot hole alerts can be used to inform emergency maintenance
- The Digital Safety System will send alerts to nearby vehicles' apps: incident, slow traffic, skidding risk, debris, pot-hole, low temperature
- An initial Digital Safety System would be purely advisory, giving audible warnings to the driver. Later systems could automatically apply the brakes to vehicles sufficiently close to the site of the alert – such a change would involve a careful safety case and a part transfer of the driver's responsibility, therefore will not be available in the short-term
- The Multi-Dimensional Management System will send management information such as road closure, diversions, lane control and variable speed settings to the in-vehicle app or black box
- Usage Charging Partners' systems will receive vehicle locations and prepare billing. In addition, aggregate, anonymised road usage data will be sent on to the Real Time Road Network Model each minute
- The Real Time Road Network Model will be the definitive source of road names and locations for the in-vehicle app or black box
- The Disruptions System will send out definitive information about events real-time to multiple partners, including social media companies, SatNav suppliers, transport data suppliers and media companies

- The Real Time Road Network Model will receive anonymised road speed data from the Usage Charging Providers
- The Real Time Road Network Model will send alerts of unusual speed and usage on section of road to the Disruptions System, which can be used as advice for operators: “check out this abnormality”

5.4 Roadside Technology

No additional roadside infrastructure is needed such as the ANPR cameras deployed to support London’s Congestion Charge. However, other existing electronic roadside infrastructure can be used:

- CCTV will continue to be as useful as now to spot stationary vehicles, verify disruptions and inform the management of disruptions
- Traffic lights, ramp metering sites and Smart Motorways sections can be controlled according to response plans from the Multi-Dimensional Management System
- Variable message signs can be used to inform travellers, especially those without a connected vehicle in the short-term – these will be of less use in the future and can be phased out
- Much roadside sensor equipment can gradually be phased out, such as loops, radar, Bluetooth detectors and ANPR cameras. Even enforcement cameras might be replaced by connected vehicle technology

6 Answers to NIC Questions

6.1 Cross-cutting issues:

Question 1

What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region? *Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.*

The Digital Transport programme outlined above will:

- Encourage journey shift: to other transport modes, other roads, other times of day
- Increase road capacity: providing the next generation of Smart Motorways for all roads
- Improve average travel times on roads
- Improve reliability (spread) of travel times
- Improve disruption information and disruption responses
- All of the above will reduce emissions
- Improve road safety: providing the next generation of MIDAS systems for all roads
- Improve and standardise the transport statistics for the whole country

The unblocking of the roads will aid all modes of transport that utilise roads.

Together, these will enable agglomeration and improve the standard of life while travelling. There is potential to return tens of billions of pounds of cost savings to the British economy.

Question 2

How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Reducing travel times and at the same time making journeys more reliable and more resilient to disruptions will reduce the travel cost within the UK. This will improve UK’s competitiveness with other countries.

International gateways will be at the edge of the national transport network model, creating demand and receiving freight and passengers. Road usage charging will incentivise international gateways gradually to be located with the lowest mix of travel times, reliability, congestion and transport infrastructure costs for both their freight and passengers.

Question 3

How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The National Transport Data Warehouse outlined above can provide transport statistics which are consistent and joined up across local government boundaries, bringing the current detail of the Strategic Road Network to all major roads & bus routes and across all modes of transport. Usage, reliability, vehicle occupancy, transport mode, origin & destination will all be available historically at most one day out-of-date. A mathematical model will be available to answer “what if” questions about proposed major housing, medical, educational and industrial projects. This transport model could be part of a wider UK national infrastructure model.

Question 4

What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? *Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.*

The road usage charging outlined above gives ample opportunities for demand management. A traveller has a background financial motivation for journey shift. In addition, the disruption management system outlined above allows travellers the ability to react to disruptions by changing their planned route, thereby avoiding areas of disruption. As they improve their own journey, the travellers will load balance the transport network.

This Digital Transport programme may increase off-peak travel or travel on little used roads or little used transport modes, but the extra journeys will not be on congested roads. Since the journey’s total costs are transparent and are recovered, any additional usage will have any additional maintenance funded.

Question 5

How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The Digital Transport programme recommends all transport costs are transparent and attributed to the traveller. This includes maintenance costs, geographic or peak bottleneck costs, emission costs and noise annoyance costs. Therefore maintenance costs can be recovered and travellers will be able to consider the cost of fixing pot-holes as they choose a journey and a mode of transport.

In addition, more accurate return on investment business cases for new assets can be made using the National Transport Data Warehouse statistics and modelling.

Question 6

What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Although this document only talks of transport infrastructure, collaboration and competition can be allowed. There will be competition between modes of transport, different transport operators and a new market of Usage Charging Providers. The collaboration and government leadership is possible by varying the road usage charges.

Question 7

What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

The Digital Transport programme describes a new method of motivating journey shift and greatly enhanced transparency of road transport costs, without increasing the overall road tax burden. These changes will reduce travel times and improve traveller satisfaction.

Question 8

Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets? Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

The programme outlined above, although clear in its return on investment, will not happen without central government leadership since

- There is a disparate budget for transport technology across modes of transport and across local government
- Local, even regional focus does not result in intelligent mobility, where a traveller often completes a journey across multiple transport infrastructure owners
- There have been deep cuts recently in operational transport spending
- Operational transport budgets are not normally set within a multi-year framework therefore transformational projects cannot be underwritten easily (Network Rail and Highways England do not have this problem)

Question 9

How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

Two things should be coordinated between different infrastructure sectors:

- A National Infrastructure Data Warehouse can be established by extending the National Transport Data Warehouse system proposed above – people and freight with their multiple locations and movement is best understood in a wider infrastructure context
- A National Infrastructure Disruptions system can be established by extending the National Transport Disruptions system proposed above – the resilience of infrastructure to unplanned and even planned disruptions should be coordinated across all infrastructure and emergency services: terrorism, major construction, natural disasters

Question 10

What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

- The planning system should have a National Transport Data Warehouse in order to provide consistent, cross-boundary statistics and “what if” modelling to aid efficiency
- Multi-year, transparent transport infrastructure funding is essential to address the crisis in congestion
- Some investments and transformational leadership must happen at a national level to address the crisis in road congestion

- Public acceptance by drivers and the freight industry to tackle congestion is best done at a national level and will be achieved only through funding transparency

Question 11

How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Emissions, noise and transport infrastructure wear & tear are best reduced by making their cost visible through road usage charging. Travellers and the freight industry will respond to transparency and financial rewards.

Question 12

What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent? *Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.*

Better transport data would help to better cost-benefit analyses. This would have to be consistent, across boundary and multi-modal as would be delivered by the proposed National Transport Data Warehouse above.

6.2 Transport:

Question 13

How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? *Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.*

Increases in the average length of journeys and average journey times will probably continue until an unacceptable crisis. This is chiefly because

- Estate managers of large organisations such as hospitals, schools, manufacturing plants and offices continually reduce the number of sites they manage to reduce costs – a smaller and smaller number of larger and larger sites – this causes longer journeys to work, hospitals, schools and work places
- Moving homes to be closer to work is too hard – stamp duty and the lack of guarantee for children during education to find new schools close to home e.g. regarding schools places, two primary school children may only be offered places in different schools, neither of which is closest to the new home

Not all technology change can be anticipated, but

1. Vehicles will gradually become more autonomous and more connected
2. The Digital Railway programme will
 - a. Increase the number of trains possible along a section of track by deploying moving block signalling
 - b. Increase the resilience of the national network after disruptions by deploying Traffic Management technology
3. The London Underground will
 - a. Increase its capacity through deployment of moving block signalling, as has already been achieved on the Jubilee and Northern lines
 - b. Increase automation to the point of not needing train drivers
4. There will be widespread Mobility as a Service as people increasingly live without owning a car but by using transport services instead
5. Personal travel assistants or SatNavs should become essential for all modes of transport, including walking. Their usage should increase even for familiar journeys, since better transport information will

help with the current state of the transport network, including disruptions. The latest transport information will also help make changing transport modes less stressful

Question 14

What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas? Note: “high value transport investments” in this context include those that enable ‘agglomeration economies’ – the increase in productivity in firms locating close to one another.

The Digital Transport programme outlined above. Please see the answer to question 1 for a summary of benefits.

Question 15

What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area? Note: *this includes travel in and between rural areas, as well as between urban areas and international travel.*

The Digital Transport programme outlined above will reduce journey times and increase journey reliability outside of an urban area, since it primarily helps road travellers. This programme could return tens of billions of pounds of cost savings to the British economy.

Question 16

What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

The Digital Transport programme outlined above, which includes road usage charging, complements “mobility as a service”:

1. Road usage charging makes roads a consumable service
2. All transport modes can be compared by price which should increase the use of public transport
3. Incentives can be given for vehicle sharing
4. Buses consume less road infrastructure per head and therefore they will become relatively cheaper than cars, thus encouraging modal shift

Reduced car ownership, which is promised by mobility as a service, will save on parking. Also, autonomous taxis would in addition increase social inclusion.

The downside of reducing car ownership is additional trips for the vehicle: the rented vehicle must move from a pool to the traveller, then do the journey, then return to a pool. These additional trips would add to congestion. This is also true for ring and ride services unless origins and destinations are shared by multiple travellers.

Dear NIA Call for Evidence

Please find below a response from Thames Valley Berkshire Local Enterprise Partnership. The response is confined to some of the questions in the Cross-cutting and Transport sections.

Where we have made no response it is because we lack access to specialist evidence or understanding of the issues as posed by your line of questioning.

We look forward to responding more fully to the draft NIA when it is published.

Thank you for the opportunity to contribute. If you would like to follow up on any of the topics please contact [name redacted] ([email redacted] [telephone number redacted])

Cross-cutting issues:	Thames Valley Berkshire response
1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region? Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.	TVB LEP has concluded that Labour Supply issues are the biggest threat to our economy ⁱ . Therefore, we would prioritise: 1. Enabling housing development and/or 2. Better transport systems which improve local, regional, national and international connectivity and/or 3. Promoting access to the best talent
2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?	TVB LEP has identified proximity to the world class airport at Heathrow as major competitive advantage for our economy. This encourages inward investment, HQ location and leads to better Trade Deals and aids exporting
3. How should infrastructure be designed, planned and delivered to create better places to live and	Please refer to " Being dense: it's the clever option " ⁱⁱ published in November 2015, which advocates master planning

<p>work? How should the interaction between infrastructure and housing be incorporated into this?</p>	<p>for high (50-100 dwellings per hectare) density with sustainable transport at the core of the plan. The report covers both greenfield and regeneration planning.</p>
<p>4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.</p>	<p>No comment.</p>

Transport:	
13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.	<p>The following is taken from an unpublished TVB LEP briefing document: However, three common themes stand out:</p> <ul style="list-style-type: none"> • although it takes different forms, the influence of London is clear and (perhaps with the exception of the SMEs) pervasive: TVB needs to recognise the complex links to the capital and the consequences of the enhanced connectivity that Crossrail will afford, particularly in seeking to recruit and retain specific groups of workers • enabled by IT, working practices are changing profoundly, and this in itself is creating different opportunities and demands in relation to sites and premises, and the infrastructure through which these are connected • patterns of service delivery are also evolving quickly, with an increasing emphasis on local service centres (reversing a long-term trend) and also on on-line services and home delivery. This is true for both for private sector services (like retail) and for healthcare delivery. In response, spatial configurations are changing – although there may, in practice, be a considerable time lag (particularly within the public sector in the context of limited resources) before these are fully realised.
14. What are the highest value transport investments to allow people and freight to get into, out of and	The following is taken from an unpublished TVB LEP briefing document:

<p>around major urban areas? Note: “high value transport investments” in this context include those that enable ‘agglomeration economies’ – the increase in productivity in firms locating close to one another.</p>	<p>Improving the transport infrastructure to enable and accommodate growth is essential. However, road capacity cannot indefinitely be increased to meet growing demand. Therefore, new development must be well served by public transport, preferably on dedicated routes. TVB is crossed by various rail lines, some of which are receiving very substantial investment to improve capacity and reliability. Looking ahead, maximum use must be made of the accessibility these lines afford. As a consequence, a high priority must be given to development in and around existing stations, to examining the scope for new or extended stations and increasing capacity on existing lines, and for other rapid transit solutions elsewhere.</p>
<p>15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area? Note: this includes travel in and between rural areas, as well as between urban areas and international travel.</p>	<p>TVB LEP has prioritised the Western Rail Link to Heathrow scheme as its top Infrastructure priority. This scheme has regularly appeared in the National Infrastructure Plan and in Network Rail Long Term Planning Documents. It was recognised by the Davies Commission report as being justified on the basis of a two-runway Heathrow Airport. Despite this good level of support for the scheme, it is not fully-funded, and now appears caught up as part of the necessary mitigation to be delivered by Heathrow as part of their 3rd runway Development Consent application.</p>
<p>16. What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?</p>	<p>No comment</p>

National Infrastructure Assessment – call for evidence Response from Thames Water

Executive Summary

London and the south-east face a growing water supply-demand deficit, which left unchecked could threaten economic growth, and expose the region to an acknowledged increasing risk of severe drought, and undermine its international competitiveness.

Thames Water is already taking action to close this deficit through an ambitious and accelerated programme to help customers use less water. However, due to the size of the deficit, demand management alone cannot release sufficient water supplies, so new resources will also be necessary. The need is urgent – if London and the wider region are to grow as anticipated, and to reduce its exposure to extreme drought, work to construct new water resource supplies must begin in 2020.

The growing pressure on the sewage network, caused by housing growth, loss of permeable areas, and the anticipated effects of climate change necessitates reform. There is an opportunity to shift from piecemeal and largely reactive provision of wastewater infrastructure to one that anticipates and enables growth on a strategic basis. This can be enabled by reform of funding arrangements for wastewater infrastructure, changes to the planning system so that more new development is sustainably drained, and the closer involvement of water companies in the planning process.

Markets present opportunities for improvements in the sector. New water resources can become strategic resources for the wider region, rather than a single company, and collaboration between all stakeholders can provide strategic wastewater investment, which will facilitate growth.

The Government can play a key role by producing a Strategic Policy Statement that clearly sets out policy in line with known customer views on resilience. In our view, a National Policy Statement for Water should be brought forward prior to any public inquiries for water companies' Water Resource Management Plans so that any subsequent inquiry focuses on whether the water company in question has produced the best value plan in response to the resilience challenges it faces and not the already established 'need' to maintain water security.

We believe the Commission could help address the question of how best to provide a water supply network resilient to the risk of severe water shortages where the risk is increasing as a result of population growth and climate change. The cost of a severe drought would be high, estimated in 2012 to be £330m a day⁵ in London alone. The potential cost of a severe drought therefore heavily outweighs the cost of increasing resilience. The Commission could play a valuable role in finding the appropriate balance between resilience, affordability, and intergenerational equity. This may ultimately mean adding more weight to the need to invest in a combination of infrastructure and demand management that will provide a safer and more reliable service, which should not come at the expense of efficiency, or an imperative to keep costs as low as possible. We recommend a call for water companies to invest in infrastructure and demand management that enables economic growth and enhances resilience to a stated standard of at very least a 1 in 300 year drought. In comparison, UK Government currently invests in tidal flood defences to protect London from a 1:1000 year coastal flood event.

