Through years of successful partnership working with the public and private sector, Peel has a clear view on where the responsibility for public and private investment lies; this view is backed up by others, most recently in the Independent International Connectivity Commission Report: “The role of the public sector is to work with the private sector, particularly to ensure that the right surfaces access is in place and the conditions for the industry to thrive and deliver the required growth are created.”

The business case and viability of new developments across the North are often challenged by local market conditions and the uncertainty of rents, prices and take up of new developments, buildings, and services.

At a local level, historic underinvestment in infrastructure and a shortage of investment capital within local authority budgets means that ‘normal’ levels of contributions from development (through s106 agreements and Community Infrastructure Levy) often do not go far enough to deliver the required transport links or upgrades.

This puts pressure on the private sector to fund the gap, thereby worsening the viability gap and slowing investment and growth in these areas. Areas where the Government is targeting productivity improvements and growth will therefore need a disproportionate amount of investment capital.

The move from grants to loans does not address the viability gap nor scale of investment often required to overcome legacy issues due to historic underinvestment in the local infrastructure, particularly with the local transport network. This problem is exacerbated by the reduction in EU grants. A combination of grant and loan is therefore required, with a recognition that loans may be repaid from the increase in business rates and council tax that will be generated in the short to medium term. This will help to unlock developments that have already stalled and are often overlooked when determining local spending priorities for limited local resources.

Infrastructure funding governance

As a private sector organisation dependent on public sector organisations we have to navigate the myriad of sources of funding for transport schemes; recent example that we have been engaged with are:

- Department of Transport: Pinchpoint, Large Local Majors
- Highway England: RIS
- Network Rail: Control Periods
- Local Authority/Combined Authority/Passenger Transport Executive funds
- Local Enterprise Partnerships: Local Growth Funds.

The governance surrounding each of these sources of funding, and the approach adopted by each of the accountable bodies to engage through public sector bodies makes it difficult

for the private sector to engage in the process of identifying and promoting projects, particularly when competing with local public sector priorities.

We recommend the Commission identifies and spreads best practice in consultation processes to ensure the private sector has a route to engage directly with the accountable body to maximise the impact of infrastructure investment programmes.

This is particularly important where sources of funding are specifically targeted at unlocking private sector investment, such as housing and employment development.

Private sector involvement/ownership of infrastructure

Inconsistent interpretation of current State Aid rules drive inconsistent approaches to investment in public transport depending on the ownership of assets. The precautionary approach adopted by the public sector transport bodies disadvantages assets owned in the majority by the private sector that are competing with assets owned in the majority by the public sector, e.g. airports. We have been collecting evidence of such investments and are willing to share this once available.

In a post Brexit world, there is an opportunity to resolve this issue through a review of the applicability of State Aid rules and provision of clearer guidance for all parties involved in such investment decisions.

Our ambitions by 2050

Peel's pipeline of projects – a potential £53 billion total capital investment, building new hubs for trade and logistics, delivering 105,000 new homes, 86 million square feet of employment floorspace and supporting more than a quarter of a million new jobs – underpins the scale of our commitment to a new industrial vision for the UK. Delivering on this commitment, however, depends on the right support from public sector partners, and the right conditions for investment.

Our pipeline in the North comprises 41,000 family homes, 31,000 apartment, 2,800 hotel rooms, 30 million square feet of industrial and logistics space, 18 million square feet of office space, 6 million square feet of retail and leisure space and 229 MW of electrical generating capacity.

We would welcome the opportunity to share our experiences and work with you to ensure the NIA is built on evidence from the grass roots, not just supporting the major infrastructure projects, working in tandem with the Industrial Strategy such that, in the Prime Ministers words:

“It will help to deliver a stronger economy and a fairer society – where wealth and opportunity are spread across every community in our United Kingdom, not just the most prosperous places in London and the South East.” Industrial Strategy Green Paper, January 2017

Annex 1

Scenario Planning : Extract from Turley review of NIA scenario development commissioned by The Peel Group

Peel commissioned Turley to review the proposed inputs to scenario development in the NIA. The focus of the review was on the economic, demographic and planning based influences on the demand for infrastructure. The recommendations from the review are captured below.

Taking Account of Economic Factors

- 1.1 The NIA should take into consideration the transformative potential of the Northern Powerhouse, Midlands Engine and a succession of devolution deals which will collectively support the Government's ambitions to rebalance the UK economy, to which it has committed unprecedented levels of investment. The resultant growth and distribution of economic growth, labour force and businesses will directly generate a demand for infrastructure, which should be taken into account to ensure that the supply of infrastructure will meet demand and support such transformational economic growth.

Taking Account of Demographic Factors

- 1.2 While it is recognised that negotiations over the UK's exit from the EU could be expected to reduce current levels of international migration, the central population projection developed by the ONS itself allows for a significant reduction in net international migration from current levels and is considered to be representative of a plausible outcome of this negotiation. Caution should be exercised in assuming that a still more fundamental change will materialise, given that this could lead to underestimation of the UK's population and future demand for infrastructure. Limited weight should be attributed to any theoretical low migration variant on this basis.
- 1.3 Nationally, there is evidence that the worsening affordability of housing and undersupply has suppressed household formation rates historically, and trend-based official projections can assume that the formation of younger households will be suppressed in future. This contrasts with the Government's commitment to boost the supply and housing and fix the housing market, which must be expected to support and enable a return to more positive market conditions for younger households. Consideration should be given to developing a sensitivity which allows for a local return to more positive levels of household formation for younger households, providing an alternative position on the number and size of households distributed throughout the country which captures the Government's ambitions.

Taking Account of Planning Factors

- 1.4 The NIA should take full account of the level and distribution of housing growth planned in assessing the future demand for infrastructure. Population projections

produced by ONS form the 'starting point' for establishing the level of housing growth needed, but cannot in themselves be uncritically viewed as an accurate or representative picture of the growth likely to occur. Local Plans provide a clearer position on how local authorities are planning for future change, and a variant scenario should therefore be developed which takes full account of adopted housing requirements and objective and robust evidence of local needs. The Government's commitment to introducing a new standard methodology for calculating 'objectively assessed need', as set out in the Housing White Paper, should ensure a consistent platform for strategic plan-making as long as the proposed methodology is robust and captures needs in full. The Government's recognition that this methodology must be consistent with the modern Industrial Strategy in this context is important in ensuring that planned requirements reflect not only historic trends but future driving factors.

- 1.5 Caution should also be exercised in using historic trends in house building as the basis for any future redistribution of growth, given the recognised longstanding imbalance between housing supply and demand. The scale and distribution of housing provision delivered in the past cannot be viewed as representative of that which needs to be delivered in the future, and greater weight should therefore be given to the level of future growth planned and needed to fix the housing market and significantly boost housing supply.
- 1.6 The approach proposed by the Commission also risks perpetuating the growing regional divide between the North and South of England, without considering the step change from historic trends required if the Northern Powerhouse is to be successful and the national economy is rebalanced. The demand for infrastructure should therefore be assessed to reflect and support the transformational change that will result from the successful delivery of the Northern Powerhouse, ensuring that infrastructure supply will meet demand and support the economic growth and potential of the North.

National Infra-Structure Assessment Consultation

Response from The Riverside Group Ltd, 09 February 2017

Riverside is one of the leading registered providers of social housing in the UK, offering affordable housing and support to people of all ages and circumstances.

We manage of 52,000 homes in 150 local authority areas in England and Scotland and house 90,000 people.

Approximately half of the homes we manage are in Lower Super Output areas ranked in the lowest 10% index of multiple deprivation.

Fuel poverty and affordable warmth is a major issue for many of our customers.

Supply

Whilst our primary expertise does not lie within the energy supply market, we can see the opportunity in distributed energy resources that could be owned or operated by Riverside.

It is currently feasible for us to invest in local energy generation that can reduce our customers' energy costs, but the regulatory complexity and cost of becoming an energy supplier is a major barrier to this. Infra-structure support for load aggregation and peer-to-peer trading is recommended.

The rate of technological change and cost reduction in generation technology and energy storage makes it likely that we could become increasingly involved in energy provision.

This will require energy infra-structure that is flexible and robust and that will allow connection of local energy resources without unfair regulation or cost.

We have already encountered infra-structure problems with a Distribution Network Operator limiting the density of solar PV systems.

Demand

There is an obvious strong correlation between the requirement for heat and the energy performance of buildings.

Riverside has undertaken numerous retrofit projects to improve fabric insulation of the homes we manage with funding through CESP, CERT, ECO and ERDF and have seen the impact this has had on energy reduction and improved comfort and health for residents.

One of the main challenges to investment in energy efficiency as a social landlord is the inability to recover costs of investment through adjusted rent or other charges.

The energy savings from insulation measures are well researched and typical monetary saving figures are published by organisations such as [Energy Saving Trust](#).

Whilst the method of decarbonising the supply of heat and the associated costs of energy are uncertain, we consider improving fabric energy performance of buildings with existing proven insulation methods is the most predictable way of reducing heat demand, carbon emissions and helping fuel poverty.

We would refer to the report commissioned by E3G '[The economic and fiscal impacts making homes energy efficient](#)' which details what economic impact a retrofit programme at scale could deliver.

The health risks of living in a cold home are well researched, particularly for vulnerable groups including the young and old. There were 24,300 excess winter deaths in England & Wales in 2015/16 with an estimated 10% of this figure linked to fuel poverty.

We would refer to '[The Health Impacts of Cold Homes and Fuel Poverty](#)' prepared by the Marmot Review team. A further report prepared by [NHS Oldham CCG](#) provides a cost benefit analysis of lifting people out of fuel poverty. A new study by Energy Saving Trust will research the poverty-illness links with a study of over 500,000 homes in the South West of England.

With reference to emissions, it is difficult to see how the binding carbon reduction targets can be met without a significant reduction in heat demand.

[The Review of Potential for Carbon Savings from Residential Energy Efficiency](#) report for The Committee on Climate Change in 2013 assessed the annual carbon savings from residential energy efficiency measures of around 49Mt excluding any uptake of low carbon heating technologies.

Riverside has gained significant expertise in the delivery of community wide energy efficiency measures using its trusted brand. We are able to mobilise resources quickly to deliver similar schemes through EU compliant procurement supply chains.

Summary

The combined benefits of reduced emissions, fuel poverty and improved health leads to recommend a large scale project to improve the fabric insulation of the UK housing stock as a national infrastructure priority.

The economic and employment benefits of this scale of project have been documented in this response and add weight to our recommendation.

The market has not responded to the challenge of residential retrofit making clear government policy with associated regulation and incentives essential.

Hutchison 3G UK Limited (Three) response to National Infrastructure Assessment: Call for Evidence

Dear Lord Adonis,

1. Three (Hutchison 3G Ltd) welcomes the opportunity to respond to the National Infrastructure Commission's *National Infrastructure Assessment*.
2. Three is the UK's challenger mobile network. Since we launched in 2003 we have focused on ensuring that our customers are able to make the most of their devices through market-leading propositions such as 4G at-no-extra-cost and Feel at Home, which allows Three customers to call, text and use their data allowances abroad at-no-extra-cost in 42 destinations. As a result, Three is the largest carrier of mobile data, with our network carrying 35% of all the UK's mobile data.
3. Three welcomes the creation of the National Infrastructure Commission (NIC). As noted in the Commission's recently published *Connected Futures*, the UK is currently languishing in the 'digital slow lane' and is ranked 54th in the world for 4G coverage. The deployment of digital communications infrastructure in the UK is the slowest and most costly in Western Europe. In simple terms, the UK builds smaller and more expensively than comparator nations.
4. This has to be addressed – and fast – if we are to turn the UK back into a world leader when it comes to digital communications. We believe that there is a clear role for the NIC to play in driving long needed reform of the legislative framework around digital communications and to simplify the current complicated and fragmented legislative structures, which militates against the efficient investment in network infrastructure.

5. Ultimately, the responsibility - and the solution to this predicament - sits jointly across sectors, regulators and Governments. However, for these stakeholders to work together effectively a coordinating body is needed, ideally one with a long-term strategic focus. Three believes that the NIC is ideally placed to fulfil this role.
6. Three has previously met with the Commission to provide our insight on the infrastructure needed to meet the future data demand, and we welcome this opportunity to provide further thoughts.
7. This submission sets out Three's priorities for a National Infrastructure Assessment (NIA); provides additional context on the current status of the mobile market and associated longer term consequences; and then answers specific questions in the NIC's call for evidence.

National Infrastructure Assessment.

8. Three fully supports the Commission's ambition to produce a NIA once in every Parliament, setting out an assessment of long-term infrastructure needs on a 30-year time horizon. We also agree that this NIA should span the work not just of Government departments but sub-national and regional bodies, as well as regulators.
9. As we note above, the UK mobile market is currently not delivering the best outcomes for UK consumers. In Three's experience, many of the regulations (or lack of) that have contributed to problems in the sector are as a result of Government and regulators favouring immediate political expediencies over tackling the most significant bottlenecks that inhibit competitive growth. Three has long been critical of this short-termism and we have set this out further detail below.¹
10. Three also welcomes the inclusion of digital communications as one of the individual sectors the NIA will focus on. Mobile communications – especially mobile data – is already integral to people's lives. More than nine in ten adults own a mobile phone, with two-thirds now owning a smartphone.² Ofcom has found an eight-fold increase in mobile data volumes between 2011 and 2015.³
11. Improved 4G services – and particularly the rollout of 5G – have the potential to further this reliance and with time replace fixed-line infrastructure. In the near future, it is highly likely that 5G will form the spine of many of the UK's key services, whether through e-health,

¹ Pages 2-6

² Ofcom, Communications Market Report 2016

³ Ibid.

internet of things or driverless cars. However, without significant reform progress will likely be expensive, patchy and slow.

12. Although Three welcomes the Commission's decision to include digital communications as a core sector, we also agree with the decision not to tackle sectors independently from each other. Undoubtedly, a cross-sector approach is the most efficient and resilient way to build a high quality and reliable mobile network – as is the case with all types of infrastructure. Three has long argued that communications requirements must be hardwired into all building regulations and long term infrastructure planning processes, be it the rolling out of energy or transport infrastructure, or the building of new commercial or residential estates.

The Future of Communications Infrastructure.

13. It goes without saying that mobile services are becoming increasingly important to the lives of UK consumers. The demand for always-on and high-quality mobile services is rapidly increasing, with consumers now expecting consistently good network performance, regardless of location or time of day. Mobile data traffic is growing at a rate that outstrips all expectations; in the month of October 2016 Three's network carried more traffic than in the whole of 2011.
14. However, it is clear that mobile infrastructure is struggling to meet current needs. Ofcom has found that only 62% of the UK landmass has access to voice coverage from all operators – and only 40% has access to 4G services.⁴ 98% of NFU members own a mobile phone, yet only one in six of surveyed could receive a mobile phone signal across the farm.⁵
15. However, it is not just coverage and the need to extend infrastructure that restricts access to mobile data services. Capacity too is also an issue. In many parts of the UK mobile networks are becoming congested as a consequence of the almost exponential growth in mobile data. Three's customers alone now use on average almost 6GB of data in a month, and this continues to grow.
16. As the operator that has consistently carried the greatest share of the UK's mobile data usage,⁶ we are acutely aware of the infrastructure that is required to deliver the ubiquitous high quality mobile services that customers expect – both now and in the future. We also understand the current problems inherent in the communications and infrastructure market which are preventing this rollout and inhibiting investment.

⁴ Ofcom, Connected Nations Report, 2016

⁵ National Farmers Unions, Spotlight on Farm Broadband and Mobile Networks, 2016

⁶ Enders Analysis, Q3 2016

17. Going forward these problems will only become more acute. For expectations around 5G to be realised, an extraordinarily dense network of small cells will be required in addition to existing mobile infrastructure. Although the full extent of any new infrastructure requirement is not yet understood, the additional equipment required will be extensive, and will likely go way beyond what the existing legislative framework for mobile envisages or enables.
18. In London alone it is estimated that as many as 500,000 small cells will be needed to support 5G services, a number far greater than the UK's entire existing stock of 37,000 mobile masts. For this to be possible - particularly in a way that maximises the benefits to not only the UK economy but also its consumers and citizens - a corollary step change in the legislation around digital communications infrastructure will be required.
19. If the UK is to become a leader in digital technology, then future NIAs must look to address the following areas
 1. The uncompetitive nature of the mobile market, underpinned by unequal spectrum holdings.
 2. Competitive bottlenecks for key infrastructure inputs, especially transmission.
 3. Government and Regulator's approach to regulation. UK mobile infrastructure is currently the smallest but most expensive infrastructure in Europe,⁷ and is inefficient in delivering connectivity needs.

Below, we set out more detail on each of these issues in turn.

1. Addressing the imbalance in spectrum holdings.

20. Spectrum is the fundamental input for the provision of mobile services. Its importance was recognised by the NIC in its 2016 report on 5G readiness. Prior to 2010, Ofcom had structured spectrum auctions to ensure that all operators had equitable spectrum holdings. In their Strategic Review of Digital Communications discussion document, Ofcom deemed this approach a success:

"In mobile, competition has cut the price of a typical bundle of mobile services by two-thirds in real terms, from around £40 in 2003 to £13 in 2012. Access to spectrum has kindled this competition [...] Lower prices have been accompanied by innovation: for example, Three, as a challenger brand, introduced 'all you can eat' data tariffs and use of Skype voice over IP (VoIP) services, and scrapped roaming charges from a number of countries."⁸

⁷ Mobile UK

⁸ Ofcom, Strategic Review of Digital Communications, Discussion Document, 2015, p2.

21. However, this situation changed consequent to a series of regulatory decisions post 2010 – in particular the liberalisation of 2G spectrum for 3G services without any remedies, a 4G auction with weak competition measures and the merger of EE and BT – has led to significant asymmetry in the UK’s spectrum holdings.

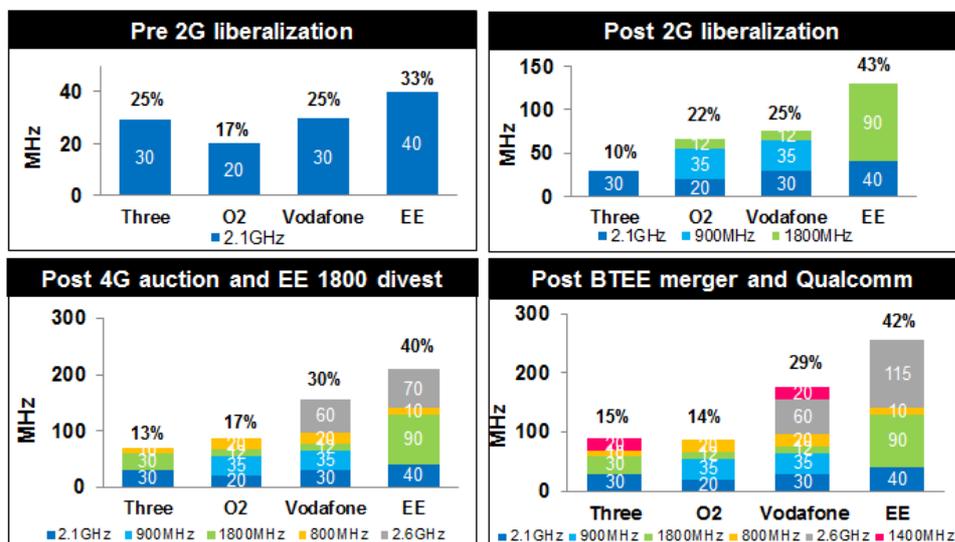

Fig 1: UK spectrum holdings.

22. Following the merger of BT and EE the UK now has one of the most extreme spectrum asymmetries in the developed world; spectrum is disproportionately concentrated in the hands of just two Mobile Network Operators, with one player – BTEE – holding 42% of spectrum usable for mobile.

23. To put into context, the UK now has the most uneven distribution of spectrum in the G20 and sits 48th out of the top 50 economies by GDP, bookended by Vietnam and Malaysia.

Table 1: The UK has one of the worst distributions of spectrum in the developed world

Group of countries	Number of countries	UK ranking (from best to worst)	Countries with larger spectrum imbalance than UK
Top 50 world economies (by GDP)	50	48 th	Thailand, Malaysia
G20	20	20 th	-
Western Europe	20	19 th	Iceland

Source: Three

24. As a result of this asymmetry, spectrum is not only concentrated in the hands of two operators, but it is effectively 'land banked' through none use or underutilisation. Irrespective of competition concerns, this is an inefficient use of a critical national resource.
25. Moreover, spectrum banking deliberately circumscribes the ability of smaller operators to price data packages competitively, denying their customers the benefits of increased capacity and speed, and constraining competitive drivers in the market more widely. Spectrum inequalities needs to be addressed to allow for greater competition in mobile markets going forward, with lower prices and a wider range of services for our customers.

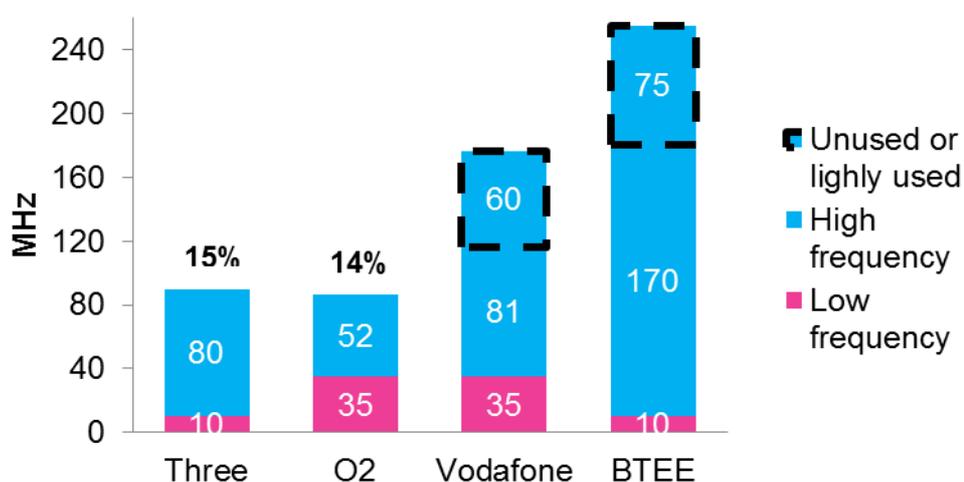

Fig 2: Unused or lightly used spectrum holdings.

26. This erosion of competition has significantly damaged the market, and has led to higher prices for UK consumers when much of the rest of Europe has seen significant price decreases. The EC's Mobile Broadband Prices in Europe 2016 Report says that UK handset plans have increased by an average of 4% between 2015 and 2016, compared to a 7% decrease on average across EU Member States.⁹
27. However, the impact of spectrum asymmetry is not confined to the poor quality services and higher prices consumers experience today. It also will impact the future of mobile services, including 5G, unless it is addressed quickly and lessons learnt from the failed approach to the 4G spectrum auction. This is why it must be considered as part of the NIA process.

⁹ European Commission, Mobile Broadband Prices in Europe, 2016, Paragraph A7.55

28. Fortunately, Ofcom has a unique opportunity to address the current asymmetry in the upcoming PSSR spectrum auction. Unfortunately their preferred competition measures for this auction are extremely weak, and would do little to address this imbalance.
29. Three therefore welcomes that the NIC has recognised the importance of this auction in their *Connected Futures* report, and believes the NIC must have a key role in holding Ofcom to account during this PSSR and subsequent auctions, to ensure that these auctions deliver the right outcomes for UK consumers and a market that can underpin the UK's future infrastructure needs.
30. Three has supported the Make The Air Fair campaign,¹⁰ which has called for a 30% cap on spectrum usable for mobile. The campaign not only gathered support from a range of industry stakeholders, but had the support of over 170,000 individual consumers, who have responded to the Ofcom consultation on the structure of the PSSR auction.

2. Uncompetitive Transmission Market

31. While spectrum is the key input, mobile networks also require transmission (or backhaul) between sites and the core network. Currently, this market is struggling to provide access to the high-capacity backhaul needed to meet the UK's future data demand. In as much of 80% of UK postcodes and a great proportion of UK physical geography, there is only one provider of transmission, BT. This fundamental lack of competition in a key wholesale market is driving up costs, inhibiting rollout and upgrades. Crucially, its impacts are felt most acutely in rural, remote and hard to reach communities, where the economics of mobile service provision and network extension are already most challenging.
32. Ofcom has failed to deliver the equal and competitive access to BT's Openreach network that is needed and in many areas BT Openreach remains an enduring economic bottleneck, one from which competition is unlikely to emerge.
33. Ofcom have repeatedly concluded that BT continues to exploit its ownership of Openreach to make strategic decisions that favour BT's interests over its rivals. BT has regularly shown that they will act on this incentive, and over the years has successfully discriminated against rivals in the provision of wholesale access to Openreach.
34. However, Ofcom's announcement in November 2016 to require the legal separation of Openreach from BT does not address these concerns. In Three's view, Openreach will not behave like a truly independent company while BT continues to own and oversee it. Instead, Three would like to see Openreach's strategic and operational independence from BT strengthened, to increase competition in the mobile market.

¹⁰ See www.maketheairfair.org

35. Three is also concerned that Ofcom needs to do more to create the right incentives for investment in the infrastructure that underpins much of the fixed and mobile markets. The introduction of dark fibre will bring benefits to the UK communications markets; greater opportunities for innovation and product differentiation, which will in turn stimulate cost efficiencies, lower pricing and allow for future deregulation of active markets. To deliver these benefits Ofcom must take a more proactive approach towards the implementation and operation of its Dark Fibre Access remedy.
36. Ofcom have highlighted the difficulties they face in tackling the dominance of BT. The NIC must have a role in scrutinising Ofcom's activities in this area and where appropriate, calling for more effective competition measures. Otherwise this infrastructure, which will underpin the extension of better quality 4G and the rollout of 5G services, will simply not be available.

3. Approach to Communications Infrastructure Regulations

37. The current planning and building regulation regime do not facilitate the necessary infrastructure to meet today's mobile data demands, for either large scale infrastructure projects or other small-to-mid sized developments. There needs to be a radical review of approach if the UK is to achieve the ubiquitous, reliable mobile data coverage that future technologies will require.
38. The current planning regime means that it is disproportionately expensive to build mobile infrastructure in the UK. It also leads to MNOs building much smaller (and therefore less efficient) infrastructure. For example, the average mast height in the UK is 17m. In France the comparable figure is 30m, in Sweden it is over 70m.¹¹ There have been some welcome changes to facilitate the building and upgrading of new infrastructure, notably planning reform in England (and proposed reform in Scotland) and reform to the Electronic Communications Code (ECC), currently being debated as part of the Digital Economy Bill.
39. However, progress towards these reforms has been painfully slow. For example, ECC reform was intended to help 4G rollout – yet the provisions are still not even passed into law. If they do come into force, the reforms will only apply to new or renewed contracts, meaning that for many sites it will be ten or fifteen years before the industry begins to see the benefit of these changes.
40. It is also worth noting that the recent planning reforms, although welcome, only provided additional height and rights within the existing framework. The infrastructure required for 5G is likely to be significantly different from that required for 3G and 4G, most notably the use of small cells.

¹¹ Mobile UK.

41. As this technology is still in development, regulation in this area cannot be simply created by providing Government with dimensions for current equipment or by estimating the likely density requirements. In fact, it will be completely the wrong approach to think of 5G planning regulation in this way. Instead, Government must look at developing a new policy, which embeds the need for ubiquitous and high-capacity mobile coverage into its provision. It must also give maximum flexibility to manufacturers and operators, to ensure the new technology develops in a way that is most effective at delivering that coverage – rather, as happens with masts, limiting the design and location of infrastructure to best fit the regulations. The NIC, with its cross-industry focus, will be an ideal position to develop this new approach to decision-making.
42. Three also believe that communications requirements should become embedded in Building Regulations. We have commented further on this issue in the answers to specific questions below.
43. It is also worth noting that planning and building regulation decisions relating to mobile infrastructure currently reside at local authority level, including across 32 Boroughs in London. As a consequence of this fragmented method of decision making, there is a lack of strategic policy direction. This has hindered mobile rollout and could have real implications for how 5G is deployed.
44. Three hopes the above provides useful context to the Commission. Our answers to specific questions in the Call For Evidence can be found below.

Answers to Specific Questions

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

45. Three believes that housing and infrastructure plans must take into account the growing demand for improved capacity, speed and coverage. This cannot be the responsibility of communications providers alone. A holistic approach to communications, with the necessary infrastructure requirements considered as part of the earliest stages of the planning process, is the most efficient and effective way to meet future demand. For example, if a developer is building a new business park or housing estate, then it makes sense that the communications requirements of future occupants are hardwired into the initial planning process. The same should also be true for road and rail infrastructure. The cost of providing high-capacity indoor coverage is not one the industry alone can bear.
46. Yet currently, not only does this rarely happen but developments are the most common reason for operators to be given NTQs (Notice To Quit), meaning we have to remove our

existing infrastructure. It is very difficult – and in some cases impossible – to find an alternative site nearby which provides the same coverage footprint. Even if a suitable replacement can be found, it can lead to a break in service while this replacement site gains the necessary planning permission to be built. Furthermore, such activity can drastically reduce the capacity on nearby sites – either because a hub site is being removed or because nearby sites have to cope with a significant increase in traffic.

47. Three believes there is scope to review the current planning and building regulation processes, to ensure that communication considerations are taken into account – both in terms of the impact of development on existing infrastructure and more importantly, how the connectivity needs associated with the new development will be met.
48. This approach must also be at the heart of large scale infrastructure projects, like HS2, A greater focus is needed to ensure that all such future strategies have a digital component, where likely communications needs are addressed. Otherwise, industry and Government will be left in a situation where they have to retrofit costly and often ineffective solutions
49. Three also believes that consideration must be given to the current process of decision making, which is undertaken at a local authority level. This fragmented approach has resulted in a lack of strategic direction inconsistency in decision-making, which has inhibited investment and rollout. If the UK is to become a leader in mobile communications, this lack of strategic leadership needs to be addressed.
50. Three, supported by Mobile UK – the mobile industry trade association – would be very happy to work across national and sub-national Governments, as well as other stakeholders, to scope out specific changes that are needed. However, from our experience such work will need someone to take a leadership role. The NIC, with its long-term focus and its understanding of future demands, would be a powerful voice influencing strategy in this area. Therefore, Three hopes the NIA also covers these considerations.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

51. Three believes that demand management is not a realistic strategy for digital communications.
52. As already stated, the demand for mobile data is growing at an exponential rate. On Three's network alone, our customers already use 5.9GB per month – a 31% increase since 2015. Any attempt to throttle this growth will have a detrimental impact not just for consumers, but for UK productivity and the wider economy.

53. Instead, Three believes that the mobile market will be able to meet this demand, but only if the current asymmetry in spectrum holdings is addressed. As shown in Figure 2, we are in a situation where not only is spectrum concentrated in the hands of two operators but a significant proportion of that spectrum is being either lightly utilised or not used at all.
54. To have any chance of meeting the capacity challenge, it must be ensured that all assets available are being used to their maximum.
55. This effective use of spectrum should also be a consideration in any NIA, as well as how additional bands could be identified and cleared for mobile use.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

56. As discussed above, the current planning regime does not promote the rollout of the infrastructure best suited to meet consumers' current connectivity needs. It is also worth reflecting that this process, even when successful, is incredibly time consuming. On average, it can take 18 months to build a site – and the planning regime is a significant contributor to that time. It is to note that the Government's Mobile Infrastructure Project, which aimed to build masts in mobile not-spots, had to radically scale down their ambitions, partly due to the requirements and delays associated with gaining planning consent.
57. The problems encountered trying to build new infrastructure in areas that were in desperate need of connectivity must be seen as a wake-up call. The planning system does not encourage investment in new infrastructure and hinders the upgrading of existing infrastructure. This must be addressed before the rollout of 5G.
58. Three believes that a new approach to planning regulation and processes should be explored. Again, while we continue to support Mobile UK in discussions with specific Government departments on specific changes to existing rules, we would like to see the NIC lead a strategic discussion about the direction and objectives of future planning policy.

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

59. Investment in high-capacity fibre backhaul – if access to it can be delivered on a competitive basis – will be crucial in improving 4G services and laying the groundwork for 5G.

60. Three also believes that the upcoming PSSR auction is an opportunity for Ofcom to influence investment levels in 4G and 5G networks and the associated consumer outcomes. If Ofcom continue to take a laissez-faire approach - content to sell spectrum to the highest bidder regardless of the long-term competitive impact -then the UK will fall even further behind the leading digital economies.
61. It must also be recognised that due to geographic or demographic realities, there are some areas in the UK which will never be reached by the market alone. Invention will be needed if connectivity is to be extended in these areas.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

62. The mobile market is failing, and is currently not delivering the reach or quality of services that consumers need. The NIC is right to say the UK is in the digital slow lane – and we risk falling even further behind. In particular, rural and semi-rural areas – not to mention hard to reach areas – are not receiving the service that they should. As pointed out in *Connected Futures*, road and rail networks also do not have sufficient access to data services.
63. These are not easy issues to solve. As outlined above, ensuring a competitive PSSR spectrum auction and effective action in the transmission market, must be the key priorities in relation to mobile networks. Leadership is needed to ensure the UK has a regulatory framework fit to facilitate competitive investment in all emerging communications technologies, including 5G.
64. The current fragmented nature of planning systems – and the decision-making within that – will make it incredibly difficult to roll out the infrastructure needed to provide a ubiquitous, high-quality and reliable mobile service. Scale is needed for such decision making that reflects the nature and geographic spread of the investment.
65. Three hopes the NIC will be successful with their ambitions and work closely with Governments, regulators and industry to secure the UK's 5G future

Yours sincerely,

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London
EC3M 8UD

NIAEvidence@nic.gsi.gov.uk

10 February 2017

The National Infrastructure Assessment (NIA) – call for evidence

Introduction

Tidal Lagoon Power is driving a critical change in the UK's energy mix with the development of low-cost, low carbon, predictable electricity sources that are sustainable, UK based and deliver long-term energy security for 120 years. Swansea Bay Tidal Lagoon, the pathfinder nationally significant infrastructure project (NSIP), gives the UK a necessary new energy generation option, required now and into the future if we are to secure a low carbon transition to meet 2050 emissions reduction targets, foster economic growth and competitiveness, and achieve quality of life aims. Although a tidal lagoon is a power plant, as our plans for Swansea Bay demonstrate, a tidal lagoon can deliver and enable a range of significant additional national, regional and local economic, social and environmental benefits.

We welcome this call for evidence consultation as the latest step towards preparation of a National Infrastructure Assessment.

We have previously responded to consultations by the National Infrastructure Commission (NIC); on the call for evidence on delivering future-proof energy infrastructure (8th January 2016), and governance, structure and operation (17th March 2016); the process and methodology of undertaking the National Infrastructure Assessment (5th August 2016). More recently we have submitted ideas on specific studies (2nd November 2016, relating to energy and flood risk management).

Independent Review of Tidal Lagoons

The Independent Review of Tidal Lagoons, led by Charles Hendry (“Hendry Review”) has concluded, a final report was published in mid-January 2017. The Hendry Review concluded

positively about the pathfinder project at Swansea Bay, and the potential for lagoons to make a significant contribution to the energy sector and the economy:

“tidal lagoons would help deliver security of supply; they would assist in delivering our decarbonisation targets; and would bring real and substantial opportunities for the UK supply chain.”

“they could play a competitive role as part of the UK’s energy mix”

“a pathfinder lagoon is, I believe, a no-regrets policy”

We now await the UK Government’s response to the Review’s findings.

Call for Evidence

We refer you to the Hendry Review report, which provides a comprehensive and relevant body of evidence to inform the development of the National Infrastructure Assessment. Below is some commentary in response to the key questions in the consultation paper, with cross reference to the Hendry Review report. Also, please refer to our previous consultation responses which continue to be relevant (referenced at the introduction of this letter).

Energy

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The UK’s decarbonisation commitments are challenging. By 2030 the UK will have closed 82% of its existing fossil fuel based power station capacity¹. At the same time electrification policy calls for more transport (cars, trains) and heat fuelled by electricity – all net new demand.

¹ Tidal Lagoon Power (2016) *The New Power Cost League Table: A clear view of the consumer cost of new build power stations.*

Bircham Dyson Bell (2016) *The Energy Crunch: Will decreasing capacity in UK energy cause the lights to go out?*

Decarbonising the electricity sector may be progressing better than other sectors (e.g. heat and transport), however predicted energy scenarios to 2030 (by National Grid) coupled with new demand from transport and heat sectors means that *'the search for low-carbon sources of electricity generation becomes more urgent'* (see Hendry Review section 3.3). The Hendry Review concludes that tidal lagoons would contribute positively to the UK's decarbonisation goals. A new tidal lagoon industry, established by the pathfinder lagoon at Swansea Bay, is aligned with the Government's emerging Industrial Strategy, across many of the identified pillars including *'delivering affordable energy and clean growth'*.

The Hendry Review report includes analysis of the *'valuable and cost competitive'* role of tidal lagoons in the electricity system, the value from longevity of operation, and the significant potential value to the UK economy (and regional economies) from industry², jobs, supply chain, regeneration, coastal and flooding protection.

The Green Paper *'Building Our Industrial Strategy'* recognises the importance of decisions that provide long-term certainty to investors in the renewables sector and realise opportunities in terms of securing jobs and supply chain benefits, illustrated by the success of the offshore wind industry. The Hendry Review report refers to the example of offshore wind in relation to realising the job creation and supply chain opportunities offered by a tidal lagoon industry.

Cross-cutting Issues.

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

The infrastructure investments that will realise the most value for regional economies to drive sustainable growth will be infrastructure that can realise multiple benefits. No doubt this would be recognised in a number of studies.

A recent report by the Cardiff Capital Region City Deal Growth and Competitiveness Commission³ (led by Professor Greg Clarke) provides analysis of different city region growth strategies and the relationship with infrastructure investment. The report provides a comprehensive suite of recommendations to drive forward sustainable growth of a city region; highlighting investment principles, growth sectors and specialisation potential, and the importance of energy infrastructure and assets as a driver of growth, particularly large-scale energy projects.

² *Tidal Lagoon Power (2016) Ours to Own: From First Mover to Mass Manufacture, Building a New British Industry from Our Natural Advantage, October 2016.*

³ *Cardiff Capital Region City Deal Growth and Competitiveness Commission (2016) Report and Recommendations.*

In the case of tidal lagoons, the sustainable growth opportunity will be at local, regional and national scale. As stated in the Hendry Review report *'I think it is beyond question that, in the case of Swansea Bay, local economic regeneration would follow a tidal lagoon'* (section 3.5.2). The Centre for Economics and Business Research⁴ estimates that the development of six tidal lagoon power plant in the UK, including the pathfinder at Swansea Bay, would contribute £27bn to UK GDP during construction and a further £3.1bn in each year of operation.