Our first step to reduce our supply-demand deficit is demand management⁶. Our progressive metering programme is the largest water efficiency programme ever to take place in the UK. In combination with the rollout of smart water meters, we are speaking one-on-one with customers, providing water saving devices and fixing leaks identified by the new meters on their property. Once there has been sufficient penetration, smart meters will improve our ability to pin-point leaks in our network and better direct investment. In addition, we plan to step-up work to tackle leakage and are planning to bring forward incentive and innovative tariffs as an option in our WRMP19. However, despite this unprecedented work to reduce demand, the size of our supply-demand deficit is such that new water sources will also be required.

The urgent need for new water resources is beyond doubt. The Commission can call for a National Planning Statement for water to be issued before any potential public inquiries into water companies' Water Resource Management Plans. This will enable work on new infrastructure to get underway in 2020, which is required if London and the south-east is to continue to enjoy water security.

To support the projected growth in London and the south-east we need wastewater infrastructure to be treated with greater urgency than it currently is. Urban creep⁷, loss of green space and climate change all put pressure on the sewer network. Development in the capital in particular has led to a 19% increase in impermeable areas in 40 years. Population growth adds to these challenges but the new development needed to accommodate it creates opportunities for improvements, provided the drainage is correctly designed.

However, the present funding arrangements for wastewater infrastructure are no longer fully efficient or effective to service the needs of new development. Successful reform would enable growth and allow all water companies to better support housing developers.

There is an opportunity for the Commission to assist in introducing an organisational and cultural shift in the way that wastewater infrastructure is planned for in the UK, towards a strategic system that facilitates growth. The Commission can encourage new development to be water efficient, including rain and grey water recycling where appropriate, and sustainably drained.

⁷ The loss of permeable ground through using impermeable materials in urbanisation.

Cross-cutting issues

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Our area of operation includes London and the Thames Valley, the UK’s most economically important and rapidly growing region. Unless the design and planning process for new water infrastructure begins in 2020, the capital will not have the water it requires for sustainable and secure growth⁸, and, after 2022⁹, will become increasingly exposed to severe drought.

Figure 2 – Potential deficit in London water resource zone without mitigating actions

Source: Thames Water

A rapidly increasing population, sustainability reductions, and the disruptive effects of climate change mean there is a growing gap between supply and demand. The predicted new housing in London and the south-east cannot be delivered without an increase in supply, even after ambitious demand management measures are implemented, including leakage reduction, universal water metering, and improved water efficiency.

The UK Climate Projections¹⁰ suggest that climate change is likely to have a disruptive effect on the availability of water in the UK. Whilst the average annual rainfall is not expected to vary, average and extreme seasonal rainfall is predicted to change, with significantly wetter winters and drier summers expected for the second half of the century compared with the baseline period. This could result in greater pressure on water supplies by reducing the amount of water available for abstraction, particularly in the south-east. The Thames is already the most intensively used catchment in the country, with more than 55 per cent of the effective rainfall licensed for abstraction. A requirement under the Environment Agency’s drought plan guidelines to be resilient to more extreme droughts confirms this national need, which is most critical in the south-east. We will need to properly account for these changing weather patterns in whatever supply-side measures we introduce.

Our existing 25 reservoirs are ageing and are expected to require significant maintenance activity in future to meet reservoirs act requirements, and to ensure they continue to provide reliable services for years to come. The

⁸ The long lead-in times for new water infrastructure (desalination, wastewater reuse, direct river transfer, interbasin transfer, reservoirs) require the planning process to begin in 2020

⁹ Thames Water [draft Drought Plan 2017](#)

¹⁰ [UKCP09, The MET Office](#)

Reservoir Act (1975) requires us to carry out detailed inspections once every 10 years, and act on the findings, often before the reservoir can be put back into service. Drawing levels down, inspecting the reservoirs, completing any work and refilling them can take a considerable amount of time, ranging from months to years if significant issues are uncovered, which has been demonstrated to become more likely with an ageing asset base.

While such exercises are planned to take place outside of periods of drought, there is a risk that the drawing down of a reservoir for statutory inspection could coincide with an unplanned outage at another reservoir - potentially putting the security of supply at risk if a lack of rainfall means that refilling cannot take place. This is not a hypothetical risk – we experienced lower than average rainfall last winter and, at the time of writing, are experiencing another dry winter. This coincides with the upcoming need for prolonged maintenance of one of our major reservoirs serving London.

London's existing water resources are not designed to cope with more intensive droughts than those experienced in the twentieth century, which had a recurrence interval of approximately 1:100 years. More severe droughts than these will reduce water availability to the capital. For example, a 1 in 500 year drought would mean our reservoirs had a yield 260-300 MI/d lower than during the twentieth century droughts.

The severe restrictions on water supply that would need to be imposed in a near worst-case drought scenario could cost up to £330m¹¹ a day in London alone. Severe water pressure reductions and rota cuts (where customers would experience a rota of temporary cuts in their water supply) could affect almost all areas of the economy, potentially forcing workplaces, schools, hotels and restaurants to temporarily close due to hygiene concerns (lack of toilets) and safety (fire suppression systems). The restrictions may also impact on other water intensive uses, such as the use of air conditioning for non-human health purposes, possibly affecting IT servers, causing IT systems to cease operating.

Water companies are required to ensure their plans are resilient to a range of hazards, which further supports the need for an improved supply and demand capability. Our Water Resource Management Plan (WRMP) for the period 2015-2040, approved by the Secretary of State in 2014, projects a supply deficit and identifies the need for a large water supply scheme from the mid-2020s. The plan identifies three potential options: wastewater reuse; the transfer of supplies into our region; and a large reservoir.

Like all water companies, we are currently developing our next WRMP. We are currently examining a range of options for new resources, including wastewater reuse; the transfer of supplies into our region; a Direct River Transfer (which would see treated effluent returned upstream of key abstraction points on the lower River Thames, rather than further downstream, as at present); desalination; and a large reservoir. There is associated infrastructure that enables these new water resources to function, including conveyancing tunnels, a possible extension to the London Ring Main, and water treatment works. These are subject to detailed studies to determine the best value combination of options for us to promote in the next revision of our plan, to be published for consultation in spring 2018. The plan will then be amended and sent to the Secretary of State for a decision in January 2019. A public inquiry may be required as part of this process.

Major new water infrastructure has long lead-in times. For example, it could take more than a decade from a WRMP being approved to a major new reservoir being delivered. However, a National Policy Statement (NPS) for water could shorten the timescale. A new NPS would have three main benefits – it would provide greater certainty and therefore lower costs, prevent delays due to the local planning process, and avoid a potential public inquiry unnecessarily having to address the issue of need.

The need for new water resources is not in doubt, as demonstrated by Water UK's long-term planning study¹² and WRSE regional modelling. According to our latest planning forecasts, as well as implementing demand management measures, we will need a large new water resource option from 2023/24. Our WRMP14 forecast an option needed by 2026/27, but since 2013 there has been an even further substantial increase in population in London. Of the new

¹¹ Analysis by NERA, commissioned by Thames Water in 2012.

¹² [Water UK, Water Resources Long Term Planning Framework](#)

resource options we are examining the very earliest could come online from 2025, assuming a NPS is introduced in time for the planning process to begin in 2020.

Once constructed, water infrastructure has the potential to be in use for centuries. For example, the New River was opened in 1613 to transport water to a rapidly expanding London and is still used today. The backbone of water and wastewater infrastructure in London was constructed by the Victorians, although it has been significantly improved and extended since,

The rapidly increasing population, particularly in London, will require significant and urgent investment in wastewater infrastructure. We are currently developing our plans for the regulatory period 2020-25, but our latest growth forecasts (GLA/Experian data) are indicating the need to **invest £750m to £900m during the five**-year period. Available space at our existing sites is a concern as the majority are 'land locked', which restricts the opportunities for conventional expansion and therefore increases costs. New major wastewater sites are unpopular with communities and elected representatives, and the necessary land is often unavailable. We are currently creating a team who will be dedicated to looking at London's long-term wastewater needs, taking a view of what is required to meet demand, where, and when up to 2100.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

London and the south-east account for 38% of the UK economy¹³. The economic engine of the country must be serviced by secure and reliable infrastructure if Britain is to demonstrate to the world that it is 'open for business' and attract investment.

A world city that cannot deliver new housing and businesses due to water shortages or inadequate drainage infrastructure, or suffers from economic chaos caused by severe drought, would not be able to achieve this.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

This question is answered through our responses to questions 1, 4, 7 and 11.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Demand management is the first step we are taking to reduce our supply-demand deficit. In WRMP14 we proposed the introduction of innovative tariffs from 2022/23 as a measure to ensure a sustained demand response by metered customers. We planned to undertake a trial of tariffs, between 2015-2020, to understand and quantify customers' responses to alternative tariffs. Over the past 18 months, we have completed a desk based review of tariffs, both in the UK and internationally, to understand the types of tariffs in use, the methods of implementation and the effectiveness of the tariffs (where this information is available).

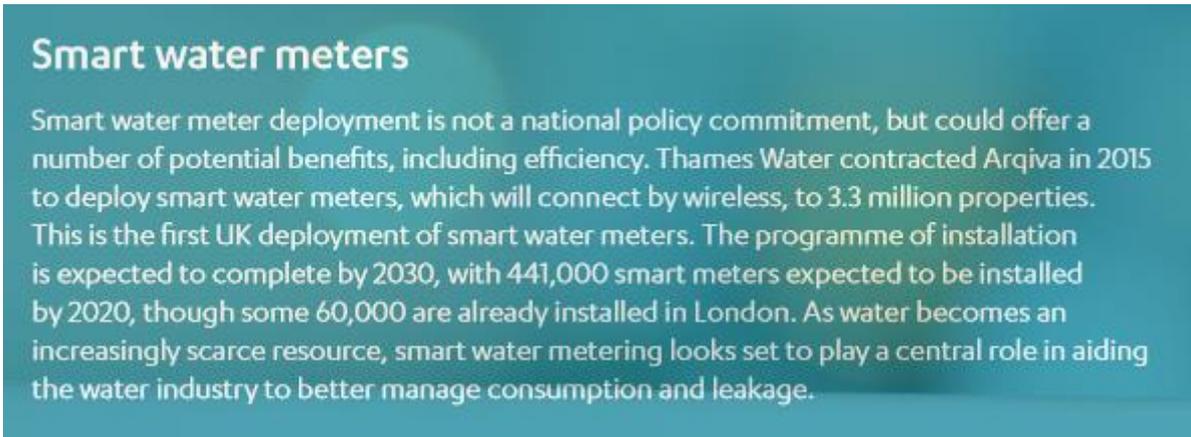

The research we have carried out with customers found that they are sceptical of tariffs; they believe that everyone should be on a meter before tariffs are introduced to ensure fairness; and education on water use is needed as a precursor for tariffs to work effectively. In response to the feedback received from customers we have developed a reward based incentive scheme and are currently trialling this in Reading. We plan to extend the trial to parts of London in 2017. The scheme is a positive intervention, to help customers understand their water use and encourage the efficient use of water through rewards. The effectiveness of the scheme will be assessed, using both quantitative and qualitative data, to inform our future strategy on incentives.

As recognised in the Commission's recent publication 'Connected Futures', we are the first water company to deploy smart water meters, which have the potential to improve how we manage leakage and consumption. Starting with

¹³ [House of Commons Library, Regional and local economic growth statistics, December 2016](#)

London, where the need is greatest, our ultimate aim is to roll-out meters to all of the 3.3million properties we supply.

Figure 3: Extract from the NIC’s ‘Connected Futures’ publication

Source: National Infrastructure Commission

In WRMP14 we included assumptions for demand reductions as a result of metering and wider demand management activities. We are currently rolling out the progressive metering programme in London, which is the installation of AMI smart meters. We are evaluating the programme as it is implemented, in respect of the costs and benefits. Customers are offered a 2-year period during which they can switch to a metered bill. At present we do not have a representatively lengthy data set on which to re-base our assumptions on the usage benefits of customers switching to a metered bill. We will share this information with stakeholders when we have a robust data set.

We are offering a free in-home water efficiency retrofit and tailored audit-advice service for every household in receipt of a new smart meter, with over 50,000 taking place in 2016/17. This Smarter Home Visit programme¹⁴ (advising customers one-on-one in their own homes, providing water saving devices and fixing leaks identified by the new meters on their property) is the largest water efficiency initiative ever undertaken in the in the water sector.

Unlike other developed nations, only a small proportion of domestic properties in London and the south-east have a water meter. On average, our metered customers use 12% less water than non-metered customers use – this represents our largest opportunity for behaviour change, by giving water an explicit value and providing our customers with the practical support and advice to reduce waste and manage usage.

The smart metering programme has recently passed an important milestone with the 100,000th meter being installed, but the current level of penetration means that the data has only just begun to be utilised. The benefits of the programme and the data available will steadily increase in the years ahead.

Currently, water companies are able only to estimate their leakage, and the figure includes leaks on customers’ properties, from pipes which the water company does not own. Only 2% of leakage is visible above ground, and we estimate that a third of our leakage occurs on customers’ land. Smart meters are a radical change for the water industry – once a significant proportion of customers have them, for the first time they will allow us to see in real-time where water is going in our network and enable us to pin-point the location of leaks.

Our smart metering programme is the largest water efficiency project ever to take place in the UK, and will improve our ability to tackle leakage, while delivering better insight for customers into their own water consumption. The programme forms a key part of our demand management, which also includes major and increased investment in our network to reduce leakage and use greater education and one-on-one proactive dialogue with our customers¹⁵.

¹⁴ Thames Water: [Smarter Homes Visits](#)

¹⁵ Thames Water: [Demand Management Options Screening Report – Phase 1 Executive summary](#)

Despite this unprecedented and highly ambitious activity to reduce demand, our optimistic forecast is for demand management to only make up half our water supply-demand deficit by 2040.

Looking internationally, there are examples from Australia and California that highlight the dangers of overestimating the extent that demand management can close water supply-demand deficits. This is set out in more detail in our answer to question 22.

The water demands and sewage generation from a number of major new development areas will exceed the capacity of our networks in some areas. We have been mapping the expected demands of major new developments onto our water and wastewater (including drainage) networks to identify where there may be insufficient capacity to supply or drain these developments. Where we have identified significant incapacities, we are working with the Local Planning Authorities to develop Integrated Water Management Strategies (IWMS) to understand the scale of the gap in more detail and to develop options, such as grey water and rainwater harvesting systems at community-level and for individual buildings, to close the gap. For example for Old Oak Common in London, the draft IWMS suggests that almost all the rain that falls on the site must be captured in sustainable drainage systems (SuDS) or used on site.

For wastewater, the roll out of sustainable drainage measures across the capital – both for new developments and retrofitted in areas prone to flooding – is an essential part of our programme to reduce the strain on sewerage infrastructure. Over the next five years we plan to retrofit sustainable drainage measures to remove surface water run-off from 20 hectares of impermeable area, including a large scheme at Battersea Nine Elms.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Since privatisation we have invested heavily in infrastructure, delivering major projects such as the London Ring Main and a new desalination plant, although much of our core infrastructure dates back to the Victorian era. Some of this, such as water treatment works, will continue to be used for centuries to come. Our investment for the past 11 years averages over £1bn per annum.

Our network of distribution and trunk mains are the oldest of any UK water company, and consequently require a sustained investment programme to reduce leakage and improve reliability of the network. Since they were laid, many in the 19th Century, the cities and towns above much of the network have been transformed, particularly in London, where arterial roads have been built on top of our pipes. The costs of replacing or relining pipes are therefore high and the necessary work causes significant traffic disruption. We use pressure management to extend the life of mains and aim to replace them once their performance drops below a critical performance threshold.

Against this backdrop, there is a falling rate of return from repair and replacement work, as illustrated by the graph below. The cost per megalitre (£M/Mld) rises as the pipes with increasingly smaller levels of leakage are fixed – those suffering the most leakage are fixed first, with work continuing down a priority list. There is a point where the level of investment required to reduce leakage even further provides customers with poorer value for money than, for example, investing in new sources of supply.

London's sewer network, designed by Joseph Bazalgette, served a city of two million people. Thanks to Bazalgette's foresight, it was built with a capacity for four million. However, it now serves a city of eight million. In response to problems caused by outgrowing existing capacity, we are building the Thames Tideway Tunnel. By rethinking the way that wastewater in London is managed we can ensure that this new tunnel is sufficient for centuries to come.

The rapid rate of growth in London means that new measures and approaches need to be introduced to provide support. New development provides an excellent opportunity to reduce the amount of surface water that enters the sewerage network through sustainable drainage measures. In London, many of the sewers are combined, that is, they convey both foul and surface water in the same pipe. Removing or reducing surface water serves to increase the available capacity in combined sewage networks to accommodate growth in foul flows without the need to construct new assets.

Extending this approach to address the requirements of others with drainage responsibilities such as Local Authorities, Highways Agency and the Environment Agency offers a unique opportunity to identify partnership projects that deliver multiple benefits. However there is no established mechanism for identifying and delivering such projects, albeit that the Thames Regional Flood and Coastal Committee has sought to encourage such thinking. As discussed later in this response we are currently examining what form a whole catchment approach should take, our role within it and in which catchments it might be most effective. However, in order for a whole catchment approach to be more routinely applied, responsibility for its execution might need to be vested in a single authority.

To enable the reduction of the amount of surface water that enters the sewerage network, water companies also need to become statutory consultees on major planning applications, the existing planning framework for SuDS requires strengthening, income from connections should not be subject to a revenue cap, and strategic investment in advance of development is required.

Many of the sewers that we operate were constructed in the Victorian era. Whilst the majority are still in good condition, collapses do occur, and the consequences of large diameter sewers collapsing can be significant. For example, many sewers in London and the south-east cross beneath railways and so have the potential to cause major disruption.

Our current approach is to survey and monitor our critical sewers, so that we can determine the exact location if and when we need to intervene to carry out repairs. We are also continuing to improve our understanding of deterioration rates to inform future rehabilitation programmes.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

The water industry in England and Wales has been regulated since privatisation in 1989, with services to households and non-households provided mainly by statutory regional monopolies. There have been attempts to introduce competition or mimic its effects, particularly the use by Ofwat of regulatory benchmarking (or 'yardstick competition'). The Water Act 2014 expanded the markets for non-household retail competition and upstream competition, both of which have struggled to develop since their introduction in 2005 due to flaws in the competitive framework. However, non-household retail competition opens for business in April this year and upstream competition is expected to come into force during the 2020s. Ofwat has recently, at the Government's request, reported on the costs and benefits of introducing household retail competition. The decision whether to proceed with household retail competition is with the Government.

For retail competition, existing water/wastewater infrastructure remains the responsibility of the regional water company (the wholesaler). Upstream competition, however, will allow entrants to provide the supply of raw or treated water into a company's network, or the removal of wastewater for treatment, without being obliged to also provide retail services.

We welcome the introduction of upstream markets, and believe it can play an important role for the industry as a whole, the size of our operation means. That said, it is unlikely to play a significant role in our future water supply

operations, either in the short or long term. For example, we supply 2,600 million litres of drinking water every day – it is extremely unlikely that another organisation would be able to create a new supply that significantly changes this figure.

There is significant opportunity for collaboration on water supply. We have existing water transfer agreements with neighbouring water companies and with private individuals and other companies. The introduction of a major new water source has the potential to act as a strategic resource for London and the whole south-east region, providing security to multiple water companies and other sectors, including farmers. For that reason we are open to the possibility of joint-ownership or another organisation owning any major new asset. Upstream markets could provide the regulatory mechanism to allow this to happen.

By not delivering major infrastructure ourselves, and instead opening the process to competition, the result can be lower costs. The Thames Tideway Tunnel (TTT) is an example of an innovative financial model that is delivering a £4.2 billion project with minimal impact on customers' bills. When originally proposed with a traditional utility model, the costs on customers' bills were estimated to be £70-£80 per year on average. Through the model used, bills will instead rise by £20-£25 per year by the mid-2020s.

The TTT model is a first for the UK water industry and involves the creation of an independent infrastructure provider (IP). The cost of capital is reduced by the external financing of a single significant asset with suitable protection against exceptional construction risks associated with deep tunnels that could not be insured against through the private sector, enabling the IP to attract substantial private investment, including from domestic institutional investors. The model is applicable to other forms of infrastructure, particularly other regulated or monopolistic assets such as transport infrastructure. Ofwat has recognised this in its proposals that encourage companies to deliver projects via direct procurement.

On the opening of a sludge market, we agree with Ofwat's proposal to set a separate control for sludge treatment and disposal. We consider this raises an opportunity to support greater efficiencies in sludge activities, for example a greater focus on sludge assets may limit poor quality liquor returns and improve the dewatering and quality of sludge for energy production. This therefore raises the opportunity to increase revenues from sludge, and reduce treatment and disposal costs.

However, the environmental regulations present a barrier to co-digestion. Overcoming this barrier may be difficult in practice and incur additional costs. We are supporting Ofwat and the sludge working group in examining how to overcome this.

As local authorities, highways authorities, the Environment Agency, and riparian land owners all have responsibilities for drainage, the potential for collaborative projects to address areas at risk of flooding is significant. Indeed, it is unlikely that water companies will be able to reduce flood risk on their own, in the face of climate change and increasing urbanisation, without working collaboratively with other drainage partners.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

There is a well-established framework of independent economic regulation which has remained broadly stable since privatisation. Although stable, this framework evolves over time, and with this evolution comes opportunities and challenges for the efficient delivery of infrastructure are created.

For example, recent changes to the framework that confer greater risk on companies in respect to population growth create challenges; whereas Ofwat's recent proposals to facilitate direct procurement of major infrastructure projects create opportunity.

The details of the regulatory arrangements are clearly matters for Ofwat, in the first instance, and therefore we are engaging with them on these topics in the lead up to the next price review.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Clear, stable Government policy and independent economic regulation reduces uncertainty and therefore lowers the cost of investment. As in all other sectors, risk is built into the cost of our borrowing and Government intervention has the ability to significantly reduce this.

Defra's Strategic Policy Statement (SPS) to Ofwat provides a mechanism for the Secretary of State to set out 'strategic priorities and objectives' to Ofwat. Its aim should be to foster a regulatory environment that has a clear strategic policy direction that supports long-term planning and investment. A SPS that focuses clearly on a small number of issues with the greatest significance, and identifies a priority, would likely be most effective.

In our view, the SPS should draw on and reflect the views of customers, as this would align it with Ofwat's primary consideration to act in the best interests of customers, and place long-term reliability of quality and service above other considerations. It should avoid treating these criteria as mutually exclusive. Beyond these strategic priorities, the views of customers can be applied to the majority of questions in the discussion document, including how the duties are balanced, the development of social tariffs, and ensuring solutions meet future risks.

A further example of Government policy would be the publication of a National Policy Statement (NPS) for water that recognised the need for additional water resources. As detailed above, a NPS would prevent proposed water resources being beholden to the traditional local planning system, therefore shorten delivery times, and provide greater certainty for investors and lower bills for customers than would otherwise be the case.

In addition, greater certainty can be provided by a commitment to maintain existing environmental regulation for a period of time as the UK leaves the European Union.

The Thames Tideway Tunnel (TTT) financial model (detailed in our answer to question 6) benefits from proactive Government involvement in new infrastructure.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

We believe that consideration of cross-cutting issues would result in a more strategic, innovative, and sustainable approach in delivering water and wastewater infrastructure. One model to overcome sporadic delivery of infrastructure at a regional level is the Mayor of London's infrastructure groups, which bring together devolved government, utility companies, and developers. This enables a strategic conversation to take place between all parties, presenting the opportunity for utility companies to identify issues in advance, for innovative solutions to be agreed, investment to facilitate development to be agreed, and ultimately speeding up the delivery of new housing.

In addition to considering the availability of water for public water supply, manufacturing, energy generation and agriculture, a predictable, affordable supply of water is essential to support the construction of new development (homes and workplaces), infrastructure (e.g. High Speed 2) and industrial processes (including fracking).

Water supply is dependent on a continuous, reliable, and affordable power supply. Without power to treat and pump drinking water and wastewater, companies would be unable to continue to supply customers, there could be sewer flooding, and environmental harm from untreated discharges, leading to economic damage. Desalination and effluent reuse are energy intensive and although we are increasingly producing our own power, for example through biogas from sludge or floating solar panels on reservoirs, we are reliant on a resilient energy sector.

The current water resource system lacks sufficient headroom to cope with a sustained period of low rainfall and this is being further reduced by the factors set out in the questions above. Absence of water supply prevents all economic activity and insufficient resilience against drought would result in severe financial damage to every sector of the economy.

The predicted new housing in London and the south-east cannot be delivered without an increase in supply, even after implementing ambitious demand management measures, including leakage reduction, universal water metering, and improved water efficiency. Although we understand that the Commission's remit does not extend to housing supply, we believe that new water sources do fall under the Commission's responsibility to coordinate the timing and delivery of new infrastructure with the delivery of new housing.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The Planning Act 2008 creates provision for a National Policy Statement for water, but unlike other NSIP-infrastructure types described in the Act, no NPS for water has been brought forward. Without a NPS, any major new water infrastructure would be subject to the traditional, local planning process, despite being of supra-regional or even national importance. This could lead to substantial delays in the delivery of major projects, which are unaffordable due to the growing deficit in supply.

We are not a statutory consultee on planning applications; we therefore have to proactively track key development sites that are coming forward in our region by liaising closely with local planning authorities. We work with councils to understand what is coming, but there are wide variations in the level of co-operation we receive, and getting clear visibility of the pipeline of future development can be challenging. This is why we are looking to develop stronger relationships with developers, to understand their portfolio of work at an earlier point to make sure we can prepare for it. However, water companies becoming statutory consultees would alleviate this issue.

Overall, we have a network of drains and sewers that were not designed to capture, convey and treat the amount of rainwater that they are currently exposed to and which we expect to increase in the future. A coordinated approach is necessary to provide greater certainty for those delivering strategic infrastructure, including the demands that would be put on the network through growth, the increase in impermeable surfaces in our cities, and the upcoming review of the NPS for wastewater, including resilience against surface water flooding from heavy rainfall. This could be considered in reference to the duty on Ofwat to act in accordance with the Government's Strategic Policy Statements (see answer to question 8).

Further consideration needs to be given to how the delivery of major long-term developments can be accelerated by better planning for water and wastewater infrastructure. For example, a significant upgrade of existing infrastructure may be required – costs for strategic upgrades need to be shared efficiently between multiple developers and existing customers, whilst avoiding a situation where the 'first mover', i.e. the first developer to begin construction, pays a disproportionate cost. We have successfully worked with the GLA on Integrated Water Management Strategies and believe this model can be refined and implemented elsewhere.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Our most recent Drought Plan¹⁶, a statutory document water companies in England and Wales are required to publish, explains that we could at present maintain supplies during a severe drought only by increasing our abstractions very significantly through the use of Drought Permits, seeing a return to the dried-out river beds that have been the feature of previous water shortages. Additional water resources have the potential environmental benefit of boosting the flow of rivers during times of comparatively low rainfall, protecting the ecology of the river, and reducing the necessity of abstracting at sensitive locations.

To reduce need for investment we need, where possible, to use SuDS to prevent rainwater from entering the sewer system, reducing the likelihood of sewer flooding. Rainwater is returned to the environment at source, rather than being transported some distance to a sewage treatment works, and passing through an energy-intensive process. A more appropriate balance between source control and an end of pipe solution would prevent the need for new or extended sewage treatment works.

¹⁶ [Thames Water draft Drought Plan](#)

Looking further ahead, there is a greater role that green infrastructure (using vegetation, soils, and natural processes to manage water in urban environments) can play as part of an integrated approach to catchment management. The natural environment can enhance infrastructure through the Payments for Ecosystem Services and natural capital, both of which can be further embedded into Government thinking.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Overreliance on conventional cost:benefit analysis alone is unlikely to lead to decisions (and outcomes) that are in the best long-term interests of the UK. In our experience, over-adherence to a framework that requires advance proof that the benefits from infrastructure investment exceed the costs can, over time, lead to under-investment in infrastructure. Costs are often uncertain, particularly for large water resource schemes, and estimating environmental, social cost, and benefits is an inexact science. We need to account for the broader benefits of an improved supply/demand balance outside of a drought. An example of these broad benefits would be using a major supply-side resource, such as a large reservoir or water transfer scheme to provide additional capacity that would allow us to reduce reliance on more environmentally sensitive abstractions.

In order to identify best value, we are using multi-criteria performance assessments, which considers cost, resilience, public acceptability, deliverability, positive and negative environmental impacts and sustainability issues. This approach is applicable across all types of infrastructure.

This approach is particularly suitable when examining investment in a future where there is significant uncertainty relating to some of the investment drivers, for example the forecast impacts of climate change, population growth and the requirements of the environment. In parallel, we are implementing an adaptive pathways approach to identify options which comprise part of a best value investment programme.