The UK industrial opportunity arising from tidal lagoons is addressed in some detail by the Hendry Review. With reference to *'Ours to Own'*, the immediate opportunity is for the UK's engineering, construction, steel and manufacturing industries to win contracts totalling over £800m for a world first tidal lagoon project at Swansea Bay and over £6bn for the first project to employ its template at full-scale at Cardiff. An effective partnership between industry and Government can sustain and grow this opportunity as the tidal lagoon market scales, with potential for further projects in Wales, the south west and the north west of England. On top of significant value captured through project design, services and operations, and more than half a billion pounds of investment in new UK industrial facilities, the potential value of the tidal lagoon sector to UK industry is:

- Domestic market for tidal lagoon turbines and generators: £17bn;
- Domestic market for tidal lagoon turbine housings: £24bn
- Exports to international tidal lagoon market: £30bn

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Please refer to the global opportunities set out in the *'Ours to Own'* report, and analysis in the Hendry Review.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

As our plans for the Swansea Bay tidal lagoon demonstrate, if approached in the right way, a tidal lagoon can also deliver a wide range of economic, social and environmental benefits. As the scalable blueprint and pathfinder for larger fleet lagoons, the Swansea Bay tidal lagoon is a

⁴ Centre for Economics and Business Research (2014) *'The Economic Case for a UK Tidal Lagoon Industry'*, report to Tidal Lagoon Power, July 2014.

demonstrator of the potential of tidal lagoons; a pathfinder project that demonstrates the energy potential of tidal lagoons, the multi-functional potential, and how to make infrastructure relevant and appealing to local communities, as well as providing a long-term positive legacy.

Effective engagement is central to achieving a sustainable development outcome and public support. The public support for the project is well documented (referred to in the Hendry Report). In addition to public support, the integration of the Swansea Bay tidal lagoon with strategic initiatives in the region is an endorsement that tidal lagoons can support long term economic development and regeneration to create better places to live and work. The project is considered a catalyst for regeneration in the Swansea Bay city region. Local development plan policies are focused on *'capturing the benefits of the planned Tidal Lagoon'* to regenerate the waterfront and attract investment for offices and homes.

5. How should the maintenance and repair of existing assets be most effectively balanced with construction of new assets?

The Hendry Review report includes analysis of the longevity benefits (such as security of supply and cost effectiveness) of tidal lagoons that are maintained to operate for 120 years.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Competition, collaboration and the potential for tidal lagoons to be hybrid infrastructure (across sectors) are all matters considered by the Hendry Review, therefore please refer to the report.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Please refer to the Hendry Review, particularly part 2, and section 12 on financing structures.

9. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Please refer to section 11.2 of the Hendry Review for commentary on the role of policy and process in supporting the consenting of infrastructure.

In previous correspondence we have referred to the importance of working with the Devolved Administrations on the matter of UK infrastructure (e.g. NSIPs situated in Wales). For instance,

there are distinct issues for consenting NSIPs in Wales (if this is a matter that NIC are able to consider further, we can provide more information, other infrastructure developers, the Royal Town Planning Institute and the National Infrastructure Planners Association may also be well placed to advise).

10. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Accelerating progress towards decarbonising the economy, including energy and transport sectors, meet decarbonisation targets will have a strategic contribution to protecting the natural environment. This is commonly understood, though not directly integrated with policy on protecting and enhancing the natural environment (therefore logic is often lost when it comes to local level implementation).

Planning policy provides clear frameworks for decision-making to ensure sequential steps are taken to minimise, mitigate, compensate and offset impacts, particularly in the case of priority habitats and species. Enhancement opportunities should also be encouraged, for example our Ecosystem Enhancement Programme⁵. Increased strategic integration of infrastructure planning with planning for the natural environment may be a way to facilitate such opportunities (see also response to questions 25 and 26).

Flood risk management

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

We were recently involved in the workshop held by the NIC on flood risk management. There is an important difference between resilience to flood and coastal erosion events, and the management of flood and coastal erosion risks. It is unclear if there is a common understanding of how resilient the UK is now to events that could cause flooding and coastal erosion, which in turn could damage property and infrastructure, cause significant economic disruption (especially true given dependencies on infrastructure), and risk to life. Understanding the baseline situation must be the starting point, including what the main vulnerabilities are, where

⁵ *Tidal Lagoon Power (2016) Ecosystems Enhancement Programme: Strategy, June 2016.*

they are, and how they might change with the effects of climate change. It is a cross-sectoral issue (relevant to transport, energy, water etc) and for public and private sectors.

There are multiple drivers to developing natural flood risk management, which means it has significant cost avoidance merits. Natural flood risk management is capable of being delivered by different sectors if plans are pulled together to identify priorities and coordinate action. For example, energy infrastructure providers may wish to invest in natural flood risk management schemes as a way to address environmental impacts⁶, water and wastewater industry may wish to invest in upper catchment initiatives, agriculture sector could be incentivised to invest in schemes through a post BREXIT settlement.

Innovation should also mean looking at alternative solutions. Tidal lagoons can act as a barrier to potentially damaging and disruptive storm surge and waves that threaten coastal communities and infrastructure vulnerable to flooding and coastal erosion, likely to be exacerbated by climate change and sea level rise⁷. Tidal lagoons:

- Are designed to be resilient to at least 1 in 500 year storm surge and wave;
- Have an asset life of 120 years, with the ability to increase the height of the structure to adapt to sea level rise;
- Have the potential to support FRM with the operating cycle.

Also, Tidal Lagoon Power's model for delivering lagoons includes creating a strategic network of wetlands through managed realignment along the coast, a natural approach to coastal protection and flood risk management.

Please note that the Hendry Review report also includes analysis of the potential of tidal lagoons to support flood risk and coastal erosion management.

Tidal Lagoon Power welcomes further engagement involvement with the process of preparing the NIA. If you have any queries, wish to discuss further or be provided with further information (as indicated in this letter), please contact me at [telephone number redacted] or [email address redacted].

Yours faithfully,

⁶ See response to question 10, and the EEP strategy.

⁷ See appended report on how tidal lagoons can support flood risk and coastal erosion management.

NIA Call for Evidence
National Infrastructure Commission
11 Philippot Lane
London
EC3M 8UD

10 February 2017

Dear Sir / Madam,

The National Infrastructure Assessment: Call for Evidence

We are pleased to respond to the National Infrastructure Commission's call for evidence for the National Infrastructure Assessment. This assessment is crucial to infrastructure planning and the long-term success of the UK economy.

Our response focuses on a small number of questions where we can offer insights based on our experience. The Tideway model was developed in response to unique circumstances (for example in relation to construction complexity, size of investment, and risk profile) but could provide lessons that are applicable more widely.

The response is high-level but we are happy to discuss any part of it further with the National Infrastructure Commission. Please do not hesitate to contact me if you have any questions or would like to arrange a further discussion.

Yours faithfully

3

How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Given the importance of infrastructure to the UK economy, it is important that it is planned and delivered in a way that maximises value for money. Beyond the direct costs and benefits of the infrastructure there are a number of considerations that need to be taken into account, including economic and social sustainability (for example minimising lorry movements in peak hours during construction to minimise disruption).

Design and planning processes need to take into account the balance between the long-term benefits of the infrastructure and the short-term disruption and other construction impacts. In the case of the Thames Tideway Tunnel (TTT), the long-term benefits accrue to a wide group of people (for example all those who live in or visit London over the next 100 years or more) and a much smaller group of people are affected by construction impacts (largely residents close to Tideway's construction sites).

Broad and deep consultation is crucial to ensuring that this balance is considered and the right infrastructure is delivered in the most efficient way. For the TTT, there were 114 days of public exhibitions and over 200 meetings held across London as part of the planning process. Consultation should cover the need for the infrastructure, the solution, and then design and delivery. Helping people understand the need for the infrastructure is important for facilitating a smooth delivery. For the TTT, the Development Consent Order (DCO) phase 1 consultation focused on the need and the solution. Consulting at this stage also ensures that the infrastructure delivers the required functionality.

Furthermore, it is important to include people living where the infrastructure is built and operated so they have a chance to feed in their views. When designing and planning, consulting those affected can lead to better value for money. The approach to the TTT was influenced by the DCO consultation process in two important ways: firstly to move construction sites from greenfield to brownfield sites where possible, and secondly to increase the proportion of construction materials and excavated material moved by river.

It is also important that infrastructure is not designed and planned in isolation so that value for money can be assessed in the round and efficiencies and synergies can be realised. For example, joined-up planning at an early stage led to changes in the design of the TTT to allow it to connect to the Lee Tunnel, which saved nine kilometres of tunnelling with knock-on cost and carbon savings of around 200,000 tonnes CO₂e and reduced disruption. Joined-up planning between similar projects may also drive higher productivity, for example by facilitating skills and knowledge transfer between projects.

In relation to the wider benefits of infrastructure, a number of obligations related to the project's legacy after the tunnel is constructed were volunteered by the

project and included in the DCO. In addition to this, Tideway has published a Legacy Statement which outlined a wider set of commitments that will ensure that we deliver a lasting legacy for London. We are now delivering against these commitments.

Our commitments include

- delivering an infrastructure that supports a more resilient biodiversity (on top of the direct environmental benefits of reducing the sewage discharges on the Thames);
- delivering three acres of new public realm along the foreshore: enhancing the Thames Path; and collaborating with local developers to enhance local space where our activities overlap;
- specific economic legacy benefits for London, including to the river economy and local businesses; and
- specific skills legacy: for river skills by supporting the launch of the Thames Skills Academy; for apprentices (1 in 50 commitment) and for the next generation of engineers through our STEM (science, technology, engineering and mathematics) programme.

We have outlined our legacy aims and objectives, and updated on the progress of our legacy delivery, through a dedicated section on our website and our Annual Report.

The integration of these commitments into planning, design and delivery supports the creation of better places to live and work. Building environmental considerations into planning conditions and then cascading these obligations into construction contracts is important to protect from cost-cutting or programme pressures during delivery. Obligations should be set on an outcomes basis where possible, to allow flexibility for efficient delivery, and should be consistent with current best practice to ensure they are appropriately stretching.

As discussed in our response to question six, competition can be used to ensure value for money, both in relation to construction costs and financing. It is important to consider how the timing of procurements relate to the planning process. This will depend on who is best placed to manage the planning process and bear the associated risk.

6 What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Both competition and collaboration play a role in the Thames Tideway Tunnel delivery model. To ensure best value for money, both the financing and construction (main works) contracts were competitively procured. The procurement of the financing was an innovative approach introducing competition for the market resulting in an overall lower cost to customers. For the main works procurement process, the works to be delivered were divided into three packages (West, Central, East) to create package sizes that were readily biddable by a wide field of contractors and to spread delivery risks.

The project also has a number of collaborative elements. Firstly, the project involves working closely with Thames Water, whose network the tunnel will be connected to once operational. Once completed, the above-ground assets, structures and equipment will be transferred to Thames Water leaving the main tunnel, connection tunnels and shafts under the Tideway's ownership. Thames Water will operate the Thames Tideway Tunnel, while Tideway will maintain and make available the deep tunnels and shafts.

Tideway has also established an overarching Alliance in order to manage and incentivise collaborative working between Tideway, its contractors and Thames Water. The aims of the Alliance are to realise the sharing of best practice, synergies between activities and the benefits of economies of scale.

Prior to commencing detailed design and construction work, an optimised contractor involvement process took place, with the purpose of providing an opportunity for the Alliance members to review the specification, information and interfaces to realise synergies, programme savings and risk mitigation. The result of this process was the identification of a number of concrete opportunities to maximise value for money, for example in marine logistics savings related to spoil disposal. In addition, the optimised contractor involvement process provided the opportunity to develop a plan to optimise and de-risk the construction programme. These plans are currently being implemented and have already led to the works starting on-site ahead of schedule.

The optimised contractor involvement process also provided the opportunity for the Alliance to review and enhance its strategy to maximise the use of the river for logistics, an initiative known as 'More by River'. Tideway believes this strategy brings several benefits, including minimisation of disruption to local communities which will facilitate the consenting process, enhanced health and safety performance due to reduced HGV use and minimisation of environmental impact with respect to carbon emissions.

Tideway is committed to continuous improvement in environmental sustainability and has joined the Infrastructure Carbon Review, a joint government and industry initiative to support carbon reduction in infrastructure.

In addition, Tideway is working with its Alliance and the wider industry to deliver a sustainable legacy of innovation by capturing and sharing our solutions via

The Great Think, hosted on i3P (Infrastructure Industry Innovation Platform).
This is intended to support the UK Construction 2025 vision of an industry that is
efficient and technologically advanced.

7 What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Infrastructure can be funded by customer charges, government, or a combination of these sources, and the source of funding may differ from the source of financing. Where infrastructure is primarily funded by customers, it is generally accepted there will be a role for regulators (in determining funding) and/or government (either in funding elements of the infrastructure or supporting efficient financing, as set out in our response to question eight).

One way in which funding policy can affect efficiency of delivery is through the arrangements established for the funding of the development phase of the project. Appropriate incentive arrangements should be put in place to address development phase risk and provide incentives for efficiency.

Funding policy during the delivery phase can also affect efficiency through its impact on financeability and the cost of finance. Well-developed and predictable regulatory funding arrangements are important. As set out in our response to question 10, the Tideway delivery model was developed collaboratively between Ofwat, government and Thames Water, with market testing of the arrangements.

Tideway benefits from a bespoke regulatory regime, which is based on the existing framework for the water sector with adaptations for Tideway's unique circumstances. In addition to the regulatory mechanics included in Tideway's licence, Ofwat has issued economic guidance which sets out the approach it intends to take in making determinations, including in determining the ongoing weighted average cost of capital (WACC) during the operational phase.

Providing a yield during construction improves financeability through attracting certain classes of investors. For example, Tideway receives a regulated revenue stream during the construction period based on a series of building blocks set out in its licence, which contributed to the 2.497 per cent competed WACC.

Tideway is not subject to periodic reviews during construction. Setting price controls to match the longer duration of projects (rather than the five year cycles of some regulated industries) reduces political and regulatory risk for investors and helps reduce the cost of finance. In the operational phase, Tideway will fall into the water industry periodic review cycle.

Furthermore, there are clear arrangements for the funding of the project under a variety of circumstances. Tideway's licence includes mechanics to address delay/overrun (as well as to incentivise delivery under budget). This regulatory certainty promotes efficient financing.

Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

In certain circumstances, risk could lead to projects not being financed, or not being financed efficiently, in particular if it is not allocated appropriately or adequately rewarded. It is important to consider what risk the market will bear and where this can be most efficiently allocated through a process of market testing. For Tideway, this process involved both consultation of the rating agencies and soft market testing.

There may be particular difficulties around the financing of greenfield projects as risk is likely to be higher than for brownfield projects. Construction risk may mean target cost contracts are more suitable than cost pass through contracts for greenfield projects. In turn this may increase risk to investors, mean the risk is difficult to price, or even lead to a lack of interest in financing the investment. Careful consideration should be given to the risks associated with projects and the overall package of legal, political, regulatory and commercial arrangements. In the case of Tideway, the design of the regulatory regime, contractual arrangements and the government support package provided a platform for the efficient pricing of finance.

Tideway's innovative delivery model was designed to mitigate some of the project's specific risks and make the project attractive to deep and liquid infrastructure investment. The design of the arrangements and the competitive procurement process led to a bid cost of capital of 2.497% for the period to 2030.

Various aspects of the Tideway delivery model have contributed to the efficient financing of the project including:

- regulatory framework that addresses some of the project's characteristics. Key elements of the framework include the provision of funding during the construction period and regulatory mechanics to address delay and/or overrun (as well as to incentivise delivery under budget); and
- government support package (GSP). The government will support Tideway in a limited number of carefully defined extreme circumstances that the market is not able to price efficiently.

The GSP improved the financeability of the project by mitigating the impact of low probability but high impact risks. Similar government interventions for infrastructure projects facing high impact-low probability risks might improve financing without distorting well-functioning markets, particularly where market testing indicates the market will not bear the risk efficiently. There may also be opportunities to introduce risk-sharing mechanisms with customers, where infrastructure is funded by users.

Government might also intervene by providing leadership during the development phase for the infrastructure, by ensuring arrangements to improve financing are developed. The appropriate scope and extent of government's role

In this process is likely to depend on the infrastructure in question and the policy and regulatory framework within which it is being built. Regardless of the exact form of government intervention, it is important for there to be collaboration between all parties involved, which may include government, one or more regulators, incumbent companies, investors and others.

10 **What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?**

Planning permission for the Thames Tideway Tunnel was granted under the Planning Act 2008 through the Development Consent Order (DCO) process. Tideway supports the aspirations of the Planning Act 2008 to optimise the planning process and reduce delays in planning, which proved beneficial for the project. For example, the naming of the Thames Tideway Tunnel as a Nationally Significant Infrastructure Project (NSIP) ensured the planning process could focus on how the project would be delivered rather than whether it should go ahead.

The Planning Act 2008 streamlines the process for getting planning permission, as although there are more steps before submission of the application, once the application has been submitted there is a fixed two year timetable. For Tideway, this created a helpful level of predictability which allowed for efficient planning and staffing of the organisation.

In order to ensure infrastructure is delivered as efficiently as possible, it is important for government to feed into the process at an appropriate time (e.g. with any required primary or secondary legislation, or other policy documents). Timely government involvement helps to minimise costs by avoiding delays to the development phase.

The Thames Tideway Tunnel project was developed in a governance framework involving government, Ofwat and Thames Water (among others). Close collaboration over a number of years allowed the delivery model for the project to be developed in line with the needs of a number of stakeholders, aided by the tension between the interests of the different parties. The discussions drew on evidence and experience, including previous regulatory arrangements, and included a process of market testing. Regulatory and political commitments also formed a key part of the process. These features ensured value for money for customers.

During the construction phase, the delivery of the project is subject to government oversight through a "Liaison Committee" comprising government, Tideway, Thames Water and the Environment Agency. The oversight stems from government's role in providing a support package (as described in our response to question eight), and is an efficient way of allowing government to monitor the project with pre-agreed reporting and governance arrangements. Agreeing reporting and governance arrangements up-front for projects where government has an interest could be replicated in similar projects.

Another element of planning and governance is the use of independent bodies, which promote credibility of the project and contribute to efficient delivery. For the Thames Tideway Tunnel, compensation under the project's non-statutory compensation policies are governed by an Independent Complaints Panel (ICP). The project also has an Independent Technical Assessor (ITA), which has a duty

to review, evaluate, comment, verify and advise on various issues including Tideway's reporting.

Transparency is important for infrastructure projects, particularly where the infrastructure is government-funded or the provider is not subject to competition. For example, transparent and appropriately assured annual reporting is important to Tideway, including transparent disclosure of governance arrangements in line with best practice.

11 How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The provision of additional infrastructure is one possible route to protecting and enhancing the natural environment. Different approaches may be most appropriate in different circumstances and may include large infrastructure projects, small infrastructure projects, or non-infrastructure solutions. It is important for decisions to be taken on a case-by-case basis with careful consideration of the options. In the case of the Thames Tideway Tunnel, the infrastructure solution provided best value for money to clean up the River Thames.

The Thames Tideway Tunnel is a major new sewer, urgently needed to protect the tidal River Thames from pollution. London's sewerage system is no longer fit for purpose and spills tens of millions of tonnes of sewage into the tidal section of the river every year. The sewers built by Sir Joseph Bazalgette in the 1860s form the backbone of London's sewerage system today. They are in excellent working condition, but have simply run out of capacity. Built when London's population was two million and designed for four million, they are now struggling to serve a capital city with more than eight million people; a figure that continues to rise. After years of study, the Government decided a new 25 kilometre interception, storage and transfer tunnel running up to 65 metres below the river was the best solution.

In addition to direct environmental benefits of the infrastructure itself, legacy commitments can usually be integrated into the planning and design of an infrastructure project in such a way as to include environmental protection or enhancement with those commitments.

In addition to the more obvious commitments or obligations (for example, for quality, integrated design of physical structures, or for environmental protection measures during construction) large infrastructure projects can best protect and enhance the natural environment by being encouraged to take a wide perspective from the outset, looking over and above their basic remit. Tideway has worked closely with a number of organisations, including London Boroughs, English Heritage, the Environment Agency and the Port of London Authority, to understand existing issues and how the project can contribute.

Our vision is to 'reconnect London with the River Thames'. This has informed how we are approaching the project, supporting activities and projects that encourage communities to engage with / use the river and which raise awareness about its health. One example is Thames River Watch, a 'citizen science' project run by environmental charity Thames21 and funded by Tideway. This project trains members of the public to collect water quality and litter surveys from the Thames and the data is used to raise awareness of issues around the health of the river.

To whom it may concern.

The Torbay Council welcomes the opportunity to respond to the National Infrastructure Commission (NIC) call for evidence for its national infrastructure assessment.

The TC adopted its Local Plan 2012 to 2030 in December 2015 which provides a policy framework for the proposed Torquay, Paignton and Brixham Peninsular Neighbourhood Plans currently being prepared. Local Masterplans that have been adopted for key growth areas will help deliver the policies of the Local Plan at a detailed level. The Council is working with partners to deliver sustainable infrastructure and develop resilience within its boundaries whilst creating a prosperous and healthy bay and a council fit to meet the challenges of the future. The Council has plans in place to create more and higher value employment in Torbay and will be looking to secure further investment in the right infrastructure, business support and skills for economic growth. Our response to this call for evidence is focused around transport requirements, energy efficiency and generation opportunities and flood resilience measures to achieve the benefits identified above.

Flooding and weather extremes

Torbay has suffered from severe weather incidents over the last few years which has highlighted the poor resilience of our local infrastructure, culminating in the events of flooding cliff collapse, seawall and harbour damage and rail network closure.

Torbay Council is the Lead Local Flood Authority (LLFA) for the Torbay as defined by the Flood and Water Management Act 2010. It has responsibility for managing local flood risk from [surface water](#), [ordinary watercourses](#) and [ground water](#) and is required to investigate all significant flood events (more than 5 properties internally flooded during a storm event). The responsibility for [consenting and enforcement on ordinary watercourses](#) within Torbay has also transferred from the Environment Agency to Torbay Council under this act. The council maintains, applies and monitors a Local Flood Risk Management Strategy (LFRMS) to address potential flood risk arising from local sources.

The occurrence and severity of flooding in Torbay has increased over recent years. Torbay is exposed to the combined potential flood risk from main river (formerly critical ordinary watercourses), tidal and coastal flooding. Both the urban drainage systems and surface water run-off also contribute significantly to the historical flooding within Torbay. In recent years flooding from surface water run-off, main rivers, ordinary watercourses, combined sewers and highway drainage has occurred in Torquay, Paignton & Brixham.

The majority of the flooding affected coastal areas of Torbay was due to overtopping of coastal defences. In many areas this flood water resulted in the closure of highways, many of which were closed during every storm event. In addition to the flooding across the whole storm period, a considerable number of fallen trees and branches on Torbay's roads, together with three embankment slips caused as a result of saturated ground and excessive rainfall

Transport infrastructure

Torbay Council will continue to enhance partnership working through the Peninsula Rail Task Force and Network Rail to further develop resilience and connectivity to ensure that the impact future extreme weather events are reduced

Transport spending in the South West peninsula is trailing behind other areas in investment, a situation that will only get worse as a result of current and planned UK rail infrastructure projects.

Torbay is served by the single mainline running west of Exeter and was severely economically impacted upon by the well reported impacts of flooding on the Somerset levels, the collapse of the seawall at Dawlish and the landslip between Dawlish and Teignmouth. Torbay as a key partners in the PRTF supports the view that the South West peninsula has suffered from under-investment in the railway network, with a resultant loss of quality, reliability and contribution to the peninsula economy. Our trains are some of the oldest in the UK, with an average age of 32 years old and currently unable to meet the regulatory requirements from 2020.

Rail growth over the last 21 years has reached 128%, and continues to grow. It is clear that both network and train capacity will not be sufficient in the future. Growth in rail travel within the region has outstripped industry forecasts, with average growth of 5.7% over the last 7 years, anomaly means that capacity will not be planned and delivered early enough to meet predicted demand. An example of this variation for 2014-15 saw passenger numbers rise by 8% within Devon and 13.1% to Torbay.

Torbay Council has recently invested £0.5M in developing plans for a new station located close to Torquay Gateway Future Growth area. Awaiting national funding to deliver the project the authority is linking new transport infrastructure with housing development. Rail and bus improvements have been delivered in recent years contributing to travel to work improvements.

Major road infrastructure projects in Torbay have recently included Western corridor and the £110M South Devon Highway which all contribute towards the long term economic development of Torbay by providing fast and reliable connectivity to national and international markets. Local travel to work studies have been based on 2001 census

data. The Council wishes to support other local authorities in the development of solutions to the A303.

Paignton railway and bus station redevelopment and town centre regeneration is being considered by the Council, NR and private developers.

Energy efficiency and generation

Torbay Council wants to accelerate the development, use and value of its energy resource, energy efficiency potential, and capitalise on its natural and physical assets by working with a partner/s to develop a way forward. The Council's new Efficiency Plan wishes to create an infrastructure investment portfolio that generates a return on investment. In the current market it is unlikely that energy projects would give a quick return on investment, but they may well be able to generate long term revenue of significant value to the Council. The viability and revenue generating capacity of projects will need to be confirmed by going out to the market and 'soft testing' any proposition.

Work on district heating networks in Torbay, as well as regional work on offshore wind, wave and tidal technologies show that there is currently limited scope for large scale deployment schemes. There is, however, some generation capacity, investment potential and market interest in solar PV in Torbay.

Solar PV projects could provide a modest income, support local supply chains and further enhance the security of Torbay's energy supply. Energy efficiency measures to reduce fuel poverty and improve wellbeing whilst stimulating demand from local installation businesses could be an area worth investing in. However, direct financial benefits are difficult to assess and the Council would not be able to generate cashable incomes. Renewable heat in the domestic and non-domestic sector supports both local supply chains and energy security with limited income potential.

Beyond renewables the decarbonisation of the UK's energy market will require the development of smart energy systems. Electricity storage could be used to reduce exported energy from distributed generation and reduce the load on the grid and entrepreneurs are already investigating the potential for 'energy barns' where rent is paid to landowners for hosting buildings with large banks of batteries. While it is possible that Torbay could host such facilities the lack of large scale renewable capacity means that there is no obvious reason why it would be a preferred location.

The highest value solution for decarbonising heat, for both commercial and domestic consumers is a mix of renewable technologies and investment in heat networks.

Torbay Councils Energy and Climate Change Strategy includes a short, medium and long term action plan considering a wide range of technologies that would contribute towards the aspiration of a zero carbon power sector.

Masterplan and Neighbourhood planning

These Council owned town centre sites are being promoted for private sector investment to deliver transformational regeneration schemes. A range of opportunity sites have been identified in Torbay including Brownfield sites, business parks, innovation centres, squares, plazas and harbours.

Delivery of improved digital infrastructure

Torbay DA is working to secure improved broadband speeds and capacity.

Waste disposal

The EFW plant in Plymouth is used for disposal of Torbay's residual waste and this method is secure for at least 30 years, but recycling position is less secure. The main problem with recycling is that central government pass the responsibility to the local authority to find the solutions and continually improve its performance. There is little effort to make the producers pay for the end of life items they make. For Instance Mattresses and Carpets are increasingly difficult to either find a market for, and often cost significantly more to dispose of than to recycle.

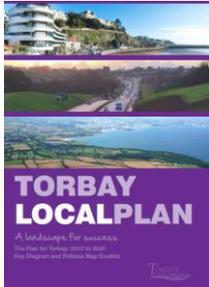

Basically if it is cheaper to dispose of than recycle why in such times of austerity would authorities make the more expensive choice.

The barriers to a circular economy are purely cost based and as said above if it is cheaper to dispose of goods than recycle then there is only likely to be one option. Unless central government put more pressure on producers (Producer pays principle) then it will be difficult realistically to improve recycling rate much beyond current rates. European countries like Germany support recycling in a more forceful way than our government and with legislative support to force people to recycle more progress will continue to be minimal.

Torbay Local Plan 2012 to 2030 Published

Torbay Council has published its new Local Plan which forms part of the development plan for Torbay and provides the basis for decisions on spatial planning within Torbay up to 2030.

*The **Torbay Local Plan 2012 to 2030 – A landscape for success** can be [viewed online](#) or purchased as a hard copy or USB memory card. Card payments will be accepted via 01803 207801 quoting the ‘new Local Plan’.*

To whom it may concern

I would be grateful if you could add the following to the response from Torbay Council.

Flooding and weather extremes

Torbay has suffered from severe weather incidents over the last few years which has highlighted the poor resilience of our local infrastructure, culminating in the events of flooding cliff collapse, seawall and harbour damage and rail network closure.

Torbay Council is the Lead Local Flood Authority (LLFA) for the Torbay area as defined by the Flood and Water Management Act 2010. It has responsibility for managing local flood risk from [surface water](#), [ordinary watercourses](#) and [ground water](#) and is required to investigate all significant flood events (more than 5 properties internally flooded during a storm event). The responsibility for [consenting and enforcement on ordinary watercourses](#) within Torbay has also transferred from the Environment Agency to Torbay Council under this act. The council maintains, applies and monitors a Local

Flood Risk Management Strategy (LFRMS) to address potential flood risk arising from local sources.

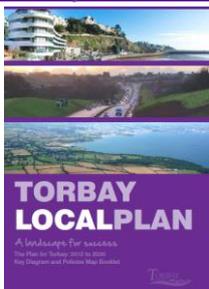

The occurrence and severity of flooding in Torbay has increased over recent years. Torbay is exposed to the combined potential flood risk from main river (formerly critical ordinary watercourses), tidal and coastal flooding. Both the urban drainage systems and surface water run-off also contribute significantly to the historical flooding within Torbay. In recent years flooding from surface water run-off, main rivers, ordinary watercourses, combined sewers and highway drainage has occurred in Torquay, Paignton & Brixham. In addition overtopping of coastal defences during Easterly storm events has resulted in significant flooding affecting coastal areas of Torbay.

In many areas flood water has resulted in the closure of highways, many of which have had to be closed during every significant storm event. In addition to the flooding, during storm events in recent years the highway network within Torbay has been affected by a considerable number of fallen trees and branches, together with three embankment slips caused as a result of saturated ground and excessive rainfall.

Transport for the North's Submission to the National Infrastructure Assessment - Call for Evidence

Context of Transport for the North

Transport for the North (TfN) is empowered by a pan-Northern Partnership Board representing political and business leaders from all 11 Local Enterprise Partnerships (LEPs) across the North, working together with Highways England, Network Rail, High Speed Two (HS2) Ltd and the Department for Transport (DfT). Under the provisions of the Cities and Local Government Devolution Act, TfN has submitted a proposal to become the first Sub-national Transport Body in England, with the expectation to gain statutory status in 2017.

TfN allows the North to speak with a collective voice on its strategic transport priorities, providing a crucial role, adding substantial value through enhancing the existing relationships between local and central government, whilst filling an important gap to plan and deliver the connectivity across the North required to underpin transformational economic growth. The outcomes of this approach is a stronger performing, coordinated pan-Northern economy where people and business can fulfil their full potential.

Through collaborative working with government, business, industry, and academic partners, TfN is currently developing a Strategic Transport Plan for the North. This will include an accompanying long term, sequenced Investment Programme, in order to align transport investment across the North in pursuit of delivering the economic objectives of the Northern Powerhouse. As part of developing the first version of the Strategic Transport Plan, TfN is pleased to respond to the Commission's Call for Evidence. The responses are limited to those questions that directly relate to TfN's ongoing activities within its current role and remit.

We would also like to make the Commission aware that during 2017, we will be publishing a range of information and evidence supporting the Draft Strategic Transport Plan, as referenced in the responses to the questions that follow. Much of this evidence is not available at the time of this submission, but we will share this evidence with the NIC at the most appropriate time, as we feel that it will assist the Commission with its task of preparing the first National Infrastructure Assessment (NIA) over the coming months.

Response to Call for Evidence

Q1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

The success of the UK in the global marketplace, and the achievement of the Government's Industrial Strategy, will be dependent on the transformation of the Northern economy. The Northern Powerhouse Independent Economic Review, published in June 2016, provided the first ever pan-Northern economic analysis and demonstrates how investment in transport can stimulate and sustain economic prosperity.

The Review set out that by 2050, in a transformed North:

- **GVA would be 15% (£100 billion) higher than business as usual projections;**
- **Productivity would be 4% higher; and**
- **850,000 additional jobs would be created.**

The Review also identified the world class, international prime and enabling capabilities that contribute around 23% of the North's GVA, that if supported can grow, increase productivity and create more jobs. Achieving this would have substantial benefit to the UK economy.

Specifically, the Review identified that improving connectivity is key to seizing the economic prize, making the North a more attractive and buoyant marketplace, and hence investment in transport infrastructure is of particularly "high value" in supporting long term growth.

Improving pan-northern connectivity is the most critical issue facing the North's ability to transform its economy. TfN wants to deliver more efficient, reliable, resilient and faster strategic transport networks that are better integrated with spatial and economic policies. This is about delivering the enabling infrastructure that will stimulate and sustain economic growth and improve productivity.

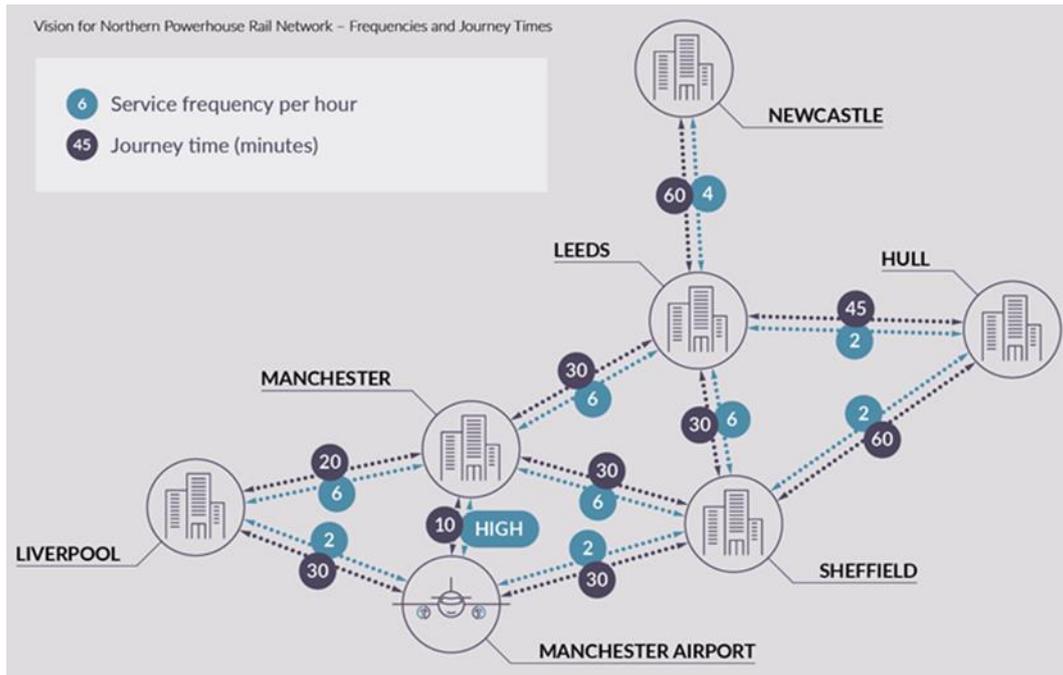

Strategic, pan-Northern transport investment to support the transformation growth scenario would also complement the Government's recently published Green Paper on its Industrial Strategy. This identified the importance of infrastructure, such as transport to drive growth and support businesses and trade, making the most of the North's world-leading sectors. Transforming the Northern economy will also require investment in a number of other critical areas, especially skills, innovation and inward investment, alongside transport infrastructure and services.

The North's businesses and local political leaders have set out the benefits of increased investment in connectivity across the North, starting with the **One North** prospectus in July 2014, through to the publication of the **Northern Transport Strategy** in March 2015, and subsequent **Spring 2016 Update**. All of these documents clearly set out how vital transport infrastructure is to drive the transformational economic growth to which the North aspires.

As highlighted in the Northern Transport Strategy in March 2015, we can see how an efficient and effective transport system in the Northern European urban areas of the Randstad and the Rhine-Ruhr unite smaller cities into one economic area and increase overall performance. Faster, more frequent and more comfortable trains will connect city centres to each other and to the rest of the country.

The need for faster and more frequent rail travel across the North was recognised by the Commission in Recommendation Two of the **High Speed North** Report in March 2016. TfN and its Partners welcomed this, with work now progressing to develop **Northern Powerhouse Rail (NPR)**. Northern Powerhouse Rail will provide the essential core for the North's rail network, potentially serving and connecting 15 economic centres, with faster, more frequent, resilient and reliable services. Northern Powerhouse Rail has the potential to:

- Change the way labour markets work, where people live and work and how businesses collaborate and will enable the North to attract and retain the people and skills it needs;
- Integrate with High Speed Two (HS2) to maximise connectivity and demand on the planned new fast north south connections. Northern Powerhouse Rail and HS2 will together deliver the North's vision of city to city links, both east-west and north-south;
- Improve access to Manchester International Airport from across the North to enable it to act as a global gateway for whole of the North of England; and
- Free up capacity for other rail services including local and commuter passenger trains and greater east west freight capacity supporting current and planned private sector investment in Northern ports.

A world-class rail network will make journeys more frequent, faster, more reliable and less-crowded, as well as ensuring it can accommodate and support growth in all sectors. It is essential for the North's economic growth ambitions to be realised.

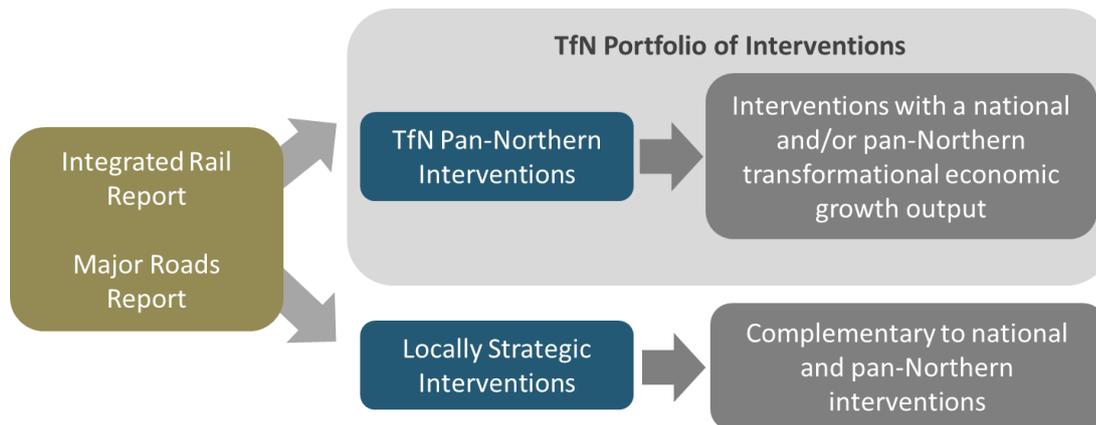

However, in addition to NPR, the need to improve the North's transport infrastructure is no longer being debated by our Partners. They understand why it needs to happen and, therefore, TfN is now focused on establishing the solutions needed and the most effective means for delivery.

TfN is aiming to publish the Draft Strategic Transport Plan and Investment Programme for public consultation in Autumn 2017, alongside the establishment of TfN as a Sub-National Transport Body. When adopted in 2018, the Strategic Transport Plan will become the statutory document for TfN, defining the priorities of TfN as a Sub-National Transport Body, and containing the most up-to-date version of the Investment Programme.