The Environment Agency has developed an approach for enhancing long-term resilience and enabling investment despite uncertainty. The Thames Estuary 2100 project¹⁷ provides a long-term strategy for managing tidal flood risk in a rapidly changing estuary. It sets out a series of flexible adaptation pathways, identifying different flood risk management options and defines the trigger points where rising sea levels require moving from one option to another. This allows options to be safeguarded and creates clear decision points on when to act. We are also applying this approach to our long-term water resources planning and, again, we would be happy to share our latest work with the Commission.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

As set out in our answer to question one, London and the Thames Valley faces an increasing water supply-demand deficit, driven by a rapidly growing population, sustainability reductions, and the disruptive effect of climate change. Without intervention, this the gap between supply and demand would equate to the water used by 2 million people in London alone by 2040.

Our first measure to reduce the supply-demand deficit is greater demand management. As detailed in our answer to question four, we are aiming to install smart meters in all of the properties we serve, which is the UK's largest ever water efficiency programme. This will radically improve our ability to identify leaks, allowing us to target high levels of investment in order to reduce leakage, and work with our customers individually to reduce usage.

Since privatisation, investment in our network has tripled, averaging £1bn per year on average for the past 11 years. We have delivered major projects such as the London Ring Main and a new desalination plant, and replaced thousands of kilometres of Victorian mains. Despite this investment and our ambitious plans for the future, the size of the growing gap between supply and demand means it cannot be closed through demand management alone.

¹⁷ [Thames Estuary 2100 project](#)

Lessons from elsewhere in the world highlight the dangers of overestimating the extent that demand management can close water supply-demand deficits - for example, the Millennium Drought in Australia and recent ongoing drought in California¹⁸. The failure to introduce new water resources infrastructure led to exposure to severe drought, although demand management played a key alleviation role during the drought itself.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

The key issues facing wastewater are a requirement to take a strategic view of the existing system and future requirements as a whole, rather than focussing solely on capacity, and ensuring that investment facilitates development. It is neither possible nor desirable for water companies to meet unlimited demand. There is considerable scope for new developments to be more water efficient and sustainably drained.

The water industry, through Water UK, has produced a document setting out the long-term challenge facing drainage and sewerage¹⁹. The industry is now drawing up a strategic planning methodology, which is intended to inform the Price Review 2019 process.

Unlike water resources, there is no statutory requirement for strategic planning of companies' wastewater infrastructure. Water Resources Management Plans are a statutory requirement that drive coordination between the water companies, Government, regulators, stakeholders, and customers. We are forming our own London 2100 wastewater team to plan for the long-term, alongside the statutory WRMP process.

Without a statutory footing any five-year wastewater plans produced by individual companies would lack recognition from key stakeholders, such as local authorities, developers, and landowners and would differ significantly in scope across the country. A formal requirement for water companies to produce long-term plans would provide a greater impetus to plan strategically and invest to facilitate development, to the benefit of housing developers and local authorities, and would recognise the environmental responsibilities that all stakeholders have. Most importantly, it would alter the culture which arguably currently exists in the UK, where wastewater infrastructure is introduced in a piecemeal fashion, reacting to new development as it occurs, rather than strategically providing for the future.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Defra's 2016 guidance on planning for Water Resource Management Plans states that *'enhancing the natural resilience of the catchment by effective catchment management planning, to increase the amount and/or quality of water available for abstraction without posing unacceptable pressures on the environment.'*

Our work in this area is fragmented, so in October 2016 we arranged a lengthy roundtable discussion with Defra, Environment Agency, our regulators, environmental NGOs, and other experts from the sector, to explore what action we could take. We face unique challenges due to our lack of uplands and highly urbanised area of operation, illustrating that catchments vary substantially across the UK.

Whole catchment management has considerable potential but as our roundtable uncovered, there is currently a lack of evidence. It requires pilots in different catchments and using different forms of governance, in order to identify the model(s) that has the greatest benefits and can be rolled out elsewhere. We are examining which catchments to run pilots in now and what form the whole catchment approach should take.

APPENDICES

Appendix 1: predicting growth (population and properties)

In May 2016, the Department for Environment, Food and Rural Affairs (Defra) published their *guiding principles for water resources planning* to explain key policy priorities that the Government expects WRMPs to address. Page 1 of this document explicitly addresses how water companies are expected to plan for growth and states: “*Water supply must support the growth predicted by local authorities within an area. You should provide clear evidence of your engagement with local authorities on joint planning.*”

The Deputy Head of the Planning (Infrastructure and Environment) Division at DCLG has emphasised that plans should fully take account of local authority development plans and ensure that water supply infrastructure does not hinder economic development.

Thames Water are fully following this guidance and we have engaged consultants (Edge Analytics) to contact each local authority and using Local Plans to produce forecasts which align with Thames Water’s operational boundaries. They will also be providing a set of what are termed ‘bottom up’ forecasts to allow Thames Water to understand spatially where growth is expected. The results of this work will be peer reviewed by Professor Adrian McDonald of the University of Leeds to ensure they are robust.

Initial Results

Initial results are presented in the following table and chart, changes are expected prior to production of our plans but these should be relatively minor.

Table 1 - Total Population – Water (000s)

	AMP6	AMP7	AMP8	AMP9	AMP10
WRMP19 Total Population	10,284	10,740	11,050	11,317	11,593
WRMP19 Total Population Growth	425	881	1,191	1,459	1,734
WRMP14 Total Population	9,878	10,194	10,518	10,862	11,232
WRMP14 Total Population Growth	357	610	934	1,278	1,647

Table 2 – Number of Households – Water (000s)

	AMP6	AMP7	AMP8	AMP9	AMP10
WRMP14 Households	3,662	3,834	4,006	4,185	4,375
WRMP14 Household Growth	146	319	490	669	859
WRMP19 Households	3,731	3,988	4,196	4,379	4,554
WRMP19 Household Growth	276	480	688	871	1,046

Table 3 - Total Population – Wastewater (000s)

	AMP6	AMP7	AMP8	AMP9	AMP10
PR19 Total Population	15,491	16,186	16,637	17,032	17,454
PR19 Total Population Growth	616	1,310	1,761	2,156	2,578
PR14 Total Population	15,310	N/A	N/A	N/A	N/A
PR14 Total Population Growth	418	N/A	N/A	N/A	N/A

Table 4 – Households – Wastewater (000s)

	AMP6	AMP7	AMP8	AMP9	AMP10
PR19 Households	6,034	6,418	6,728	7,007	7,280
PR19 Household Growth	323	708	1,017	1,297	1,570
PR14 Households	5,537	5,820	N/A	N/A	N/A
PR14 Household Growth	210	493	N/A	N/A	N/A

Good infrastructure: a vital opportunity to improve health equity

*A joint **response from Health Foundation and Institute of Health Equity** to the National Infrastructure Commission's call for evidence on **National Infrastructure Assessment***

February 2017

About this response

This is a joint response from the Health Foundation and the UCL Institute of Health Equity. We welcome the opportunity to submit evidence to shape the development of the National Infrastructure Assessment (NIA) for Britain - exploring outcomes and opportunities for changes in infrastructure over the next 30 years. This submission sets out how investment and design for high quality infrastructure has the potential to positively and equitably shape health and wellbeing outcomes across the UK. Our aim is to provide evidence to show why improving health outcomes must be considered at the heart of decisions about planning and investing in infrastructure.

We have focused on the consultation questions that have the scope to include assessments of the social determinants of health and considerations of health, health equity and wellbeing.

Our response is structured in two parts.

Part 1 sets out our key points, a summary of our recommendations in response to the consultation questions, and a summary of how actions to improve infrastructure can be used to meet health equity policy priorities.

Part 2 presents evidence outlining the important role infrastructure has on health, with a background section outlining the principles of the social determinants of health (p6), followed by five sections responding chronologically to the six pertinent questions outlined by the NIC's call for evidence, these are:

- cross-cutting questions 1 (p8) ,3a (p9), 3b (p12) and 11 (p13),
- transport questions 14 and 15 (p16)
- digital communications question 17 (p19).

In each section, we set out ways that investments in infrastructure can be developed to have best possible impacts on health, health equity and wellbeing, with examples.

PART 1

Key points

1. **The National Infrastructure Assessment (NIA) is a significant opportunity to shape health in the UK.** The provision of good quality work and housing, environmental protections, accessible and inclusive transport in connecting people and places and improvements in digital communications can all significantly improve health and wellbeing. These factors are highly dependent on our infrastructure.
2. **Evidence clearly shows that infrastructure and policy changes in broad realms of economics and business have considerable and lasting impact on health, and health inequalities.** As highlighted by the Prime Minister in 2016, there are clear and systematic differences in health across England, which are closely related to socioeconomic status. These inequalities in health are largely determined by factors outside the health care sector.
3. **Infrastructure planning can improve this social class gradient for the whole of England.** A social class gradient in health is evident. There is not just a gap between the wealthiest and very poorest – everyone below the very top suffers from some degree of unnecessary health inequity – lower life expectancy and healthy life expectancy – than that enjoyed by the wealthiest.
4. **Good infrastructure investment will decrease health inequalities and release savings to the national purse.** Health inequalities are costly to the economy, individuals, families and communities. The 2010 Marmot Review¹ calculated that, annually, inequality in health accounts for productivity losses of approximately £31bn-£33bn, lost taxes and higher welfare payments in the range of £20bn-£32bn and additional NHS healthcare costs in excess of £5.5bn. In assessing best value for infrastructure investment an understanding of these substantial costs of health inequality and policy levers such as the ‘social value’ return on investments are essential.
5. **At present, this consultation misses the opportunity to raise considerations of health, health equity and wellbeing impacts from its scope and questions.** We also note that the advisory and technical groups to the NIC lack members with a health perspective. The NIC so far has not directly considered the potential to improve health as an outcome of the infrastructure investment strategy. To support this, we are interested in convening organisations with acknowledged expertise on national and international health, wellbeing and inequalities, and how to shape infrastructure to improve health, to support the important work of the National Infrastructure Commission.

Summary of recommendations in response to consultation questions

NIC questions	Recommendations	Page reference for supporting evidence
1 'What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?'	<p>The NIC should encourage the government to:</p> <ul style="list-style-type: none"> • ensure national investment in infrastructure engenders positive social, environmental, economic and health impacts through the implementation of exemplar procurement contracts that emphasise social value. • work with companies that adopt corporate social responsibility and corporate citizenship models that emphasise the social impacts of spending. • assess and promote health and wider social value when awarding contracts. 	Pages 12-13
3: 'How should infrastructure be designed, planned and delivered to create better places to live and work? '	<p>The NIC should encourage the government to:</p> <ul style="list-style-type: none"> • provide new work schemes for the unemployed, and job training offered by organisations commissioned to deliver contracts. • provide good quality jobs, with commitment to a living wage and decent contracts embedded in infrastructure investments. • provide good working conditions which promote health, rather than harm it. • ensure employers offer a fair wage and are mindful of issues in balancing benefits. • ensure employers explore possibilities in work contracts for worker involvement and participation. 	Pages 14 -17
3: 'How should the interaction between infrastructure and housing be incorporated into this?'	<p>The NIC should encourage the government to:</p> <ul style="list-style-type: none"> • support and improve older properties and private rented properties, particularly in terms of improved energy efficiency and general repair and improved conditions. • work with housing colleagues to enable improvement in the physical quality of existing homes. • work with the health sector to gain evidence, data and expertise to ensure that the specifics of policy making on new homes (e.g. building regulations) promote health equity. 	Pages 18-19

<p>11: 'How should infrastructure most effectively contribute to protecting and enhancing the natural environment?'</p>	<p>The NIC should encourage the government to:</p> <ul style="list-style-type: none"> • effectively protect and enhance the natural environment by aligning closely with new concepts of 'green' rather than 'grey' infrastructure. • build infrastructure around increasing quality green spaces wherever possible and designing open spaces, street furniture and retail planning for maximum health benefit. • consider evidence that better stewardship of existing green infrastructure and attention to green infrastructure connectivity should be woven into infrastructure investment. • think broadly about the value of different possible infrastructure spending patterns. Having health as a centrepiece in decision-making is entirely compatible with efforts to mitigate climate change. 	<p>Pages 20-22</p>
<p>14: 'What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?'</p> <p>15: 'What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?'</p>	<p>The NIC should encourage the government to:</p> <ul style="list-style-type: none"> • focus on overall improvements to health through transport infrastructure projects, but also on reducing inequalities across the social gradient. • invest in infrastructure that supports an increase in public transport and reduced car travel. • ensure planning applications for new infrastructure developments always prioritise the need for people to be physically active as a routine part of their daily life, encouraging active travel such walking and cycling. • build investment in traffic restrictions into infrastructure development plans. 	<p>Pages 23-25</p>

<p>17: What are the highest value infrastructure investments to secure digital connectivity across the country?</p>	<p>The NIC should encourage the government to consider:</p> <ul style="list-style-type: none"> • infrastructure investment to redress digital exclusion by location (particularly rural) and to known socially disadvantaged groups. Digital infrastructure particularly needs to reach areas of high rented accommodation and social housing and those people living on low incomes. • potential social by-products of infrastructure installation in improving streets and local environments. 	<p>Pages 26-28</p>
---	--	--------------------

Summary of how actions to improve infrastructure can meet the health equity policy priorities highlighted by the Marmot Review

The Marmot Review² set out six high-level policy objectives to tackle, improve and reduce inequalities in social determinants of health. To realise these goals, action is needed across all sectors of society. This includes the policies of all government departments, the private, public and third sector, civil society and working with and for local communities and the national population. The importance of infrastructure is evident across all of the policy priority areas outlined by Sir Michael Marmot in his review, as shown in the following table.

Marmot Review Policy Priority	Action to Improve Infrastructure
1. Give every child the best start in life	<ul style="list-style-type: none"> • Boost active travel involving walking, cycling and public transport • Reduce car travel to decrease air and noise pollution • Restrict traffic speed and decrease child road accidents • Plan new roads that do not pass schools and play areas. • Create more green spaces and develop those that exist • Provide work place crèches • Employ parents under flexible working conditions
2. Enable people to have control over their lives and maximise their capabilities	<ul style="list-style-type: none"> • Instigate training and apprenticeships for new jobs resulting from infrastructure investment • Build individual resilience and mental health protection through good work, green environments and a more diverse range of environmentally friendly and health inducing transport options (particularly walking, cycling and public transport). • Support disadvantaged people into employment • Training for existing staff
3. Create good work for all	<ul style="list-style-type: none"> • Re-integrate vulnerable groups through employment • Employment of particular groups, for example, ex-offenders and those with long-term health conditions, • Ensure employers adhere to equality guidance • Make social and employment indicators part of the selection criteria for funding • Demand well managed jobs with opportunities for on job training and promotion and offer workers support • Maintain strict health and safety in the workplace, particularly regarding physically strenuous jobs • Where possible, protect workers from adverse conditions like shift work. • Implement guidance on stress management at work. • Encourage jobs where workers are valued, with participation in decision-making and implement board-level representation. • Develop security and flexibility in employment

² The Marmot Review Team. Fair Society, Healthy Lives: Strategic review of health inequalities in England post-2010. London: Marmot Review Team, 2010.

4. Ensure a healthy standard of living for all (income)	<ul style="list-style-type: none"> • Implement standards on a fair living wage and balancing benefits. • Provide flexible employment but avoid insufficient hours, temporary work, and work with constant risk of redundancy or job loss. • Longer term contracts with sickness and other benefits • Take collective bargaining on conditions and wages into account
5. Create and develop healthy and sustainable places and communities	<ul style="list-style-type: none"> • Embed social values in company contracts and engage companies that emphasis social and environmental impacts (not just cost) • Reduce air and noise pollution from transport • Encourage increase in public transport infrastructure and reduction in car use • Incentivise walking and cycling –active transport • Encourage green infrastructure and increase open spaces • Recognise green infrastructure as a productive asset. • Procure for green infrastructure conditions and outcomes attached to all contracts. • Improve access and quality of open and green spaces available across the social gradient, and reduce walking distance to quality green space.
6. Strengthen the role and impact of ill-health prevention	<ul style="list-style-type: none"> • Reduce sickness absence of employees through improved health and wellbeing support • Improve employee health through good working conditions • Develop open spaces to reduce incidence of pollution and sedentary activity related disease

PART 2

The impact of infrastructure on health, health equity and wellbeing

Modern infrastructure planning originated in the nineteenth century in response to basic health problems – such as supply of fresh water, drainage and sewages systems. Since then, planning our infrastructure has become largely divorced from health and often ‘we have been literally building unhealthy conditions into our local human habitat’.³ The manner of development activity in our built environment often compromises public health.⁴

For example, hierarchical road systems and segregated land use patterns prevent pedestrian street life and impede the development of the social networks vital to mental wellbeing for those who live locally. If housing supply is limited and prices increase, so does social exclusion in the housing market and health inequalities are exacerbated. If there is only investment in new housing, the poor quality of existing housing damages health. In cities, locating business, retail and leisure parks on the edge of cities, forces car-dependent travel, enshrines inequalities of access and decreases chances for regular exercise, while increasing pollution. If people and businesses in rural areas cannot access fast broadband it affects their health, their educational opportunities, social cohesion and cultural life. This document aims to show that the infrastructure that underpins where and how we live is vitally important to all our health and wellbeing.

The social determinants of health

The Marmot Review, commissioned by the Government to assess and make proposals to reduce health inequalities developed scientific evidence around “the social determinants of health” in 2010. “People’s health is affected by the nature of physical environments; living in poor housing, in a deprived neighbourhood with a lack of access to green spaces impacts negatively on physical and mental health.”⁵ Access to health care accounts for as little as 10% of a population’s health and wellbeing.⁶

The evidence showed that many of the drivers of avoidable health inequalities relate to inequalities in power, money and resources, and the way that these affect the conditions in which we are born, grow, live, work and age. The “social determinants of health” play out in the quality of early years experiences, of education, economic status, employment and quality of work, of housing and environment and effective systems for preventing ill health. Infrastructure planning has at its heart the attempt to manage those very same determinants of health.

⁶ The Marmot Review Team. *Fair Society, Healthy Lives: Strategic review of health inequalities in England post-2010*. London: Marmot Review Team, 2010.

The Marmot Review recommended adopting an approach to fully integrate the planning, transport, housing, environmental and health systems to address the social determinants of health in each locality. The recently published National Planning Policy Framework has similarly noted that: ‘The planning system can play an important role in facilitating social interaction and creating healthy, inclusive communities’.⁷

The social gradient

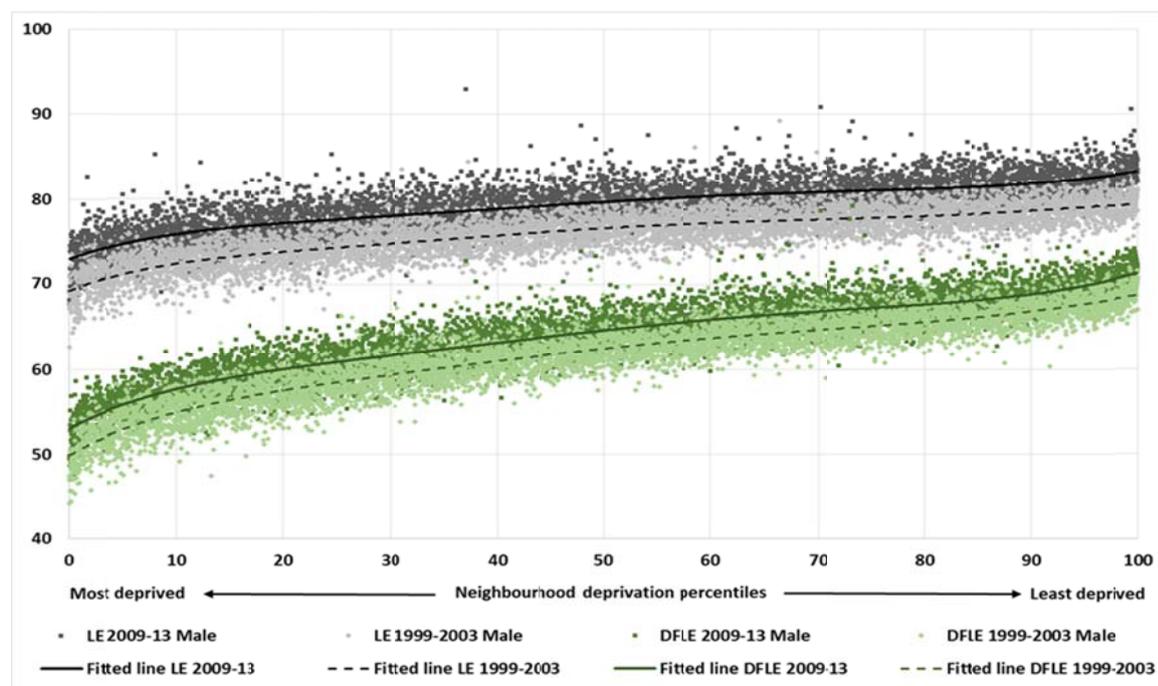

Within the same society, those lower down the socio-economic distribution in society have worse health than those higher up. The Marmot Review cited evidence showing that people living in the poorest areas die seven years earlier than people living in the richest. Health inequalities relate to life expectancy, infant mortality, healthy life expectancy, mental health, and a wide range of physical health conditions.⁸ In England there is a difference of 17 years in ‘disability free life expectancy’ – the number of years someone can expect to live free of life-limiting illness. These differences fall on a social gradient as shown in Figure 1. This is not just an issue of rich and poor. Everyone below the top 1% has slightly worse health than they could have. So although people are living longer, the same improvement has not been seen in healthy life expectancy, meaning that people are spending more of their lives with disease and disability⁹. It is therefore crucial to consider investment in people’s long term health to be integral to the long term investment which is necessary to build transport, housing, energy and digital infrastructure.

Action on infrastructure to improve health, health equity and wellbeing

Strong evidence now exists describing clear actions we can take to plan for health and health equity as a key part of our infrastructure with potentially significant long term and large-scale impacts. In the 1930s, the United States embarked on a national infrastructure programme- Roosevelt’s New Deal. This initiative was in effect the biggest public health programme ever to be implemented in the US¹¹. It created good work for eight and a half million jobless Americans on the new construction projects and as has been repeatedly shown, poverty and unemployment are among the greatest risk factors when it comes to health. Further, the work was supported by wider social schemes such as making home ownership affordable and thus the impact on health was even more significant. The National Infrastructure Commission could make the case for a similar transformation of people’s quality of life and life chances by putting health, health equity and wellbeing at the centre of their deliberations. Tackling inequalities is an important current message, echoed by Theresa May, Prime Minister, in her maiden speech – for ‘a country that works not for a privileged few but for every one of us.’¹³

¹³ Statement from the new Prime Minister Theresa May, 13 July 2016. <https://www.gov.uk/government/speeches/statement-from-the-new-prime-minister-theresa-may>

A good case-study example of a recent, large-scale infrastructure planning campaign that acknowledged and embraced health, health equity and well-being is the World Health Organization's (WHO) Healthy Urban Planning Initiative.¹⁴ WHO Europe initiated a campaign for 'healthy urban planning' in the late 1980s. By 2003, a European Healthy Cities club linking 800 cities produced strategies showing:

- how health, planning, transport and regeneration agencies in the area could work together with citizens to improve quality of life
- how health objectives were to be integrated into planning
- how health equity criteria were going to be systematically used to assess development projects.

The WHO initiative showed one way that political and professional will to act on infrastructure and health can be galvanised. Integrated programmes, across departmental and agency responsibilities, with commitment from key decision-makers and awareness-raising at grass-roots level were all important factors for success. If public health and the NIC could form a real alliance beneath the banner of health, health equity and wellbeing for the NIA in this way, such programmes suggest it would be a powerful way to forge improvements to health, health equity and wellbeing and a range of other desirable outcomes – good quality employment and raised income for instance.

Question 1: 'What are the highest value infrastructure investments that would support long- term sustainable growth in your city or region?'

Social value

All infrastructure investments should, and have a legal duty to, take full account of the 2013 Social Value Act, which requires public sector commissioners (including government) to consider economic, social and environmental wellbeing when they procure services. It seeks these wider public benefits beyond just service provision and delivery. For example, a road construction company could contract with a social enterprise that employs and trains local unemployed young people. Recent studies show that, there has been more 'social value' action locally than nationally¹⁵. The NIC offers a real opportunity to take action on a national platform.

One powerful case-study example from the private sector is Landmarc Support Services Limited¹⁶. Landmarc is a commercial business which partners with the Ministry of Defence, 'to ensure that the military training estates deliver a safe and sustainable place to train for our armed forces'. Landmarc committed to increasing the economic, environmental and social value it generates through its activities, using the Social Value Act. Landmarc placed

¹⁶ CANInvest. The Landmarc Difference: Social Enterprise UK, Landmarc, 2013.

over half of its supply chain expenditure with small and medium-sized enterprises, including social enterprises; partnered with Recovery Careers Services to support wounded, injured and sick ex-service officers into employment; set up an apprenticeship scheme, a Rural Enterprise Hub; trained 1300 staff in sustainability awareness; and generated £90m gross value added (GVA) for the UK in the financial year 2012, and £474m GVA since 2008.

Landmarc also reinvested profits of almost £2m Environmental impact and reduced its CO2 emissions by 7% in the financial year 2012–13.

A public sector example is Oldham local authority. Oldham adopted a social value procurement framework to ensure that the £232m spent each year with 5,700 trade suppliers considered social value consistently. The framework included the themes ‘jobs, growth, and productivity; resilient communities and a strong voluntary sector; prevention and demand management; and a clean and protected physical environment’. Each of these themes had one or more outcomes and a range of examples of what this meant in practice for suppliers. Each procurement exercise and each contract included at least one of the outcomes from the framework.

Embracing social value within the NIA agenda means adopting ‘social value’ procurement processes like Oldham, commissioning companies like Landmarc with an ethical commitment to corporate citizenship, and encouraging Government to manage contracts and ‘bend the spend’ to influence a broad range of outcomes.

The NIC should encourage the government to:

- **ensure national investment in infrastructure engenders positive social, environmental, economic and health impacts through the implementation of exemplar procurement contracts that emphasise social value.**
- **work with companies that adopt corporate social responsibility and corporate citizenship models that emphasise the social impacts of spending.**
- **assess and promote health and wider social value when awarding contracts.**

‘Question 3: How should infrastructure be designed, planned and delivered to create better places to live and work?’

Good quality work

Programmes and policies on employment within the initiatives that the NIC proposes to fund are key to designing, planning and delivering better places to live and work. The NIC needs to ensure that initiatives and contracts that arise from the infrastructure projects it recommends tackle unemployment, provide good quality work, pay a fair wage and encourage worker participation in decision-making. The evidence in support of such measures and the impact on health and health equity is extensive and incontrovertible. Good quality work is of central importance to health and a range of other desirable outcomes¹⁷, providing skills, income, recognition and social status. The Marmot Review presented clear evidence that being in good employment is protective of good health, while unemployment and poor quality work contributes to poor health.

1. Tackling unemployment

Research shows that for all socioeconomic groups the unemployed had higher mortality than the employed¹⁸. Getting unemployed people into new work through the infrastructure initiative is therefore of critical importance for reducing health inequalities. Marmot Review evidence showed that participation in training programmes enhances skills and knowledge that help people gain entry into the job market and by having a positive effect on individual well-being and psychological health. The NIC should ensure the Government includes new work schemes for the unemployed in its commissioning strategy and encourages in job training, to be offered by organisations commissioned to deliver contracts.

2. Good quality work

Evidence shows ‘good work’ is linked to positive health outcomes. Jobs that are insecure, low-paid and that fail to protect employees from stress and danger make people ill. Getting people off benefits and into low paid, insecure and health-damaging work is not a desirable option. Jobs need to be sustainable and offer a minimum level of quality, to include, not only a decent living wage, but also opportunities for in-work development, the flexibility to enable people to balance work and family life, and protection from adverse working conditions that can damage health. When developing the country’s infrastructure, creating good quality, secure work opportunities will directly improve physical and mental health and reduce health inequalities.

The type of new work created across sectors is important. In the UK unemployment rates have been generally falling since 2011, to 5.6% for the period between March and May 2015¹⁹. However, this has been associated with more part-time employment, increased use

of zero-hours contracts and higher levels of in-work poverty. Poor quality jobs are an issue for health and health equity as they are concentrated at the lower end of the social gradient and have significant health impacts there. It is vitally important that good quality jobs are encouraged through infrastructure development to help reduce such health inequalities. This implies a need for commitments to a living wage and decent contracts being embedded in infrastructure investments.

3. Good working conditions

The conditions in which we work have a huge impact on our health. While there has been general decline in the incidence of workplace-related illness, it still affects millions of workers each year. Between 2013 and 2014, 1.2 million working people in the UK had an illness or condition believed to be caused by, or exacerbated by their current or previous work placement.²⁰ Ill health and injuries place a considerable burden on the NHS and result in significant costs to society, estimated at £14.9bn to the British economy in 2012-13.²¹ 23.5 million days are lost due to work-related ill health and 4.7 million days due to workplace injury in 2013-14.²² Research evidence across the EU demonstrated that low productivity is attributable to unhealthy work.²³ In economic terms, providing good quality working conditions pays.

People's health can be damaged at work by factors including exposure to physical hazards, physically demanding or dangerous work, long or irregular working hours, shift work, health-adverse posture, repetitive injury and extended sedentary work²⁴. Work-related ill health, including mental health, is a risk that affects lower occupational groups much more than higher occupational groups²⁵. Reducing stress and improving mental health is particularly significant to employers, employees and health services as 39% of the 27 million days lost to work-related sickness absence in 2011–12 were due to stress, depression or anxiety²⁶. Investing in health-protective and health-promoting work and employment conditions supports health and produces economic benefits. Such policies are investments that result in important returns to the national economy, rather than burdens on public spending. The NIC should ensure that all employment generated by investments in national infrastructure are in good working conditions and promote health, not harm it.