The Strategic Transport Plan and Investment Programme, and its supporting evidence, will be used to agree with Government, Network Rail, Highways England and HS2 Ltd the investment priorities that would transform the economy of the North. This Plan will be a multi-modal plan that sets out an evidence-led case for investment, focusing on smart ticketing and integrated travel, major highway improvements, pan-Northern rail enhancements, strategic access for freight and logistics, and interventions to support international connectivity. It will have a wide ranging and ambitious scope, setting out a portfolio of strategic transport investment interventions to transform economic performance up to 2050.

TfN's Investment Programme will represent the set of prioritised and sequenced transport interventions that are required to deliver transformational economic growth across the North. To that end, they should all be considered as "high value" and important.

In developing the Strategic Transport Plan, between now and Autumn 2017, TfN will also be working closely with its Partners to take forward the extensive and innovative evidence base that has been developed, and to confirm that this is sound and robust for developing the long term TfN Investment Programme, comprises a mix of pan-Northern and more local interventions, as shown below:

Q2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

The North is aiming to increase international business activities, including global trade, inward and outward investment, to deliver its transformational economic growth objectives. Improving international connectivity can make a substantial contribution to increasing productivity and supporting effective agglomeration through global proximity.

In 2016 TfN's Chair, John Cridland CBE, launched an Independent International Connectivity Commission of business experts to identify the international connectivity needs of the North, taking into account the needs of key capabilities and the opportunities arising in global markets.

The North's airports handle 15% of the UK's airport passengers (39.6 million air passengers per year up to October 2016). International passenger connectivity contributes £5.5 billion towards the North's GVA. This is 1.7% of the £317 billion GVA contributed by the North to the UK economy. Achieving the targeted NPIER transformational growth will require the economic contribution of international connectivity to grow and air connectivity to become more of a priority than it is today, reaching £13 billion, £2.1% of GVA. This would require passenger's in the North to reach 75 million per year by 2050, 90% of which would be via direct routes. An increase in direct routes would also see an increase in high value bellyhold freight from around the world. The Commission highlighted the need to harness a capacity, available now, of 60 million across Northern airports to support this growth.

Northern ports directly contributed (through both global and domestic freight) £1.5 billion, or 20% of all GVA generated by UK ports (£7.7 billion) in 2014. This represents a contribution of 0.5% to the North's GVA in 2016. TfN is currently undertaking further work on the opportunities of freight and logistics in the North. It is clear that Northern ports can play a key role in the transportation of goods across the North and the UK. Improving East-West connections would make the business of trade more cost effective and reduce congestion of North-South distribution routes. Both airport and port GVA contributions noted here do not account for the wider business and leisure supply chain impacts across the North.

The Independent Commission believe that transformation will not be achieved by simply continuing to trade with our traditional partners and markets. They noted a key issue for the North is how to secure innovation and open up new markets, as well as attracting new sources of foreign direct investment FDI. Particularly in the context of Brexit, achieving transformational growth will require businesses to maintain important links to traditional core partners in Europe and North America,

but also be able and willing to trade with more distant markets which are forecasted to see growth in trade, FDI and business travel.

The Independent Commission recently published its recommendations to improve the North's access to the global economy through its ports and airports, stating that, in order for the North to achieve transformational economic growth, there should be:

- More support of the North's highly productive, internationally regarded prime and enabling capabilities as set out in the Northern Powerhouse Independent Economic Review, many of the sectors that will drive growth have a higher dependency on international connectivity and travel than more traditional sectors;
- Beneficial consequential effects on the supply chain across the North;
- Agglomeration effects from faster more reliable connections between key areas of employment;
- Improvements in both productivity and a higher employment rate;
- Improvements to the North's position in the global market place through profile raising activity; and
- A leveraging of the benefits of a higher income population in to private and public services.

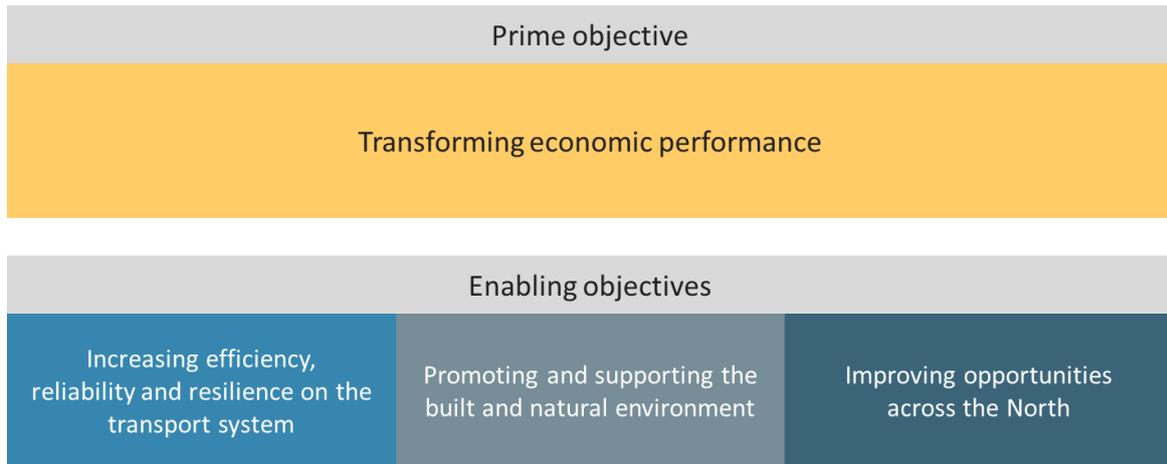

The Independent Commission's report makes it clear that enhancing global connectivity starts on the ground, and sets out the key landside enablers for ports and airports. The North's ambitions for improved global connections would increase the proportion of trips which have the choice of direct international connections from the region's airports and ports. Improving surface access to these key international gateways, will ensure that the potential of the North's airports is exploited for the benefit of the wider economy.

TfN will ensure that the Strategic Transport Plan and supporting Integrated Rail and Major Roads reports, along with the freight and logistics analysis incorporate the Independent Commission's recommendations for surface access improvements and interventions to airports and ports across the North.

Q3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Creating and sustaining transformational economic growth, that goes beyond business as usual, requires a high quality environment in which the businesses of the future will want to invest and where individuals have access to a wider range of opportunities including employment, skills, education, healthcare and other services. The long term sustainability impacts of transport infrastructure investment is therefore a key consideration for TfN.

The following objectives have been agreed for the Strategic Transport Plan:

These objectives will be used to understand and drive the development of what interventions are required within the long term Investment Programme, and demonstrate how TfN will try and address the issue about creating better places through its work.

TfN's remit is related to transport, but we recognise the inter-relation between housing, jobs and transport, since the latter is a derived demand. In our answer to Q13 below, we explain some of the innovative work that TfN has been doing to understand the travel demands between now and 2050 in a transformed Northern economy.

These travel demands will inevitably relate to housing and employment locations, determined by TfN's Partner authorities. This is why we will be working with Partners over the coming months to refine the forecasts based on the economic and spatial growth priorities of individual authorities.

Q4. What is maximum potential for demand management, recognising behavioural constraints and rebound effects?

No response.

Q5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

TfN's long term Investment Programme will contain a mix of upgraded and new transport infrastructure, and the approach taken in the initial Integrated Rail and Major Roads reports has been to identify where best use can be made of existing assets in the first instance.

At a strategic level across the North, the approach taken in the initial Major Roads Report has been to conceptualise the North's major road network as a ladder that will only support transformational growth by ensuring strong north-south routes alongside multiple "rungs" for east-west connectivity. At present, north-south connectivity in the North is generally seen as better than east-west connectivity, with one only one "rung" – the M62 providing a continuous east-west dual-carriageway road in an area stretching from the Midlands in the south (A50 corridor) to the Edinburgh/Glasgow (M8-A8 corridor). Prioritised interventions in the initial Major Roads Report seek to strengthen east-west links to reduce demands on the M62, while at the same time providing better access to a series of the North's economic assets.

However, under a transformational economic scenario, there will also be a need for new infrastructure, particularly to significantly improve inter-city region connections. For example, the rail network in the North is severely constrained by geographical challenges, urban history and track capacity. Rail travel has grown rapidly with a threefold increase in passenger journeys since the mid-1990s, and the existing largely 'two-track' network in the North is no longer able to cope reliably with existing demands, and has no practical capacity for significant growth in passenger and freight services.

Projects such as HS1 and Crossrail have shown the transformational impact of new infrastructure is supporting economic growth, and TfN's proposals for Northern Powerhouse Rail, along with the plan for HS2, aim to replicate this approach across the North, to improve commuting, business to business, and leisure travel across the North.

Q6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

TfN's view is that increasing collaboration will certainly help bring forward the necessary transport infrastructure investment in the North at the right time, aligning it with spatial and economic policies. TfN is all about working in partnership across the North, with 19 local authorities and 11 LEPS, plus DfT, highways England, Network Rail and HS2 Limited taking a collaborative approach to develop proposals for strategic transport intervention.

TfN's Smart North programme of work, which aims to transform improve the customer experience on public transport, is a good example of collaborative working across the public and private sectors. It has a vision for simplified fares, integrated ticketing and payments and improved passenger information. This will mean allowing someone to make a contactless payment for their train travel, arrive in a northern town or city, and make a further contactless payment to take a tram or bus journey to their final destination. All of this will be possible with the confidence of a 'fair price promise' and real-time journey planning information available for passengers.

Integrated and Smart Travel is TfN's first investment programme funded by government, and will start to deliver tangible benefits for passengers before the end of this Parliament. The programme is being delivered in four separate but related tranches as a means of managing the risk and complexity associated with the programme, meaning that customer products and benefits will be incrementally rolled out across the North.

In addition, Rail North has demonstrated the potential of strong partnership working between the North's local authorities and the DfT. Transformational investment is being made in the North's two new rail franchises, Northern and TransPennine, which will provide more frequent services to more places, with improved journey times.

Investment includes 500 brand new carriages for the North of England as well as removal of the unpopular, outdated Pacer trains. The economy will be boosted by the operation of an additional 2,000 services per week and space for an extra 40,000 passengers at peak times. The Northern franchise will provide nearly a 40 per cent increase in capacity and introduce a new, faster, higher quality Northern Connect service on 12 routes between major centres.

Over the next year, TfN will feed into Highways England's and Network Rail's industry processes, RIS2 and CP6, using the prioritised portfolio of interventions in the initial Integrated Rail and Major Roads reports, which incorporate investments that would be delivered by the national agencies in

the early years of the Strategic Transport Plan, and through agreeing a joint narrative with Highways England and Network Rail on the content of these two investment programmes across the North.

The Strategic Transport Plan will also contain proposals for a number of corridor studies to where investment is needed in future years. This will involve TfN and Partners working together to identify interventions and to develop business cases needed for funding them. TfN is also engaging with cross boundary organisations, including the Welsh Assembly Government, Transport Scotland, and Midlands Connect, to ensure that pan-Northern transport interventions in the North are aligned with those being undertaken in adjacent areas.

Q7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

TfN is exploring with Partners different possible funding and financing options. Much remains to be done in the area, particularly once TfN is established as a Sub-National Transport Body.

Unlike London, the North does not have as democratic or revenue raising entity. Once it is established as a statutory body, TfN will encompass the geography of the North but will have limited powers associated with its remit. There are currently no democratic, governance or administrative mechanisms that would allow material funds to be raised directly on a pan-Northern basis.

In addition, TfN will not have the ability to borrow. Therefore, its ability to raise revenue will be highly restricted (effectively voluntary from TfN Partners) and it is very difficult to envisage how this could be used to fund infrastructure investment.

Moreover, the economy of the North is significantly less productive and robust than that of London and whilst projects in the latter generally seek to tackle congestion or address pent up demand, TfN interventions are more likely to be about providing infrastructure that will allow the North's economy to be transformed.

In addition, the economic benefits arising from inter-urban interventions will be more diffuse and harder to localise, reflecting the larger and more diverse geography of the North, whilst land values and commercial and residential property prices are significantly lower across the North as a whole than in London. It is clear, therefore, that models which might be successful in London and the South East are not necessarily applicable in a Northern context. In particular, there is a strong possibility that imposing value capture mechanisms will undermine the economic transformation the North needs to achieve.

For these reasons, "the North's" ability to contribute to TfN programmes needs to reflect these differences and challenges, the scale, timing, and structure of any contributions would need to be aligned to the strategic policy objectives of the North and its ability (economically, politically or practically) to generate funding.

The current systems for raising revenue available to central and local government are not structured in such a way as to allow an organisation like TfN to raise or 'capture' revenue (particular in the absence of specific TfN revenue raising powers). As part of developing the Strategic Transport Plan, TfN intends to discuss with Government and the private sector ways of testing new and innovative approaches to the funding the infrastructure identified in the plan.

Q8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Much of TfN's current position with regard to funding principles are outlined above. Going forward, the North should also explore opportunities for systematically raising revenue that do currently exist, largely through the levers that already exist in relation to the two Northern rail franchises. Such an approach has the benefit that it incentivises the North to make decisions that optimise outcomes from the franchises. In addition, pan-Northern rail usage could be seen as an effective proxy for the health of the economy as a whole and therefore, in addition to straightforward pricing opportunities, growth that is facilitated by strategic interventions should impact on the volume and length of journeys being undertaken across the network.

Similarly, revenue raised on a national basis, such as Vehicle Excise Duty, could be allocated to support Northern programmes broadly in proportion to how it collected. This would allow future Highways England and Network Rail investment programmes to be managed more effectively on a programme basis across the North.

Q9. How can we most effectively ensure that our infrastructure system is resilient to the risk arising from increasing interdependence across sectors?

As noted in the answer to Q5 above, TfN's remit is related to transport at this time, and the Strategic Transport Plan and long term Investment Programme will focus on transport investments, although the former will consider the possible impacts of social, technological, economic, political and environmental change.

Two recent documents from the Institution of Civil Engineers (ICE) provide some potential answers for how the interdependence across sectors can be addressed. The National Needs Assessment provide a sector-based analysis of infrastructure needs up to 2050, whilst the State of the Nation 2016: Devolution report recommends the development of regional infrastructure strategies.

Taking a regional approach to infrastructure planning, as is being done with the Strategic Transport Plan, but then examining interdependencies at this level, is more likely to identify key risks and bring forward the necessary mitigation measures.

A key factor in the North of England is poor resilience in the strategic transport networks due an overall lack capacity and choice. Providing more capacity such as that proposed through NPR will deliver a wider range of benefits than just faster journey times and better connectivity.

Q10. What changes could be made to the planning system and infrastructure governance arrangements to ensure that infrastructure is delivered as efficiently as possible and on time?

In October 2016, TfN submitted its formal proposal to the Secretary of State for Transport to become the first Sub-National Transport Body in England. The proposal was endorsed by all of TfN's Partners and sets out the range of powers which TfN needs to ensure that the required connectivity improvements can be delivered. It is seen as a model for future governance arrangements relating to transport in other parts of England, and could well be applied to other infrastructure sectors over time.

The integrated longer term approach to economic, spatial and transport planning at a Northern level that TfN is adopting in the Strategic Transport Plan is unique for the UK, and enhances the ability of the North to capture additional investment and align funding streams. Having a long term programme will provide greater certainty, thus providing greater confidence to public and private investors and supporting the development of the wide range of skills needed to develop, deliver, operate and maintain the transport investments.

Multi-modal planning by bodies such as TfN, will also provide better value for the taxpayer by developing the right interventions, regardless of modal basis, through more efficient analysis, modelling, appraisal and commissioning.

TfN's Strategic Transport Plan is to be seen as adding value to Local Transport Plans, supporting business cases through pan-Northern economic growth and transport demand analysis, to ensure planning at a local level can support and complement pan-Northern transport infrastructure. In addition, strategic interventions delivered by TfN could free up or create capacity for local enhancements thereby supporting the local economic and spatial plans of local authorities and LEPs.

Q11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

As noted in the answer to Q3 above, TfN has agreed a set of objectives for the Strategic Transport Plan including a specific one relating to the environment. Our view is that establishing this as an objective at the outset should provide the means by which environmental considerations are at the forefront of the planning of all transport infrastructure.

In addition, TfN has commissioned an Integrated Sustainability Appraisal of the Strategic Transport Plan. At this point, an Integrated Sustainability Appraisal - Scoping Report has been prepared and used for consultation with the relevant statutory bodies. This process will ensure that TfN meets all legislative requirements in producing the Strategic Transport Plan, recognising that as the first Sub-National Transport Body, we are leading the way in establishing the boundaries between roles and responsibilities for setting transport policies at a national, sub-national and local level.

Reducing greenhouse gas emissions, improving air quality, protecting the landscape and heritage, enhancing transport choice, enabling access to opportunity and improving economic prosperity are some of the key considerations for the Integrated Sustainability Appraisal. However, TfN also recognises that meeting government targets such as carbon reductions by 2050, will involve many other organisations than just TfN and include issues that TfN has no direct control over, and so our approach will be one of understanding the impact of our work on the natural environment and ensuring mitigation where appropriate.

It should also be noted that a more detailed consideration of environmental issues is likely to be undertaken at a scheme-specific level by the delivery organisation(s) involved.

Q12. What improvements could be made to current cost-benefit techniques that are credible, tractable and transparent?

The current DfT consultation on the application of Wider Economic Impacts (WEIs) within the WebTAG suite of appraisal documents is a welcome addition to the debate on understanding the much wider benefits to the economy arising from transport investment. Also the approach taken to

appraise individual schemes often does not reflect the contribution of that scheme to a wider programme of measures.

TfN is developing its long term Investment Programme on a pan-Northern, multi-modal basis, with the aim of identifying interventions that will deliver the long term economic growth set out in the Northern Powerhouse Independent Economic Review. Given that this will be a 30 year programme, some of the interventions will be relatively well-defined, but others later in the programme, will be less specific. Yet all of the interventions will be needed to deliver and sustain the overall levels of growth required to transform the economy in the North.

The challenge for TfN and Government over the coming months will be to work together to develop a method that appraises the overall programme of interventions against the wider economic objectives, but that allows flexibility for individual schemes to come forward as and when necessary, with an appropriate value for money assessment.

Q13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

TfN has been undertaking some innovative work to investigate the likely range of future travel demand scenarios that a transformed Northern economy will place on the transport network across the North, as well as to and from other key regions. These scenarios reflect the economic growth potential envisaged in the Northern Powerhouse Independent Economic Review.

A Northern Transport Demand Model is being produced using a baseline of demand for road and rail based on current travel patterns. TfN is also creating dynamic simulation model of how activities at locations would generate demand for travel, including understanding better the relationship between jobs and labour markets.

The initial results from this model show a significant uplift in both population and employment across the North when compared with a “business as usual” scenario in the core DfT transport models, as shown in the table below.

	Business as Usual 2015	Business as Usual 2050	NTEM 2050	NPIER 2050
Population	15.6m	18.1m	17.8m	19.6m
Employment	7.6m	8.3m	8.8m	9.2m

The outputs of this work will inform the overall strategic case for the Strategic Transport Plan including future growth predictions, and also provide the supporting evidence base for developing interventions.

To reflect future uncertainty, and to add robustness to our forecasts, two future influencers of travel needs have also been modelled to understand future transport demand across the North in the transformational economic growth scenario:

- Technological and socio-cultural change: meaning the relative impact of technology and socio-cultural attitudes to travel demand.
- Enabling policy and plans: meaning the relative impact and focus of local transport and land-use policy and planning on the drivers of travel demand.

These factors were specifically chosen as having significant impacts on future travel demand that need to be understood and allowed for within any forecasting work, but which sit outside the current remit of TfN's work. Therefore, TfN is exploring what the impacts of Mobility as a Service (MaaS) solutions will have on future travel demand, and would be pleased to share the results of any research with NIC when it is available.

The forthcoming Economic Growth and Transport Demand Analysis report will set out the analysis that has been done to date, and how the work will be taken forward with Partners to refine the forecasts based on specific economic and spatial growth priorities.

Taking into account these factors, the Strategic Transport Plan is aiming to deliver a transport system that is user centric, smart, autonomous and connected, as well as resilient and sustainable. However, more importantly given the uncertainties that surround how and when things will change, the policy measures and interventions proposed must be flexible.

Q14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

As explained in the answer to Q15 below, TfN's remit is to concentrate on pan-Northern investments that help deliver transformation economic growth, with Partners bringing forward complementary local investments. We are fully aware, however, that such local investments will help build the business cases for the larger scale investment, and are fundamental to improve the door-to-door journeys of the workers, residents and visitors across the North. In addition, carefully planned strategic interventions can also help unlock local transport solutions.

Mindful of this, TfN commissioned a report on Strategic Local Connectivity as part of the early evidence base for the Strategic Transport Plan, which identified a series of over 120 transport interventions across the North. TfN's role will be one of supporting in Partners in making the case for such investments at the appropriate time.

Rail North has also developed its Long Term Rail Strategy, which contains a mix of national, Pan-Northern and local interventions across the North's rail network, all of which are considered necessary to support the economic growth set out in the Northern Powerhouse Independent Economic Review. Over the coming year, Rail North will develop proposals and a business case for the next phase of devolution, localised 10 year plans that will be owned by Partners, and an approach to possible re-openings of closed railway lines.

Q15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

TfN's long term Investment Programme will be a key part of the Strategic Transport Plan, and the outputs from two new and important pieces of evidence are providing a prioritised portfolio of interventions. Initial versions of an Integrated Rail Report and Major Roads Report have been produced to complement the previously published Freight and Logistics Report and the

International Connectivity Commission's independent report. These can all be made available to the NIC as and when they are made public.

The Integrated Rail Report has identified interventions for long term investment in the North's rail network, encompassing the latest proposals for Northern Powerhouse Rail, Rail North's aspirations and franchise specifications, and the new Network Rail Northern Area Programme, as part of a single plan for improving capacity, connectivity, coherence and cost effectiveness across the North of England.

The response to Q1 highlighted the importance of Northern Powerhouse Rail, and the recognition from the Commission of the importance of this package of transformational to the North's rail network.

Working with the DfT, Network Rail and HS2 Ltd, TfN has identified a number of feasible engineering options that will either deliver, or move substantially towards meeting the conditional outputs for the Northern Powerhouse Rail network. The next stage of development of the Northern Powerhouse Rail programme aims to identify preferred options for different components of the network, including:

- A decision on options for connections to important economic centres outside of the six major cities of the North and Manchester Airport;
- Interfaces with HS2 Phase Two to allow single options decisions and inclusion in the HS2 Phase 2B Hybrid Bill;
- Phasing of delivery for the preferred network options and developing a Strategic Outline Business Case; and
- Working with industry partners to present proposals for integration of Northern Powerhouse Rail into the redevelopment of Manchester Piccadilly station, as noted in the Commission's previous report.

The Major Roads Report has developed the concept of a Major Route Network for the North, which incorporates the Strategic Road Network, plus other major pan-Northern routes that connect the North's important economic centres to provide a logical, coherent and integrated network that needs to be resilient, reliable and efficient.

TfN has been working with the DfT and Highways England on three Strategic Road Studies that reported in Autumn 2016:

- **Trans Pennine Tunnel** – looking at options to improve road connections between Greater Manchester and Sheffield City Region by building a road tunnel under the Peak District National Park;
- **M60 North West Quadrant** – looking at options to relieve congestion on one of the busiest parts of the national motorway network, the north-west section of the M60 motorway around Manchester; and
- **Northern Trans Pennine Routes** – identifying options for a new east-west strategic road corridor in the Northern Pennines, linking Cumbria and the North East by upgrading the A66/A685 and/or the A69.

In the Autumn Statement 2016, the Government confirmed that the recommended A66 and M60 North West Quadrant schemes would be implemented during the RIS2 period, and TfN is now working with the DfT and Highways England to complete Strategic Outline Business Cases for the two schemes and begin to look at option identification.

TfN is also completing the Strategic Outline Business Case for the Trans Pennine Tunnel and the Wider Transport Connectivity Assessment of the benefits of a tunnel beyond the Sheffield City Region and Greater Manchester.

In each of the Integrated Rail and Major Road Reports, an evidence base has been developed to identify where improvements are needed to achieve a set of conditional outputs. Conditional outputs have been developed with a view to creating a transport system that can support the economic growth envisaged in the Northern Powerhouse Independent Economic Review.

More efficient movement of goods is also important to the growth of the North. Further freight and logistics analysis is being undertaken by TfN to understand why the sector adds such significant value to the Northern and UK economy. To ensure freight is considered as a fundamental part of the Strategic Transport Plan, TfN has integrated the freight analysis into both the Major Road and Integrated Rail reports to understand the key priorities in the North. Greater understanding of how the markets work, with more intelligence about road and rail freight choices and decisions, and this will inform the development of more sustainable freight movement options across the North in the future.

The initial reports set out those interventions that TfN has prioritised to meet the economic aspirations of the North, and also identify the business cases and strategic investment studies that will be developed by TfN to support future iterations of the long term Investment Programme. They will be used to inform the development of the upcoming Road Investment Strategy 2 (RIS2) programme with Highways England and the Control Period 6 (CP6) programme with Network Rail, along with providing inputs to the Initial Industry Advice.

Q16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Mobility as a Service (MaaS) solutions are increasingly based around individual preferences and specific daily travel needs – journey planning and management, optimised travel choices, lowest cost options, personalised service and flexible payment. As the use of mobile technologies and applications increases, MaaS will challenge conventional attitudes towards travel and create wider opportunities for the personalisation of services. This will present both challenges and opportunities for transport planning in relation to future service provision and capacity, and is one of the reasons why TfN is considering various future scenarios for transport demand to support its development of strategic investment programmes, as described in our answer to Q13 above.

BY EMAIL & POST

Dear Lord Adonis

Transport for West Midlands (TfWM) response to the NIC National Infrastructure Assessment Call for Evidence

On behalf of Transport for West Midlands, we would like to thank you for inviting us to respond to the National Infrastructure Assessment call for Evidence.

On the back of the NIC's January visit to the Midlands, we are working with you to further explore:

- Congestion, Air Quality and Network Resilience;
- New Technologies and their impact on Capacity and Utilisation; and
- Next Generation Operational Infrastructure, with a potential focus on freight.

Our response builds from those issues and raises a number of related points which are summarised below:

1. For the UK to prosper in the future global economy, the West Midlands, and the UK's other city regions must have high performing economies, which are underpinned by attractive, healthy, liveable urban environments with good air quality. Achieving this will require a per capita spend on urban transport solutions which is closer to that of London and European cities, recognising the historic long term underspend in the UK.
2. City region high performing economies and attractive, liveable urban environments need high performing city region transport systems and effective inter-urban links, especially when growth and increased population are factored in. These must be resilient networks, with effective use of adequate capacity.
3. Investment planning for these links needs to be less siloed with more scope for investment in strategic (heavy and light) rail capacity to directly accommodate demand for additional road capacity constraints that might otherwise occur.
4. City regions such as the West Midlands need effective, high capacity rail and rapid transit networks to get workers to work, and students to skills, across the city regions (integrated with effective local bus networks).

5. Smart mobility has a key role to play in assisting the development of effective city region and inter urban transport systems – strategic planning and investment needs to make better account of changes in models of car ownership and technology with a greater emphasis on enabling investment to support emergent technologies like Connected and Autonomous Vehicles.
6. The UK needs to significantly enhance the offering of existing inter-urban infrastructure, including rail rolling stock capacity and technology. There is a need to explore and implement new technology for capacity utilisation, network resilience, improving air quality and next generation infrastructure operation.
7. The West Midlands is keen to explore this aspect of future transport requirements with the Commission.

Please do not hesitate to contact Laura Shoaf, Managing Director, TfWM if there are any queries related to our response or in relation to how TfWM can collaborate further with you as work developments.

Yours sincerely

Transport for West Midlands (TfWM) Response

NIC - Infrastructure Assessment Call for Evidence

Key Points from TfWM

1. For the UK to prosper in the future global economy, the West Midlands, and the UK's other city regions must have high performing economies, which are underpinned by attractive, healthy, liveable urban environments with good air quality. Achieving this will require a per capita spend on urban transport solutions which is closer to that of London and European cities, recognising the historic long term underspend in the UK.
2. City region high performing economies and attractive, liveable urban environments need high performing city region transport systems and effective inter-urban links, especially when growth and increased population are factored in. These must be resilient networks, with effective use of adequate capacity.
3. Investment planning for these links needs to be less siloed with more scope for investment in strategic (heavy and light) rail capacity to directly accommodate demand for additional road capacity constraints that might otherwise occur.
4. City regions such as the West Midlands need effective, high capacity rail and rapid transit networks to get workers to work, and students to skills, across the city regions (integrated with effective local bus networks).
5. Smart mobility has a key role to play in assisting the development of effective city region and inter urban transport systems - strategic planning and investment needs to make better account of changes in models of car ownership and technology with a greater emphasis on enabling investment to support emergent technologies like Connected and Autonomous Vehicles.
6. The UK needs to significantly enhance the offering of existing inter-urban infrastructure, including rail rolling stock capacity and technology. There is a need to explore and implement new technology for capacity utilisation, network resilience, improving air quality and next generation infrastructure operation.
7. The West Midlands is keen to explore this aspect of future transport requirements with the Commission.

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

Connectivity across the Midlands is essential for supporting people and businesses, as well as highly skilled workers. To fully deliver on their potential - areas such as the West Midlands need efficient and effective local transport networks as well as good connectivity with each other and wider. Connectivity with other cities, and with the wider world, attracts investment and skills and enables access to domestic and international markets.

Cities need to be smart, and embrace and facilitate transformative social and technological change, such as the electrification of transport, growth in cycling and the way in which open data, smart devices and Connected/Autonomous Vehicles can revolutionise transport information, access and planning. This in turn will draw in investment and skills whilst also, improving air quality and making cities more attractive and dynamic places to be.

The West Midlands Combined Authority (WMCA) is playing a major role in strategic and devolved approaches to pan regional infrastructure like better east-west transport connections – through Midlands Connect, as well as on planning and development of regional rail services through West Midlands Rail.

The WMCA area has a clearly defined strategy for growth, aligned to a robust and deliverable transport strategy. This is summarised in 'Movement for Growth' and is articulated in the ambition and subsequent delivery plans of stakeholders across the region.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

It is crucial that Government continues to back the Midlands in promoting jobs and growth, boosting productivity and attracting inward investment whilst recognising the importance of improving infrastructure to increase connectivity. The Midlands Engine region has an economy of £222 billion each year and is home to over 11.5 million people.

The West Midlands population is forecast to grow by 444,000 people by 2035 (Office of National Statistics). The number of new homes which will need to be built to help accommodate this growth over 20 years is in the order of 165,000.

The West Midlands lies at the heart of the UK's road and rail networks, the mix of long-distance, regional and local travel needs is placing heavy demands upon them. There are connectivity challenges that will constrain the ability of the West Midlands to realise its ambitions for growth.

Road

The West Midlands motorway network is subject to heavy congestion, with traffic delays and poor journey reliability, meaning that businesses, commuters and leisure travellers have to schedule additional time into the journey to give confidence that they can arrive at destinations on time.

The analysis completed to date as part of Midlands Connect highlights that we will need to tackle congestion and resilience and quality of journeys provided by the Strategic Road Network. Particular pressures include the South East of the West Midlands, the M6 between M54, usage of the M6 Toll and Birmingham Central (A38M). There needs to be targeted strategic highway capacity to support connectivity to modal interchanges and network resilience to the A5 to rail-freight, A46 to support Birmingham Motorway Box, wider HS2 access, long term M5 Capacity and Strategic Park and Ride.

Rail

There are fast, frequent rail links connecting large parts of the Midlands to the north and south, via the West Coast, Midland and East Coast Main Lines. However, there are major challenges travelling by rail between the Midlands cities and there is an increasing problem of capacity and crowding on services entering and crossing Birmingham. This will cause problems both in accommodating growth in Birmingham and in improving rail connections across the whole Midlands.

To ensure that our transport network provides the future capacity it needs, Government needs to work more collaboratively with TfWM, West Midlands Rail and Midlands Connect. Future service

improvements and infrastructure enhancements such as the Midlands Rail Hub need to be delivered faster to cope with the existing increase in rail patronage, unlock early benefits of HS2 and to offer credible alternatives to the private car.

HS2

The importance of integrating growth plans and transport plans should also be recognised. Improving sustainable connectivity across the West Midlands will create investment opportunities but will also tackle development viability and issues such as poor air quality.

HS2 will transform north-south travel and will also significantly improve connections between East and West Midlands. However, it is critical that the Commission fully support the WMCA in delivering HS2 Local Connectivity Package to fully capitalise on the opportunities provided by new stations serving the West Midlands.

Aviation

Enhanced global aviation connectivity will help grow our export led economy further, securing extra benefits and opportunities for the region. HS2 will see Birmingham Interchange station built in close proximity to Birmingham Airport.

Birmingham Airport is a local, regional and national economic asset, a gateway for our businesses to export their services around the world. In the long term Birmingham Airport has the ability to provide a wider national and global function. Birmingham Airport is well placed to support the UK aviation capacity needs up to 2043.

HS2 brings Birmingham Airport closer to the rest of the country and can provide immediate capacity up to 27 million passengers.

CAV and Technology

The UK and Midlands based automotive industry is a significant part of our overall economy, but is intrinsically global in nature. CAV initiatives can offer opportunities for the Midlands transport system and economy as well as continuing to raise the already established West Midlands profile and UK leadership in the field.

CAV technology will and is entering the system irrespective of any action by Government or a local authority. Failure to support and nurture emerging automotive technology as part of the Midlands and UK transport system will lead to inevitable global investment migration.

The UK and Midlands would specifically benefit from putting in place a coordinated programme of support working closely with those Authorities and companies which have already established activity in order. The Commission may be required to investigate the upgrading of intelligent infrastructure and energy supply capacity to support CAVs and wider advanced manufacturing development.

Freight

Freight and logistics are vital to our economic activity and development. They support people and businesses in their daily activities, ranging from deliveries to homes and shops through transferring goods to and from factories or getting supplies to offices.

WMCA would like to work with the Commission to explore planning for major strategic rail freight capacity enhancement to central Birmingham rail capacity above and beyond the Midlands Rail Hub. As well as providing extra strategic freight capacity including autonomous platooning freight which are being explored in main land Europe.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Infrastructure should be delivered at the outset for new developments, with sustainable transport capacity completed and public transport operational when new housing becomes occupied. Best practice from the Netherlands should be considered for sustainable urban extensions in relation to this.

Consideration should also be given to innovative financial vehicles where key infrastructure and services are delivered to unlock development and costs are then paid back once occupied. There are examples where this has been successful, such as the Birmingham City Centre Enterprise Zone and Bond financing in the US.

The design of infrastructure and opportunity for physical activity has a major impact on health. Obesity is predicted to be an increasingly major public health issue by 2050. Based on current trends, the Foresight report on obesity (Tackling Obesities: FutureChoice) predicted that by 2050, 60% of the male population and 50% of the female population (aged 21-50) are predicted to be obese with an additional 35% of the adult population in both groups predicted to be overweight.

This will increase the amount of people who develop serious medical complications and impact on economic growth. Designing and delivering the right physical environment plays a role in preventing that scenario. The Foresight report specifically highlights the walkability of living environments, reducing the dominance of motorised transport, and providing opportunities for the promotion and safety of unmotorised transport as part of the system that causes obesity.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

There needs to be extensive market research exploring views of different demographic groups of the extent of their "love of the car" and the potential role of demand management of some private car and road freight demand for urban and inter urban journeys, allied to improvements to different models of car use and ownership and to public transport, cycling and walking.

Consideration of what demand management has achieved in other comparable industrial countries would also be of value. The role of technology and information on travel choices available has much potential in relation to deploying demand management measures.

Thought also needs to be given to planning for demographic changes which is seeing significant changes in travel behaviours. For example, fewer younger people are driving but the level of over 65s driving has increased significantly.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

A useful overarching principle is to make best use of existing capacity and create new sustainable transport capacity. Making best use of existing capacity includes effective planned asset management of highways, footways, cycle paths and street lighting.

The condition of the road network for example can have an impact on congestion in terms of traffic speeds, the impacts of remedial or emergency maintenance work and the knock on effects for congestion or damage to vehicles as well as road accidents. Research in the West Midlands suggests that an accelerated maintenance programme would generate economic returns of £6.50 for every £1 of public funding invested¹.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

The WMCA, the design consortium of Egis, Tony Gee and Pell Frischmann and contractor Colas Rail have come together as the Midland Metro Alliance. The Alliance will implement a 10 year programme of tram system enhancement works to deliver a lasting legacy for the West Midlands that will enable social & economic regeneration, and deliver local jobs and training. This longer term partnership will help to address skills shortages – enabling consultants and contractors to plan and grow more strategically rather than to cycle through shorter term contracts.

Alliancing is a form of relationship contracting often used for complex projects or programmes which require speed of delivery and cost certainty. Pure Alliances include the owner, designer and contractor as alliance members who collectively seek outstanding outcomes through an integrated team, characterised by aligned goals, innovative thinking and collaborative behaviours.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The greater certainty that has been brought to national rail and road spending through five year funding periods and investment programmes as well as Devolution Deals is welcome, as is the creation of the National Infrastructure Commission.

The availability of capital funding for Combined Authorities to tackle transport problems fluctuates and there is a strong case for capital spending to be agreed over a long term (10-20 year) period. We would like to see the widening of the devolved Single Pot funding approach to the WMCA.

In addition, the proliferation of competition funding creates additional pressures on declining resource funding in terms of uncertainty around when such funding competitions will emerge. Bidding for grant funding have non-negligible cost (Urban Transport Group estimates the amount of up to 1.8% of total costs for a £5 million scheme), and creates unpredictable peaks and troughs in workloads which are difficult to plan for efficiently.

To help improve the efficiency of planning, financing, developing and delivering infrastructure, Government and the Commission must commit to fiscal devolution and avoid competitive bidding processes.

¹ CH2m Hill, (2015), Highways Maintenance Challenge Fund - West Midlands Road Condition Maintenance Improvements

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

An area to consider with this issue is how an active state can quickly increase diesel rolling stock capacity much more effectively than that provided by existing mechanisms in the rail industry.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

There is a growing awareness of the scale and timing of a series of major infrastructure works which particularly impact the Strategic Road Network and West Midlands Key Route Network (WM-KRN) across the West Midlands. This includes:

- HS2 Phase 1: with significant rail, local road and motorway interfaces and diversion works;
- Network Rail and Highways England investment programmes;
- WMCA investment as well investment in major maintenance and utilities works; and
- Major development in Birmingham city centre and other locations such as Cannock.

This infrastructure investment will bring many significant direct benefits and unlock further regeneration and growth opportunities. However, during the delivery period there is a risk that un-coordinated delivery undertaken by different agencies working in siloes could generate significant short-term adverse construction disruption impacts, as well as negatively impacting upon air quality.

TfWM and the HS2 Growth Strategy Board commissioned a study and the headline preliminary findings identify the probable loss of 1 or 2 lanes (approximately 12.5 to 25%) capacity from the SRN at multiple locations during the same period, with potential for 20 mins plus delays for each vehicle for extended periods across significant elements of the network.

Based on the consultants findings and the most impactful mitigation options focus on:

- **Making use of empty seat capacity in cars:** There is a high proportion of single occupancy car trip making over the local and strategic highway network, with significant level of short distance motorway travel (often referred to as junction hopping);
- **Shifting the time of travel and mode choice:** Through a mixture of technology enabled incentives (easy payment systems and public transport pricing; traveller information; and Mobility as a Service solutions) and intelligent management of parking supply and pricing. These would be most effectively implemented through targeted engagement with main traffic generating areas and organisations, and at pinch point hot spots;
- **Traffic management** - Physical and enforcement measures: Introduction of temporary measures such as High Occupancy Vehicle Lanes; Clearways (or Red Routes) and making best use of underutilised highway capacity such as the M6 Toll; and rigorous traffic enforcement (including moving traffic offences); and
- **Communications, data, technology and intelligence:** The use of optimised Urban Traffic Control systems and systems performance monitoring within an environment of open data shared between agencies and published openly. This would be used to optimise construction planning and scheduling; as well as to drive joined up public information through multiple communications channels.

The issue has been raised as part of the Devolution Deal 2 discussions. This has been with a view to securing Central Government support for the strategic response, recognising that the scale and importance of the issue has impacts which are beyond the West Midlands.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The role of elected Mayors for city regions is critical to any changes to the planning system and infrastructure governance arrangements to improve the delivery of infrastructure. Please see points raised in question 3.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Creating city region transport systems with much lower private car modal share and much greater use of low emission or emission free power sources will be a great contributor to protecting and enhancing the natural environment.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

The ability to capture more effectively the wider economic benefits of transport schemes and the economic public health benefits of transport schemes would be very positive improvements.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport

Within the urban environment, travel will have to cope with increased density as the population increases both from growth and agglomeration. The key aim will be to maximise asset efficiency to best utilise road, cycle, rail, tram, air, etc. in terms of the number of passengers, the frequency of services, the delivery of goods and the "always on" transport system. Tailored personal services for transport are seen to be the ultimate approach to mobility, this will have to be balanced with mass-transit although mode choice may affect this. The use of information, location, incentivisation and machines understanding our daily life patterns will be the enablers that will encourage uptake of new technology and increasing mode choice, all combining to make movement easier as a result of convenient transport based on personal preference.

The opportunities that platooning of autonomous vehicles bring to rapidly enabling transport systems to develop will lead to changes in inequalities within the urban environment. There will be opportunities to enable people with mobility problems to move around more freely with mobility on demand. Potentially tackling isolation for the elderly or access to jobs for deprived areas. The important aspect of this will be to manage private sector business models with public policy to develop solutions that work for the city-region.

The impact of a more digitally aware citizen, as the millennials grow older, combined with improved communication technologies via the internet will be a major factor in altering travel behaviours – the impact however is difficult to predict. The current unreliability of

communications, the desire for face to face interactions and the ability to keep in touch with people more often over wider distances has in fact led to greater travel demand and movement.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Significantly enhancing the offering of existing inter-urban infrastructure through exploring and implementing new technology for capacity utilisation, network resilience, improving air quality and next generation infrastructure operation is one aspect. The second is to invest in city region rail and rapid transit networks, integrated with local bus networks, alongside high quality cycling infrastructure and decent conditions for walking.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Initiatives to improve the West Midlands economy, air quality and quality of life all need to be supported by transport improvements. This is in the context of the - still valid - strategic economic priorities for transport policy identified in the Eddington Review:

- Supporting the UKs successful agglomerated urban areas and their catchments;
- Maintaining or improving the performance of the UKs key international gateways; and
- The key inter-urban corridors between these places.

In line with the above, there is a need for a successful integrated transport network supporting the growth and development of the West Midlands. Support to deliver the HS2 Local Connectivity Package will maximise the benefits for the West Midlands.

As previously mentioned, a key infrastructure challenge we face is ensuring the effective and reliable operation of the Strategic Road Network in the West Midlands. This is to serve the West Midlands regional and national needs whilst simultaneously serving movement of people and goods traversing the West Midlands. Wider use of the M6Toll is required as part of the solution to this challenge. This also improves our issues around Network Resilience, as highlighted in Question 9.

Better utilisation of the M6Toll is of importance to the WMCA area and the Commission should acknowledge that the M6Toll has a critical role to play nationally.

As part of overall corridor approaches, the role of national and regional rail, including HS2 and rail freight, also need to be considered as priorities, including the Midlands Rail Hub improvement which is the main rail passenger and freight bottleneck of the Midlands and national network. Midlands Connect, TfWM and Network Rail has strengthened the proposal to undertake a joint business case for central Birmingham capturing the wider economic benefits underpinning the case for investment.

The Midlands Rail Hub will bring national, regional and local benefits to the rail network and help support the economy and reduce air quality.

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

MaaS removes the consumer traveller from directly paying the transport operator or infrastructure provider (i.e. car parking charges or indeed tolls). It is a single payment for the end to end activity

with the incentive to minimise the costs against the experience received with the MaaS service provider.

Once a MaaS platform is established and the MaaS service provider can call on transport services as the consumer needs, to get them from where they are to where they really want to go. This has the potential over time to remove some inefficiencies in the transport network.

The other dimension for MaaS is disruptive providers such as Uber, who enter the market and provide a customised service that can be priced on demand. When the network is very busy Uber prices are higher. This could allow for demand pricing on road charging. We will also see more disruptive services like Uber and Slide in Bristol starting up across our urban networks that could take advantage of road user charging by providing a tailored ride sharing service.

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

Digital infrastructure is the poor relation in terms of profile compared to traditional infrastructure, however it is vital to support more effective existing infrastructure. The growth in use of digital communications related specifically to the digital railway and connected vehicles allied with the potential impact of cyber security breaches are being researched through projects such as the UK Connected Intelligent Transport Environment (UK CITE).

The key infrastructure investment to prioritise is through fibre backhaul to offload data as quickly as possible to a rapid, resilient network. This supports 4G/5G, small cell, mesh networks and even new approaches such as Mobile Edge Connectivity, where the processing is localised but ultimately the information has to feed back to elsewhere in the ecosystem. It is only through a more rigorous understanding of the traditional infrastructure, allied to real time decision making using data, that an effective, resilient and maximum use of the existing assets can be achieved.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?"

The difficulties related to the deployment of digital infrastructure are well documented. The urban environment is known to have "not-spots" especially where it has been deemed commercially unviable, often this is in the location of agglomerated businesses where there is need and gain to the economy, but perhaps not directly to the digital provider.

To facilitate this it requires the opportunity for the public sector to help manage the gaps where the commercial sector is not working, without implications to state-aid rules. A body similar to that of Network Rail is required to manage the infrastructure network, divorced from the content / digital providers. This would aid the deployment in commercially unviable areas and create a competitive market for the digital services provision.

The resulting uplift in economic activity, allied with the benefits of a wider use of digital infrastructure in traditional infrastructure would be directly reflected in the national economy.

Energy:

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

WMCA asks the Commission and Government to accelerate and relax the rules around the adoption and roll out of alternative fuels such as Hydrogen.

UK HFCA Response to 'National Infrastructure Assessment Call for Evidence'

The National Infrastructure Commission is seeking views on the development of a National Infrastructure Assessment of the UK's long-term needs over a 30-year time horizon.

Introduction

This response to the 'National Infrastructure Assessment Call for Evidence' is submitted by the UK Hydrogen and Fuel Cell Association (UK HFCA). The UK HFCA works to ensure that fuel cell and hydrogen energy can realise the many benefits offered across economic growth, energy security, carbon reduction and beyond. Through the breadth, expertise and diversity of our membership, we work to trigger the policy changes required for the UK to fully deliver the opportunities offered by these clean energy solutions and associated elements of the supply chain.

A future national infrastructure must include a cost effective, low carbon, resilient energy system which builds on synergies across and convergence between heat, transport, industrial processes and power sectors. Hydrogen and fuel cells are innovative solutions which can deliver all the above, and are thus crucial components of the future infrastructure.

As per our earlier submission to 'National Infrastructure Commission National Infrastructure Assessment plan' in August 2016, we urge the Commission to provide specific recommendations for the development of nation-wide hydrogen infrastructure.

Please see our detailed answers to questions 9, 19, and 21.

Questions

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

To achieve a resilient infrastructure system, the Government needs to adopt a holistic approach to energy which takes into account the interconnection between heat, power and transport. There are synergistic opportunities to use hydrogen to contribute to the decarbonisation of these three sectors without requiring major changes to the existing gas or electricity infrastructures.

Game changing solutions such as hydrogen and fuel cells offer a range of benefits for the flexibility of the system - please see Figure 1 below. Clear understanding, and their interconnections, of these will help to optimise outcomes. For example, hydrogen is an excellent energy storage medium - avoiding the cost of renewables curtailment and simultaneously decarbonising heat, power and transport. Similarly, fuel cells as stationary power or CHP sites are delivering substantial benefits to the energy system - better grid resilience, increased use of renewables, localised carbon reduction, air quality benefits etc. as highlighted by a recent European study¹.

¹ http://www.fch.europa.eu/sites/default/files/FCHJU_FuelCellDistributedGenerationCommercialization_0.pdf

Alongside the recently published UK Hydrogen and Fuel Cell Roadmap², three evidence based White Papers will be published in March 2017 by Hydrogen and Fuel Cell Research Hub (H2FC Supergen)³; these will cover:

- i) The role of hydrogen and fuel cells in the future energy system;
- ii) The economic impact of hydrogen and fuel cells in the UK; and
- iii) The role of hydrogen and fuel cells in delivering energy security for the UK.

We encourage careful consideration of these as evidence.

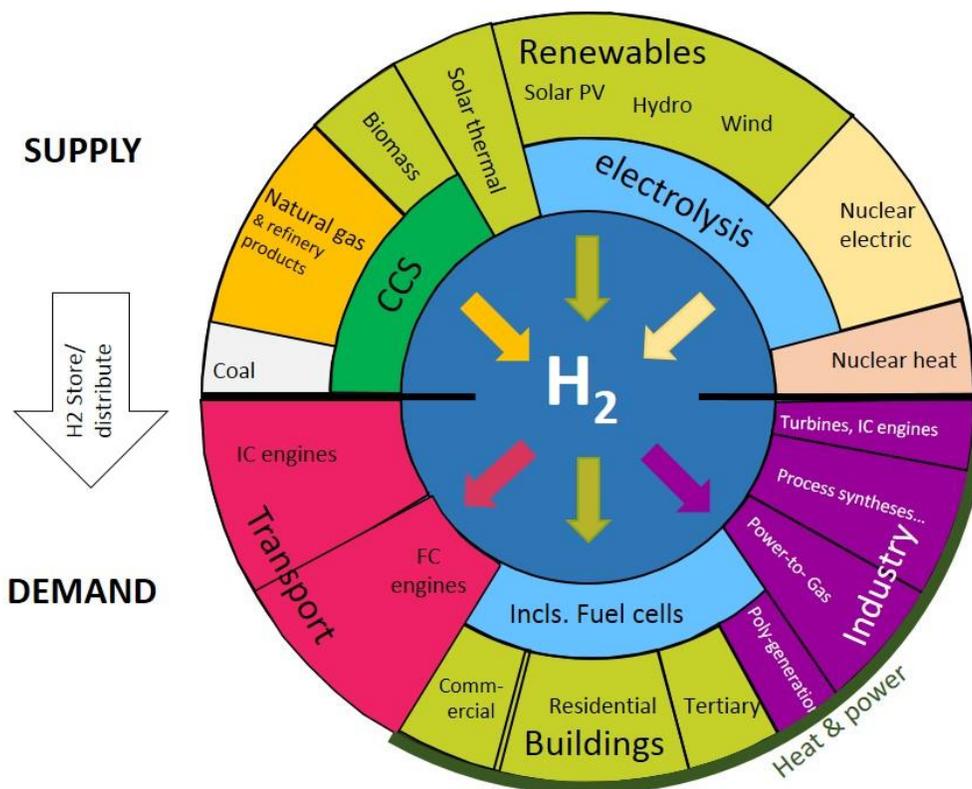

Figure 1: Hydrogen and Fuel Cells into as Innovative Solutions for a Resilient System⁴

The rollout of hydrogen as an alternative energy vector would maximize use of existing infrastructure, decarbonise at lowest social cost, increase innovation options, and maximize consumer value with the lowest regulated system bills. The role of hydrogen as an energy vector is summarized in Figure 2 below. This allows the UK to exploit existing assets and known skills to deliver low carbon, non-polluting energy for heating homes and businesses, transport, and energy security across the UK. It should be noted that an initial tranche of hydrogen refueling stations is now being rolled out in the UK, based on either the

³ <http://www.h2fcsupergen.com/our-work/whitepapers/>

⁴ Adapted from: <http://hho-hydrogen-energy.com/html/abouthydrogen.html>

delivery of hydrogen to the station or the production of it on site by electrolysis, and that the UK H2Mobility project⁵ called for 1150 HRS to be implemented by 2030.

In addition, storage is critical to guaranteeing the resilience of the energy system, particularly given that the main indigenous energy sources left to England, Wales and Northern Ireland are renewable sources such as wind, solar and waves. Thus, a key factor in system resilience is the development of these sources and the means of integrating them into the energy system. Hydrogen can play a key role in maximising the benefits for the national economy of indigenous energy sources.

Hydrogen represents an excellent storage option and, therefore, route to delivering resilience, as it can act as both a short and as a long-term energy store to balance supply and demand at different scales, geographies and weather conditions. As the UK moves to a low carbon economy, hydrogen is a cost-effective and technically proven solution to distributing energy between sectors, addressing the intermittency of renewables and managing variation in demand.

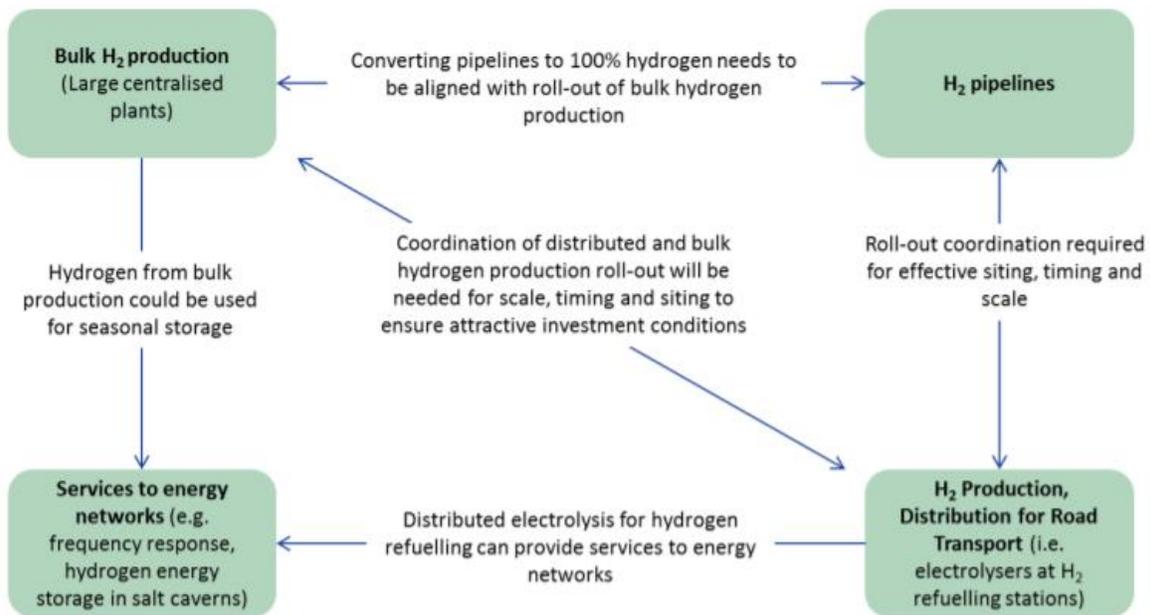

Figure 2: Role of hydrogen in the future energy system, UK HFC Roadmap

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

As per the recent H21 Leeds City Gate project, hydrogen represents an optimum solution for low carbon heat. The evidence based report showed that a UK-wide conversion to hydrogen gas will reduce carbon

⁵ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/192440/13-799-uk-h2-mobility-phase-1-results.pdf

emissions associated with heat by a minimum of 73%.⁶ This conversion of the natural gas distribution network in a city the size of Leeds to hydrogen would reduce by over 0.9million tCO₂/year the emissions from present consumers, as well as facilitating hydrogen supply for transport – delivering further CO₂ reduction and ultra-low air quality emissions. Scenarios produced for the Committee on Climate Change show that by 2050 around 60% of heat demand in domestic, commercial and industrial applications could come from hydrogen, reducing GHG emissions from the residential sector from 29 MtCO₂/yr in CCC's central scenario to 3 MtCO₂/yr.⁷

The report also highlighted the necessary steps that the Government would need to take and a timeframe for their completion. As explained, it is imperative that the decisions are taken now (before 2020) for a UK wide transition to a hydrogen based system by 2050.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

While we believe that different types of low carbon vehicles will be part of the future mix, we would like to emphasize that different options have significantly different implications for the future energy system. By way of example, a Battery Electric Vehicle (BEV) constitutes a very large electrical load in comparison to the entire electrical load of a typical domestic dwelling. Additionally, the timing of each recharge event is under the control of consumers. Thus, if a significant amount of BEV users choose to recharge their vehicles on the basis of lifestyle schedules or range anxiety concerns, rather than upon time-of-use electricity tariffs, then very substantial increases in power flows will occur in distribution networks at peak times and often at locations that do not currently have adequate electrical supply (such as car parks etc.). This will lead to increased use of high-carbon power plant, and will soon require distribution network reinforcement. Hence, there is an intrinsic incompatibility between BEV recharging and achieving a cost-effective low-carbon power system, simply because many consumers will wish to exercise control of when their BEV is recharged and how fully charged it is before they use it. Conversely, electrolytic hydrogen production can occur during off-peak hours by design, and the hydrogen storage tanks of a Hydrogen Refuelling Station (HRS) enable production and demand to be decoupled in time phase. Electricity networks can utilise electrolyser (HRS) to provide grid balancing services and assist use of renewable and nuclear power to offset present and future peak power demands.

In addition, it is worth noting that while BEVs are suited to smaller vehicles and shorter trips, hydrogen fueled vehicles are the lowest carbon solution for medium/larger vehicles (including passenger cars and buses and longer trips as showcased by various reports⁸.

There are opportunities to produce hydrogen, and fuels derived from hydrogen (such as SNG), via power-to-gas systems which utilise excess renewable energy to produce hydrogen by electrolysis. The wide adoption of such systems would enable a much greater exploitation of the UK's substantial renewable resource without incurring substantial wind/solar curtailment.

⁶http://www.kiwa.co.uk/uploadedFiles/Our_Services/Energy_and_Carbon_Advice/H21%20Report%20Interactive%20PDF%20July%202016.pdf

⁷ <https://www.theccc.org.uk/publication/e4tech-for-ccc-scenarios-for-deployment-of-hydrogen-in-contributing-to-meeting-carbon-budgets/>

⁸ https://www.hydrogen.energy.gov/pdfs/htac_02_2011_mckinsey_thomas.pdf

Hydrogen is a low carbon fuel which can be delivered from a range of production methods, including fossil fuels. Currently, the majority is produced from natural gas through steam methane reforming (SMR). It is anticipated that all hydrogen production methods will be part of the future energy portfolio; this will provide greater flexibility and resilience to the system than would be the case with any single method.

Hydrogen fueled vehicles offer significant carbon reduction and air quality benefits when compared to conventional vehicles:

- Fuel Cell Electric Vehicles (FCEVs) powered with renewable hydrogen have zero well-to wheel (WtW) emissions (of all types, CO₂, NO_x, SO_x etc). Those powered by hydrogen produced from natural gas produce ~85g of CO₂/km on a WtW basis. In comparison, a gasoline fuelled internal combustion engine produces approximately ~170g of CO₂/km on the same basis. By 2030, increasing FCEV deployment could lead to total annual projected CO₂ abatement in the UK of 3 million tonnes. In addition to CO₂ reduction benefits, FCEVs offer significantly improved general air quality by eliminating all oxides of nitrogen and particulate matter from vehicle exhausts, thus addressing a growing area of societal concern.
- As well as FCEVs fueled by hydrogen, adapted conventional engines can also run on hydrogen. In air, particulates and many other by-products of combustion with hydrocarbon fuels are reduced significantly; however, the combustion process needs to be controlled to prevent by-products of the presence of nitrogen (e.g. NO_x). If emission control strategies are implemented and the combustion is carefully optimised it is possible to gain the benefits of very low carbon and improved air quality from hydrogen within conventional engines.

Consolidated thinking is needed between the transport and power teams in Government to appropriately manage the greater adoption of BEV and hydrogen vehicles in the UK. In the context of a holistic energy system, it is important for the Government to recognise the attributes of hydrogen vehicles when fuelled by electrolytic hydrogen produced outside of peak times and as a means of absorbing excess renewable electricity.

Thus, we would encourage the Commission to highlight the importance of the development nation-wide HRS network in the National Assessment Plan, building on the recommendations of the UK H2Mobility report as mentioned above.

National Infrastructure Commission: National Infrastructure Assessment call for evidence

United Kingdom Onshore Oil and Gas response

A. Introduction

- 1) United Kingdom Onshore Oil and Gas (UKOOG) is the representative body for the UK onshore oil and gas industry for both developers and supply chain companies. We welcome the opportunity to provide evidence to the National Infrastructure Commission's call for evidence for the National Infrastructure Assessment.
- 2) As an energy trade association, we are responding to the energy part of the call for evidence. This includes the interplay between energy production, storage and distribution and the transport system.
- 3) As an industry, we would like to make clear that we believe that UK energy policy should provide secure, affordable and climate-friendly energy, with an emphasis on home-grown energy, primary fuels and innovation for the future. To achieve this, we will need a balance of natural gas to provide heat, electricity, essential chemical feedstocks and to improve air quality; renewables and nuclear to generate electricity; and oil to power transportation and provide essential chemical feedstocks.
- 4) Our **response** is centred on four areas:
 - The need for **more UK energy production**, including oil and gas onshore, renewables and nuclear;
 - The critical importance of the UK's **gas infrastructure**;
 - The role of **oil**;
 - The potential to **decarbonise the gas system** in the longer term.

B. Executive Summary

- 5) As we detail below, all the UK energy scenarios and forecasts see oil and gas demand remaining roughly stable for the next 20 years. **In that timeframe, we therefore have a choice of whether to import that requirement or produce it ourselves.** This has major implications for our economy and the environment:
 - Producing oil and shale gas onshore in the UK could together provide more than 100,000 jobs at peak and deliver more than £50 billion of investment, together with substantial tax revenues;
 - By contrast, without onshore production, imports of gas and oil could cost the UK economy £20 billion per year by 2030;
 - Lifecycle greenhouse gas emissions from UK-produced shale are around 10% lower than for gas imported by LNG or long-distance pipeline;
 - Producing oil in the UK also reduces greenhouse gas emissions as it does not require the use of long-distance tankers and pipelines, together with the corresponding inherent energy requirements.

- 6) In the longer term, the **UK's heating needs to be decarbonised**. At present, there are two clear choices:
- Electrify heating, which would require an order of magnitude increase in low carbon power and electricity grid capacity well beyond anything thus far imagined, and which would lie idle in summer, would result in the gas network becoming obsolete, and would lead to major disruption to people's homes costing an average of £10,000 per household.
 - Use the existing gas network, which carries far more energy than the electricity network and can store it seasonally, to carry hydrogen made from methane in an industrial fashion with the carbon stored or used in other processes. This has the benefit of less cost, less disruption and probably a quicker roll-out.
- 7) In order to decarbonise heating, as the Committee on Climate Change and others have concluded, a proper strategy needs to be developed, which includes the prioritising of methane reformation and carbon capture and storage (CCS). At the same time, we need to ensure that the UK maintains the option of our own indigenous gas sources for the same reasons as given above.
- 8) We have two key **recommendations**:
- i. Allow **onshore oil and gas production** to reduce import dependency, generate significant tax revenues and support jobs, the balance of payments and UK industry, while reducing global greenhouse gas emissions by producing more of our energy needs ourselves.
 - ii. Support the progressive **decarbonisation of the gas system**, including through hydrogen and CCS.

C. UK energy production

- 9) Alongside cost-effective decarbonisation, one of the crucial energy infrastructure questions is the **security of supply** of the UK's energy. Security of supply can partly be addressed by a diversity of sources, and a range of gas and electricity interconnectors and oil and gas import terminals. But the **proportion of energy produced indigenously** is also critical.

From a net energy exporter to a big net importer

- 10) Over the last two decades, the UK has shifted from being a major exporter to a **major importer of primary fuels and related energy**, as Chart 1 and Table 1 below show.¹ In 2000, UK net energy/primary fuel *exports* were equivalent to 23% of UK consumption. By 2015, net *imports* had reached 36% of UK consumption, although this was a slight fall from the previous three years.

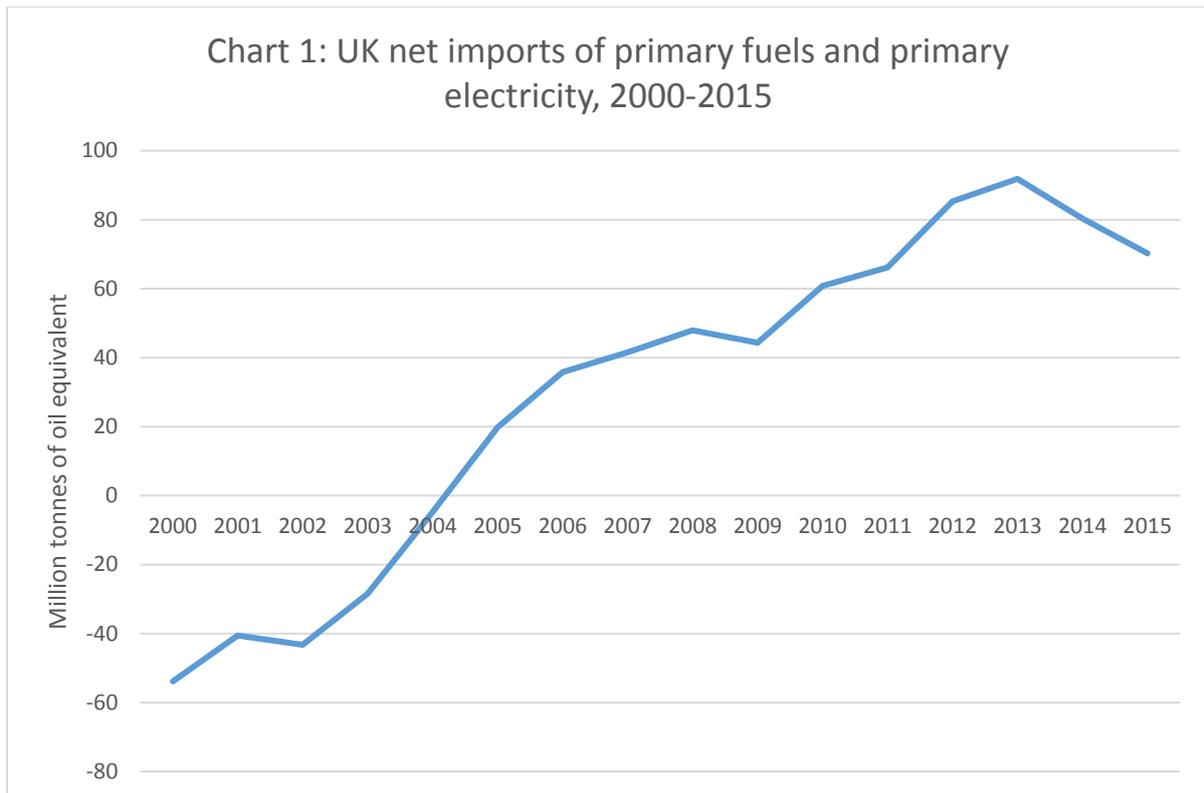

Table 1: UK net imports of primary fuels and primary electricity, 2000 and 2015

	2000		2015	
	Net imports (mtoe)	% of UK consumption	Net imports (mtoe)	% of UK consumption
Coal	19.0	49%	19.7	79%
Petroleum (oil)	-61.6	-80%	17.1	26%
Natural Gas	-12.5	-13%	28.3	42%
Bioenergy and waste	0.0	0%	3.4	25%
Primary electricity	1.2	6%	1.8	8%
Overall	-53.9	-23%	70.2	36%

NB: Negative sign denotes net exports

11) As Table 1 shows, in volume terms, in 2000, the UK was a net *exporter* of 54 million tonnes of oil equivalent (mtoe) of primary fuels and primary electricity. By 2015, the UK was a net *importer* of 70 mtoe. This represents a change of 124 mtoe

Large falls in UK energy production

12) As Table 2 shows², declines in coal, oil, gas and nuclear production (total fall of 176 mtoe from 1995 to 2015) were not offset by increases in bioenergy, waste, wind, solar and hydro production (total rise of 12 mtoe), nor by a fall in consumption (40 mtoe lower). **The key problem is that the UK no longer produces enough primary fuels to meet its energy demands.**

Mtoe	UK production, 2000	UK production, 2015	Change, 2000-2015	% change, 2000-2015
Coal	19.6	5.4	-14.2	-72%
Petroleum (oil)	138.3	49.5	-88.8	-64%
Natural Gas	108.4	39.6	-68.8	-63%
Nuclear	19.6	15.5	-4.1	-21%
Bioenergy and waste	2.3	9.9	+7.6	+330%
Wind, solar and hydro	0.5	4.7	+4.2	+840%
Total UK production	288.7	124.6	-164.1	-57%
<i>Total UK inland consumption</i>	<i>234.8</i>	<i>194.8</i>	<i>-40.0</i>	<i>-17%</i>

Negative impacts of relying on imported energy

- 13) Relying on imports for an increasing share of the UK's energy consumption has a number of detrimental effects. First, it **increases the risk of supply disruption**, if, for example, there is an interconnector failure or a disruption to LNG shipments:
- In November 2015, half the 2GW capacity of the electricity interconnector between the UK and France was lost following a storm. This capacity will stay offline until the end of February.³
 - While Russia is frequently cited as a source of insecurity when it comes to energy, much less discussed is the physical security of LNG supplies. It is of course true that the sources of LNG supplies, including from the US, are growing. At the same time, however, Qatar currently accounts for almost a third of global LNG supply, and over 90% of the UK's LNG imports.⁴ If the Straits of Hormuz were closed, for example due to renewed US-Iran tensions, it would not only represent a catastrophe for global oil supplies, but also a major threat to UK and global LNG supplies.
- 14) Second, it could lead to **increased price volatility**, with electricity and gas prices spiking during cold weather periods, when there is less gas and electricity available from the continent. It also exposes the UK to **international currency fluctuations**, with imported LNG, for example, priced in dollars. The post-Brexit fall in Sterling has therefore had a direct knock-on impact on the price of gas imports.
- 15) Third, it harms the UK's balance of trade, tax revenues and jobs. In 2015, the **UK spent over £14 billion on net primary fuel/energy imports** – crude oil, oil products, natural gas, coal and electricity – and the figure was over £20 billion in 2012 and 2013, when prices were much higher.⁵ We estimate that by 2030 imports of gas and oil alone could cost the UK economy £20 billion per year.⁶ This is money that could be generating jobs and tax revenue in the UK.
- 16) It should therefore be a priority, alongside efforts to decarbonise in a cost-effective manner, to reverse the UK's recent decline in energy production. This should be achieved through a balanced mix of **higher renewables, nuclear and gas and oil production** in the UK.

D. The importance of the UK's gas infrastructure

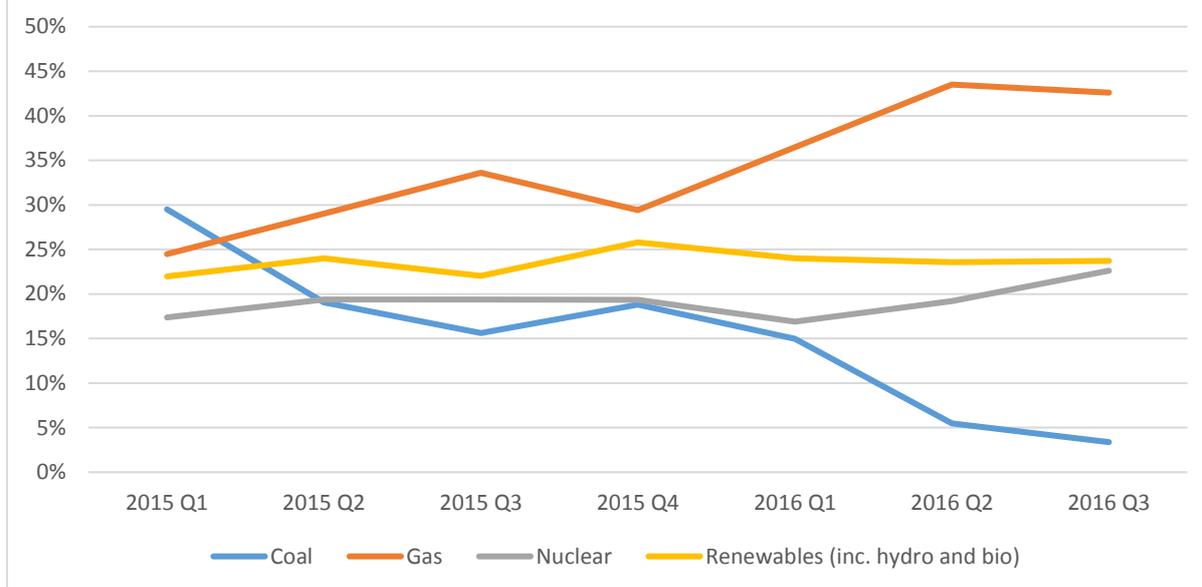

17) **Gas plays a crucial role** in the UK's **energy** system, as well as its **manufacturing** and **agriculture**. The gas network transports and stores more energy, especially in winter, than the electricity network. Gas use will remain high for some time to come, as the UK decarbonises, and therefore **indigenous production of gas** should be supported, including onshore shale gas.

The importance of gas

18) Gas is a vitally important source of **energy** for the UK:

- **Domestic heat:** 84% of homes are heated by gas⁷ and 61% of homes use gas for cooking⁸. Overall, gas meets 77% of domestic heating needs once space heating, water heating and cooking are combined.⁹ A typical household will use 12,500 KWh of gas annually, compared with 3,100 KWh of electricity.¹⁰ Looking at the whole economy, gas accounts for around 80% of domestic, commercial and industrial heating.¹¹
- **Industrial heat:** Heat accounts for around 80% of industrial energy use and can represent 20-40% of final product costs.¹² Sectors such as food and drink, chemicals and pulp and paper often require low temperature process heat of around 300-500°C. Energy intensive industry sectors, including the use of kilns or furnaces to produce glass, cement, iron, steel and chemicals, often require high temperature process heat of above 1,000°C. Gas is the most important industrial heating source, and in many industrial processes cannot be replaced by electricity – this is because for some high temperature processes, the burn characteristics of the fuel (namely calorific value, flame stability and cleanliness) are critical. In Scotland, 43% of all gas consumed is by industry.¹³
- **Electricity:** As Chart 2 shows, gas has become the UK's largest source of electricity, accounting for around 45% of electricity generation and allowing the share of coal-fired generation to fall to record lows.¹⁴ Gas-fired power stations can run continuously or as flexible back-up for intermittent wind and solar. In the absence of large-scale electricity storage, wind and solar cannot be successful without gas, and hence the Government's welcome policy to close coal-fired power stations by 2025 would not be possible without gas.

Chart 2: UK quarterly electricity generation 2015 and 2016 - main sources

- **Transport:** Compared with Euro VI diesel, natural gas-fuelled HGVs emit 41% less harmful NOx and 74% less NO₂.¹⁵ Compared with older diesel standards, the savings would be even greater. Natural gas trucks and buses could therefore help to reduce high levels of air pollution in cities. Companies such as Waitrose are already starting to use HGVs fuelled by compressed natural gas,¹⁶ while Reading has a fleet of natural gas buses.¹⁷

19) Gas is vital for the UK's **manufacturing** industries:

- Gas, together with natural gas liquids such as ethane and propane, is a **building block for everyday goods** such as food packaging, textiles, mobile phones, medicines, cosmetics and paints. It is also a raw material used in the construction of **green goods**, including loft insulation and solar panels.¹⁸ The UK's chemical and pharmaceutical industries, which rely on natural gas as a raw material, support **500,000 jobs**.¹⁹

20) Gas is also essential for **agriculture**:

- Natural gas is one of the main components of ammonia (the hydrogen (H) in ammonia (NH₃) comes primarily from natural gas). Ammonia is widely used in nitrogen-based fertilisers that are needed for food production.²⁰ **Nitrogen fertiliser** was applied to **75% of all farmland** (both crops and grass) in Great Britain in 2015.²¹

21) Improvements in **sustainability** also require the support of gas:

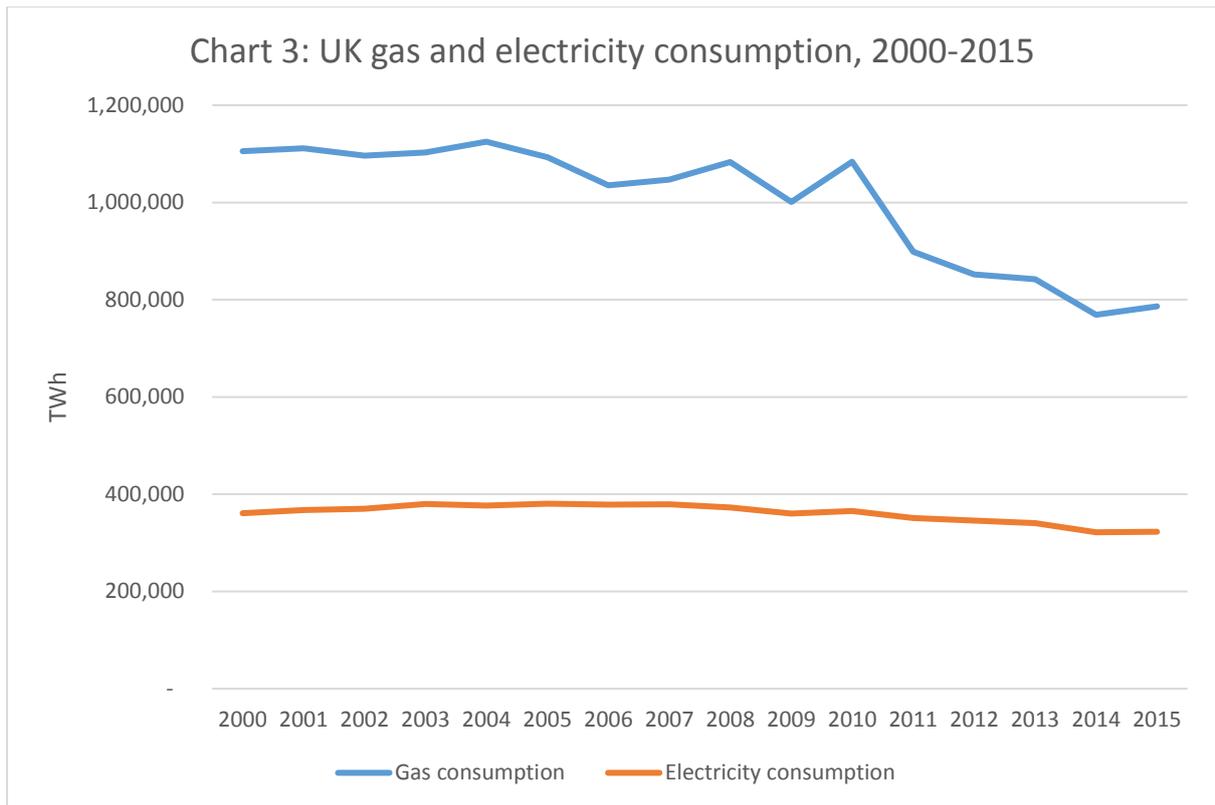

- As noted above, gas provides electricity when the wind doesn't blow and the sun doesn't shine, and is used as a raw material in the manufacture of items such as insulation material and solar panels. Gas is also a vital heat source in **recycling** – glass recycling furnaces in the UK use 1 million cubic metres of gas per day.²²

The UK's gas network infrastructure

- 22) The UK's gas network infrastructure consists of nearly **300,000 km of pipelines** of various dimensions, capacities and pressures, which transport the gas to over 20 million homes and businesses as well as the UK's gas-fired power stations.²³ It has been built up over 200 years, with local pipeline networks originally transporting gas derived from coal ('town gas').
- 23) In the 1960s and 1970s, the National Transmission System (NTS) – the very high capacity and pressure gas pipelines (the motorway network is a useful analogy) – was built to transport natural gas newly-produced from the North Sea across the country. At the same time, local gas networks switched from transporting town gas to natural gas, and conversions to the appliances in millions of homes were carried out systematically to enable natural gas to be used.
- 24) Overall, the UK's gas system remains a very high capacity, extremely reliable means of **transporting and storing energy**. As Table 3 shows, it has a far higher level of capacity and storage than the UK's electricity network, and at the same time is cheaper and lower carbon when used for heat.