4. Fair wages

Wilkinson and Pickett's recent book *The Spirit Level*²⁷, Michael Marmot's work and other studies have shown the adverse effects on health caused by having a low income. According to the Joseph Rowntree Foundation²⁸, insecure, low-paid jobs are leaving record numbers of working families in poverty, with two-thirds of people who found work in 2014 taking jobs for less than the living wage. By 2016, there were two million more people in working families in poverty, taking the figure up to 7.4 million, than a decade earlier. During that decade only a fifth of low-paid workers managed to move to better paid jobs. The living wage was calculated at £7.85 an hour nationally, or £9.15 in London – much higher than the legally enforceable £6.50 minimum wage.

Commissioners should ensure that all infrastructure project employers offer a fair wage. They should also be mindful to address the income gradient, as it is not always just those on the lowest incomes who find it most difficult to make ends meet. Living standards initially fall as income begins to rise, due to a loss of state benefits, creating 'cliff edges'.

5. Worker participation and involvement

Underpinning action to promote health and wellbeing is the idea of creating an organisational culture that enables individuals from all groups in society to have greater control over their working lives and participate in society. Included in this approach is the role of individuals and community groups in helping to shape the services they use and the jobs that they do. Evidence suggests that interventions to increase autonomy and control over work, provide in-work development, line management training, flexible working and staff engagement – can all be beneficial for health²⁹. Systematic reviews of the health effects of improvements to the work environment have found that interventions increasing participants' job control and degree of autonomy at work produced fairly consistent results showing positive effects on mental health and sickness absence.³⁰ It would be very valuable if any work contracts commissioned for infrastructure development involved workers in their development and allowed participation in decision making.

Case-study examples of good work programmes include the University of Manchester, the city's largest employer. In 2012 the university set up a programme to help unemployed local residents find work in non-academic sectors of the university and in other areas of business across Manchester. The university recently signed a recruitment agreement with three major construction firms. Laing O'Rourke, Balfour Beatty and Sir Robert McAlpine share the contract for a £1bn programme of building works for the university over the next decade. Under the agreement, the companies commit to hire 1,000 local unemployed residents every

year.³¹ Another example is Whitehill Bordon Ecotown in Hampshire. In 2009 it used eco-town allocated funding to convert an exhibition house informing residents about low carbon living, provided a bio-mass boiler, free loft insulation to householders, over 50 green spaces around the town and hopes to create 5,500 jobs by 2028.³²

The NIC should encourage the government to:

- **provide new work schemes for the unemployed, and job training offered by organisations commissioned to deliver contracts.**
- **provide good quality jobs, with commitment to a living wage and decent contracts embedded in infrastructure investments.**
- **provide good working conditions which promote health, rather than harm it.**
- **ensure employers offer a fair wage and are mindful of issues in balancing benefits.**
- **ensure employers explore possibilities in work contracts for worker involvement and participation.**

Question 3: 'How should the interaction between infrastructure and housing be incorporated into this?'

Housing

Housing is also an important social determinant of health. On average those in the least deprived neighbourhoods in England live seven years longer than those in the most deprived.³³ About three in 10 people in England live in poor quality housing, either non-decent or overcrowded, comprising 3.6m children, 9.2m working age adults and 2m pensioners.³⁴ Inequalities are clearly evident. There are differences in the quality of housing by tenure, with particular problems in the rented sector. Thirty per cent of homes in the private rented sector failed to meet the Decent Homes Standard³⁵ in 2013, compared to 19% of owner occupied homes and 15% in the social rented sector.³⁶ Issues include poor energy efficiency, condensation, damp and mold.

Cold houses are health damaging, especially for older people, but poorly heated homes also affect babies' weight gain and increase the frequency and severity of asthma symptoms in children. Teenagers who live in cold houses are five times more likely to risk developing multiple mental health problems than adolescents who have always lived in warm homes.³⁷ Fuel poverty is an increasing issue of concern. In 2008, 18% of UK households were estimated to be living in fuel poverty.³⁸ Fuel poor households must choose either to spend over 10% of their income on heating, which has a detrimental impact on other aspects of health and well-being, or to under-consume energy and live in a cold home to save money. Resultant health and social impacts are far-reaching and unequal –affecting physical and mental health, the ability to find a job or even do well at school.³⁹ There is also regional variation in the quality of housing across England. For example, in London 15% of the population lives in overcrowded conditions, compared to 3% in the East and South East. The interaction between infrastructure and housing needs to be incorporated into future planning at the national level to reduce such stark and regionally differential inequalities.

Poor housing is estimated to cost the NHS £1.4bn a year. If £10bn could be found to improve all of the 3.5m 'poor' homes in England, evidence suggests the investment would pay for itself in just over seven years and then continue to accrue benefits into the future.⁴⁰ However, public expenditure on housing has fallen considerably since the 2008 recession and it is unlikely that this will reverse in the near future. In considering the impact of infrastructure on housing supply, the NIC needs to be mindful of the need for innovative

solutions, which work across sectors at the national level and make best use of local assets and programmes. Poor quality housing needs to be upgraded. Insulating homes to stop them wasting energy would improve people's health and wellbeing and protect the environment at the same time. About £3- 8bn is needed annually to eradicate fuel poverty. New homes should be highly energy efficient, built with sustainable principles, good transport and social and community facilities.

Examples of housing infrastructure development projects that have been successful in health equity terms, include the Government 'Housing Market Renewal' programme which ran from 2003 to 2011, and aimed to tackle poor housing in areas of severe deprivation. Overall, over £3 billion was invested in the programme, and the National Audit Office concluded that the programme improved the quality of the housing stock, reduced crime, and increased jobs and training opportunities.⁴¹ The Decent Homes Programme aimed to make all social housing, and 70% of vulnerable households in the private sector, 'decent' by 2010. The programme improved housing conditions for approximately 1.4 million local authority homes as of November 2009, and the percentage of social housing that was 'non-decent' had been reduced from 39% to 14.5%. For housing with registered social landlords, the rate reduced from 21% to 8%. The number of vulnerable households in decent homes increased from 57% in 2001 to 68% as of April 2006.⁴²

The NIC should encourage the government to:

- **support and improve older properties and private rented properties, particularly in terms of improved energy efficiency and general repair and improved conditions.**
- **work with housing colleagues to enable improvement in the physical quality of existing homes.**
- **work with the health sector to gain evidence, data and expertise to ensure that the specifics of policymaking on new homes (e.g. building regulations) promote health equity.**

Question 11: How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Building healthy and sustainable places

The role of the built and natural environment as a determinant of health, and its relationship with health inequalities is again direct. Green spaces have multiple significant health and environmental benefits. Infrastructure can most effectively contribute to protecting and enhancing the natural environment by adopting sustainable development and building in specific interventions that we know can change health and reduce health inequalities as well as protect green and natural spaces. New infrastructure could effectively protect and enhance the natural environment by aligning closely with new concepts of 'green' rather than 'grey' infrastructure, helping to tackle health inequalities head on and improve quality of life and environments. The health evidence in this area is strong and gives clear direction for action.

Living close to green spaces such as parks and woodlands can improve health, regardless of social class.⁴³ Studies show green spaces are of clear and significant benefit to mental health and well-being as well as improved air quality (reducing urban heat island effects), physical health and activity levels. Green spaces are associated with mental health improvements including reduced stress levels and improved ability to deal with problems and physical health benefits like decreases in blood pressure and cholesterol.⁴⁴ Research increasingly shows green spaces also encourage social contact and integration through physical activity and play.

New research on healthy high streets shows that when designed well, high streets can support well-being in local communities, by improving the local economy, promoting social cohesion, improving mental health, and protecting people from toxic levels of pollutants, risk of traffic accidents and crime⁴⁵. Introducing and enhancing street furniture and communal spaces on high streets, improves well-being and health for a range of groups, including disabled people, older people, and children – particularly in the most deprived neighbourhoods. Proven street design principles, effective at improving health include: pedestrianisation, lighting, seating, crossings, pavement width and quality, shelters, street planting, blue space and water features, healthy and affordable food outlets, and limiting alcohol, betting and payday loan outlets. Infrastructure design and development should be built around increasing green spaces wherever possible and designing open spaces, street furniture and retail planning for maximum health benefit.

Better stewardship of existing green infrastructure (a network of multifunctional green space such as parks, playing fields and woodland) is also key to infrastructure development. The Chartered Association of Building Engineers note that many of the elements of green infrastructure in the UK are already in place, 'but (like roads) its value lies in being

networked. So new skills are required to connect the different elements: the tree-lined streets, parks, gardens, allotments, cemeteries, green roofs, woodlands, rivers and waterways, so that they all work together as a functioning system.⁴⁶ Green corridors linking town centres and transport nodes to major employment and residential sites are important. Also critical is the role of river corridors and links to the green belt. An understanding of such green infrastructure connectivity should be woven into infrastructure investment.

Addressing climate change and issues around biodiversity are also important. Climate change is a fundamental threat to health.⁴⁷ Under the Climate Change Act (2008) reduction in UK greenhouse emissions by at least 34% in 2020 and by at least 80% by 2050 are legally binding targets. The UK Low Carbon Transition Plan (2009) proposed all government departments share responsibility for reductions, affecting planning for homes and communities, electricity generation, workplaces and transport. As a first step, the NIC needs to frame its plans within outcome focused targets on carbon emissions. Emission reduction measures include recycling 75% of waste, reducing waste by 25% reducing water consumption by 25% and increasing energy efficiency.

In November 2016, the government lost a High Court ruling over illegal air pollution targets, with evidence showing the UK needs a national network of clean air zones to be in place by 2018 in cities across the UK, not just in token cities.⁴⁸ Cities, like London, with the worst air pollution records are being seriously challenged. The NIC is encouraged to think broadly about the value of different possible spending patterns. Having health as a centrepiece in decision making will greatly influence what kind of plans for the environment are thought acceptable and are entirely compatible with efforts to mitigate climate change.

There are many examples globally showing green or environmental infrastructure investment makes sound economic sense, paying for itself many times over. For example, in Chattanooga, Tennessee, USA, the rust belt city was transformed by the decision to build a 10-mile park along each side of the Tennessee River, which inspired developers, and led to more investment. Other examples provide evidence describing new planning driven by reaction to the severity of current environmental problems and the urgency to do something about them, such as recent smog reports in London. Sadiq Khan's (London Mayor) current plans for London include expanding ultra-low emission zones and clean bus corridors, limiting new bus purchases to electric or hydrogen buses from 2020, installing electric charging infrastructure for increased electric vehicles, opposing a third runway at Heathrow Airport, reducing congestion around schools, instigating tree-planting, improving cycling and a diesel vehicle scrappage scheme.⁴⁹

⁴⁹ Khan, S. 2017 *Manifesto: A Greener Cleaner London*. http://www.sadiq.london/a_greener_cleaner_london

The East London Green Grid⁵⁰ is a good example of good quality environmental infrastructure investment. The East London Green Grid was one of four sub-regional landscape frameworks developed for the Thames Gateway. The East London Green grid changed the environment and changed the perception that east London was characterised by post-war housing and poor-quality neighbourhoods, dominated by industry and highways. The East London Green Grid includes sustainable projects like Rainham Marshes, the Olympic Legacy Park and Barking Riverside, London's largest housing development site. It is one of the first spatial frameworks of its kind to use a landscape and human-centred approach to green infrastructure, designed to respond to climate change and future development. The programme is large scale, worth about £0.5 billion, and 300 projects have been identified, 70 of which are prioritised. Skills, training and employment have become a key priority.

The NIC should encourage the government to:

- **effectively protect and enhance the natural environment by aligning closely with new concepts of 'green' rather than 'grey' infrastructure.**
- **build infrastructure around increasing quality green spaces wherever possible and designing open spaces, street furniture and retail planning for maximum health benefit.**
- **consider evidence that better stewardship of existing green infrastructure and attention to green infrastructure connectivity should be woven into infrastructure investment.**
- **think broadly about the value of different possible infrastructure spending patterns. Having health as a centrepiece in decision-making is entirely compatible with efforts to mitigate climate change.**

Questions 14 & 15: What are the highest value transport investments to allow people and freight to get into, out of, and around major urban areas? What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Connecting people and places – transport

The highest value transport investments that can be used to connect people and places and to transport goods are those that prioritise health and take a long term view. Transport gives rise to some significant public health and health equity challenges relating to road traffic accidents, physical inactivity, air and noise pollution, social exclusion and community cohesiveness and access to work and services. The single major cause of death in childhood for the over 5s is unintentional injuries on the roads.⁵¹ Like other social determinants traffic accidents are closely related to socio-economic status. The social class gradient is steeper for road traffic accidents than any other cause of death in childhood (eg leukemia, meningitis). Children in deprived wards are four times more likely to be hit by a car than those in the least deprived wards. Road deaths are particularly high for children of the long term unemployed. Poorer communities experience higher concentrations of pollution and associated cardio-respiratory diseases and socially disadvantaged people are more likely to live near busy roads and are at greater risk of the negative effects of noise pollution.⁵² Children who attend schools by busy roads are prone to vastly increased risks of health problems linked to air pollution.

Two in five job seekers say lack of transport is a barrier to getting a job and almost half of 16- to 18-year-old students experience difficulty with the cost of transportation.⁵³ Over 1.4m people say they have missed, turned down, or chosen not to seek medical help over the last 12 months because of transport problems. Transport-related noise pollution (predominantly from roads, railways and airports) can adversely affect the cardiovascular system (including increasing blood pressure and heart attack), mental health and school performance in children. There are age factors at play too as transport affects people differently over the lifecourse. For example, 12% of older people would like to visit their family more often and of these 76% cite transport or mobility as an issue.⁵⁴ Almost half of 16- to 18-year-old students experience difficulty with the cost of transportation⁵⁵

⁵⁵ Social Exclusion Unit, 2004, *Making the Connections: The Final Report on Transport and Social Exclusion*. In: Minister OotP,....

Transport also enables access to work, education and social networks.⁵⁶ The highest value transport investments that the NIC could consider are those that specifically describe and evidence how they link people and places to enable equality promoting, health enriching social cohesion and access for all to work and education, community facilities and other services across the social gradient. Transport also accounts for about 29% of the UK's carbon dioxide emissions.⁵⁷ There is now strong evidence that poor transport links can create barriers to social inclusion, whereas effective transport links can benefit social cohesion.⁵⁸ Those in more out-lying or rural areas are not surprisingly less likely to be able to access suitable transport. This impacts on employment across the social gradient. The Infrastructure Commission needs to focus on overall improvements to health through transport infrastructure projects, but also on reducing inequalities across the social gradient.