	Gas network (for heat)	Electricity network
Peak demand (GW)	300	60
Storage duration (hours)	900	9
Storable energy (TWh)	50	0.027
Retail energy cost (£/MWh)	48	154
Carbon intensity (gCO ₂ /KWh)	185	375

- 25) The price differential between gas and electricity is significant. **Electricity costs consumers at least three times more per KWh than gas**, and this is true for domestic, commercial and industrial consumers.²⁵
- 26) As Chart 3 shows, although gas consumption has fallen in recent years, the **gas network** can carry **1,100 TWh** of energy a year, including gas used for electricity generation. By contrast, the **electricity network** carries up to around **400 TWh** a year.²⁶ And, as Table 3 shows, at peak times the gas network is meeting demand that is around five times higher than electricity.

27) Making best use of the UK's extensive gas infrastructure to support decarbonisation will be essential to avoid the costs of increasing the size of the electricity network several times over.

Projections for UK gas consumption and production

28) Over the next two decades, the UK is projected to continue to need a **considerable amount of gas**, including in scenarios where the carbon budgets are achieved:

- The **Committee on Climate Change's Fifth Carbon Budget** report, for the period 2028-32, expects that natural gas demand will fall slightly, from 810 TWh in 2014 to 700 TWh in 2030, in a scenario consistent with meeting the fifth carbon budget.²⁷
- In **National Grid's 'Gone Green' scenario**, natural gas demand (excluding 'green gas') falls from 78 billion cubic metres (bcm) in 2015 to 55 bcm in 2040.²⁸

29) At the same time, the UK's **production of natural gas offshore** is expected to continue to fall, leading to ever **greater import dependency**.²⁹

- Currently (2015), the UK produces around 400 TWh of gas, with an **import dependency of roughly 50%**.
- In 2030, the Oil and Gas Authority (OGA) expects UK offshore production to fall to 200 TWh, meaning an **import dependency of over 70%**, assuming demand is at the 700 TWh level projected in the Committee on Climate Change's Fifth Carbon Budget report (see above).
- In 2035, the OGA expects offshore production to fall further, to 155 TWh, or 14 bcm. This would mean **import dependency of 75%**, assuming gas demand (excluding

green gas) in line with National Grid's 'Gone Green' scenario of around 55 bcm by 2040. The 'Gone Green' scenario itself expects offshore production to fall faster than the OGA, meaning that **import dependency would rise to 89%** by 2040.

The benefits of indigenous onshore shale gas production

30) In order to address the negative effects of import dependency described earlier, and take advantage of a number of substantial opportunities, **indigenous onshore shale gas production should be permitted**. This should take place alongside the development of the UK's renewable and nuclear capacity. There are three key benefits:

- **Energy security:** As described above, without indigenous onshore production, gas imports will continue to rise to very high levels. By contrast, National Grid projects that shale gas production could reduce gas imports to around 25% of consumption by 2030.³⁰
- **Economy:** In 2014, UKOOG and the then Department for Business, Innovation and Skills commissioned EY to assess the level of materials, equipment and skills that a shale gas production phase would need. The report concluded that shale gas production could see £33 billion of spending in the supply chain over the next 20 years, creating 64,500 jobs.³¹ If the UK's onshore gas resources are not developed, these jobs and investment will go overseas.
- **Environment:** As Professors McKay and Stone have concluded, lifecycle greenhouse gas emissions from UK-produced shale are around 10% lower than for gas imported by LNG or long-distance pipeline.³² And this conclusion isn't surprising. Imported gas can come from parts of the world that lack the environmental safeguards we have in the UK, and it takes a lot of energy to freeze gas, transport it on a ship and then re-gasify it at a British terminal.

31) The UK has the **industry experience** to make a success of shale gas production. Over 2,000 wells have been drilled onshore, with around 200 having been hydraulically fractured to enhance recovery.³³ The Wytch Farm oilfield – western Europe's largest onshore – is located in an Area of Outstanding Natural Beauty, on a World Heritage Coastline, and amongst the highest property prices in the country, and produced 100,000 barrels of oil a day at peak production. Today, the industry has **230 operating oil and gas wells onshore** on 120 sites, producing about 8 million barrels of oil equivalent per year – this is enough to fuel the equivalent of around **1 million cars** or heat nearly **1 million homes**.³⁴

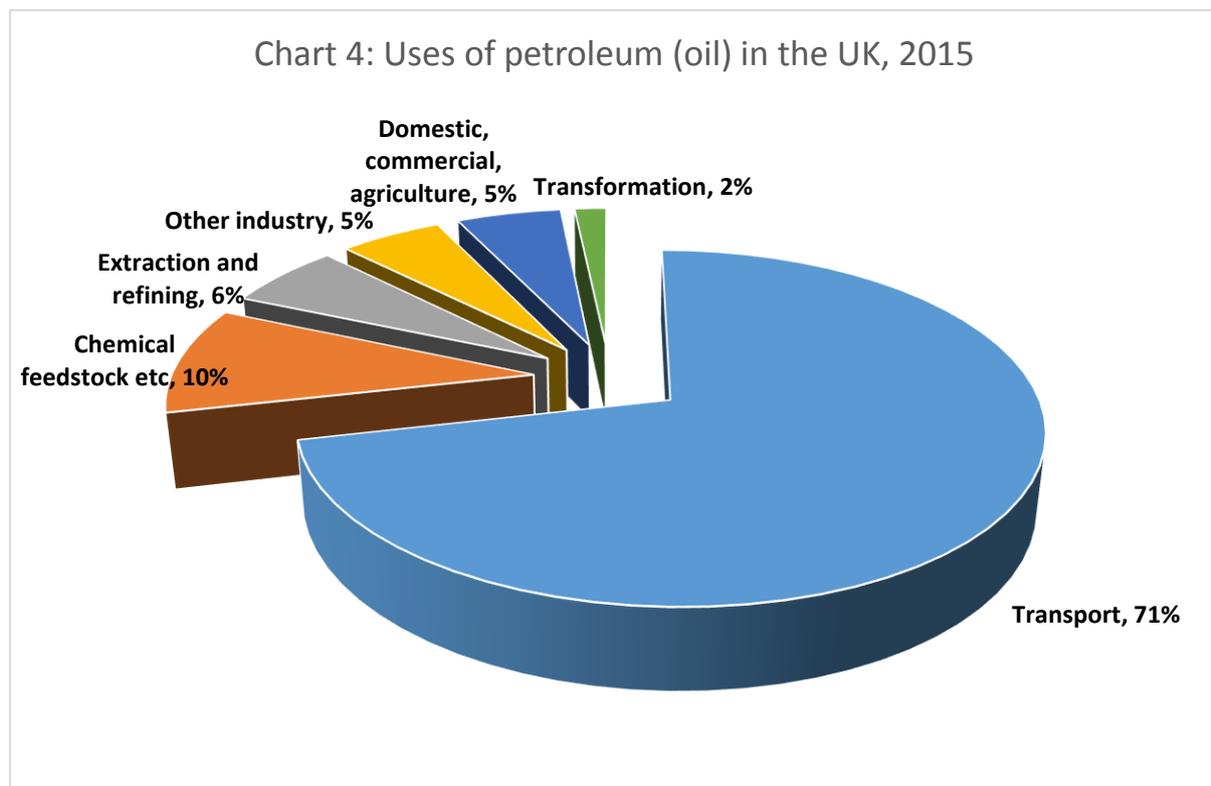

32) The UK also has **very large shale gas resources**, which make the aim of reducing gas imports a realistic prospect. An estimated 1,300 trillion cubic feet of shale gas lies in the Bowland Shale in the North of England³⁵ – if only 10% could be extracted, it would be equivalent to 40-50 years of UK gas consumption (the UK consumes around 2.75 trillion cubic feet of gas a year).

E. The importance of oil

33) Oil plays a vital role in the UK's energy system, providing **fuel for transport and vital chemical feedstocks**. Oil will continue to be needed in large quantities for some time to come, and like gas, the UK should prioritise **indigenous production**, including from onshore.

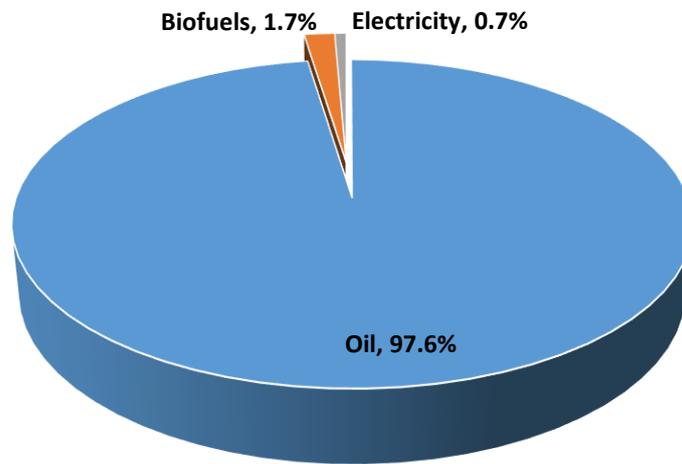

How oil is used in the UK

34) Chart 4 provides a breakdown of the UK's consumption of petroleum products (oil) in 2015. **Transport accounts for over 70% of oil demand**, while industrial and chemical feedstock use account for much of the rest.³⁶

35) Examining transport specifically, as Chart 5 shows, **oil accounted for 97.6% of all transport energy demand** in 2015, with 1.7% coming from biofuels and just 0.7% from electricity (mainly for trains).³⁷

Chart 5: UK transport energy use, 2015

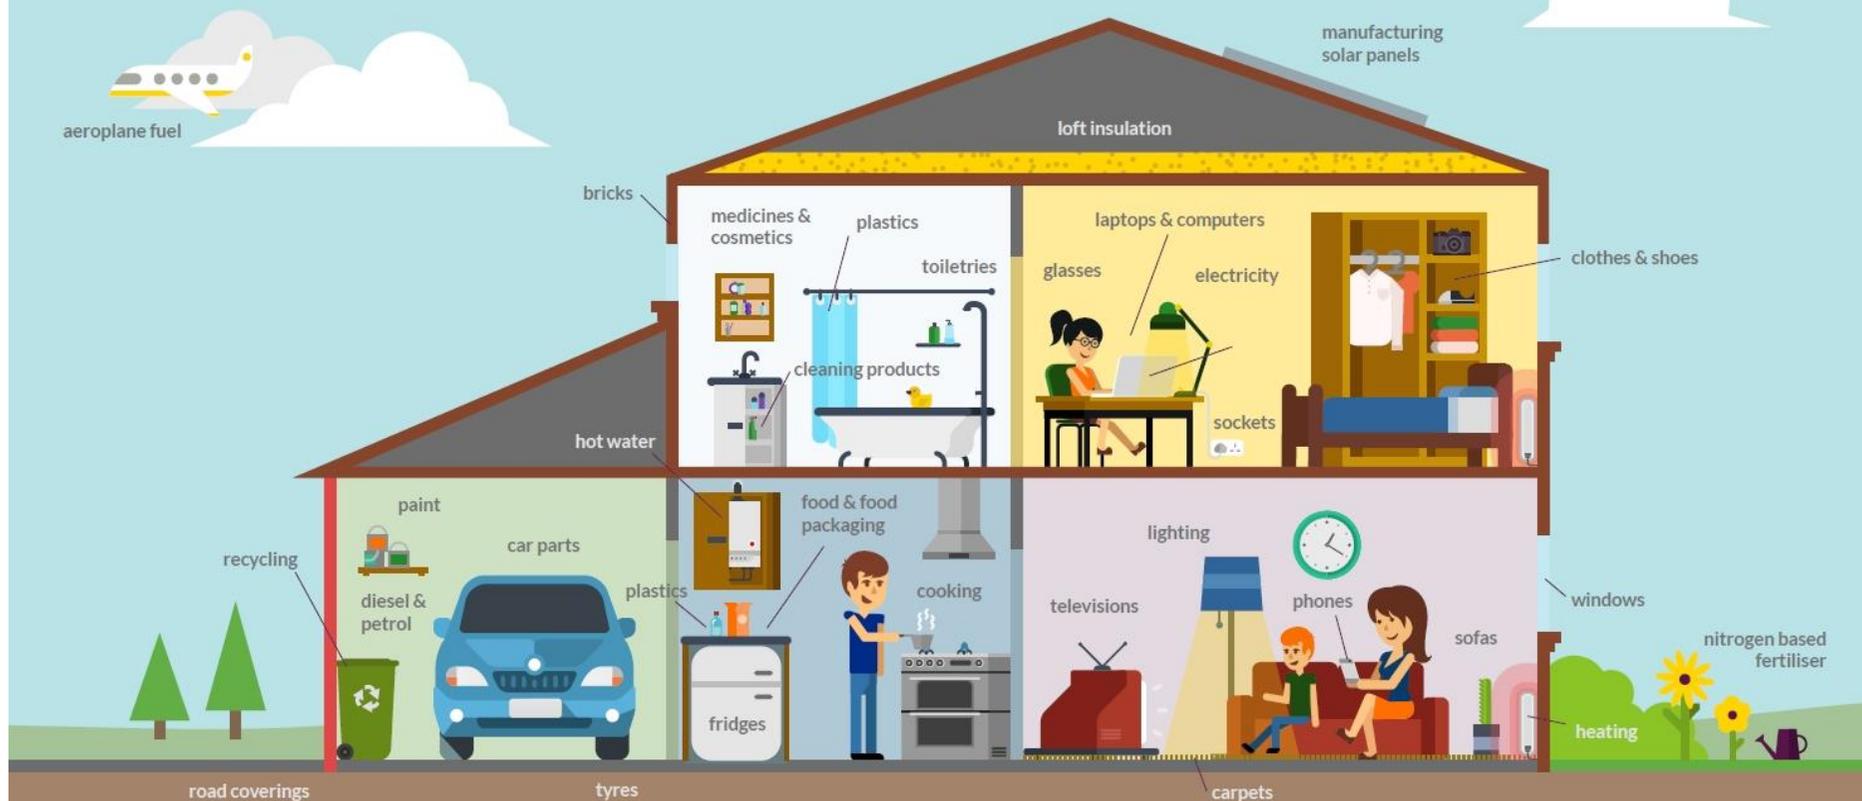

36) Oil, however, is not just vital as a transportation fuel. Alongside gas, it provides the **raw material** for a wide range of everyday products. The diagram on the next page provides examples of how oil and gas support so many of the products we use and the things we do at home. Further examples of products partly made with oil are listed below:

- **At school:** rulers, crayons, ink and cartridges, glue, coverings on books, binders.
- **For your health:** coatings for pills, binding agent for creams, disposable syringes.
- **In the home:** contact lenses, cosmetics, clothing, fabrics, nail polish, deodorants, shampoo, paint, upholstery and carpets, detergents for washing up and laundry, dry-cleaning fluid.
- **Out shopping:** shopping bags, credit cards, egg cartons, plastic milk bottles.
- **While cooking:** non-stick pans, cling film, storage containers.
- **For building:** roofing tiles, pipes, insulating material, paint.
- **On the move:** petrol, diesel and tyres for cars and lorries, emergency services and trains, marine and aviation fuel, asphalt road surfaces.
- **In the office:** computer hardware, phones and faxes, diskettes, pens, chairs, printing ink.
- **At your leisure:** CDs, videos, cassette tapes, camera film, artists' paint, bicycle handlebar grips, tyres, crash helmets, football boots, trainers, shin pads, windsurfers, roller blades, tents.
- **Garden:** fertilisers, pesticides, garden furniture.

Thanks to oil and gas...

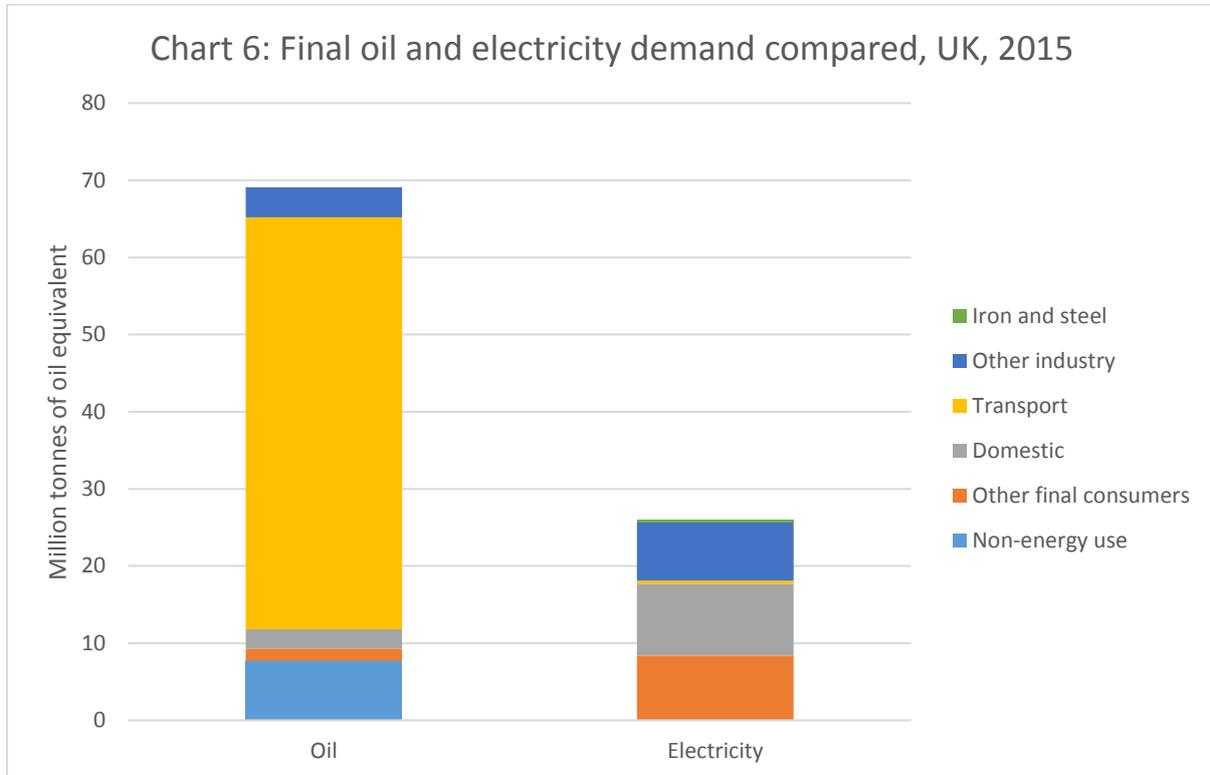

So many of the products we use and the things we do at home would not be possible without oil and gas and the compounds and materials produced from them. Oil and gas are used in all of the following:

The Natural Gas Coalition

What would you do without them?
Let's look under our feet

37) Oil is no longer a major generator of electricity, with less than 1% of the UK's oil demand being used in this way.³⁸ But like gas, **oil provides far more energy than the electricity system**. As Chart 6 shows, final oil demand was nearly 70 million tonnes of oil equivalent (mtoe) in 2015, compared with final electricity consumption of 26 mtoe in the same year.³⁹

Projections for UK oil consumption and production

38) Similar to gas, over the next two decades, the UK will continue to need a **considerable amount of oil and petroleum products**, including in scenarios where the carbon budgets are achieved:

- The **Committee on Climate Change's Fifth Carbon Budget** report, for the period 2028-32, expects that petroleum product demand will fall by 29%, from 890 TWh in 2014 to 635 TWh in 2030, in a scenario consistent with meeting the fifth carbon budget.⁴⁰
- The most recent projections from the Oil and Gas Authority envisage oil product demand falling more slowly, from 77 million tonnes of oil equivalent (mtoe) in 2015 to 71 mtoe in 2035.⁴¹

39) At the same time, the UK's **production of oil** is expected to continue to fall, leading to ever **greater import dependency**.⁴²

- Currently (2015), the UK produces just under 50 mtoe of crude oil and natural gas liquids, with an **import dependency of 36%**.
- In the **Committee on Climate Change's** fifth carbon budget scenario, petroleum product import dependency rises to 65% in 2030.

- In 2035, the Oil and Gas Authority (OGA) expects UK production to fall to 23 mtoe, meaning an **import dependency of 68%**.

The benefits of indigenous onshore oil production

40) The UK has **large onshore oil resources**:

- The **Weald Basin** in the South of England has been estimated to hold 124 billion barrels of oil in place (P50, best estimate), including 19.5 billion barrels (P50, best estimate) in the Kimmeridge Limestones,⁴³ which have seen successful initial flow-tests at Horse Hill in 2016.⁴⁴ Longer term Kimmeridge Limestones flow-tests and further drilling are planned in 2017-18.
- The British Geological Survey has estimated that the **Midland Valley of Scotland** holds 6 billion barrels of oil in place in the Carboniferous shales.⁴⁵

41) It also has a **long history of safe and sustainable production** onshore:

- The first oil was produced onshore in Scotland in **1851**.
- In the **second world war**, over 100 oil wells were drilled in Sherwood Forest, producing 3.5 million barrels of oil to support the war effort.⁴⁶
- As noted previously, the **Wytch Farm oilfield** – western Europe’s largest onshore – produced 100,000 barrels of oil a day at peak in the late 1990s, with minimal impact on the sensitive surrounding countryside and residential housing. Similarly, the industry today maintains 120 producing sites without negative impacts on communities or the environment.

42) There are a number of **economic advantages** of indigenous onshore oil production:⁴⁷

- A recent report by EY projected that Kimmeridge Limestones oil production in the South of England could reach up to 330,000 barrels a day at peak production in the High scenario. This is approximately 27% of current UK consumption and would represent oil that would no longer need to be imported. At an oil price of \$50 a barrel (£40 a barrel), this would **boost the UK’s balance of payments** by \$16.5 million (£13.2 million) each day, or over \$6 billion (£4.8 billion) a year.
- Over several decades, the EY report found that Kimmeridge Limestones oil production could **contribute between £7.1 billion to GVA in the Low scenario and £52.6 billion to GVA in the High scenario**, generating a peak of 8,000-49,000 jobs.
- **Lifetime tax revenues** from the development of Kimmeridge Limestones oil are estimated to be between £2.1 billion in the Low scenario and £18.1 billion in the High scenario.

43) The key **environmental benefit** is that production in the UK is strictly regulated by the Health and Safety Executive, Environment Agency, Oil and Gas Authority and local Mineral Planning Authorities to protect the health and safety of workers and the environment. UK production reduces the need for imports from parts of the world that may lack the UK’s stringent environmental safeguards and health and safety regime, and avoids the need for significant energy used in the transportation of oil across large distances.

F. Decarbonising the gas system in the longer term

44) The gas system not only provides important benefits in the next two decades, but has the potential to contribute directly to deeper decarbonisation. A **decarbonised natural gas infrastructure**, using hydrogen and other low carbon gases, could complement the development of renewable and nuclear electricity.

The great potential of hydrogen to help decarbonise heating and transport

45) **Hydrogen emits no CO₂ at the point of use** and has great potential to help decarbonise heating and transport – which currently account for around 50% of UK greenhouse gas emissions⁴⁸ – supporting the vital roles that renewables, nuclear and energy efficiency will play in meeting our carbon reduction commitments:

- Hydrogen could **directly replace natural gas use** for heating homes and businesses;
- Hydrogen could be distributed to customers using the **existing gas distribution network**, which is one of the most extensive in the world. Through the current Iron Mains Replacement Programme, older metal gas pipes are being replaced with polyethylene, which will allow hydrogen to be transported;
- Hydrogen therefore repurposes existing gas networks, **avoiding both expensive stranded assets and significant additional electrical network expenditure**;
- Hydrogen could **power cars, buses and HGVs**, with a similar driving range to diesel and petrol, with no carbon dioxide and no air pollutants – improving city air quality.

46) Modelling for the Committee on Climate Change carried out by E4tech, University College London Energy Institute and Kiwa Gastec showed that hydrogen could become the main source of energy for heating and transport by 2050, enabling dramatic reductions in emissions.⁴⁹ On more modest assumptions, Energy Research Partnership calculations suggest that **80 million tonnes a year of CO₂ could be saved** from domestic and commercial heat and from transport by 2050 – based on 9 million homes heated by hydrogen and 16 million fuel cell cars, with some additional commercial buildings, HGVs and buses also using hydrogen.⁵⁰

Hydrogen and electric heating are complementary, avoiding the major costs and challenges from relying solely on electricity

47) A fully decarbonised heating system will need a mix of solutions:

- **Hydrogen-based central heating**, using the current infrastructure for the delivery of gas;
- **Better insulation and technologies** such as more efficient boilers, gas-driven heat pumps and gas-fired micro CHP units, which can reduce the carbon intensity of the current gas-based heating system;
- **District heating and electric heat pumps** will have a role to play in some areas, and can complement the widespread use of hydrogen.

48) An electric-only UK-wide heating system would be very difficult and costly. Conversely, a grid of gaseous energy has proved its ability to meet the very high and time-varying

heat demands of the UK's buildings, and therefore the development of a low-carbon gas grid is fundamentally logical:

- **Meeting the UK's winter heating needs:** As noted earlier, peak electricity demand is up to 60 GW, but peak winter heat demand, (currently 80% gas-based) is over 350 GW – six times as high.⁵¹ A recent report by Policy Exchange found that installing electric heat pumps in 80% of homes would require an additional 105 GW of electricity generating capacity,⁵² more than double the current level and equivalent to more than 30 Hinkley Point C nuclear power stations. Much of this new electricity infrastructure would lie idle in the summer when heating is not needed.
- **Minimising cost to consumers:** For large parts of the UK heat system hydrogen has cost advantages over electricity. As it can be stored at scale (in similar facilities to those used for natural gas) and can make use of existing distribution infrastructure (to which 84% of homes in the UK are connected), hydrogen has much lower seasonal storage and distribution costs than wholesale electrification or district heating. Installing electric heat pumps in 80% of homes would be hugely expensive, costing an estimated £200 billion to install (nearly £10,000 to change the central heating system in each home) and an additional £100 billion to expand and upgrade the power system.⁵³ Overall, an electric-only solution could cost an additional £274-318 billion by 2050, compared with a predominantly gas-to-hydrogen route costing £104-122 billion – both scenarios would meet the 80% carbon reduction target in 2050.⁵⁴
- **Avoiding major infrastructure and storage impacts:** There would be significant landscape impacts from a large number of new electricity generating facilities and electricity pylons criss-crossing the country, or large additional costs from burying electricity cables. These landscape impacts can be avoided by displacing additional electricity generation facilities and networks with repurposed existing underground gas networks. At the same time, as noted earlier, the electricity system can currently only store 0.027 TWh⁵⁵ – a tiny fraction of electricity use – and so a major investment in inter-seasonal storage can be avoided by harnessing the value of the existing gas system.

Carbon capture is key to producing low-carbon hydrogen at scale

49) Hydrogen can be created in several ways:

- First, **fossil fuel reforming** is the most common way to produce hydrogen, accounting for more than 95% of the world's hydrogen production. The most common method is **steam methane reforming**, which produces hydrogen from natural gas. This process alone accounts for almost half of the world's hydrogen production.⁵⁶ With carbon capture, emissions from this process fall to just 33-39 gCO₂/KWh, at an estimated cost of around £2 per kg of hydrogen produced.⁵⁷
- Second, **electrolysis** of water produces hydrogen and oxygen using electricity. Once the UK's renewable electricity infrastructure is fully developed, the process could be powered with excess renewable generation at times of low demand – excess energy levels are predicted to rise considerably due to the rapid growth in intermittent renewables. It is currently estimated to cost around £4-6 per kg of hydrogen produced.⁵⁸
- Third, **biomass gasification** uses a controlled process involving heat, steam, and oxygen to convert biomass to hydrogen and other products, without combustion.

Combined with carbon capture, it offers the potential for negative emissions – up to minus 500 gCO₂/KWh. It is currently estimated to cost £4-5 per kg of hydrogen produced.⁵⁹

50) All these methods of hydrogen production will be needed, but the key to producing hydrogen in a low-carbon way at scale is to add carbon capture onto steam methane reforming:

- Excess renewable electricity could produce between 10 TWh and 32 TWh of hydrogen a year, providing up to around 10% of the UK's domestic heating needs.⁶⁰ **Meeting the UK's entire domestic heating needs from hydrogen produced by electrolysis, however, would require about 150 GW of wind power, a ten-fold increase on today's level of 15 GW.**⁶¹
- The ultimate contribution of biomass gasification could be limited by the amount of indigenous biomass available in the UK, depending on the sustainability criteria attached to imported biomass.

There is a major opportunity for low-carbon hydrogen production in the UK

51) **Hydrogen production from natural gas with carbon capture** is already proven:

- Two steam methane reforming plants in Port Arthur, Texas, have been retrofitted with carbon capture technology, and 1 million tonnes a year of CO₂ is now being captured and used;⁶²
- The Quest CCS project in Canada has been operating since November 2015,⁶³ and has stored over 1 million tonnes of CO₂ to date.⁶⁴

52) Overseas projects, however, will not help the UK to produce low-carbon hydrogen at scale – the carbon needs to be captured and stored or used here in Britain.

53) CCS is often thought about as capturing emissions from power stations post-combustion, but it can also be used to create low-carbon hydrogen before distribution to customers and therefore support decarbonisation of homes and industry. As specialist bodies have recommended, a **carbon capture strategy is urgently needed:**

- **Committee on Climate Change:** *“CCS is of critical importance to meet the UK's climate targets at least cost, and requires a strategic approach to its development ... There is no strategy for the development of CCS following the cancellation of the Commercialisation Programme in November 2015. Lessons learnt in that process enable a more strategic approach to be adopted, which can support commercialisation of CCS at a lower overall cost to the consumer and taxpayers. The new approach should ... be based around shared infrastructure for CCS ‘clusters’ in areas of industrial activity and requires a new funding mechanism for industrial CCS, to operate alongside contracts for difference for power plants.”*⁶⁵
- **Imperial College:** *“The most important precondition for using hydrogen would be the development of large scale, low cost production facilities. This could be by electrolysis of water, although this is currently very expensive and not yet suited to large scale production, or through conversion of natural gas by steam methane reformation (SMR) ... SMR produces carbon dioxide as a by-product and its use would therefore be very dependent on the availability of CCS.”*⁶⁶

54) The UK has **solid foundations** to build a carbon capture industry:

- Carbon capture infrastructure could be built around a number of **existing industrial clusters**, including Grangemouth, Teesside, the Humber, South Wales and North West England – including the Atlantic Gateway corridor;
- The **North Sea has ample CO₂ storage opportunities**, estimated to be around 78 billion tonnes. Simply utilising the top 15% of this storage capacity would be enough to meet UK needs for 100 years;⁶⁷
- The UK has a **world class oil and gas industry** with the expertise needed to deliver a CCS industry;
- As a recent government report highlighted, there is also great potential in Carbon Capture and Utilisation (CCU), whereby the captured **CO₂ is used to make chemical products and solid materials**, including more advanced building materials, putting UK companies at the forefront of new markets.⁶⁸

55) It takes many years to construct a CCS infrastructure and to develop CCU technologies to commercial readiness. It is imperative that progress is made now so that a large source of low carbon hydrogen can be provided to support the UK's decarbonisation in line with statutory targets. As the recent Lord Oxburgh review of CCS concluded: *"Carbon capture and storage is an essential component in delivering lowest cost decarbonisation across the whole UK economy. Current CCS technology and its supply chain are fit for purpose. There is no reason to wait for international projects or for technological progress in either the components or overall system of CCS ... UK action on CCS now will deliver lowest cost to the consumer ... Ample, safe and secure CO₂ storage capacity is available offshore in the rocks deep beneath UK territorial waters."*⁶⁹

56) The Committee on Climate Change has also drawn a similar conclusion: *"Hydrogen pilots can also begin and must be of sufficient scale and diversity to allow us to understand whether this can be a genuine option at large scale. As large-scale hydrogen deployment would require use of carbon capture and storage (CCS), a strategy for CCS deployment remains an urgent priority."*⁷⁰

G. Recommendations

57) We have two key **recommendations**:

- i. Allow **onshore oil and gas production** to reduce import dependency, generate significant tax revenues and support jobs, the balance of payments and UK industry, while reducing global greenhouse gas emissions by producing more of our energy needs ourselves.
- ii. Support the progressive **decarbonisation of the gas system**, including through hydrogen and CCS

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
LONDON
EC3M 8UD

By email to: NIAEvidence@nic.gsi.gov.uk

10 February 2017

Dear Sir

National Infrastructure Assessment Call for Evidence

Thank you for the opportunity to respond to the Commission's call for evidence to provide input into the development of its National Infrastructure Assessment. This letter should be regarded as a consolidated response on behalf of UK Power Networks' three distribution licence holding companies: Eastern Power Networks plc, London Power Networks plc, and South Eastern Power Networks plc.

We have responded to three questions in the call for evidence that are relevant to our activities as a distribution network operator. Our comments are set out in the appendix to this letter.

We would also draw your attention to our response to the call for evidence on A Smart, Flexible Energy System by Ofgem and the Department of Business Energy And Industrial Strategy, which we attach separately.

I hope that you will find our comments helpful. If you have any questions, please do not hesitate to contact me.

Yours faithfully

Appendix: UK Power Networks' response to selected questions in the Commission's call for evidence (October 2016)

Cross-cutting issues:

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

There are key interdependencies between transport, heat and electricity demands. As the solutions to decarbonising these systems develop, through low carbon electricity and other low carbon energy sources such as hydrogen, it will be important to consider the interactions and resilience implications, as is already the case between the gas and electricity sectors.

The future energy system will also be reliant on the resilience and security of information systems that allow the control of smart demands (e.g. smart domestic appliances and electric vehicle (EV) charging). A risk based, proportionate and flexible approach to cyber security will be required.

Energy:

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.

A zero carbon system will need to have flexibility at the core of its operation, including flexible demand and energy storage technology (comprising of grid scale, behind the meter domestic and commercial and vehicle to grid technologies).

We believe that the transition of distribution network operators to active distribution system operators will be key to this transition. In this respect, we would highlight our attached response to the call for evidence on A Smart, Flexible Energy System by Ofgem and the Department of Business Energy And Industrial Strategy.

The approach to decarbonisation of heat will be a key issue for electricity systems in the period beyond 2030, given the 300GW of heat demand compared to the current 60-70GW of electricity demand.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The anticipated uptake of low carbon technologies such as EVs, storage and distributed generation means that, by the mid-2020s, we could see over two million active devices providing flexibility on our three distribution networks.

Current forecasts indicate that by 2030, EVs could introduce as much as 3GW of additional demand to the peak demand in UK. Recent analysis showed that electrification of taxis and buses in London could see the connection of approximately 1.5GW of charge points by 2030. This can be compared to the current peak demand on the London network of 4.8GW.

The need for additional generation, transmission and distribution resources will depend on how the energy demand coincides with existing demands or can make use of periods of lower demand. A key priority for government, which we have highlighted in our response to a Smart, Flexible Energy System, should therefore be the development of a smart vehicle charging framework. This needs to encourage cross-sector cooperation to develop the technology (both vehicle and charging control), infrastructure, markets and incentives that encourage customers to adopt EVs in a way that allows the transport and supporting energy infrastructure to develop efficiently. For example, low cost energy is currently available during the daytime when demand is lower and solar generation output is at its peak, so it would seem sensible, from an energy system perspective, to provide the infrastructure and incentives to encourage charging of EVs at this time, rather than in the evening when demand is higher. This may require a framework where users are encouraged to charge vehicles away from home.

Improving visibility of the location, characteristics and use of charge points will be vital to realising the benefits of smart charging for customers and electricity networks, and to enabling the efficient development of the supporting energy system. We would welcome government support in this respect.

Finally, fast charging infrastructure (with output up to 350kW) may require significant infrastructure investment to support; therefore, understanding the likely development will be a key input into future planning. We are already working with Transport for London on the implications for the electrification of the London bus fleet and how best to connect the additional demand (potentially 800MVA). Attention is also turning to planning for the provision of charging infrastructure to support the electrification of the London taxi fleet.

Executive summary	5
1. Removing policy and regulatory barriers	14
Enabling storage	14
Question 1: Have we identified and correctly assessed the main policy and regulatory barriers to the development of storage? Are there any additional barriers faced by industry?	14
Question 2: Have we identified and correctly assessed the issues regarding network connections for storage? Have we identified the correct areas where more progress is required?	17
Question 3a): Have we identified and correctly assessed the issues regarding storage and network charging?	20
Question 3b): Do you agree that flexible connection agreements could help to address issues regarding storage and network charging?	22
Question 4a): Do you agree with our assessment that network operators could use storage to support their networks?	22
Question 4b): Are there sufficient safeguards to enable the development of a competitive market for storage?	23
Question 4c): Are there any circumstances in which network companies should own storage?	23
Question 5: Do you agree with our assessment of the regulatory approaches available to provide greater clarity for storage?	25
Question 6: Do you agree with any of the proposed definitions of storage?	25
Aggregators	26
Question 7: What are the impacts of the perceived barriers for aggregators and other market participants? Please provide your views on:	26
Question 8: What are your views on these different approaches to dealing with the barriers set out above?	27
Question 9: What are your views on the pros and cons of the options outlined in Table 5? Please provide evidence for your answers.	27
Question 10: Do you agree with our assessment of the risks to system stability if aggregators' systems are not robust and secure? Do you have views on the tools outlined to mitigate this risk?	27
2. Providing price signals for flexibility	29
System value pricing	29
Question 11: What types of enablers do you think could make accessing flexibility, and seeing a benefit from offering it, easier in future?	29
Question 12: If you are a potential or existing provider of flexibility could you provide evidence on the extent to which you are currently able to access and combine different revenue streams? Where do you see the most attractive opportunities for combining revenues and what do you see as the main barriers preventing you from doing so?	31
Question 13: If you are a potential or existing provider of flexibility are there benefits of your technology which are not currently remunerated or are undervalued? What is preventing you from capturing the full value of these benefits?	31
Question 14: Can you provide evidence to support changes to market and regulatory arrangements that would allow the efficient use of flexibility and what might be the Government's, Ofgem's, and System Operator's role in making these changes?	31
Smart tariffs	32
Question 15: To what extent do you believe Government and Ofgem should play a role in promoting smart tariffs or enabling new business models in this area? Please provide a rationale for your answer, and, if you feel Government and Ofgem should play a role, examples of the sort of interventions which might be helpful.	32
Question 16: If deemed appropriate, when would it be most sensible for Government/Ofgem to take any further action to drive the market (i.e. what are the relevant trigger points for determining whether to take action)? Please provide a rationale for your answer.	34

Question 17: What relevant evidence is there from other countries that we should take into account when considering how to encourage the development of smart tariffs?	34
Question 18: Do you recognise the reasons we have identified for why suppliers may not offer or why larger non-domestic consumers may not take up, smart tariffs? If so, please provide details, especially if you have experienced them. Have we missed any?	35
Smart Distribution tariffs: Incremental change	35
Question 19: Are distribution charges currently acting as a barrier to the development of a more flexible system? Please provide details, including experiences/case studies where relevant.	35
Question 20: What are the incremental changes that could be made to distribution charges to overcome any barriers you have identified, and to better enable flexibility?	35
Question 21: How problematic and urgent are any disparities between the treatment of different types of distribution connected users? An example could be that that in the Common Distribution Charging Methodology generators are paid 'charges' which would suggest they add no network cost and only net demand.	36
Smart Distribution tariffs: Fundamental change	36
Question 22: Do you anticipate that underlying network cost drivers are likely to substantively change as the use of the distribution network changes? If so, in what way and how should DUoS charges change as a result?	36
Question 23: Network charges can send both short term signals to support efficient operation and flexibility needs in close to real time as well as longer term signals relating to new investments, and connections to, the distribution network. Can DUoS charges send both short term and long term signals at the same time effectively? Should they do so? And if so, how?	37
Question 24: In the context of the DSO transition and the models set out in Chapter 5 we would be interested to understand your views of the interaction between potential distribution charges and this thinking.	37
Other Government policies	38
Question 25: Can you provide evidence to show how existing Government policies can help or hinder the transition to a smart energy future?	38
Question 26: What changes to CM application/verification processes could reduce barriers to flexibility in the near term, and what longer term evolutions within/alongside the CM might be needed to enable newer forms of flexibility (such as storage and DSR) to contribute in light of future smart system developments?	38
Question 27: Do you have any evidence to support measures that would best incentivise renewable generation, but fully account for the costs and benefits of distributed generation on a smart system?	38
3. A system for the consumer	40
Smart appliances	40
Question 28: Do you agree with the 4 principles for smart appliances set out above (interoperability, data privacy, grid security, energy consumption)? Yes or No (please explain)	40
Question 29: What evidence do you have in favour of or against any of the options set out to incentivise/ensure that these principles are followed? Please select below which options you would like to submit evidence for, specify if these relate to a particular sector(s), and use the text box/attachments to provide your evidence.	40
Question 30: Do you have any evidence to support actions focused on any particular category of appliance? Please select below which category or categories of appliances you would like to submit evidence for, and use the text box/attachments to provide your evidence:	41
Question 31: Are there any other barriers or risks to the uptake of smart appliances in addition to those already identified?	41
Question 32: Are there any other options that we should be considering with regards to mitigating potential risks, in particular with relation to vulnerable consumers?	41
Ultra-low emissions vehicles	41
Question 33: How might Government and industry best engage electric vehicle users to promote smart charging for system benefit?	41

Question 34: What barriers are there for vehicle and electricity system participants (e.g. vehicle manufacturers, aggregators, energy suppliers, networks and system operators) to develop consumer propositions for the:	43
Question 35: What barriers (regulatory or otherwise) are there to the use of hydrogen water electrolysis as a renewable energy storage medium?	45
Consumer engagement with demand side response	45
Question 36: Can you provide any evidence demonstrating how large non-domestic consumers currently find out about and provide DSR services?	45
Question 37: Do you recognise the barriers we have identified to large non-domestic customers providing DSR? Can you provide evidence of additional barriers that we have not identified?	46
Question 38: Do you think that existing initiatives are the best way to engage large non-domestic consumers with DSR? If not, what else do you think we should be doing?	46
Question 39: When does engaging/informing domestic and smaller non-domestic consumers about the transition to a smarter energy system become a top priority and why (i.e. in terms of trigger points)?	47
Consumer protection and cyber security	47
Question 40: Please provide views on what interventions might be necessary to ensure consumer protection in the following areas:	47
Question 41: Can you provide evidence demonstrating how smart technologies (domestic or industrial/commercial) could compromise the energy system and how likely this is?	50
Question 42: What risks would you highlight in the context of securing the energy system? Please provide evidence on the current likelihood and impact.	51
4. The roles of different parties in system and network operation	52
Roles and responsibilities	52
Question 43: Do you agree with the emerging system requirements we have identified)? Are any missing?	52
Question 44: Do you have any data which illustrates:	53
Question 45a): With regard to the need for immediate action, do you agree with the proposed roles of DSOs and the need for increased coordination between DSOs, the SO and TOs in delivering efficient network planning and local/system-wide use of resources?	58
Question 45 b): With regard to the need for immediate action, how could industry best carry these activities forward? Do you agree the further progress we describe is both necessary and possible over the coming year?	61
Question 45 c): With regard to the need for immediate action, are there any legal or regulatory barriers (e.g. including appropriate incentives), to the immediate actions we identify as necessary? If so, please state and prioritise them.	62
Question 46a): With regard to further future changes to arrangements, do you consider that further changes to roles and arrangements are likely to be necessary? Please provide reasons. If so, when do you consider they would be needed? Why?	63
Question 46 b): With regard to further future changes to arrangements, what are your views on the different models, including:	68
5. Innovation	72
Question 47: Can you give specific examples of types of support that would be most effective in bringing forward innovation in these areas?	72
Question 48: Do you think these are the right areas for innovation funding support? Please state reasons or, if possible, provide evidence to support your answer.	72
Annex 1: Stakeholder engagement	73
Annex 2: Bibliography	74

Executive summary

The priorities for Government and Ofgem in 2017

Distribution networks have already responded to the challenge of the changing energy market, connecting 27GW of distributed generation (DG), of which 8.5GW has connected across UK Power Networks' service area (with a further 2.4GW contracted to connect). We have already begun the roll-out of active network management of DG allowing 330MW of generation to connect saving over £100m to DG customers. Current forecasts for the development of low carbon technologies indicate that the capability to use flexibility extensively will be needed from the mid-2020s.

Research undertaken by Imperial College for our Low Carbon London project¹, The Carbon Trust² and E3G³ clearly demonstrate the benefits from a smart, flexible energy system which will be enabled by the transition of Distribution Network Operators (DNOs) to Distribution System Operators (DSOs).

In developing our response, we have actively engaged with stakeholders, including renewable generators, storage providers, aggregators, suppliers and new IT platform providers. Our engagement has provided us with first-hand experience of the issues which these stakeholders face, both in their interaction with us as a network operator and also the wider market place. We have used this experience to inform this response.

We consider that Ofgem and BEIS's should:

- Start the work needed to build on the RIIO regulatory framework to develop aligned incentives for transmission and distribution in time for RIIO-T2 and RIIO-ED2, to deliver whole system flexibility benefits and cost effective decarbonisation;
- Engage with DNOs and the System Operator (SO) to understand the additional costs of developing the advanced monitoring and control systems and enhanced organisational capabilities which will be critical to ensure an efficient flexible energy system, and the additional costs that will need to be incurred developing and deploying these capabilities;
- Clarify the regulatory framework to ensure DSOs can build storage as the least cost technical solution to provide security of supply if specific local circumstances inhibit those services being provided by third parties;
- Support the development of the commercial frameworks and platforms that will allow markets and DSOs to support the complex interactions of a smart, flexible energy system including the visibility of actions to all parties; and
- Support the development of standards to ensure the visibility and control of smart EV charging in conjunction with the Department for Transport and their work on the Modern Transport Bill.

The role of different parties in system and network operation: DNOs must become DSOs and lead the transition to a smart, flexible energy system

The benefits of smart, flexible systems are estimated to be up to £8bn a year by 2050⁴ and rely on the optimisation of distribution connected resources. Since 2010 we have invested heavily in innovation to understand how to deliver these benefits and our highly successful innovation projects are helping us to develop DSO capabilities across our business. Our response draws on the learning from successful projects including:

¹ [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-\(LCL\)/](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-(LCL)/)

- The Low Carbon London (UK Power Networks) and Customer Led Network Revolution (Northern PowerGrid) trials on many of the elements of flexible networks needed for a DSO, testing smart tariffs, EV charging, and demand-side response (DSR);
- The Flexible Plug and Play (UK Power Networks) project which pioneered flexible connections using active network management to allow customers to connect more quickly and at a lower cost;
- The Smarter Network Storage (UK Power Networks) project which demonstrated the value of grid scale storage and highlighted many of the issues raised in the call for evidence;
- The Kent Active System Management (UK Power Networks) and Equilibrium (Western Power Distribution) projects are developing the tools DSOs will need to optimise the use of distribution networks to increase the output of distributed energy;
- The My Electric Avenue (SSE Power Distribution) project which was the first project to look at smart domestic EV charging;
- The Flexible Approaches to Low Carbon Optimised Networks (FALCON) (Western Power Distribution) and Flexible Networks for a Low Carbon Future (Scottish Power Energy Networks) projects which demonstrated tools and techniques including dynamic ratings and network modelling and monitoring to optimise the use of networks;
- The Customer Load Active System Services (CLASS) (Electricity North West) project which has proven that distribution network management can provide cost effective solutions to wider system management;
- The energywise (UK Power Networks) project which is looking at how to engage fuel poor and vulnerable customers in the smart energy transition; and
- The TDI 2.0 (National Grid and UK Power Networks) project which will pioneer the integration of systems and commercial arrangements between SO and DSO to optimise the whole system benefits of flexibility.

In the past few years, our networks have been at the forefront of the low carbon transition. We have issued connection offers to 54GW of storage and generation since 2012, requiring us to change the way we operate as a business to meet the associated challenges. This has involved deploying the DSO capability from innovation trials into our business, particularly in our Eastern and South Eastern regions. This has been successful in helping to reduce the cost of connecting for generation customers by over £100m. UK Power Networks will continue to develop our work on flexible generation connections, using the pioneering tools being developed in our Kent Active System Management project and our other innovation projects to see how we can minimise system constraints and optimise the use of the generation connected to our networks.

The anticipated uptake of low carbon technologies such as electric vehicles, storage and distributed generation means that, by the mid-2020s, we could see over two million active devices providing flexibility on our three distribution networks. To deliver the scale of benefits cited in the Call for Evidence, DSO capabilities will need to be focussed on optimising the resources on our distribution network, not only to avoid distribution reinforcement but to deliver whole system solutions that support cost effective decarbonisation. We are actively working with National Grid, including through the joint TDI 2.0 innovation project, to further develop our capabilities in this area.

The transition to DSO represents a paradigm shift in the complexity of system operation and the smart control systems needed to support it. Network operators should be empowered to develop and deploy the supporting DSO infrastructure so that flexibility can develop efficiently in response to local and whole system needs. The regulatory framework should fully recognise the risks and costs associated with the development and deployment of new technologies, and clear incentives are needed to facilitate a timely evolution towards a smart DSO future. Clearly, enhancing the present commercial and regulatory framework.

Incentive regulation in Great Britain has been successful in promoting innovation to deliver efficiency and service improvements within the individual parts of the energy system. Indeed, regulators in

many parts of the world are looking at the totex incentives used in the RIIO framework as a good foundation for developing flexible energy systems. We believe that the current RIIO model can be adapted to support DNOs to complete the transition to DSOs and optimally manage the resources on their networks. We would like to see Ofgem and BEIS build on this Call for Evidence by establishing a work programme with industry to develop the regulatory incentive frameworks to incentivise transmission and distribution network investments to reduce whole system costs in time for the start of RIIO-ED2 and RIIO-T2. We believe that our track record in delivering safe, reliable networks with excellent customer service puts DNOs in a good position to develop into effective DSOs.

The DSO model will need to be supported by appropriate commercial frameworks that provide a level playing field for all technologies. We believe that contractual frameworks for flexibility services can best provide the conditions to support investment needed to develop new flexible resources (including storage and demand side flexibility), particularly where these are being used as alternatives to traditional solutions to provide security of supply. As the number of flexible distributed energy resources grow, more complex market platform arrangements for flexibility may be required. We are therefore supporting and learning from a number of novel commercial platforms that are being proposed and trialled, for example Centrica's Cornwall Local Energy Market, and a recent bid for EEF funding by Open Utility, looking at both marginal price platforms and peer to peer markets. We believe DNOs, Ofgem and BEIS should support these to explore the different information needs and interfaces they will require from the DSO.

Removing policy and regulatory barriers: Enabling storage

Our Smarter Network Storage (SNS) project has demonstrated that clear benefits to network customers are deliverable by DNOs using storage to manage the network. SNS first highlighted many of the issues which are raised in the Call for Evidence.

Storage is a key technology in ensuring security of supply at an efficient cost as it provides:

- An alternative customer for generation output that is local to the point of production, and able to relieve export constraints;
- An option that allows DSOs to balance supply and demand local to needs;
- An alternative to traditional network reinforcement, or allowing it to be deferred thereby creating option value where there is uncertainty in load forecasts;
- A fast response to address frequency control for the whole system and address power quality issues in distribution networks where there are many variable loads; and
- A source of voltage control to manage issues such as high voltages at times of low demand and high generation.

We are fully supportive of the development of a competitive market in this fast moving sector, so that storage can provide services to the whole value chain. Over the last 15 months we have witnessed a buoyant storage market. We have received over 600 applications for the connection of 12GW of storage.

Many DSO services needs are likely to be very specific and highly locational. When procuring flexibility services for specific constraints it will be important for DSOs to have the least cost technical option, including storage, available to ensure customers get the most efficient outcome. Where storage is developed by the networks, the enduring framework that we are putting in place for SNS should be considered as the template for arrangements to maximise the value of the investment to the benefit of customers.

The typical size of a storage application we have seen to date is 20MW (the equivalent to a small town of 9,000 domestic homes) often with complex and specific technical requirements which we need to assess and accommodate. It is therefore not surprising that connections costs can be high where there is not the capacity to accommodate such large demands without reinforcement. The scale of applications for storage connections has represented a significant challenge for us as a

business. We have responded by undertaking substantial engagement with storage providers to understand their needs and improve the service we provide to them and have taken the following steps:

- Introduced a connections guide specifically for storage providers which provides clarity to new entrants on how their application will be treated from a network design perspective. This guidance is now becoming industry best practice;
- Introduced a simple and clear common connections application template for storage which has since been adopted as industry best practice through the Energy Networks Association (ENA);
- Introduced demand heat maps (alongside our existing generation ones) to provide a transparent picture of where there is available capacity on our networks;
- Run customer surgeries to improve our understanding of the needs of stakeholders and collect feedback on the processes we have introduced to improve our service; and
- Offered flexible connections to storage providers whose connection request triggers reinforcement. The availability requirements of the first Enhanced Frequency Response (EFR) tender from National Grid did not favour flexible connections but we strongly believe that future service requirements should be developed to facilitate these.

Whilst these initiatives have been successful to a large degree, we are identifying further improvements through our ongoing engagement with customers. For example: we are considering whether allowing developers to specify a range of capacities on their application could allow a more effective and efficient discussion with planning engineers. Equally, developers still find they need access to planners with knowledge of the system and status of existing connection applications, which we could better support if we were able to charge assessment and design fees to cover the costs. The industry has also started the work to clarify how storage is treated under planning standards and look at the differences between transmission and distribution.

We have been supportive through our SNS project of clarifying the status of storage in the regulatory framework. We support the definitions proposed in the Call for Evidence, and are of the opinion that these make a distinction between systems developed for the purpose of storing electricity and devices such as capacitors in use on the distribution networks to maintain technical compliance.

The work to codify the distinct needs of storage in the industry codes and as a category of generation needs to be undertaken whatever enduring legal arrangements are put in place. Ofgem and BEIS should consider creating a separate licence category when the opportunity arises to amend legislation.

However, we think there are some key policy aspects which Ofgem and BEIS should examine at to help the development of the storage market:

- Support the industry in the development of a whole system framework which allows storage (and other providers) to stack the value of services they can provide to different industry parties;
- Progress the introduction of assessment and design fees to recover the costs of providing better services to flexibility developers whilst providing an incentive against excessive speculative applications;
- Address the issue of undue levies on imports to energy storage systems; and
- Provide clarity on the regulatory treatment of storage to ensure that distribution networks can provide bespoke cost reflective charges to storage and own storage assets where the market does not deliver.

Pricing for flexibility

The development of the resources to enable flexibility needs a framework that supports investment. Current contracts for flexibility such as National Grid's Enhanced Frequency Response Contracts and

DNO demand side response services are trying to provide this. We currently see contracts as key to allow resources to be procured as an alternative to traditional assets. Contracts for flexibility help ensure that they are available when needed, and can provide an appropriate fixed term income against which flexibility providers can invest in new services. Price based flexibility has not provided sufficient certainty to avoid the need for the Capacity Mechanism in the wholesale market and we are concerned that, on its own, it would not support a flexibility market either. However as the volume of flexible resources increases, price flexibility may become a more valuable tool in dispatch of resources and we would expect the market arrangements to evolve to support this.⁵

Price signals and the development of smart tariffs

Existing network tariffs already exhibit some smart characteristics. Existing DUoS tariffs provide time of day signals (CDCM) for all half hourly metered customers (including an option for domestic smart meter customers) and locational and seasonal signals (EDCM). They also have to fulfil two key objectives to provide:

- Stable forward price signals and ensure fair recovery of fixed and sunk costs; and
- Signals to promote the efficient development of the network.

Our experience gained in Low Carbon London indicates that consumers are receptive to smart tariffs but that the differentials between peak and off peak charges required to incentivise changes in behaviour need to be significant (between 2 and 6 times normal tariffs)⁶. One of the key challenges with smart tariffs will be the balance between the fair recovery of fixed and sunk costs against the need to send price signals most customers respond to as highlighted by CEPA in on the following page.

The needs of the tariffs and service contracts that emerge will be driven by the framework under which flexibility is ultimately procured or scheduled. Experience in existing markets indicates that a structure of markets and price signals is needed that:

- Incentivises or procures sufficient flexible capacity at the location required (provides predictable investable signals);
- Schedules or allocates the systems' available resources efficiently (in near real time); and
- Recovers the fixed and sunk costs of the system in a fair manner.

Industry experience is that significant tariff changes can take several years to design and implement.⁷

⁷ The distribution structure of charges projects started in 2000 and did not fully conclude until 2012.

Objectives and principles for network charging in a more flexible electricity system

Electricity network charges have two primary objectives: (i) the **recovery of electricity allowed revenues**; and (ii) the **provision of price signals** to beneficially influence system user (consumer and producer) behaviour. Changes may be required in future to GB network charging methodologies to address the challenges of a more flexible electricity system and to capture the opportunities such a system creates. As is the case today, however, the underlying charging issue will be how these two primary objectives are reconciled.

To achieve this, the general principles that underlie network charging decisions today should continue to apply in a more flexible electricity system. Those principles include:

- **Cost reflectivity** – as is the case today cost reflective network access charging is important to help convey the costs market participants create at the time they make their operational or investment decisions to use the network;
- **Transparency and predictability** – in the context of practically shaping network user behaviour, the quality of price signals is also relevant, making transparency and predictability relevant principles for charging; and
- **Non-discrimination** – charges for electricity network access should be non-discriminatory, dependent on how the network is used rather than based on the particular activities that it is used for.

With the increasing uptake of distributed energy resources (DERs), charging structures will increasingly need to balance the following in the practical application of these principles:

- The expected or necessary spatial and temporal granularity of network charge signals to encourage the **efficient use of and investment in resources** to deliver the services the electricity system needs;
- Transparency and predictability are generally achieved through simple tariffs, but this may create some tension with the principle of cost-reflectivity as truly **cost-reflective network tariffs should capture network costs that are specific to (i) capacity; (ii) volume; (iii) location; and (iv) time**;
- Competition between different resources and solutions to system needs based **on a level playing field**;
- Tariff structures that create a **fair and sustainable basis** for cost allocation and recovery between network user groups; and
- A future basis for cost recovery that distorts price signals and decisions of potential flexibility providers as little as possible from cost reflective levels, while remaining non-discriminatory.

Reconciling the primary objectives of network charging (recovering allowed revenue and providing price signals to beneficially influence system user behaviour) may as a consequence not be easy to achieve in a more flexible electricity system.

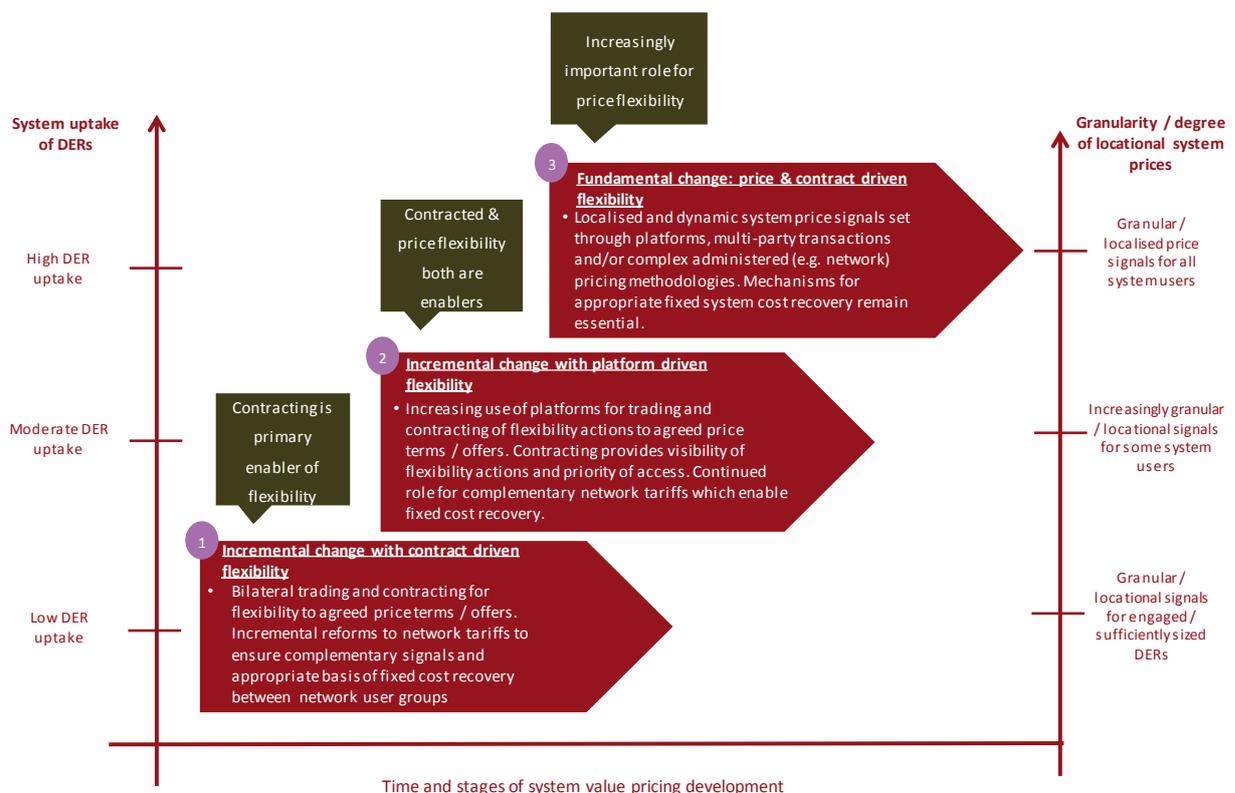

The emphasis which is placed on the different principles may need to adapt as the system and other aspects of the electricity market architecture evolve.

CEPA 2017

We believe that a practical way forward as illustrated in Figure 1 will be to:

- Use contracted flexibility routes to provide the price signals and incentives for flexibility actions and stimulate the development of flexibility resources in the market in the near term;
- Make incremental changes to current (e.g. network) charging methodologies when issues are identified to ensure that: price signals complement the value signals for flexibility from contracted system services; and there continues to be appropriate contributions to fixed system cost recovery between system user groups; and
- In the longer term, as the number of DER and system user price responsiveness increases, price driven flexibility can increasingly enable response through localised, granular, marginal energy and network price signals.

Figure 1 Role and complexity of system value pricing in different stages of future distribution flexibility system development – CEPA adapted from Berkley Labs⁸

In the longer term, there needs to be further thought about the contributions different network users make to DNO cost recovery through tariffs. We see the potential for prosumers and local community energy groups start to be more self-sufficient for their energy needs but they will still rely and benefit from network infrastructure for security of supply, and therefore need to contribute to networks' capacity in a fair manner. This issue (of fixed and sunk cost recovery) must be a key focus of any future review of tariffs, along with what is needed to support the development of flexibility markets. There are a number of charging approaches (a good summary is provided in the NARUC rate design

⁸ CEPA : Adapted from Berkley Labs Future Energy October 2015

https://emp.lbl.gov/sites/all/files/FEUR_2%20distribution%20systems%2020151023.pdf

manual⁹) which all have strengths and weaknesses, which we summarise in our main response. As flexibility develops, a combination of approaches over time will likely be needed.

The pricing approach used will have to support suppliers' tariffs and the commercial processes used to manage flexibility in the system. A number of novel approaches are being explored or proposed through innovation projects (including those by Centrica, Open Utility, Electron, InnovateUK and the National Grid / UK Power Networks TDI2.0 project) which we are actively engaged with, and believe this is an area which should be explored further. Our experience from our innovation projects shows that trials are the ideal way to develop the best approach for the GB system. Ofgem and BEIS should be promoting innovation in this area with a view to a common approach will being developed when active DER volumes increase.

A system for the Consumer: Ultra Low Emission Vehicles, Smart Appliances and Cyber Security

One of the most significant flexible future demands on distribution networks will come from electric vehicles (EVs). EVs will be a key enabler in achieving improvements in air quality and meeting carbon reduction targets for transport.

Optimising the use of existing networks to keep network reinforcement costs low will be key, especially given the needs of fast and high capacity charging. To facilitate the cost effective decarbonisation of transport, we believe that we will require:

- Visibility of where chargers are installed, their usage and future planned installations in order that we can plan and manage our network effectively;
- Smart tariffs to customers to incentivise charging outside network peak demand; and
- An ability to control charging to ensure network infrastructure operates within its technical capabilities and ensure efficient development of the network infrastructure required to accommodate charging points.

To support this, BEIS and Ofgem should work with vehicle manufacturers, network operators, suppliers and aggregators to:

- Develop technology and commercial standards to enable visibility and control smart charging of vehicles; and
- Develop and trial smart tariffs to support smart charging.

EV charging is a specific area where smarter charging structures may have a role. EV customers are more likely to be more engaged with and accepting of smart tariffs. The charging infrastructure or the vehicles themselves could also have in-built enabling technology to deal with complex price signals, simplifying user interactions and providing certainty of response.

As with all consumer devices, it will be important for government to support standards that enable interoperability, and provide confidence for consumers and security for the power system. The government should support the development of smart home systems with appropriate risk based cyber security controls.

Innovation: supporting the transition

Our successful innovation projects have demonstrated that using trials to develop and demonstrate solutions to the needs of a smart flexible energy system will be essential to its successful delivery. The key areas for ongoing innovation we have identified include:

- Supporting innovation that delivers value across the whole system, beyond individual network or system operator business scope, as is being trialled in TDI2.0;

⁹ NARUC Distributed Energy Resources Rate Design Manual November 2016

<http://pubs.naruc.org/pub/19FDF48B-AA57-5160-DBA1-BE2E9C2F7EA0>

- Supporting trialling of emerging commercial and market models and platforms, not just technology to be embedded into network/system operator operations;
- Facilitating cross energy vector projects (e.g. Hydrogen or heat projects) and not just electricity in NIA/NIC;
- Supporting local energy (including community energy schemes) to ensure approaches exist to allow those least able to adopt smart flexibility technologies;
- Supporting the development of smart EV charging technologies and commercial frameworks to facilitate the development of interoperable standards and visibility of EV charging to network operators; and
- Supporting the development of vehicle to grid technologies with the UK automotive technology sector.

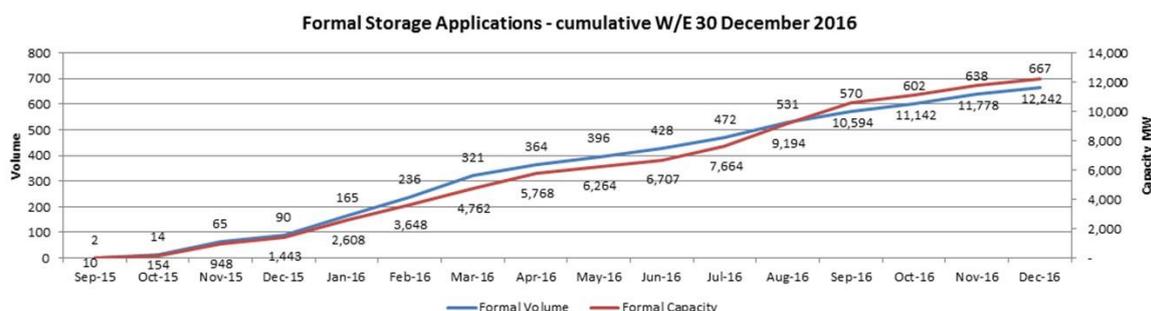

The subsequent sections of this document provided detailed responses to the questions raised in the Call for Evidence.

1. Removing policy and regulatory barriers

Enabling storage

We have practical experience of the issues highlighted in the Call for Evidence, having successfully delivered and operated the largest battery storage project in the UK (smarter network storage – SNS). We worked closely with National Grid and aggregators to use battery storage as an alternative to £6m of traditional reinforcement in Leighton Buzzard. We have also processed 12GW of applications from over 600 storage providers (as shown by Figure 2 below).

Figure 2: Storage application requests to UK Power Networks September 15 – December 16

As the first project in the country to go through the full design and implementation process, our SNS project has outlined many of the barriers mentioned in the Call for Evidence¹⁰. Our learning from the SNS project is that an effective market for storage providers has the potential to allow us to procure lower cost services and help to deliver network outputs at a lower cost to our customers.

Question 1: Have we identified and correctly assessed the main policy and regulatory barriers to the development of storage? Are there any additional barriers faced by industry?

The feedback we have received from storage providers mostly aligns with the regulatory barriers set out in the Call for Evidence. We draw attention below to some of the additional barriers in facilitating the whole system value of storage which, if addressed, could better facilitate the storage market.

The Call for Evidence outlines six main barriers, which we cover in turn below. We also list the additional barriers where support from Ofgem/BEIS would be welcomed.

a) New connections

We have covered new connections for storage in detail in our response to question 2. In summary, the one element missing from the Call for Evidence is an acknowledgement that the high cost for new storage connections is largely driven by their size (typically 20MW, equivalent to a small town). The current 'shallowish' connections charging boundary has been successful in incentivising customers to connect where there is existing spare capacity. However, the size of typical storage plant and its need to ramp between import and export, means that there are a limited number of areas on the network with the capacity to connect them without reinforcement.

We have trialled a number of approaches with developers to help inform where capacity is available, including heat maps. However, customer feedback continues to support access to an informed planner who can advise them and provide information on the current position on connections activity, which we support with regular customer surgeries where prospective applicants can discuss options with planners. There are clearly issues for DNOs who have limited resources with the skills and

¹⁰ [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-\(SNS\)/Project-Documents/Report+9.5+19Oct_v2.1_%28Final+Photos%29.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-(SNS)/Project-Documents/Report+9.5+19Oct_v2.1_%28Final+Photos%29.pdf)

experience to advise on complex storage applications in providing a balance between supporting pre-application advice and meeting obligations relating to quotation timescales. However, our experience (which our discussions with developers supports) is that we need:

- Regulatory support for the introduction of reasonable assessment and design fees to support the delivery of a higher level of service and deter highly speculative enquiries; and
- To adapt our processes to allow developers to specify a range of capacity (e.g. a minimum and maximum) that they would consider in an application for a connection quote; this could improve the dialogue with the DSO as it would allow the DSO to indicate the capacity that could be taken up without reinforcement.

We have been proactive in finding solutions for our customers, including offering flexible connections through active network management. However, our experience shows that storage providers have not yet taken up our offers because they did not align with the service requirements for National Grid's first Enhanced Frequency Response (EFR) tender. We are actively working with National Grid and other DNOs to understand how better alignment can be achieved in the terms for future services to enable faster and cheaper connections to take place.

b) Network charging

The Call for Evidence raises the issue of whether storage should be treated as intermittent or non-intermittent within the charging methodologies. We treat storage as non-intermittent for the purposes of network charging because most storage customers would tend to have quite predictable import and export patterns. This is beneficial for storage providers as it allows them to claim greater credits for exports under the charging methodologies.

As fully explained in our response to question 3, analysis from our SNS project has demonstrated that the charging methodologies provide appropriate cost signals for the various impacts storage can have on the network.

One of the challenges of smarter locational price signals (such as the EDCM charges) is that it is not possible for developers to calculate these for themselves, making it difficult to predict their future costs when assessing their business case for investment. This is part of the trade-off which must be considered between flexible pricing and complexity.

c) Consumption levies

The issue highlighted in the Call for Evidence was outlined in our SNS findings; storage devices currently pay the same levies as demand customers when energy is imported. Demand customers pay these levies again when the energy is released from the storage system and consumed. The levies are therefore charged twice, making the energy derived from storage more expensive than necessary. We agree that this is a challenge government needs to address. Defining storage as a separate activity would be a clear step towards being able to create specific charging arrangements for storage that avoid discrimination issues with demand and generation.

d) Planning

As a purchaser of services from storage providers, we want to ensure that these services are low cost and available in a timely manner. Storage facilities such as SNS are not comparable to traditional generation stations in terms of the impact on the local environment (be that visual or emissions based) but are currently subject to the same process and requirement. The construction costs of the building for SNS were shown to be a significant factor in the business case assessment¹¹ and could be a significant issue in the development of storage to support local network issues. Therefore, we

¹¹ SNS The business case of storage October 2016

[http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-\(SNS\)/Project-Documents/The+business+case+of+Storage.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-(SNS)/Project-Documents/The+business+case+of+Storage.pdf)

are supportive of the development of planning rules and guidelines more suitable for storage than those in place for generation. Our experience from our SNS project is that planning changes could reduce the construction costs of storage and help to make storage a more financially viable alternative to reinforcement.

e) Use of storage for network operation

Through our SNS project, we have proved that storage is a valuable source of flexibility. Contracts for services from storage are providing an effective signal for investment in storage, as we have seen from the EFR and Capacity Markets.

We agree that the competitive provision of storage is most likely to deliver low cost solutions for customers, as has been evidenced by the prices seen in the EFR procurement. However, DSO services needs are likely to be very specific and highly locational. We believe that DSOs should always have the least cost technical solution available to them to meet network constraints, including the use of storage. When procuring flexible solutions to address network needs, the least cost network solution provides a key control on the costs customers will pay for the network service, and limiting this to traditional solutions for DSOs may be counter to delivering an efficient outcome for customers. We respond to this matter in detail on question 4.

f) Regulatory clarity

We agree with the need for greater regulatory clarity as without this there is uncertainty for investors. We believe that only by defining and creating specific rules for storage will we be able to maximise the benefits that it can deliver. We have supported the development of a separate licensed activity for storage, and this should be considered when the opportunity arises. We provide further thoughts in this area in our response to question 5.

Additional barriers faced by industry

Overall, we agree with the barriers mentioned above and in the Call for Evidence. However, we recommend that Ofgem and BEIS provide a clear policy steer to industry to help develop:

- **A whole system framework for flexibility services.** We consider that a commercial and regulatory framework that sets out the guidance to minimise exclusivity in service specifications and enables providers to stack whole system benefits is crucial. The development of network for services supporting supply security will need appropriate governance arrangements to ensure that such services are reliable, which could include licensing where appropriate. We can play our role in helping to develop this framework but it requires coordination of different industry parties with separate (and sometimes competing) commercial drivers. Consequently, we welcome Ofgem's participation in the ENA's TSO-DSO Project. We can see a role for Ofgem/BEIS in developing the correct regulatory incentives which empower industry to implement the roles and commercial framework to deliver these benefits. At present, regulatory incentives and commercial drivers are not well aligned across transmission and distribution which makes delivery of this framework difficult. We expand on this in our response to questions 45 and 46; and
- **A regulatory framework that permits limited network ownership of storage.** The regulatory and legal framework for storage should not deny network operators the ability to own storage where this is the least cost network solution. We expand on this further in our response to question 4.

Question 2: Have we identified and correctly assessed the issues regarding network connections for storage? Have we identified the correct areas where more progress is required?

We broadly agree with the issues identified in the Call for Evidence. We undertake extensive work with stakeholders to improve the process as part of our Incentive on Connections Engagement (ICE) plans including:

- Running two DG Fora each year, attracting around 70 participants;
- Establishing an Industry Panel of 12 invited industry experts (from the customer base) which meets regularly to review our plans and initiatives for each market sector;
- Issuing consultations on new policies and processes to ensure stakeholder input; and
- Holding over 40 surgeries with stakeholders.

Despite having customer satisfaction scores for DG customers reaching 86% in our Eastern area, there are still some areas where more progress can be made. However, we think we have put in place a range of new policies and processes in the wake of the unprecedented number of storage applications we have received:

Network Connections

a) Clarity on connections process – how to connect and where to connect

Based on extensive market engagement with our customers, we do not entirely agree with the presentation, within the Call for Evidence, of where further progress is required. Our stakeholder engagement has helped to shape our process and service offerings to storage customers. Specific improvements we have made include:

i) Clear storage process guidance

In August 2016, we issued clear guidance to help our customers understand how we will treat storage applications from a planning and design perspective¹². This provides clarity to customers on both the network planning and technical requirements associated with their application. We acknowledged that at a domestic level there is some uncertainty on how the installation of energy storage when combined with existing generation will be treated. With this in mind we are developing a separate guidance document, through consultation with the industry, to provide clarity on the application process and costs attributable to different types of installations.

In addition, we are working within the current Electricity Safety, Quality and Continuity Regulations (ESQCR) requirements to develop a 'fast track' process for the majority of domestic schemes, allowing for quicker and cheaper connections. To further inform this process, we are now running an NIA project Domestic Energy Storage and Control (DESC)¹³ where we are working closely with a small scale storage developer (Powervault) to install storage units at premises with solar generation.