There are three specific health related imperatives that should drive transport investment linked to the social determinants of health.

1. Greater investment in public transport and car travel reduction

Changing transport systems can dramatically affect the travel choices of individuals, groups and businesses. The time that people spend travelling each day has remained remarkably constant over the years. Yet, as road transport systems become faster, people can travel further during that travel time. It is widely recognised that better roads encourage people to use them. The time perceived to be saved by getting somewhere more quickly tends to encourage people to find it acceptable to travel further. Long distance commuting is encouraged. There is also a dependency on cars to facilitate modern family living. These patterns are evident in many countries comparable to the UK and research suggests they link closely to public health travesties such as the increase in obesity across the western world. In Atlanta, USA, a study of 10,808 households in Atlanta found that every hour spent in the car raises the likelihood of being obese by 6%. However, each kilometre walked per day was associated with a 4.8% reduction in the likelihood of obesity.⁵⁹ The social gradient again has an impact. A health impact assessment in Edinburgh showed potential health and health inequality benefits from increased public transport use.⁶⁰

2. Increased investment in walking and cycling

As recently as the 1960s, roughly one in two children walked or biked to school. Today, only one child in ten gets to school under his or her own power.⁶¹ To increase active travel, the

⁶⁰ Gorman, D., 2003, Health Impact Assessment: of the City of Edinburgh Council's Urban Transport Strategy [www.HIAofEdinburghCouncilsTransportStrategy%20\(1\)](http://www.HIAofEdinburghCouncilsTransportStrategy%20(1))

⁶¹ Fleming Fallon and Neistadt (2006) *Land Use Planning for Public Health: The Role of Local Boards of Health in Community Design and Development*. National Association of Local Boards of Health.

NIC should invest to encourage more walking and cycling, reduce car speed, improve walking and cycling routes, and improve public transport. Many studies show that opening new sections of cycle trails leads to long term increases in cycling and reduces cycle accidents, especially when located in highly populated areas. Increasing the number of cyclists overall reduces the proportion who are seriously injured or killed. Investing in high quality surfaces of foot and cycle paths and pavements and street lighting increases the number of walking and cycling trips.

3. Increased investment in traffic restrictions

Action on traffic speed and volume is also important for health and evidence suggests clear measures that can be incorporated in considering new road structures. Lowering speed limits improves pedestrian and cyclist safety across the board, not just in high collision areas. In London, where 20mph zones have been introduced, injuries decreased by 40%. Modelling these figures suggests that in deprived areas this equates to 580 deaths prevented in one year. Re-locating and considering accessibility of crossings also helps dramatically. There is an age factor here. The elderly (over 65s) inhibit their travel due to crossing busy roads with good reason – this group tend to be injured more seriously, more often with fatal injuries than other age groups.

Examples of good transport programmes can be found in other countries. Curitiba is the capital city of the Parana state in Brazil and nearly 2 million people live there. The city has had an urban master plan since 1968 and part of that plan is the Bus Rapid Transport (BRT) System. A bus rapid transit system operates which is cheaper to run than a tube system and some employers subsidise their employees who use it. 80 per cent of travellers use it and it carries 2 million passengers a day. The bus fare is the same wherever you go and no-one lives more than 400 metres from a bus stop. Tall buildings are allowed only along bus routes. The system was revamped in 1991 and possibilities for increasing bicycling are now being integrated.⁶²

The NIC should encourage the government to:

- **focus on overall improvements to health through transport infrastructure projects, but also on reducing inequalities across the social gradient.**
- **invest in infrastructure that supports an increase in public transport and reduced car travel.**
- **ensure planning applications for new infrastructure developments always prioritise the need for people to be physically active as a routine part of their daily life, encouraging active travel such as walking and cycling.**
- **build investment in traffic restrictions into infrastructure development plans.**

Question 17: What are the highest value infrastructure investments to secure digital connectivity across the country?

Digital participation and communications

The highest value infrastructure investments to secure digital connectivity across the country are those that everyone can benefit from and at the moment, not everyone benefits to the same degree from good digital connectivity and some do not benefit at all. So a primary impetus is to consider very carefully who needs to be digitally reached for maximum benefit in terms of health and social outcomes.

With the rise in digital technology, we have seen an associated transformation in how we work, communicate, consume, learn, engage and think. Opportunities for improved wellbeing have been part of this, with people benefiting from wider connections, improved access to knowledge and new forms of communication. Digital innovation is also directly impacting on health care, enabling remote monitoring of health conditions and people with health conditions to be better supported in their own homes in the community. Improved education resources and access to them improve equality among students in different areas and remote working enables rural communities in particular to become less fragmented. Many people's lives are, in short, made easier and there are some early suggestions that internet access enables active living and cultural engagement. People with internet access are less likely to have poor mental health.

Yet sections of society still do not access this technology and are left behind in the digital revolution. According to Ofcom, around 2.4 million homes and small businesses in the UK are unable to receive broadband speeds above 10 Mbps, with 1.5 million of these in rural areas^{63 64}. Government figures show that the average broadband speed in rural areas is just 5 Mbps compared to some cities at 27 Mbps. As a result, research suggests that rural dwellers are more limited in their access to public services, to channels for civic and democratic participation, to a wide array of knowledge and information, to opportunities for cultural and social engagement, to the labour market and to opportunities for education and learning.

Addressing these disparities is an enormous social challenge and one in which infrastructure planning is key. Fast broadband needs modern infrastructure, but network operators struggle to make these economically viable in remote areas and so they miss out on upgrades. The broadband that is available is impacted by technological limitations. ADSL (asymmetric digital subscriber line) gets slower the further you are from the exchange, and latency, contention ratios and reliability are issues. The government's 'Broadband Delivery UK' policy⁶⁵ committed to a national minimum speed of 5Mb and is helping to fund upgrades, with £1.14bn placed in government funds in last month's Autumn Statement to improve fibre broadband and develop 5G. By the end of 2017, 95% of UK premises could be able to buy

⁶³ Ofcom (2016) The Communications market report. www.ofcom.org.uk/opensdata.

⁶⁴ Griffiths S, 2016, Broadband in the backwaters: rural Britain's fight for faster internet. Ingenia online, issue 58, Sept. <http://www.ingenia.org.uk/Ingenia/Articles/1034>

⁶⁵ Broadband Delivery UK (2013) Details of the plan to achieve a transformation in broadband in the UK by 2017. Available at: <https://www.gov.uk/guidance/broadband-delivery-uk>

superfast broadband – defined as 24Mbps, but critics say BT’s roll-out is slow, the broadband network delivered is only semi-fast and still leaves some communities isolated. The government has specified fibre direct into the home as the gold-standard (rather than reliance on copper cables) but progress here is acknowledged to be expensive and slow. One example of a rural area that has recently achieved superfast broadband is the Isles of Scilly in Cornwall, where the £132m Superfast Cornwall initiative repurposed a defunct undersea fibre cable to upgrade the islands’ network infrastructure to its 2,200 residents. Formally, the Isles of Scilly had relied on a radio link with the mainland to access the internet.

People who are most likely to be digitally excluded are the same people who are also most likely to be identified as disadvantaged or excluded and at risk of poor health according to a range of other socioeconomic and health indicators – such as those in rented housing, on low income and older people, particularly those over 75 yrs. Paradoxically, these factors also mean that these are the groups who could disproportionately benefit from the advantages of digital systems described above. A recent Scottish study showed that those most likely to have internet access are households with a working couple (non-working single adult households are the least likely), the more qualified the respondent is, the more likely the household is to have internet access and the younger the highest income householder, the more likely that a household will have internet access. Those least likely to currently have internet access include households without cars and/or in social rented accommodation and/or without children and those on lower incomes.

The NIA needs to consciously plan new digital infrastructure to better reach areas where social housing is predominant, where there is a higher proportion of rented accommodation and where a higher proportion of people on low incomes live. Careful consideration of increased need among older people, single parent families and those without children is also important. In considering infrastructure investment, the NIC needs to redress digital exclusion by location (particularly rural) and to socially disadvantaged groups.

The NIA could also usefully consider where by-products of the process of installing new digital communications might offer opportunities for increased social value. One example is in thinking about children’s play. The Street Play project⁶⁶ aims to activate street play in communities. Evidence has shown that children are three to five times more active outdoors than indoors – when outdoors, more time is spent with friends which increases opportunities for greater levels of social interaction for children and families. An evaluation in Hackney showed that the project was directly responsible for 8,100 hours of physical activity. Hence, infrastructure decisions about how services like digital connections are brought to a wider group of people through under street cables may have some impact in also creating, as a socially valuable by-product, increasingly safe and wider pavement and grass areas where children can play.

⁶⁶ A national project led by Play England in partnership with Playing Out, London Play and the University of Bristol

The NIC should encourage the government to consider:

- **consider infrastructure investment to redress digital exclusion by location (particularly rural) and to known socially disadvantaged groups. Digital infrastructure particularly needs to reach areas of high rented accommodation and social housing and those on low incomes.**
- **consider potential social by-products of infrastructure installation in improving streets and local environments.**

About the Health Foundation

The Health Foundation is an independent charity committed to bringing about better health and health care for people in the UK.

Our aim is a healthier population, supported by high quality health care that can be equitably accessed. We learn what works to make people's lives healthier and improve the health care system. From giving grants to those working at the front line to carrying out research and policy analysis, we shine a light on how to make successful change happen.

We believe good health and health care are key to a flourishing society. Through sharing what we learn, collaborating with others and building people's skills and knowledge, we aim to make a difference and contribute to a healthier population.

www.health.org.uk

About the UCL Institute of Health Equity

The Institute is led by Professor Sir Michael Marmot and seeks to increase health equity through action on the social determinants of health, specifically in four areas: influencing global, national and local policies; advising on and learning from practice; building the evidence base; and capacity-building.

The Institute builds on previous work to tackle inequalities in health led by Professor Sir Michael Marmot and his team, including the *Commission on Social Determinants of Health*, *Fair Society Healthy Lives* (the *Marmot Review*) and the *Review of Social Determinants of Health and the Health Divide for the WHO European Region*.

National Infrastructure Commission

National Infrastructure Assessment Call for Evidence October 2016

Response on behalf of The Peel Group

10 February 2017

Introduction

The Peel Group is one of the leading infrastructure, transport and real estate investors in the UK, with collective investments owned and under management of more than £5 billion.

Established by our Chairman, John Whittaker, over 40 years ago, The Peel Group has grown through an ethos of recycling capital and delivering long-term investment, primarily in the North West of England.

The family-owned Group is an investor in tangible assets comprising land, air or water. Our principal investments encompass the transport, retail and leisure, residential and commercial property, land, energy and media sectors.

Our investments are made either directly through Peel Land and Property Group or via a wide range of partnerships and shareholdings in private and public companies.

The Peel Group businesses with particular interest in this consultation are:

- Peel Ports Group: one of the largest port groups in the UK, handling over 70 million tonnes of cargo per year and has 15% of the UK's total port traffic moving through its waters. 50.1 percent owned by the Peel Group with 49.9 percent owned by Deutsche Bank's RREEF Infrastructure Fund. Peel Ports plays a major role in getting freight off the UK's roads, with six major gateways strategically located across the UK: the Port of Liverpool, the Manchester Ship Canal, Heysham Port, Great Yarmouth, Medway Ports and Clydeport's Scottish ports. Peel Ports is currently investing around £650 million in the North West including the recently opened deep water container terminal, Liverpool2, and biomass import terminal to support the decarbonisation of Drax power station. The century old Manchester Ship Canal plays an important role in sustainable transport with key sites to support logistics along the Atlantic Gateway corridor including planned investments at Port Ince, Port Warrington and Port Salford.
- Peel Airports: the Peel Group has invested more than £250 million in airports and associated infrastructure – our key airports are Liverpool John Lennon, Robin Hood Doncaster Sheffield and Durham Tees Valley. Our investment in Liverpool John Lennon Airport has helped grow passenger numbers ten-fold from 450,000 in the mid-1990s and the airport is a key driver of the economies of both Merseyside and the wider North West of England. Recent investments include the newly opened

£56 million motorway link road, Great Yorkshire Way, connecting the M18 south of Doncaster to Rossington and Finningley. The £12 million Peel Group and £10 million Harworth Estates investment (along with investment from Doncaster Council and Verdion) into this project will help to unlock a predicted £1.7 billion of investment, 20,000 jobs and 5,000 homes and support significant further opportunities for growth in the Sheffield City Region.

- Peel Logistics: the Peel Group's strategic approach to logistics is to combine the strength of our land holdings and transport investments to deliver a potential 60 million sq ft (5.5 million sq m) of new build logistics space across the UK, in partnership with Macquarie Capital.
- Energy: the Peel Group's energy and utility interests are driven by the delivery of a diverse energy portfolio. Peel Energy, Peel Environmental, Peel Utilities and Peel Gas & Oil work together to ensure that energy is sourced, delivered and utilized as efficiently as possible via low carbon, environmental technologies, gas and oil, local generation and distribution.
- Land & Property: placemaking through a series of large strategic destination projects, The Peel Group invests in regeneration and the revitalisation of communities across the UK. Key schemes in the North include MediaCityUK, Liverpool Waters, Wirral Waters, and Trafford Waters. Our pipeline includes the potential for 31,000 apartments and 41,000 family homes in the North.
- Harworth Group: the Peel Group holds a substantial shareholding in Harworth Group plc. that wholly owns Harworth Estates – one of the largest property and regeneration companies across the North of England and the Midlands, owning and managing 27,000 acres (11,000 hectares) across 200 sites, including some key logistics sites such as Logistics North in Bolton.

The Peel Group takes a long term view on its investments and development projects and has achieved significant growth over several decades through an ethos of recycling capital within its companies and across the Group. MediaCityUK, a £650 million scheme that was delivered through the last recession, and Liverpool2, a £400 million pound investment at the Port of Liverpool, are recent examples of the Group's commitment and ambition. Major regeneration and development schemes such as Liverpool Waters, Wirral Waters, Trafford Waters, Liverpool John Lennon Airport, Robin Hood Airport Doncaster Sheffield and the Advanced Manufacturing Park in Rotherham will be delivered using the same approach in the coming decades.

continued ...

National Infrastructure Assessment Evidence

The Peel Group welcomes the opportunity to respond to the National Infrastructure Commission's Call for Evidence for the National Infrastructure Assessment (NIA). We have set out below some overall observations and responses on specific topics triggered by questions raised in the NIA consultation document and a statement in the Government's Industrial Strategy green paper.

We appreciate we have not responded directly to many of the questions, however we believe we have much commercially sensitive information to share with the Commission if it can be done in a confidential manner. **We therefore request a meeting to explore the questions further and allow us to provide further information to inform the NIA.**

Government's Industrial Strategy Green Paper January 2017

The green paper states:

There has been an historic lack of clear long-term thinking in the Government's approach to national infrastructure strategy – in how we join up at a national level, and in a way that more consistently considers the interdependencies of infrastructure sectors.