The outcome of this project is threefold:

- Determine the impact of these units on the distribution network by defining the load profile changes of these households;
- Understand the potential network benefits by having control of the storage units; and

¹²http://library.ukpowernetworks.co.uk/library/en/g81/Design_and_Planning/Planning_and_Design/Documents/EDS+08-5010+Energy+Storage.pdf

¹³ <http://www.smarternetworks.org/Project.aspx?ProjectID=1967>

- Understand how the connection process can be improved and specifically understand what information should be required from customers and how best to ensure the information and visibility is given to the network operator when these units are connected.

ii) Storage specific application form

We led the development of a specific application form for storage providers which has since become industry best practice after being adopted by the ENA¹⁴. The form allows storage applicants to provide specific details of how they plan to operate allowing our network design team to provide a more bespoke connection quote based on this information. This means that we do not make 'worse case' assumptions when assessing the connection assets needed to connect the storage device. We have found that the application form can stimulate a useful dialogue with storage providers on how their planned operation can be adapted to help reduce the network investment (and connection charge to the customer). Our ongoing engagement with developers continue to seek ways to improve the information gathered. For example, we are considering whether to ask developers for an indication of the range of capacities acceptable to them as part of the application process in order to allow us to explore alternative connection designs as part of a standard application.

iii) Clarification of Engineering Recommendation P2/6

There are two aspects of P2/6 which require clarification which are being taken forward in 2017 by the ENA's P2/6 working group:

- Currently P2/6 does not recognise the contribution which storage can make (when exporting) to the network, in the same way that generation does. We agree that this needs to be amended and we are working with other DNOs, through the ENA, to make the necessary changes to P2/6. Through our SNS project, we have worked with Imperial College to develop a methodology outlining how the contribution of storage can be taken into account in network planning.¹⁵ We will be using this as an input to the ENA work on P2/6; and
- There also needs to be clarity on the treatment of storage demand under P2/6, assessing whether it is treated as a firm demand in reinforcement assessments associated with connection applications.

iv) Clarity on treatment of changes to existing applications

We have taken a lead on this issue and have been clear that the addition of storage to an existing application is a 'material change' to that connection. The addition of storage is a considerable technical change to an existing connection of application in progress, which requires a reassessment and potential redesign of the scheme. Our stance has been driven from feedback from our stakeholders, who want fair, non-discriminatory treatment.

Stakeholders have indicated that they do not think that allowing such a change while maintaining the position in the queue is fair or provides a good process. These issues have also been debated through the ENA and the consultation it produced in conjunction with stakeholders reflects the stance

¹⁴ http://www.ukpowernetworks.co.uk/internet/en/our-services/documents/2016_Energy_Storage_System_-_Futher_Information_Request_V1-5.docx

¹⁵ [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-\(SNS\)/Project-Documents/SNS_P2_6_SDR9.6v1.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-(SNS)/Project-Documents/SNS_P2_6_SDR9.6v1.pdf)

we have taken¹⁶. We will continue to work through the ENA to ensure a consistent approach on this issue across all DNOs.

v) UK Power Networks' range of tools to inform providers where to connect

We have provided heat maps for generation applications since 2013 with over 700 customers now signed up to use them. To further assist our storage customers, we have recently developed additional functionality to this mapping tool to provide demand data from our networks. This has resulted in another 50 customers signing up to use the application. Our customers have told us that the addition of load data to our heat maps has been helpful in their pre-application assessment of storage schemes. However, our customers still value direct engagement with network planners on the current state of connection applications. To assist this engagement, we have conducted over 40 developer surgeries in the last year to allow customers to discuss possible storage project locations to our network infrastructure planners and identify the most accessible locations.

To support the efficient development of a more interactive service for developers, the introduction of assessment and design (A&D) fees should be expedited to allow the additional costs to be appropriately recovered and encourage developers to make best use of the freely available information published such as our Long Term Development Statements. The introduction of A&D fees would also act as a strong deterrent against speculative enquiries and allow us to provide a higher quality of service to genuine connection applications.

b) Cost and time of connecting

The Call for Evidence highlights the high cost of connection for storage. While we recognise the ongoing work highlighted by Ofgem/BEIS on releasing unused capacity, the current legal provisions to reclaim unused capacity can only be applied retrospectively by agreement with the customer. In addition, we have been offering flexible connections to storage providers but the majority have found it difficult to accept these as it impacted their ability to meet the availability criteria set out by National Grid for services such as the first enhanced frequency response tender. We have set out the issues as we see them below:

i) High cost of connecting

We do not fully agree with the way that this barrier has been presented in the Call for Evidence. The high cost of connecting storage is a feature of the typical size of storage plant (20MW, or the equivalent of 9,000 domestic homes) and the shallowish charging boundary in place. There are very few places on the network which can support this size of connection without reinforcement and the charging rules mean that the connecting customer pays a proportion of these reinforcement costs up front in a connection charge. It is important to recognise that this shallowish boundary is a vital element in keeping distribution costs down for customers, since it incentivises connection where there is existing spare capacity. It has incentivised a large volume of generation to connect to the distribution networks where there is spare capacity, avoiding the need for reinforcement.

As unconstrained capacity on our networks is becoming increasingly limited, we are looking to be innovative in how we can provide better information to our customers on the extent of constraints and likelihood they will occur. Our customers want to be able to sign up to a flexible connection agreement but still retain the ability to provide services to the SO. Ultimately this will require better co-ordination between the SO and DNO in providing contracts that optimise existing assets and get the most out of energy storage within ANM areas. We are already starting the required work with National Grid, through our TDI 2.0 project.

¹⁶ <http://www.energynetworks.org/assets/files/news/consultation-responses/Consultation%20responses%202016/Fair%20and%20Effective%20Management%20of%20DNO%20Connection%20Queues%20Treating%20Changes%20within%20Applications.pdf>

- ii) Storage may need to queue for a long time behind generation for a connection even if it can relieve constraints.

We agree that that this is an issue and one where the commercial relationships are as important as the physical network. Removing a generation constraint using storage requires that the storage device imports energy at the times needed to relieve the constraint. An agreement to arbitrage energy in this manner would logically be handled today by a supplier/aggregator providing a service to the generators rather than by the DSO. At present, it is not clear to the DSO if promoting the storage provider might commercially disadvantage a generator that was ahead of it in the queue. Therefore, the DSO should not make such a decision unilaterally. We believe that this can be addressed through our contracted queue process below, but we are also looking at other approaches as part of our development work on flexible connections.

The connection queue process can be considered in two parts:

- Applications Queue: All enquiries are dealt with in application date order. This is in line with the Common Connection Charging Methodology Statement (CCCMS) and the application of our interactivity methodology. Prior to making a formal application customers are encouraged to attend a developer surgery. This allows customers to discuss their potential project with our network planners and assess the viability of connection to our network, including timescales and likely costs.
- Contracted Queue: Post offer, where slow moving projects are otherwise preventing the connection of a scheme until reinforcement is completed, we will assess the possibility of expediting those customers adversely positioned in the contracted queue but ready to connect. This assessment is carried out on a case by case basis where certain criteria can be met and agreement made between parties to ensure that system security is maintained.

Question 3a): Have we identified and correctly assessed the issues regarding storage and network charging?

The Call for Evidence highlights three issues regarding storage and network charging. We broadly agree with these and provide views on each below:

- i) Treated as non-intermittent or intermittent

We are currently treating storage as non-intermittent for the purposes of DUoS charging. We think this is appropriate in that it allows storage providers to access the same credits (i.e. payments for exports that are set against charges for imports) available under the use of system charging methodologies as non-intermittent generators. However, we would stress that this principle does not necessarily translate as counting as non-intermittent generation for contributions to network security within Engineering Recommendation P2/6. Any contribution to security of supply depends on exactly how storage is being used. For example, where a storage device is providing a service to the network such as peak lopping and has a contract to export at local demand peak, this is effectively non-intermittent. However, where a storage device is providing services such as frequency response, we have no guarantee that it will export and not import at local demand peak; therefore, it cannot be treated in the same way under P2/6.

- ii) Cost reflective import and export charges

Our experience from operating a battery on the GB system suggests that existing tariffs do not present an undue barrier. Existing tariffs provide payments to generators for export at peak times and provide a cost signal to storage not to import energy at peak times.

In terms of the connection charge levied, if a storage provider enters into a flexible connection arrangement whereby they guarantee to export at peak load, then we can account for this in the

connection design and subsequent costs. Without the contract in place it would be wrong to make the assumption that the storage device will export at peak. The storage provider may be contracted for a service which means it imports at peak and had we assumed that it only ever exports at peak, then it would threaten system security.

We agree that network charges should represent the fair recovery of network costs and should offer a level playing field. Based on the evidence from our SNS trial, we believe that distribution charges do not prohibit the business case for storage. We consider that the current EDCM charging methodology provides cost reflective import and export charges for storage. As part of our SNS project, we modelled the DUoS charges paid by the storage device. These are shown in Figure 3 below:

Figure 3: DUoS charges paid under SNS project (E=Export, I=Import)

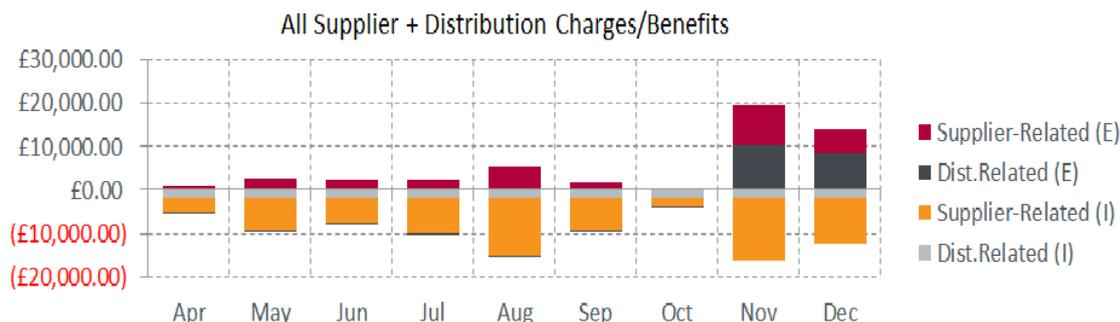

Figure 3 illustrates that DUoS charges were a very small part of the costs incurred by the battery. Due to the fact that the battery was exporting at peak demand to defer reinforcement, it received a credit under the EDCM and the net DUoS bill was a credit of £3,700 for the year. This seems appropriate since the storage device was actively supporting the network during winter months.

If the storage device was not supporting the network by exporting at network peak, we accept that there would be a different picture than that presented above. However, this would also be appropriate since the storage device would be contributing to peak and imposing costs on the network.

iii) Transparency of network charges

The Call for Evidence correctly highlights the difficulty for storage developers when estimating their network charges. We have engaged a number of our customers to understand their perspective. They have highlighted that under the EDCM, it is difficult for them to understand what DUoS charges they will be liable for once connected. Consequently, we have put in place a policy whereby we engage with customers on the likely EDCM distribution charges once they have an acceptable connection offer.

Within our Use of System Charging Statement, published in April 2015¹⁷, we address demand-side management (DSM) and the ability for customers to have interruptible import capacity in order to benefit from a reduced Use of System charge. Specifically, we outline:

¹⁷ <https://www.ukpowernetworks.co.uk/internet/en/about-us/documents/EPN-LC14-Statement-Effective-1st-April-2015-V2-Final.pdf>

5.8. New or existing Designated EHV Property Customers may wish to offer part of their Maximum Import Capacity (MIC) to be interruptible by us (for active network management purposes other than normal planned or unplanned outages) in order to benefit from any reduced UoS charges calculated using the EDCM. Several options exist in which we may agree for some or the entire MIC to be interruptible. Under the EDCM the applicable demand capacity costs would be based on the MIC minus the capacity subject to interruption.

5.10. If you are interested in making part or all of your MIC interruptible as an integral irrevocable feature of a new connection or modification to an existing connection you should in the first instance contact our connections function

In line with this statement, we have made it clear to storage providers and other customers that we are open for discussions on how to create flexible contracts and manage the application of import charges. We encourage all customers to approach us to discuss these possible arrangements.

It is important to highlight that this is an example of the trade-off between specific locational tariffs that reflect specific customer impact on the network and broader, more predictable tariffs.

Question 3b): Do you agree that flexible connection agreements could help to address issues regarding storage and network charging?

As stated above, flexible connections can help to address any issues around connection charging through providing the network operator with certainty on how the storage device will be operated. This allows our network design teams to take account of this when assessing the connection assets required.

As highlighted in our response to questions 1 and 2, our experience to date has been that despite making flexible connection offers to storage applicants, developers have not been keen to take these up. We have engaged with these providers to understand why and the feedback is that they are not compatible with the terms of National Grid's current services, particularly the EFR service. As stated elsewhere in this section and in our responses to chapter 5, this highlights the need to develop a process which allows for efficient allocation of flexible resources across the whole system.

Question 4a: Do you agree with our assessment that network operators could use storage to support their networks?

We fully agree that network operators can use storage to support their network. Our SNS project has proven that storage can be used as an alternative to network reinforcement, where our 6MW/10MWh/7.5MVAR battery has provided an alternative to £6m of conventional reinforcement at Leighton Buzzard.

The benefits of storage to networks are comprised of:

- A potentially lower cost alternative to reinforcement to meet demand needs;
- Using reactive power capabilities for:
 - Losses/power factor improvement, (the benefits passes to the customers); and
 - Voltage control.
- Allowing more generation customers to connect or reducing constraints on existing generation, therefore enabling more renewable energy; and
- Extensive adoption of domestic storage could offset the impact of increased LCT demands and reduce high voltage problems resulting for example from solar output at times of low demand.

The RIIO framework provides equalised incentives for network companies to develop the most efficient network solutions. As flexibility develops, we will increasingly contract for demand side services as a lower cost alternative to traditional reinforcement. Our SNS project demonstrated a positive NPV outcome but costs still need to fall and it requires the stacking of different services from other parties within the energy system. One of the key issues for battery storage supporting the network is the need for longer duration export capability than a similar level of frequency response capability alone requires, thus requiring a more expensive battery system. As and when the technology costs of storage fall and it is the least cost solution to meet the network needs alone, it should be available as an option to ensure that any process to procure flexibility does not result in a higher cost for consumers than is necessary (the least cost solution available to the DNO, as signalled in any long term development statements would set the benchmark for the value of any services offered).

Question 4b): Are there sufficient safeguards to enable the development of a competitive market for storage?

We would like to see active markets of all forms of flexibility including storage, as this would limit the possibility of one type of flexibility or provider from gaining excessive market power. This is particularly important for us given the highly localised nature of our constraints. It may be necessary for DSOs to procure flexibility capacity in a similar manner to the Capacity Market to ensure sufficient capability exists to defer traditional investment to secure the system or address emerging issues caused by the growth of low carbon technologies such as EVs.

Our experience is that the current framework has enabled competition. For example, the EFR tender successfully allocated 201MW to provide frequency capabilities to National Grid. However, the projects allocated will only be providing value to National Grid and will not be used, at least in the first four years of operation, to support local distribution network constraints. The wider question is how to ensure competition and enable the whole system benefits that storage can provide.

To extract maximum value from a storage asset, commercial capabilities are required across a number of services, interfacing with the system operator, network operator, suppliers and generators. Establishing commercial relationships with aggregators and suppliers will enable DNOs to interface with the commercial markets for further revenues, which at this point are critical for the business case of storage to add up.

Question 4c): Are there any circumstances in which network companies should own storage?

We have demonstrated in our SNS project that storage has the potential to provide benefits to the network. To deliver these benefits, the storage must be at a specific location on the network and available when needed. At the Leighton Buzzard site, we successfully used a 6MW battery for peak demand shaving instead of a £6m traditional network reinforcement¹⁸. Demand side services, including storage, potentially create option value compared to incremental investment in traditional assets and may be highly valuable given current unpredictable demand and generation patterns.

Wherever possible we agree these services should be provided through an active market. This should allow network companies to highlight where they need a service from storage or other demand side service and tender to see if providers can meet the requirements at a cost lower than other alternatives. Storage providers should be able to optimise the use of the storage asset by selling services to others when the DSO does not require it, thereby reducing the cost to the DSO. To ensure that these services offer the lowest cost solution for customers, the DSO must have the least cost network option available to it, and this should include storage assets (even if limited to network use only).

¹⁸[http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-\(SNS\)/](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-(SNS)/)

For a highly specific constraint service there may be some circumstances where the market cannot deliver the precise service at the specific location which meets network companies' needs. Any system operator needs confidence that a service will be available at the location it is needed where it is providing security of supply. This is an important consideration in allowing ownership.

Ideal markets should provide the lowest cost services to the DSO. However, this relies on there being sufficient numbers of providers to ensure a competitive process. We note there are examples in the connections market where competition has not developed despite efforts to promote it and demand side markets that have not provided the required response to calls¹⁹. We have set out scenarios where the market may not deliver the least cost solutions for customers without the ability of DSOs to develop storage:

i) Incremental storage required

Network operators may already be managing constraints through flexibility and need a small amount of available storage to supplement current contracts. The storage would have a high option value to the network company in avoiding investment. The local market may be constrained on locations and participants (e.g. in a residential area where some domestic storage exists). If economical, yet not provided by the market, it seems unfair to prevent network companies building the limited storage asset themselves to provide this option value and save the reinforcement.

ii) Driving lowest cost solution from the market

Allowing network companies to own storage for network purposes can help extract the lowest cost solution from markets. For example, take the following hypothetical cost scenario:

- Standard DNO reinforcement costs – £15m
- Costs to DNO of procuring and operating storage to alleviate constraint (no other use) – £10m
- Cost of DNO service for market storage provider allowing for other revenue streams – £7m

Without the option of DNO owned storage, a market provider will know from the DNO's long term development statement that the baseline costs for a traditional network solution would be £15m. In a perfect market the costs for a storage operator to provide an equivalent solution to meet the DNO's needs, taking into account other revenue streams would be £7m. However, the DNO's minimum intervention is likely to be known to bidders which would encourage bids as close to this value as possible, say £12m to win the contract. If the DNO is allowed to own storage to resolve constraints, and could do this for say £10m then bidders would be encouraged to bid closer to the true cost to them of £7m, ensuring that the market provides an efficient outcome for consumers.

Keeping the door open on network ownership

As the storage and wider flexibility market develops, there may be other circumstances where the market cannot deliver. At this stage, we do not think Ofgem and BEIS should rule out network ownership of storage in specific circumstances where it can provide benefits to customers.

We fully recognise the competition issues surrounding selling services from a storage asset funded by regulated allowances. We believe that the enduring model for SNS provides a solution to these issues. Under SNS, all market transactions were undertaken through a supplier or aggregator. This allows for the stacking of benefits required to make storage viable but without direct DNO involvement in the market. This demonstrates that network ownership of storage does not need to equate to participating in the market and therefore any competition issues can be avoided.

¹⁹ WPD did not secure the service it sought in the 2016 demand turn up service
<http://www2.nationalgrid.com/WorkArea/DownloadAsset.aspx?id=8589938135>

We note that other regulators and the European Commission are recognising that in specific circumstances network ownership of storage can be permitted. The recent 'Winter Package' released by the European Commission outlines that unbundled DNOs should be able to own storage where the market has not delivered in order to deliver efficient and secure network operation. Other regulators in Europe and Australia²⁰ are also supportive of limited network ownership of storage. We think our SNS model is broadly consistent with this approach. Consequently, we would urge Ofgem and BEIS to develop a regulatory framework for storage which outlines the specific circumstances where network companies can own storage.

Question 5: Do you agree with our assessment of the regulatory approaches available to provide greater clarity for storage?

The Call for Evidence adequately captures the range of regulatory approaches available to provide clarity for storage. As a network operator, there are two key things which the regulatory approach for storage needs to deliver:

- i) Ability to provide cost reflective charges

In the future, we may need to develop commercial arrangements which are specific to storage. We have some concerns that our ability to do this may be restricted if storage remains defined as generation. We have a licence requirement not to restrict, prevent or distort competition in the generation of electricity²¹. If the legal and regulatory definition of storage is as generation, we may be limited in our ability to treat the two differently (i.e. not able to discriminate between types of generation), even where there are legitimate reasons to do so.

- ii) Allowing network ownership where the market cannot deliver

As outlined in our response to question 4c) above, we think it is essential that network companies are not denied the ability to own storage in specific circumstances where the market has not been able to deliver the service needed. Our preference is that specific circumstances for network ownership and safeguards (such as no participation in the market) are outlined as part of the regulatory approach.

Given the above, we do not think it is ideal to continue treating storage as generation for licensing purposes (option a in the Call for Evidence). We think that options b, c and d could deliver our two objectives. We would highlight that if BEIS goes to the time and effort of defining storage in primary legislation (option c) then it will be worthwhile going the extra step of creating the new licensable activity (option d).

Question 6: Do you agree with any of the proposed definitions of storage?

We support the definition proposed by the Electricity Storage Network which is outlined in the Call for Evidence. This is on the basis that it is specific to electricity storage and it covers the conversion of electrical energy, not its generation. We consider that both of these elements are important in order to distinguish electricity storage from other network systems such as capacitors.

²⁰ <http://www.aemc.gov.au/Major-Pages/Technology-impacts/Documents/AEMC-Integration-of-energy-storage-final-report.aspx>

²¹ Standard licence condition 4 of the Electricity Distribution Licence.

Our view is supported through our discussions at the BEIS/Ofgem storage working group, which has been debating these issues, and the specific work we undertook on a proposed storage licence as part of the SNS project.²²

Aggregators

Question 7: What are the impacts of the perceived barriers for aggregators and other market participants? Please provide your views on:

- **balancing services;**
- **extracting value from the balancing mechanism and wholesale market;**
- **other market barriers; and**
- **consumer protection.**

Do you have evidence of the benefits that could accrue to consumers from removing or reducing them?

Ofgem and BEIS have identified a number of barriers which we recognise. Removing these barriers requires a clear framework for flexibility in wholesale and balancing services.

Product design and procurement

If the SO procures services to support the system and aims to be technology agnostic, then it must set out its requirements for these services. The challenge for the SO is to set out its requirements in a manner that allows new technologies to contribute, while maintaining security of supply. It is relatively straightforward to specify services that replicate existing system requirements (e.g. for frequency response) and this might allow existing providers to deliver these services but seem to exclude new entrants.

Real time services are certain to have more stringent requirements than those aimed at supplier balancing positions (half hourly flexibility). For demand-side services there is more work to be undertaken to ensure that actions taken by DSR providers are clearly visible to the procurer of the service. This is particularly the case for real time services (where half hourly metering is inadequate). It may be important to ensure that new service providers have a framework through which they can demonstrate capability ahead of contracting for system security services (critical constraint management, reserve or frequency services).

Cross party impacts

We agree that actions taken by aggregators should have the impact reflected on related parties. The points raised in the Call for Evidence identify a number of issues with regards to the design and operation of markets supporting the operation of the system.

The impact depends on the relationship of the aggregator to the other parties:

- The aggregator is providing flexibility to a supplier within the wholesale markets: the aggregator should be responsible for the costs of any transaction costs between suppliers where it is contracting services from DERs; and
- The aggregator is providing services to the system through balancing services: we would agree that suppliers' imbalance positions should be mitigated.

As a DSO we believe that there is a need for transparency of DER contracted to respond to any participant in the operation of the system. This transparency is needed to ensure that:

²² [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-\(SNS\)/Project-Documents/Report+9.5+19Oct_v2.1_%28Final+Photos%29.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Smarter-Network-Storage-(SNS)/Project-Documents/Report+9.5+19Oct_v2.1_%28Final+Photos%29.pdf)

- The extent of flexibility being used and the net-demand position is understood for planning, developing and operating an efficient system; and
- Resources are not called upon that are already in use and are unable to respond (there is a linkage here to the value of services provided – flexibility providers should see fair value for the services provided).

There is a need to have clear roles for the different market functions in the operation of the system so that parties understand where the value is derived and managed. There is also a need to identify means to assess whether behind the meter actions have had the contracted effect. Actions taken that reduce demand that are offset by other uncontrolled increases within the same metered demand are not possible to determine.

Suppliers, aggregators and customers will all seek value through flexibility services, so consideration should be given as to whether there should be separate licensing for:

- Retail services to customers (and associated customer protection); and
- Flexibility services (to suppliers and system services) with conditions associated with inter market actions.

Question 8: What are your views on these different approaches to dealing with the barriers set out above?

Ofgem should develop a range of approaches to the barriers described. It may be appropriate that there are different entry requirements for different flexibility services. For example, it may be appropriate to have lower entry requirements for services that are provided to suppliers for commercial positions in the wholesale markets than it is for providers of Balancing Market services or constraint management services where system security or the maintenance of customer supplies is at risk. It is important to start developing these entry requirements now so that they are in place before the volumes of aggregated services increase dramatically.

Question 9: What are your views on the pros and cons of the options outlined in Table 5? Please provide evidence for your answers.

Ofgem should keep a watching brief to see if providers of flexibility and system operators can find suitable service offerings for flexibility to access all markets. We are observing a number of aggregators and suppliers offering converging capabilities, particularly demand-side frequency response.

We support a clear regulatory framework for all participants in delivering system services. Contracts for services can mandate obligations on to providers, but there may be merit in licensing to avoid duplication or inconsistencies. In our response to question 10 below we highlight that licensing for those wishing to participate in system critical services may be appropriate to ensure the security of the system, as many of those services are now procured from licence exempt flexible resources not operating under a licence framework.

Question 10: Do you agree with our assessment of the risks to system stability if aggregators' systems are not robust and secure? Do you have views on the tools outlined to mitigate this risk?

It is inevitable that loads behind the meter will be controlled through bypassing smart meters, and this creates a risk that large amounts of load could be switched simultaneously. These devices will almost certainly be controlled through internet technologies with the inherent risk of cyber-attack or communications failure. It is therefore important that those systems be made as reliable and secure as possible.

We agree that this will require cross system thinking including those manufacturing and selling smart devices, but it is likely that different services would require different specifications. For example, a demand-side service providing frequency services (should this be possible) would be likely to require much faster ramp rates than normal balancing services. As such it should be for the system operator to set the required service standards.

As with a number of services supporting system security, the merits of licensing need to be considered. It is unclear whether purely contractual terms for non-delivery or failure to meet underpinning standards (e.g. for IT security) are sufficient. This is because commercial contracts require penalty mechanisms that are linked to damages and it might be difficult to make these appropriate for managing system security risks. Any associated provisions could be seen as excessive risks producing barriers to entry. For example, it is conceivable that a service provider could establish individual corporate entities, to deliver individual services. This could leave the SO unable to enforce any penalties wider than for that service or discriminate against the operator in other services. However, a licensing regime could place responsibilities on the controlling shareholders, while minimising barriers to entry.

Ofgem should consider the merits of licensing participants in such services in order to underpin 'good behaviour' and essential service rules.

General Authorisation Regimes similar to those used in IT may be appropriate to ensure transparency in services to wholesale markets but it is not clear that they provide sufficient powers to support system critical services, therefore licensing for such services may have some merit.

2. Providing price signals for flexibility

System value pricing

Question 11: What types of enablers do you think could make accessing flexibility, and seeing a benefit from offering it, easier in future?

Our view is that the enablers that could make accessing flexibility, and seeing a benefit from offering it, easier in the future will include:

- i) Development of half hourly settlement as a minimum;

The development of half hourly settlement (as a minimum, as shorter time periods are being considered) will be essential in ensuring value signals to domestic customers (or intermediaries offering energy management services). Existing DUoS tariffs' design has been developed to provide price signals that should encourage the usage 'off peak'. However, DUoS tariffs are only one component of the charges to customers and it will be up to suppliers to provide them with smart tariffs or other incentives.

- ii) Sufficient flexibility in licence arrangements to allow us to set charges or procure services to promote efficient use of the network;

In theory, price flexibility could indicate full system cost variations, locationally and over time, and this could then provide the right amount of flexibility. Price flexibility already drives many large customers' flexibility to avoid high peak energy charges and triad costs, but this is to some degree allowing users to avoid fixed and sunk costs. There are practical challenges to price flexibility. For example, for EV users it would require producing different price signals, in real time, in several thousand locations across our network. Highly local constraints affecting small numbers of users also may not result in effective flexibility markets. Complexity can be a disincentive for customers but this is likely to be moderated for end users by smart intermediaries and technology.

There are other charging considerations, including stability, transparency and non-discrimination, which need to be addressed. Network charges are strongly defined by the need to recover allowed revenue in a non-discriminatory manner. Highly locational charges, where customers pay different prices in adjacent streets, may not be seen to be fair. DNOs' revenue recovery licence compliance should not be a barrier to the use of seasonal time period charges. Consequently, licence charge restrictions should have sufficient flexibility so that they do not penalise DNOs who are targeting their charges to provide minimum long term cost to consumers by incentivising efficient use of their network.

The final charges consumers responding to price signals see are a composite of fixed and variable costs, generation costs (which combine fixed charges from investment and mechanisms such as FiT and CfD with variable production costs), network charges (which could be considered to be fixed), and suppliers' operating costs. Network charges (including transmission) currently represent approximately 25% of the final costs, so reliance on price flexibility to secure demand response to meet local constraints may not be sufficient, as it is only a proportion of the energy bill²³.

- iii) Visibility of resources that exhibit flexibility (and their use);

Visibility of resources that exhibit flexibility (and their likely use) will be critical to enabling system operators to forecast demand, plan and develop the network to provide the most efficient outcome for consumers (whether they provide contracted services or not). The current market arrangements do

²³ <https://www.ofgem.gov.uk/consumers/household-gas-and-electricity-guide/understand-your-gas-and-electricity-bills>

not promote the visibility of which customers are providing flexibility (for example, to suppliers to manage triad positions).

We are actively engaging with projects looking at how these challenges might be addressed, such as Centrica's Cornwall Local Energy Market that uses learning from California, Open Utility's proposals for a flexibility trial under EEF using learning from their peer to peer Piclo project, and Electron's ideas for block chain driven systems.

We intend to start recruiting and procuring flexibility in 2017, using the engagement experiences under LCL and relationships with aggregators and directly with industrial and commercial consumers. As a SO, using contracted or market procured flexibility as is the case of balancing services, is more likely to provide the certainty required for services vital to ensuring continuity of supply. Transparent market places that allow visibility of available resources and service requirements could assist this.

- iv) the development of commercial and market models for flexibility, where procurers of flexibility share costs according to the priority of access required.

We support the development of commercial and market models for flexibility to complement the existing industry systems and in doing so develop a more adaptable future system that can adapt to the widespread flexibility that domestic storage and smart appliances may provide. A key issue in making use of and remunerating demand side services is visibility of the actions occurring amongst other variables on the system. As noted above, we are aware and supportive of the initiatives being developed by Centrica, Electron, Open Utility and InnovateUK and would encourage support for these as the industry determines its future needs. Block chain technology, distributed settlement platforms, and smart contracts that implement merit orders in procuring flexibility all need to be explored and developed in parallel with existing improvements to settlement systems to improve current markets.

There are two ways of stacking the value of flexibility:

- Providers of flexibility buy into multiple revenue streams, with the ability to extract value providing the incentive to act flexibly; or
- Flexibility providers offer their services at a price which the procurers of flexibility then share according to the priority of access required (which could change over time).

It is probable that the first option will drive the initial development of flexibility but future flexibility platforms could enable the second and permit greater optimisation of the system.

We are already seeing examples of the potential challenges from the first option:

- Price sensitive flexible demand will be responsive to the largest price risk it faces, e.g. flexibility will be used to manage exposure to high half hourly imbalance costs rather than provide lower value demand side response services;
- Service offerings have to be designed to be complementary, not exclusive, but avoid paying twice for the value provided to the system; and
- Customers/providers of flexibility have to navigate a complex array of services.

As we have seen with the generation capacity, marginal price driven markets may not provide capability ahead of need and establishing markets for future flexibility equivalent to the Capacity Market may be necessary to drive the business case for the incremental costs of investing in flexibility.

Question 12: If you are a potential or existing provider of flexibility could you provide evidence on the extent to which you are currently able to access and combine different revenue streams? Where do you see the most attractive opportunities for combining revenues and what do you see as the main barriers preventing you from doing so?

Our experience from SNS as a provider of flexibility to National Grid is that a key barrier to combining revenues can be the definition of the services themselves, e.g. STOR and EFR. We note that flexibility is procured through individual contracts: for example, National Grid has 12 frequency and reserve services and distribution services are currently procured through specific contracts to address specific network issues. The development of effective market places for the forward procurement and real time despatch of flexibility resources may reduce the barriers created by this complexity.

Question 13: If you are a potential or existing provider of flexibility are there benefits of your technology which are not currently remunerated or are undervalued? What is preventing you from capturing the full value of these benefits?

As a DSO we are incentivised to procure demand-side flexibility where we are certain of the requirement in order to minimise costs to our customers. Demand growth has been low and uncertain over recent years and this has created only a limited need for flexibility. This uncertainty 'limits' our ability to create a wider market for demand-side flexibility services to our system and may be seen by some to be limiting their ability to enter the market.

We intend to start recruiting and procuring flexibility in 2017, using the engagement experiences under Low Carbon London and relationships forged with aggregators and directly with industrial and commercial consumers. As the use of flexible connections expands and more storage looks to connect, demand-side flexibility will need to be facilitated through the connections process and agreement, which we are well positioned to enable.

Given that we are a procurer of flexibility we will leave it to providers to comment on technologies which are not currently remunerated or are undervalued.

Question 14: Can you provide evidence to support changes to market and regulatory arrangements that would allow the efficient use of flexibility and what might be the Government's, Ofgem's, and System Operator's role in making these changes?

Flexibility is already used both in the balancing system and by customers and suppliers to mitigate high peak charges and triads. We are also using it from export customers in order to connect them without the need for reinforcement. In developing efficient markets for flexibility, procurers of flexibility need to understand the resources that are acting in the system and therefore forecast the additional resources that need to be procured. In designing an overall framework, we need to understand the relative opportunity value of different services and how resources will respond.

It should also be clear for providers of flexibility where services would be remunerated, for example.

- Price driven flexibility provided to the wholesale market to match supply and demand is remunerated through those markets and use of system charges; and
- System operators procure additional flexibility to meet the needs of the system and remunerate this through contractual payments, or through flexibility markets.

Inherent price driven flexibility is not directly visible to system operators. As we have stated above, future markets should have visibility of all flexibility in order to allow system operators to efficiently develop the network and extend future services.

Government and Ofgem have a role in developing a regulatory framework that supports flexibility. Ofgem should look at where incremental changes to the existing systems and codes will not suffice and drive the development of systems which will support future markets, much as it did with previous market reforms.

Ofgem must also enable industry to collaborate across the value chain – for example, on flexibility platforms – to develop the solutions needed in collaboration with new entrants. Ofgem's role should be to ensure that these are developed in an open manner that does not create barriers to entry and supports a market for flexibility, but should encourage innovation. System operators (SO and particularly DSOs) should be incentivised to lead these developments for two reasons:

- They have a critical role in optimising use of resources, including networks, to ensure the best outcome for customers; and
- They can be incentivised to have no interest in excluding providers of services as their incomes are regulated (i.e. they have no incentive to limit competition in services in order to extract value from providing flexibility).

As explained in our response to question 46, Government and Ofgem have a role in ensuring there is a clear regulatory framework to promote flexibility, recognising the risks, costs and benefits that the shift to a smart, flexible network represents. If this framework can be put in place then it allows industry to develop the commercial incentives and tariffs for customers to provide flexibility.

Smart tariffs

Question 15: To what extent do you believe Government and Ofgem should play a role in promoting smart tariffs or enabling new business models in this area? Please provide a rationale for your answer, and, if you feel Government and Ofgem should play a role, examples of the sort of interventions which might be helpful.

We believe the industry should be allowed to develop products and services to meet customers' needs, consistent with the recent findings from the CMA markets review. Ofgem and Government's role should be to encourage the industry to develop the right frameworks to meet customers' needs. There are many approaches to developing smart tariffs (the NARUC rate design manual is a good summary of the approaches²⁴), as highlighted in Table 1 below. There are competing needs between long term signals and short term optimisation.

We can develop smart network tariffs but are reliant on suppliers to reflect these on to our customers. Different suppliers have different appetites, simpler distribution tariffs can be easier to administer, but complex pricing and optimisation can offer a competitive advantage for suppliers.

²⁴NARUC Distributed Energy Resources Rate Design Manual November 2016
<http://pubs.naruc.org/pub/19FDF48B-AA57-5160-DBA1-BE2E9C2F7EA0>

Table 1: Strengths and weaknesses of different charging approaches

Charging approach	Strengths	Weaknesses
Fixed capacity charges	Equitable charges for access to capacity and standby services; revenue certainty	No price signals to promote efficient utilisation of the networks
Demand charges (kW)	Reflect drivers of costs if largely fixed; revenue certainty	Difficult to respond to Penalises low demand low load factor customers No overall efficiency signal Drive cost avoidance (e.g. Triads)
Unit based volumetric (kWh)	Half hourly unit rates reflect demand and efficiency	Can drive fixed cost avoidance High peak charges can be difficult for some customers to avoid
Locational Marginal Pricing	Strong costs signals to optimise variable costs on the system	Complex pricing signals (day, hour, 5 minute) Variable Requires separate mechanism to recover fixed cost Certainty to promote investment needs longer term prices Advanced Metering infrastructure
Standby and Back Up	Option for recovering costs from customers who want grid availability for when they do not have enough capacity to meet their own needs	Can be seen to affect business case for DER
Flat rates	Ensure predictability	No efficiency signals
Block rates	Increasing charges in each consumption can drive efficiency	Need for consumer to understand ongoing consumption Can drive under recovery of fixed costs Decreasing block charges (fixed cost recovered up front can damage efficiency incentive)
Time Variant rates	Drives efficient use of resources	Require all customers to have time of use metering (e.g. half hourly)
Value Resources	Target value specific types of resources create	Ensure values only accounted for once (e.g. in FiTs or tariffs but not both)
Value Services	Value provided to the grid Technology neutral	Requires technology to implement
Transactive Energy Charges	Supportive of peer to peer interactions (SO earns revenue from promoting interactions) Value based on services provided	Requires technology and communications platforms Advanced Metering infrastructure

Through our Low Carbon London project, we conducted an extensive, first of its kind, dynamic time of use tariff with over 1,100 customers in our London area. We also conducted extensive analyses of both the quantified effectiveness of the tariff to flex customers' demand and domestic customers' attitudes towards flexibility²⁵. We observed clear and strong support for flexibility-oriented tariffs with customers responding to surveys showing as evidence of customer attitudes:

- 91% of participants reported that the tariff should be offered to everyone and 81% even reported that the tariff should be a default or standard tariff. This was an impressively clear finding of support for more cost-reflective pricing, which was viewed as fairer and actually promoting efficiency for customers;
- 79% of participants reported that a dynamic, three rate time of use tariff was not experienced as complex in the course of living day-to-day with the tariff. This finding suggested that more consumers accept, or even have an appetite for some types of complexity; and
- The trial showed a clear response from customers, delivering up to an 8% reduction in their average peak consumption during high price periods.

As discussed earlier, smart tariffs may come from a combination of price signals and services. Further research may be helpful in understanding the incentives consumers react to – for example, whether negative cost avoidance incentives have the same power as positive payments for flexibility through contracts.