This has contributed to the disjointed provision of infrastructure and a legacy of underinvestment. The recent introduction of National Policy Statements and the development of the National Infrastructure Plan (now the National Infrastructure Delivery Plan) has helped, but this underinvestment has led to low confidence among investors and undermined planning in the supply chain.

The absence of a clear national strategy has been compounded by the lack of joined-up policies to meet local needs. The fault lies partly in the poor coordination between central and local government, but also the lack of strong infrastructure institutions such as Transport for London outside the capital.

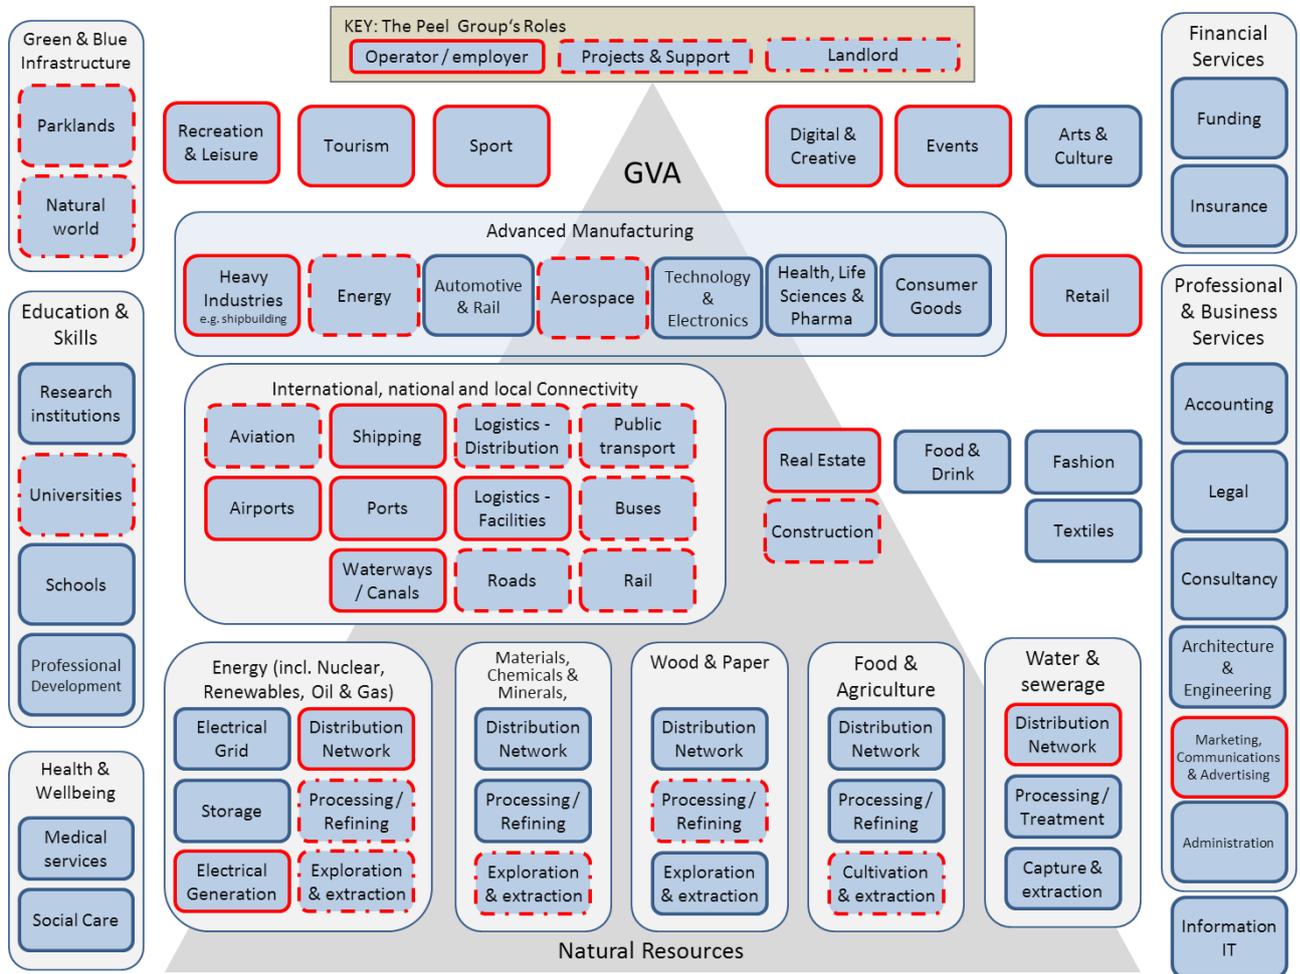

Peel's Pipeline of Infrastructure Projects

The Peel Group operates in a diverse range of sectors giving it a broad base of interest in the UK economy. We also perform a variety of roles from land owner, through developer, to investor and operator of infrastructure assets and businesses. We are a major investor in transport, property and energy infrastructure and have a track record of delivering ambitious visions with recent examples including the conversion of RAF Finningley to Doncaster Sheffield Airport, Salford docks to MediaCityUK and wind farms at Scout Moor and Frodsham. We also carry out major research to promote infrastructure including the recent Mersey Tidal Power feasibility study and the Ayrshire Power station planning application which was shortlisted in the Government's first Carbon Capture and Storage competition.

We are a private sector organisation with many public sector partnerships. Our investments are often highly dependent on national and local policies and public infrastructure. We also have many private sector partners and raise finance from international financial institutions and markets.

We therefore have a unique perspective on the relationship between the economy, placemaking and investment in infrastructure.

The Peel Group's economic sector interests

The Peel Group has a pipeline of projects, each with an infrastructure component, which we believe are 'high value' for the local and UK economy and align with the objectives of the National Infrastructure Commission ('the Commission'), namely support sustainable economic growth in many parts of the UK, improve competitiveness for local business and the UK as a whole, and improve quality of life for the local communities and visitors. Our latest Northern Powerhouse booklet (attached) provides a snapshot of our current priorities in the North. We also have a list of infrastructure projects ranging in scale from motorway signage (e.g. to ensure motorists follow the most direct route to Doncaster Sheffield Airport along the new Great Yorkshire Way) to the Mersey Tidal Power scheme. We would welcome the opportunity to share further details of our Northern Powerhouse projects and our wider UK pipeline with the Commission's team on a confidential basis to help inform the NIA.

Infrastructure spending and budgets

We welcome the current Government's commitments to infrastructure spending as seen in recent Budgets, Autumn Statements and as expressed in the Industrial Strategy Green Paper. However, the headline figures fall short of the level of funding needed to address the historic underinvestment across the country, particularly in the North of England. There is a significant backlog of local infrastructure projects that have not been funded, including refurbishment (e.g. potholes in the road, and stations and interchanges in state of disrepair), upgrades (e.g. additional capacity for freight and passengers on railways, and at road junctions), and new infrastructure (e.g. reducing journey times, relieving congestion, increasing resilience, and opening up land for housing and employment).

The impact of the Government's statement that infrastructure spending will be between one and 1.2 per cent of GDP between 2020 and 2050 cannot be assessed until there is a better handle on this backlog, alongside the pipeline of new opportunities driven by economic growth, housing and industrial policies. Work by some local authorities has helped to identify the backlog and devised an objective set of priorities in their area. However, this has often been done in isolation and without input from the private sector and local communities.

Similar issues exist with the National Infrastructure and Construction Pipeline – it does not contain many private and public sector projects, including many that we are involved with.

As far as we are aware, there is currently no single source of data to understand the investment required to bring our transport system up to modern standards, let alone keep apace with changes required due to technological shift such as decarbonisation, electrification, and digital transformation, including smart ticketing and metering.

We recommend the Commission spreads best practice in preparing and characterising the project pipeline at a local level and then amalgamating this at a national level so there is greater transparency for both the public and private sector at the local and national level.

This will then serve to determine what level of spending is required to maintain current levels of productivity in each area, and what additional investment is required to raise productivity and support economic growth in line with Government policies on matters including the Northern Powerhouse, Housing, Aviation and Industrial Strategy.

This will also help to ensure there is a clear and transparent process for identifying transport investment priorities at a local, regional and national level that will allow the private sector to engage effectively.

Research and Development funding

The state of existing assets and pressure on local budgets means most authorities have not been able to set aside funds to develop their business cases for their pipeline of projects, let alone work with the private sector on growth opportunities. Access to the level of development funding required to progress a WebTAG compliant business case therefore needs to be taken into account in the funding and budgeting process to enable

all authorities, and private sector promoters of public infrastructure schemes, to put forward their case for further capital investment.

The loss of funding through schemes such as ERDF and TEN-T will be a big loss to research, feasibility studies and early stage development of infrastructure technology and schemes as the UK exits the EU. We strongly recommend that the Commission assists the Government in identifying programmes that need support to advance not only the development of infrastructure technologies but also the deployment of infrastructure to ensure the UK seizes economic opportunities and does not lag behind its international competitors.

Approach to prioritising investment

As the UK prepares for a new future outside of the European Union, a new approach to support regional investment will be essential to grow the whole of the UK economy. We must end the practice of distributing public sector funds based on current population and historic trends and consider how we reverse the endemic under-investment in some parts of the country while others are overpopulated and congested. We support the work of this Government and the Commission as it looks ahead and considers the opportunities and needs of the future economy, and future populations, and how proactive investment in infrastructure associated with key projects can lead the transformation.

The Chancellor was correct to observe in the Autumn Statement that “no other major developed economy has such a gap between the productivity of its capital city and its second and third cities, so we must drive up the performance of our regional cities”. However, modelling growth based on current population and historic trends fails to account for some of the biggest potential growth areas – looking along transport corridors or between cities can often yield the sweet spot of available land, expertise, ambition and infrastructure potential. Spending commitments should be strategically developed and coordinated to catalyse transformative place-based growth, and injected into individual projects where there is consideration of their wider impact.

The WebTAG method of evaluating “Highest Value” and ranking projects by their benefit to cost ratio favours projects in congested productive areas, leading to higher concentration of activity in the overheated centres, higher costs to ensure resilience and bigger impact when failures occur. A new approach to prioritisation of funding is needed in order to rebalance the economy, not only between the South and North, but also across the North.

There will also have to be a change in emphasis from National meaning central or South East, as recently exemplified in the recently published “Airports National Policy Statement: new runway capacity and infrastructure at airports in the South East of England”. Promoting long haul routes directly from airports with spare capacity in the North of England, therefore requiring significantly less investment than would otherwise be required to increase capacity in the already congested South East, would:

- reduce the pressure on Heathrow and Gatwick
- avoid leaking value to other European hubs

- reduce road congestion caused by passengers and freight traveling from the North, and
- increase the economic activity, productivity and competitiveness of the North.

Truly national policies, along with other measures to prioritise investment in the North, would help to rebalance the economy and reduce pressure on other infrastructure in the South East.

There also needs to be a greater focus on forward looking opportunities, and identifying wider benefits through an integrated approach to different modes of transport and types of infrastructure. This will require greater levels of engagement with the private sector across the country, often on a confidential basis, in order to reveal the opportunities and threats to productivity and growth in each area. This would also allow for better co-ordination between public and private investment and ensure that public investment delivers in the same timescales as the private investment, thereby avoiding delays to private sector investment, and maximising the positive impact on the economy while avoiding any negative effects, e.g. relieving rather than adding to congestion in existing local communities.

Spatial and Scenario Planning

Peel appreciates the spatial dynamics which influence both the demand for infrastructure and the operation of the planning system, which each seek to accommodate and plan for future growth.

Peel is equally aware of the limitations and challenges which need to be taken into account in planning for future growth. We commissioned Turley to undertake a review of the scenario planning aspects of the NIA. Turleys have suggested areas of further analysis and consideration by the Commission as the NIA is developed. We have included an extract of their report in Annex 1.

Infrastructure as a catalyst for growth

Peel has long been a champion of integrated development projects – coordinating public and private sector partnerships that bring together businesses, public bodies, communities and third sector organisations to deliver regeneration and innovation. One of our best known examples is the delivery of MediaCityUK in Salford which is now a major employment site housing national brands like the BBC, ITV and Coronation Street, and the University of Salford. We worked closely with Salford City Council bringing in £700 million of public and private sector investment, to deliver a thriving creative and digital hub, now employing and housing more than 7,000 people, and providing 400 new homes. We are now working with L&G Capital and other partners to deliver the next phase of investment and growth.

In this example, the Government's decision to relocate BBC departments was a major economic catalyst which allowed our organisation, working with public sector partners, to

create the vision and investment in the physical and digital infrastructure to drive the growth and productivity of the digital and creative sector in an underperforming part of the city.

The last mile

While the National Infrastructure Delivery Plan and Government announcements focus on the 'big ticket' projects [and ribbon cutting opportunities], productivity and growth in the UK economy is impacted by 'the last mile' as much as the major trunk routes.

For example, development at Port Salford – our £138 million investment, creating the first tri-modal freight hub on the UK's inland waterways, served by ship, rail and road, which received planning consent in 2009 – has been delayed by lack of budget and prioritisation of investment in the local road network to alleviate historic congestion on local roads and the M60.

Our investment in the Port of Liverpool will not unlock the potential benefit to the Northern and wider UK economy if the Government does not deliver a long term solution to the congestion on the A5036 Princes Way/Dunningsbridge Road, a project which has not been delivered despite years of strong collaboration between the local private and public sectors.

Improving connections between the city 'hubs' is only part of the solution; the hubs need better connection to the 'spokes' of local commercial districts and residential communities. Most successful international cities have the benefit of urban transport infrastructure that allows mass rapid transport to ensure short journey times to destinations within their city regions. Large schemes such as HS2 and HS3 are important to provide better connectivity between cities but they will only connect the hubs. They will not deliver the anticipated benefits and connectivity improvement if the spokes are neglected. Major hubs in London are already served by buses, the underground and overland trains. New high speed hubs in other UK cities will not serve the people of those cities if the connections from their homes are not improved. For example, anyone currently travelling to London from the south of Manchester or Cheshire has the option of using any one of Wilmslow, Stockport, Crewe, Warrington or Manchester Piccadilly stations to get to London – local journey times are therefore short. These passengers will not be inclined to use HS2 if the saving of time on the high speed journey is lost in the time (or convenience) of getting from their home to the hub. This is equally true of HS3, whereby it is typically just as quick to travel across the Pennines in your car than make all the necessary connections on public transport. Increased investment in local transport is therefore crucial to address these and other existing issues and thereby achieve the benefits from the High Speed Rail programme.

In addition there is no point in delivering savings in one leg of the journey if increased congestion increases the journey time, or reduces the reliability and resilience, on another leg. Any large programme such as HS2 must therefore include a funding package to ensure the integration to existing networks is also delivered.

Public vs Private Sector Infrastructure Investment