There are areas where Government or Ofgem could have a role in mandating smart tariffs, particularly in areas such as EV charging or electrification of heat, which will have a significant impact on the supporting network infrastructure and which could be reduced through smart tariffs. As previously mentioned, ensuring consistent approaches such as full half hourly settlement will play an important role in driving benefit from changing consumer behaviour.

Question 16: If deemed appropriate, when would it be most sensible for Government/Ofgem to take any further action to drive the market (i.e. what are the relevant trigger points for determining whether to take action)? Please provide a rationale for your answer.

We consider that action from Government/Ofgem should focus on setting firm objectives and a timetable for implementing future change linked to the forecast uptake of DER. This approach ensures that all parties understand the priorities and their regulatory obligations. Ofgem/Government should maintain an oversight of delivery against these objectives but only intervene where necessary; for example, to prevent barriers to competition developing, or to arbitrate where industry consensus is needed but cannot be achieved.

This timetable must recognise the needs of the price control frameworks of RIIO-T2 and RIIO-ED2 that will set the incentives, obligations and funding for the network operators during the 2020s.

Question 17: What relevant evidence is there from other countries that we should take into account when considering how to encourage the development of smart tariffs?

There are many options for smart charging approached that should be monitored. In the USA, nodal marginal pricing is being used more widely for day ahead and real time markets (e.g. PJM have a system of approximately 10,000 nodes, equivalent to pricing at the level of larger distribution primary substations (11kV))²⁶.

²⁵ [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-\(LCL\)/Project-Documents/LCL%20Learning%20Report%20-%20A2%20-%20Residential%20consumer%20attitudes%20to%20time%20varying%20pricing.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-(LCL)/Project-Documents/LCL%20Learning%20Report%20-%20A2%20-%20Residential%20consumer%20attitudes%20to%20time%20varying%20pricing.pdf)

²⁶ <http://www.pjm.com/about-pjm.aspx>

Question 18: Do you recognise the reasons we have identified for why suppliers may not offer or why larger non-domestic consumers may not take up, smart tariffs? If so, please provide details, especially if you have experienced them. Have we missed any?

Our experience in Low Carbon London echoes the Call for Evidence in terms of consumers' appetite for smart tariffs but also identified that significant price signals were required to invoke any behavioural change.

Larger non-domestic consumers may be indifferent to smart tariffs simply because understanding energy use is not part of their core business or immediate priorities. They may also feel that there is no scope for changing consumption patterns due to their business needs, or it may simply be that the business cost disturbance of a meter change is an unnecessary event. There may also be inertia due to expectation that energy costs may increase and that consumers do not expect decreasing costs as change happens.

We believe that half hourly tariffs will see lower cost consumers 'cherry picked' by innovative suppliers who offer appropriate products. These products will make use of seasonal time-banded tariffs which will benefit those consumers who are currently paying a 'penalty' on single unit rate average tariffs due to the consumer's actual lower cost usage. Over time the consumers who remain on tariffs that are not cost-reflective will face increases to reflect their higher than average costs as the low cost consumers migrate to the seasonal tariffs.

Smart Distribution tariffs: Incremental change

Question 19: Are distribution charges currently acting as a barrier to the development of a more flexible system? Please provide details, including experiences/case studies where relevant.

We do not think that distribution tariffs are acting as a barrier to a more flexible system. Distribution charges are designed, within limitations, to reflect the time when the system is most congested and therefore promote flexible use of the system. They are limited in that CDCM charges are not locational within the distribution service area. However, for larger customers, the EDCM produces a 'bespoke' charge that recognises their location in the system and the impact their actions have on the network.

We consider that the distribution charges provide a basis on which to layer other flexible products, such as contractual flexibility. As highlighted earlier in this response, contractual flexibility can provide the certainty of response which we need as well as the certainty of income required by providers of flexibility. We consider that trying to deliver flexibility solely through tariffs will make those tariffs too complex. DNOs have already been challenged about the differential in prices between service areas by suppliers desiring to reduce their costs, which illustrates one of the challenges that will emerge between smart tariffs and the opposing desire for simplicity/predictability.

Question 20: What are the incremental changes that could be made to distribution charges to overcome any barriers you have identified, and to better enable flexibility?

Since the introduction of the CDCM in 2010 and EDCM in 2012, many types of incremental change have been implemented. Some of the changes implemented have been to improve the stability of prices so that a consistent or predictable cost signal is provided and the risk of volatility is removed. Having a consistent cost message has been promoted as a way to reduce supply costs by removing unnecessary risk premiums applied by suppliers.

Feedback from our stakeholder engagement with suppliers and aggregators has revealed that incremental changes to the DUoS charging mechanism, through change modifications, can be seen to drive uncertainty and affect the business case for investment.

It is likely that changes to enable flexibility will have an effect of removing consistency and predictability. With this in mind it would be better to enact flexibility with 'active' flexible network participants such as demand aggregators (e.g. through contracts or market places), who will be best placed to manage the volatility of the charges. A separate charging regime for electric vehicles may also be an opportunity for 'incremental' change using smarter tariffs.

A clear path forward needs to be signalled to allow a flexible system to be developed and business cases made for users to participate.

Question 21: How problematic and urgent are any disparities between the treatment of different types of distribution connected users? An example could be that that in the Common Distribution Charging Methodology generators are paid 'charges' which would suggest they add no network cost and only net demand.

Given the average principles of the CDCM we feel that the current array of charges for demand and credits for generators are appropriately applied for the different types of users. One of the main underpinning concepts of the charging methodologies is that demand consumers are the ones who will ultimately pay for any charges applied to generators. With this in mind there should be no arbitrary charging of generators unless there is a real time cost driver for that generator.

However, there are issues relating to the interaction of the generation connection arrangements and the need to reinforce or constrain generation which may interact with generation use of system charges. Connection charges are currently used to signal where it is efficient to connect generation, but as constraints become more remote from the location of a generator, these signals are weakened by the connections charging framework (in particular the voltage rule which limits charges to one voltage above the point of connection). This may require DSOs to begin constraining generation off or to require a flexible connection, because of the high costs of addressing constraints. As constraints that are addressed by flexible connections are removed there will also be a need to ensure that the costs are appropriately assigned to those who benefit from their removal. This may require consideration of generation use of system charges in conjunction with the connections framework to ensure fair recovery of costs.

Smart Distribution tariffs: Fundamental change

Question 22: Do you anticipate that underlying network cost drivers are likely to substantively change as the use of the distribution network changes? If so, in what way and how should DUoS charges change as a result?

Potentially, the main way that the underlying network cost drivers will change is in the way that the costs of system operation (e.g. for services from DER) will vary from the costs of network asset provision. System operation will change as network operators become more innovative in seeking alternative solutions to traditional network problems. This will drive dynamic approaches that will be designed to reduce long term cost and improve system reliability. The costs of traditional network provision are likely to change over time as localised generation replaces the need for upstream reinforcement and the consequential maintenance of those assets.

With the advent of new low carbon technologies such as EVs, heat pumps and domestic storage, it is possible that some customers' demands will increase and others' will decrease or become more intermittent, and there will be a need to ensure that costs are recovered fairly from all users. It will be important to monitor the balance between fixed charges to recover the provision of standby capacity and variable charges that promote flexible response.

The other area of interaction is that between connection charges and flexibility, noted in question 21 above. Our current flexible connections provide the benefits of flexibility to the generators through lower upfront charges, with the DSO not incurring costs to curtail for the relevant constraints.

Question 23: Network charges can send both short term signals to support efficient operation and flexibility needs in close to real time as well as longer term signals relating to new investments, and connections to, the distribution network. Can DUoS charges send both short term and long term signals at the same time effectively? Should they do so? And if so, how?

While prices can in theory send long term signals, many market mechanisms seem to require longer term signals in addition to network charges (e.g. capacity payments) to provide sufficient certainty to enable investments in flexibility. The complexity of using DUoS for short term price signals may make transparency and predictability difficult as the system changes to support growing low carbon technologies. It may therefore be better to allow DUoS to provide long term signals and use separate flexibility charges/services to manage short term system requirements, initially through contracts, but eventually through flexibility markets.

Short term pricing signals are best placed with those who can contribute to active network management. We feel that those that will be able to contribute most will be active network participants such as aggregators. The costs and benefits of active network management will need to be split from longer term cost signals and should be reflective of specific network problems and reinforcement alternatives.

Longer term pricing signals are best placed to recover the DNOs' longer term or sunk costs that form the majority of the current allowed revenue. While these costs will only change over the longer term, it is still important that appropriate cost signals are synchronised so that consumers avoid behaviour which would drive the need to reinforce.

Question 24: In the context of the DSO transition and the models set out in Chapter 5 we would be interested to understand your views of the interaction between potential distribution charges and this thinking.

Our view is that in the short to medium term i.e. the next 10 years, the DSO will continue to evolve around purchasing contractual flexibility. This can provide the certainty needed for both DNOs (in knowing resources are available) and for providers of flexibility (in terms of certainty of revenue). In the longer term, it may become possible and potentially more practical to use pricing as a way to procure flexibility once there is an abundance of active distributed energy resources connected.

For example, as the demand and resources served by the networks develop greater flexibility, both the DSO model and the energy markets will evolve and charging structures will need to evolve to support them. There are also challenges in flexible systems in determining rights to capacity (currently a connections issue), particularly as the system evolves. Charges may therefore need to reflect users' rights to capacity as well as their actual use of it. We will use our TDI 2.0 project to look at how flexible capacity rights can be assigned using more market based mechanisms.

We are already seeing local and peer to peer services emerge where local trading reduces some users' reliance on upstream infrastructure. These customers will still need to contribute fairly to the maintenance of upstream capacity (physical or flexible) if they want to retain rights to secure capacity in all circumstances, in which instance an element of fixed capacity charges may also be appropriate.

Other Government policies

Question 25: Can you provide evidence to show how existing Government policies can help or hinder the transition to a smart energy future?

One example of where Government policy impacts the transition to a smart energy future is around connection charging. The current connection charging regime at distribution levels reflects, in part, the deep connection costs (one voltage level above the point of connection) and encourages generation to connect where there is capacity or to make best use of capacity. Transmission connected generators have a different regime where the charges are shallow and use of system and constraint payments are used to manage access (connect and manage). This can impact decisions generators make over whether to connect at distribution or transmission level.

If DNOs were to trigger transmission reinforcement because of generation connections at lower voltages, then these costs can only be recovered by being passed through to the generators. These costs are typically significant such that the generators cannot fund them and thus they limit the capacity available, prohibiting our ability to make further connections. Our TDI 2.0 project will look at interfacing active network management across the T&D boundary to enable more connections without the need for reinforcement. A consistent commercial framework is needed across this boundary.

In addition, we would support changes to renewable incentives that support the co-location of storage with generation where this supports the networks through reduced intermittency. At a system level, intermittency can be addressed by storage located remotely from generation, but this does not have the same overall benefit as energy has to be transported between the two locations.

Question 26: What changes to CM application/verification processes could reduce barriers to flexibility in the near term, and what longer term evolutions within/alongside the CM might be needed to enable newer forms of flexibility (such as storage and DSR) to contribute in light of future smart system developments?

A suitable framework is needed to promote investment in flexibility ahead of need, both storage and demand flexibility, but there should be a debate as to whether a single mechanism can procure the underlying capacity needs and the flexibility needs. Flexibility will have different values in different localities, and to the system as a whole, and it is not evident that the current capacity market is designed to deliver local needs.

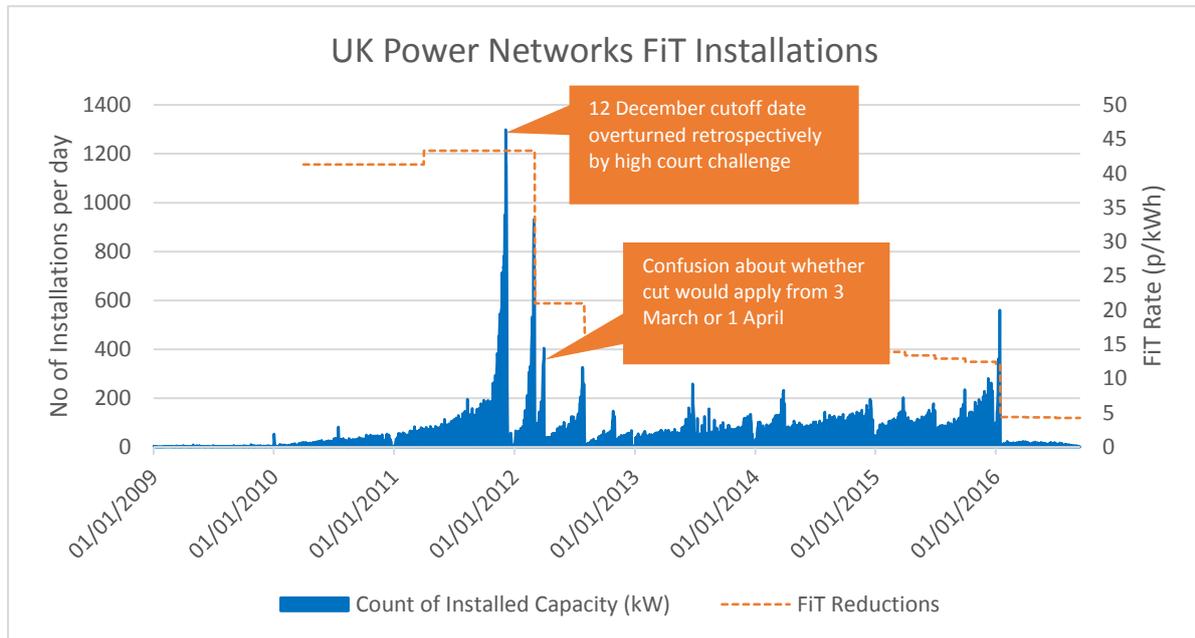

Question 27: Do you have any evidence to support measures that would best incentivise renewable generation, but fully account for the costs and benefits of distributed generation on a smart system?

The American NARUC Distributed Energy Resources Rate Design Manual (November 2016) considers approaches to valuing resources. This discusses designing the tariffs or rates to value the many aspects of renewable energy value. A clear and enduring framework will both promote investment and allow the SO and DSO to plan to integrate renewables, sending clear cost signals about the costs/value they can bring. An enduring framework would also ensure clarity on where benefits provided are credited and costs are met. For example, if carbon benefits are credited to generators through mechanisms such as renewable obligations, then any mechanism should make clear where the costs should fall for addressing constraints justified by reduced carbon emissions from increased exports.

We have clear evidence that Government support measures (and their level) can have a significant impact on the take-up of renewables in a way that can affect network operation and our business investment needs. Changes to renewable subsidies can create bursts of activity, shown in Figure 4

below, as investors seek to access the incentives. It is therefore important for Government to set out a long term, clear plan on where it will provide support and to what extent.

Figure 4: Number of FIT installation in UK Power Networks

3. A system for the consumer

Smart appliances

Question 28: Do you agree with the 4 principles for smart appliances set out above (interoperability, data privacy, grid security, energy consumption)? Yes or No (please explain)

We broadly agree. In order to maximise the benefits that smart appliances offer to customers, networks would require visibility of where these devices are acting in order to coordinate with demands for the network. Standards would also be crucial to allow scalability with networks interacting with smart appliances from various manufacturers. This would also mitigate 'consumer lock in'.

In our Low Carbon London Learning Laboratory, we utilised data from over 2,800 detailed customer appliance surveys to complete an analysis of the flexibility available from smart appliances. This survey data was used to populate a device-level household model developed by Imperial College London that used real network data. This work showed a peak reduction opportunity of between 8.8% and 12.9% for those customers on the trial, when industry coordination of appliance demand is assumed. However, this model also showed that uncoordinated smart appliances create a clear possibility of significant new network peaks as a consequence of loss of demand diversity and widespread (i.e. coordinated) price incentives. We take this to be clear evidence that both visibility and the ability to maintain or promote diversity in the use of smart appliances is essential.

Question 29: What evidence do you have in favour of or against any of the options set out to incentivise/ensure that these principles are followed? Please select below which options you would like to submit evidence for, specify if these relate to a particular sector(s), and use the text box/attachments to provide your evidence.

- **Option A: Smart appliance labelling**
- **Option B: Regulate smart appliances**
- **Option C: Require appliances to be smart**
- **Other/none of the above (please explain why)**

We view consumer trust, understanding and therefore informed and confident adoption as essential success factors to allowing smart appliances and services to drive the flexible energy system of the future. The requirements are likely to be dependent on the technologies in question.

Product labelling and British Standards (option A) can promote or advertise equipment meeting minimum standards. This might be an appropriate approach for consumer goods where British standards will have to align with international standards.

Technologies that provide key flexibility or have a very significant impact on system demand (e.g. EVs and heat pumps) may require more stringent regulation (option B) and potentially have to have minimum levels of functionality mandated (e.g. public EV charging infrastructure).

Robust, agile and scalable approaches to cyber security will be critical in developing and maintaining consumer trust, understanding and adoption. Smart appliances that are vulnerable to disruption are unlikely to be accepted or made use of.

Question 30: Do you have any evidence to support actions focused on any particular category of appliance? Please select below which category or categories of appliances you would like to submit evidence for, and use the text box/attachments to provide your evidence:

- **Wet appliances (dishwashers, washing machines, washer-dryers, tumble dryers)**
- **Cold appliances (refrigeration units, freezers)**
- **Heating, ventilation and air conditioning**
- **Battery storage systems**
- **Others (please specify)**

We do not have any specific evidence to submit.

Question 31: Are there any other barriers or risks to the uptake of smart appliances in addition to those already identified?

The perceived value of enabling the smart functionality over user convenience may be a barrier. Many non-smart devices such as dishwashers and washer/dryers offer users flexibility (e.g. deferred operation) and additional functionality may not be perceived to have sufficient added value, in a similar manner to Industrial and Commercial customers, who do not engage in flexibility.

Internet of Things (IoT) devices have already been used in internet denial of service events. Public perception of the risk to their own data security from such devices could limit their uptake.

We have highlighted our experience and observations about cyber security in our response to question 41.

Question 32: Are there any other options that we should be considering with regards to mitigating potential risks, in particular with relation to vulnerable consumers?

The fuel poor may be the biggest beneficiaries of flexibility but least able to access it through smart devices. Our energywise project has used a flexible approach to engagement that can be tailored for different groups. The energywise recruitment strategy was based on:

- Contact from a local trusted organisation with an excellent understanding of the local area and languages;
- An engagement strategy and materials tailored to the target population; and
- Face-to-face communication and support.

We would recommend that Ofgem and BEIS consider further engagement with community groups and support for community energy schemes as worthwhile initiatives to help engagement with fuel poor customers.

Ultra-low emissions vehicles

Question 33: How might Government and industry best engage electric vehicle users to promote smart charging for system benefit?

We believe that there are three key elements that will require a coordinated effort from Government, the transport industry and the energy industry:

- i) Information and education at the time of purchase

Informed and engaged customers will improve the user acceptance of smart charging. EV users already tend to be more engaged as the technology requires a change in behaviour. At the early stage, where EV purchase is being considered, the consumers can/should be engaged to promote the value/benefits of smart charging. Better informed customers can be empowered to take control over when and where their vehicle receives a charge.

ii) Ensuring the smart option is simple and easy to choose

Our Low Carbon London project demonstrated the value of smart charging to shift electricity consumption during vehicle charging and release capacity on constrained networks²⁷. This would enable increased demand on the network at a lower cost to customers. The EV trials in the Low Carbon London project highlighted that there are two interventions that can be applied in relation to smart charging of EVs:

- Behavioural interventions: such as time-of-use tariffs which require the customer to take action. This could be supported by offerings from energy suppliers, vehicle manufacturers and suppliers, which could minimise the costs of charging to customers; and
- Technical interventions: which automate the process for customers. In order to maintain safe and secure supplies to customers, technical interventions offer more scalable, reliable and sustained responses.

To ensure the smart option is simple and easy to choose, it clearly requires vehicle manufacturers, Government and the energy industry to develop a technical and commercial framework that supports smart charging being the default choice for customers. This will require standards for smart charging infrastructure, development of supporting energy products and infrastructure to allow the vehicles to be used as smart devices by the energy system.

iii) Ensuring smart tariffs are available and benefit smart users

While it must be easy to choose the smart option, smart tariffs that support both technical coordination of smart charging and can be used to indicate the benefits of smart charging to customers will be a necessary innovation.

We are already thinking about these areas as part of developing a strategy to manage EV take-up across our networks. To achieve the three outcomes above we propose the following:

1. The EV Network Group²⁸ is used to promote wider engagement and knowledge dissemination between vehicle manufacturers, aggregators, energy suppliers, networks and system operators to promote the understanding of the benefits of smart charging and kindle the development of smart charging solutions;
2. There are further Innovation trials building on the work of Low Carbon London and My Electric Avenue²⁹ to develop smart charging standards; and
3. The Modern Transport Bill is used to ensure the development of the technical standards and interoperable systems needed to underpin smart charging.

²⁷ [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-\(LCL\)/Project-Documents/LCL%20Learning%20Report%20-%20A10%20-%20Smart%20appliances%20for%20residential%20demand%20response.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-(LCL)/Project-Documents/LCL%20Learning%20Report%20-%20A10%20-%20Smart%20appliances%20for%20residential%20demand%20response.pdf)

²⁸ <http://www.lowcvp.org.uk/projects/fuels-working-group/EVNetworkGroup.htm>

²⁹ <http://myelectricavenue.info/>

Question 34: What barriers are there for vehicle and electricity system participants (e.g. vehicle manufacturers, aggregators, energy suppliers, networks and system operators) to develop consumer propositions for the:

- **control or shift of electricity consumption during vehicle charging; or**
- **utilisation of an electric vehicle battery for putting electricity back into homes, businesses or the network?**

There is clearly a need for the electricity system participants to work with the vehicle and transport providers to develop products that enable the system to work for consumers. We have identified two key barriers, discussed below.

i) Visibility of Information

The visibility of the location, characteristics and use of chargepoints will be vital to enabling smart charging to support the efficient development of the supporting electricity networks. We would welcome mandating this visibility.

Maximising the benefits to customers from smart charging is inextricably linked to the location of the chargepoints on the network. Demands on the network are by their nature typically limited to specific locations as a result of the local load and generation. Therefore, in order to maximise the benefit to customers from the smart functionality in chargepoints and vehicles, it is vital that DSOs have access to static data such as the geographical location and dynamic data such as the availability and usage of chargepoints. This would provide the minimum information required for the DNO to value and request a smart intervention for that network. The case for visibility is a key recommendation from our Low Carbon London report on smart charging³⁰. We do recognise that there will be data privacy concerns, as there have been with smart meter data, but we believe that these can and must be addressed to enable smart charging that enables network operators to deliver a service that will meet customers' expectations.

DNOs currently capture public chargepoints through their connections processes. The ENA has established a notification process³¹ to capture data on the location and rating of behind the meter chargepoints through the EV chargepoint installation notification process. This is recommended in the IET Code of Practice on chargepoint installations. This is a voluntary recommendation which there is no means of currently enforcing. We therefore welcome and support initiatives that set out clear requirements on chargepoint installers to notify the DNO in order to facilitate the benefits of smart charging to customers. We are also proactively engaging with local authorities and EV chargepoint manufacturers to understand where larger scale roll-outs of EVs are planned.

Considering evidence from a similar example of the notification requirement that DG installers have to inform a DNO when a small-scale generator (e.g. G83 classified) is commissioned: When we gained access to the feed in tariff (FIT) register of G83 connected devices in our networks, we discovered that we had only been notified of around 40% of devices through the voluntary mechanism. We would propose this evidence as justification for a more formal or enforceable position on DNO notification of electric vehicle connection. For example, enabling vehicle registration data to be shared with DNOs, and/or a data sharing agreement between charging infrastructure providers facilitated by OLEV or another body.

Visibility would entail the following data fields being provided, as a minimum, to inform the DNO on the suitability of smart enabled EV chargepoints to mitigate a local network constraint:

³⁰ LCL report [B5 'Opportunities for smart optimisation of new heat and transport loads'](#)

³¹ <http://www.energynetworks.org/electricity/futures/electric-vehicle-infrastructure.html>

- Static data: location of chargepoint, number of sockets, rated power (kW) per socket, mode of charge (AC/DC), smart functionality e.g. stop charge, vary charge rate; and
- Dynamic data: charge rate, charging status.

We have established views, which have been presented in papers³² such as the IET Hybrid Electric Vehicle Conference on the importance of dynamic data to facilitate the benefits of smart charging. The 'availability' of an EV charging load which is described as the volume of EV chargepoints in use, and their associated load, at the time of constraint on the network is an important metric informing the value of smart charging. With the right level of availability, a given volume of EV chargepoints will be able to provide a suitable level of response to mitigate the network constraint. Dynamic data is particularly vital to the management of the network in response to the live load and generation on the network – this is described as active management of the network.

The visibility of this data coupled with smart charging options will provide the opportunity for EVs to provide network services, such as constraint management. This has the potential to ensure the costs of facilitating the low carbon transition are minimised, which will also result in lower customer costs.

ii) Standards

Standards allow for safe, secure and interoperable smart charging to be realised. Standards also enable smart functionality to be scaled and applied consistently to ensure the realisation of the benefits to customers.

Standards are particularly important to ensure that customers have safe and secure smart functionality designed into a system that is also open, interoperable and scalable. Standards can be designed to allow consistent interaction and information exchange between the smart chargepoint and grid management systems as well as protection from cyber-attack. An additional benefit of standards is the opportunity to maintain consumer confidence without hindering the competitive development of chargepoints. These open standards can be developed akin to 3G/4G/5G in the telecoms industry, which have allowed the market for smart phones to thrive and grow with various offerings.

We are aware that similar work is underway in the Netherlands by ElaadNL. ElaadNL is the knowledge and innovation centre in the field of smart charging infrastructure in the Netherlands. Their work to develop smart charging standards could provide valuable learning for the UK. ElaadNL's 'Living Lab Smart Charging' demonstrator has involved a sizeable upgrade operation across the country to ensure the existing charging stations will be able to technically facilitate smart charging and all new installed chargepoints are smart charging ready³³. The proposals under this consultation present an opportunity for the UK to take the lead as the international frontrunner for smart charging.

Standards can also be designed to accommodate varying degrees of energy supply balancing including:

- Simple On/Off instruction; This could be established as the minimum requirements or standard for smart functionality in chargepoints;
- Instruction to vary the rate of charge;
- Varying the rate and duration of charge disruption relative to the EV battery state of charge; and
- Bi-directional power transfer through 'Vehicle-to-Grid' (V2G) applications. Demonstrators such as the V2G project³⁴ have investigated the potential of battery-powered vehicles to use their

³² Regulating EV demand: Distribution Network Operator perspective on Electric Vehicles.' HEVC 2016 conference publication

³³ <https://www.elaad.nl/nieuws/nederland-als-living-lab-voor-het-slim-opladen-van-elektrische-autos/>

³⁴ <http://www.smarternetworks.org/Project.aspx?ProjectID=1291>

excess rechargeable battery capacity to provide power to the grid in response to peak load demands. This project involved retro-fitting an EV to allow bi-directional power flows from the EV as well as the development of a bespoke V2G chargepoint. The project successfully demonstrated this but concluded that in the long term the vehicle and chargepoint manufacturers would need to see the value of V2G to develop the technology at a scale that would allow benefits to the customers and grid. With V2G applications, utilisation of an electric vehicle battery for putting electricity back into homes, businesses or the network is possible. There are currently very few vehicles and chargepoints which allow for bi-directional power transfer to facilitate this. Nissan and ENEL are most notable for trialling this technology currently with the Nissan Leaf and a suitable V2G chargepoint respectively.

Visibility and standards go hand in hand towards realising the value of smart charging and we would welcome initiatives from manufacturers, aggregators, energy suppliers, network and system operators to develop these standards. We have developed a strategy to help facilitate electric vehicles on our network and this includes the continual development of innovative solutions, using learning from innovation projects such as 'My Electric Avenue'³⁵.

Question 35: What barriers (regulatory or otherwise) are there to the use of hydrogen water electrolysis as a renewable energy storage medium?

As a DNO we would be agnostic to the storage technology used and cannot comment on the barriers to this technology. We encourage early engagement from customers seeking to utilise this technology in order to adequately meet their needs and support the adoption of the technology. Clearly the impacts on the system will depend largely on where the storage occurs. Co-located with generation (and using its output) is likely to have a much lower impact than if it presents an additional demand like any other storage system.

Consumer engagement with demand side response

Question 36: Can you provide any evidence demonstrating how large non-domestic consumers currently find out about and provide DSR services?

Since the completion of our Low Carbon London project in 2014 there has been an increase in activities from established buyers. This includes National Grid's Power Responsive campaign and the new Enhanced Frequency Response (EFR) service. Changes in imbalance pricing have also created new supplier-specific products/service offerings such as DONG Energy's Renewable Balancing Reserve (RBR), as new aggregators are entering the market³⁶. DNOs will also become increasingly active in the market for flexibility and will be raising awareness of the DNO DSR requirements. We see the bigger challenge in converting awareness into participation.

Our four-year Low Carbon London project investigated the impact of a wide range of low carbon technologies on London's electricity distribution network, including DSR. A key learning from the Low Carbon London trial was that the industrial and commercial sector are largely familiar with established DSR services such as peak demand avoidance and short term operating reserve (STOR) marketed through suppliers and National Grid, as well as aggregators.

In the Low Carbon London project, we marketed a new service offering, requiring significant up-front and continuous engagement with providers and aggregator partners played a significant role in recruitment. There were trial-specific challenges, such as some reluctance to sign up to a trial of short duration and an unclear business case (the purpose of the trial). However more generally, the

³⁵ <http://myelectricavenue.info/about-project>

³⁶ <http://www.dongenergy.co.uk/news/press-releases/articles/dong-energy-launches-flexibility-service-to-balance-renewable-portfolio>

challenges and approaches taken in the project gave us good insight into how non-domestic consumers engage with DSR³⁷. This learning will inform our approach when we go out to tender for further demand side services later this year.

Question 37: Do you recognise the barriers we have identified to large non-domestic customers providing DSR? Can you provide evidence of additional barriers that we have not identified?

We completed a detailed survey and analysis of larger, non-domestic customer's attitudes towards participation in DSR schemes on the Low Carbon London programme in 2012. This analysis identified that the most significant barriers related to:

- Negative perceptions of potential risks to comfort if building services are turned down; and
- Effects on service levels to customers and building residents, costs, time, equipment and other resources.

These negative perceptions were found to outweigh technical and financial barriers to participation. An additional, important point that we noted during the Low Carbon London programme is that the different layers of owners, operators, and users of flexible assets which all need to be involved to support participation in DSR. For example, a CHP generator may be owned (e.g. a property owner), operated (e.g. a facilities company), and utilised (the business tenant) by three different companies who would all need to approve participation in flexibility programmes.

These findings are consistent with that of Ofgem's survey that identified that the most commonly quoted risk was "risk to business from providing (further) DSR, including third party control of processes"³⁸.

Question 38: Do you think that existing initiatives are the best way to engage large non-domestic consumers with DSR? If not, what else do you think we should be doing?

The current engagement initiatives have raised awareness of DSR amongst non-domestic consumers. However, it is important that these initiatives try to address the barriers, otherwise increased awareness will not necessarily lead to greater up-take.

We launched the first of our ED1 DSR schemes in our Eastern area in 2016. We intend to start recruiting and procuring further flexibility in 2017. These programmes benefit from the engagement experiences under Low Carbon London, relationships with aggregators, and relationships with direct with industrial and commercial consumers. We will continue to share our experiences with Ofgem and BEIS as we embark on this programme.

We would urge Ofgem and BEIS to clarify the market structure and the role and responsibilities within it to facilitate the development of DSR. We expand on this comment in our response to questions 45 and 46.

³⁸ <https://www.ofgem.gov.uk/publications-and-updates/electricity-system-flexibility-demand-side-response-survey>

Question 39: When does engaging/informing domestic and smaller non-domestic consumers about the transition to a smarter energy system become a top priority and why (i.e. in terms of trigger points)?

We believe that the need to engage with smaller customers has already arisen. Customers are starting to be exposed to low carbon technologies, such as smart meters, electric vehicles, neighbours installing solar panels in their rooftops. As this rapidly changing world evolves it is really important that all consumers start to understand the future impacts and opportunities that, for example, energy efficiency and demand response measures, could provide them.

Consumer engagement will occur through many channels, suppliers and the roll-out of smart metering, home automation technology and service providers, smart appliance providers and vehicle and transport providers.

Our LCNF funded projects have consistently engaged with smaller customers and communicated the challenges and opportunities the transition represents. These projects are providing useful learning on how to engage and revealing the issues that will need to be overcome to get smaller customer to engage.

- Our Low Carbon London project installed 5,815 smart meters in domestic homes with a number participating in trials of dynamic time-of-use tariffs. The trial participants were also invited to complete detailed energy behaviour surveys. We found enthusiasm to participate but behavioural change required significant price signals; and
- Our energywise project is using community agencies to engage with vulnerable customers in the London Borough of Tower Hamlets (one of the most deprived areas in London) to address the best ways to engage with fuel poor customers to deliver energy efficiency (including smart meters) and DSR opportunities.

The learning from these projects is that the engagement will need to be enduring and the importance of engagement will grow as the number of controllable devices increases to the point where they have a notable impact on the system. Key developments which will need enhanced engagement include the electrification of transport and heat. Smart charging of vehicles will be one of the major opportunities to engage with customers on smart energy behaviours.

Consumer protection and cyber security

Question 40: Please provide views on what interventions might be necessary to ensure consumer protection in the following areas:

- **Social impacts**
- **Data and privacy**
- **Informed consumers**
- **Preventing abuses**
- **Other**

As the first DNO-led innovation project specifically addressing fuel poverty, energywise is seeking to understand how the industry can better engage with traditionally hard to reach groups on energy initiatives and how we can work in collaboration with energy suppliers and local trusted organisations to support them to access the benefits associated to smart technologies and new tariff structures. While the project is still running, we have already gathered key learning on what are the potential barriers in delivering smart benefits for hard to reach customers and tested a locally-based approach to overcome some of these barriers.

The consultation outlines four main areas where customer protection issues may arise within the context of a smart, more flexible system:

Social impacts

Time of Use tariffs are facilitated by the national roll-out of smart meters. The take-up of smart meters and smart tariffs is voluntary; customers have to willingly opt-in to have a smart meter installed and to switch to a new tariff. Some consumer groups are expected to be less likely to accept a smart meter and therefore will be unable to receive some of the new tariff offers. This includes those aged over 75 years, those who cannot speak English well or those who have a disability, such as being partially sighted or blind³⁹. Our Low Carbon London project has also shown that the Inner City Adversity social group (in the widely used ACORN classification system for social groups, the Inner City Adversity group are low income, high unemployment groups typically earning less than £10,000 per annum) was the most prevalent to refuse to have a smart meter, owing to it being too technical or confusing. In order for the transition to a smart energy system to be successful and that the benefits are accessible to all, it is vital that it reaches all customers, including those who are vulnerable or low income.

energywise has proposed a flexible approach to engagement that can be tailored for different groups. The energywise recruitment strategy was based on:

- Contact from a local trusted organisation with an excellent understanding of the local area and languages;
- An engagement strategy and materials tailored to the target population; and
- Face-to-face communication and support.

This approach proved to be very successful in achieving the impressive 40% sign-up rate while ensuring inclusive recruitment of consumers that are considered hard to reach, including elderly households, and black or minority ethnic households which lack English as a first language. Based on our experience we recommend the following considerations in order to make sure the transition to a smart system is inclusive to those that are hard to reach:

- Consider a tailored approach for those that are most difficult to engage;
- A local approach may be preferable to target ethnic minorities living in specific areas or hard to reach communities;
- It is important to identify who are the organisations or individuals trusted by specific demographic segments and what are the messages that resonate with them;
- Work in partnership with trusted intermediaries or with champions with local intelligence and language skills;
- Consider face-to-face engagement to communicate to consumers the benefits they may realise if they opt in to smart interventions and respond to smart tariff; and
- Local champions have to be trained up professionally to identify vulnerability and to deliver key messages such as energy efficiency advice.

energywise is currently setting up the second phase of the project that will test the ability of fuel poor consumers to respond to DSR opportunities. Early considerations on how to increase the response to smart tariffs include:

- Tariff structures for those that are most vulnerable and hard to reach should be easy to communicate and understand;
- While energy efficiency advice is now very common and delivered through a multitude of channels, educational materials on how best to shift the energy consumption away from peak hours and access the benefits of different pricing signals should be made available to consumers on smart tariffs; and
- It is important to put in place a series of measures that will ensure that the change of behaviour is sustained over time, otherwise consumers may be worse off in the long term.

³⁹ Smart Energy GB, 2015, "Smart energy for all; identifying audience characteristics that may act as additional barriers to realising the benefits of a smart meter".

Data and privacy

We agree that the move to a smart energy system requires a careful consideration of data protection matters due to the expected increase of the amount of data that will be available to energy suppliers, network operators and other parties. We believe that this is a critical area for consumer protection.

We also agree that appropriate privacy safeguards need to be in place for handling personal data and that personal data needs to be managed in accordance to the Data Protection Act. Transparent processes should be in place to regulate how data is used only as intended for the purposes of a specific organisation. Data privacy should not be a barrier to develop new smart tariffs, new business models, or using the data to efficiently manage the system. As networks and the loads connected to them become more active then visibility, forecasting of customer behaviour will become more important for the system operator and this may require more disaggregated customer data to be available to network operators.

However, consumers' privacy should be central when defining new procedures to process their data. We already have robust processes in place to manage the customers' data which we receive, particularly for managing outages. Our innovation project energywise set up a Data Privacy Strategy to define the approach taken by the project partners in handling and processing personal data (as defined in the Data Protection Act 1998).

Informed consumers

In order to ensure that all consumers are taking part in the transition to a smart energy system by making informed decisions on how they wish to participate, we recommend that information is accessible and transparent to all community groups. These should include ethnic minorities, consumers living in areas of financial deprivation or in disadvantaged areas and households that may experience language and communication barriers.

Many customer groups are hard to reach or have vulnerabilities that limit their chances to access information. Through our engagement with vulnerable customers we have gathered invaluable learnings on best ways to engage with these groups and support them to understand the benefits available to them when accessing smart technologies and smart tariffs.

The following measures should be taken into consideration when informing consumers about the opportunities in a smart energy system:

- Develop key messages and identify trusted messengers that resonate with different consumers' groups and vulnerable people;
- When targeting hard to reach customers, tailor the communication strategy and materials to the specific demographic group; face to face engagement also works best;
- Make partnerships with trusted intermediaries that can support customers in breaking the barriers in understanding how to operate smart technologies and the benefits associated to smart interventions and smart tariffs;
- Consider using multiple languages, different media and communication channels and include as much visual content as possible; and
- Ensure that the consumers receiving the information, signing up to a smart tariff or attending the demonstration of smart technologies, are briefing others living in the household, otherwise the benefits from smart energy systems and smart tariffs will be limited.

Through our project energywise targeting households who may be struggling with their energy bills, we have learned that low income customers are likely to be primarily motivated to opt in for smart meters and DSR by the prospect of saving money on their bills. In the case of smart meters, better visibility of energy costs and easier top up methods for prepay customers are also key features that

make them attractive. This demonstrates the importance of providing clear information on what are the benefits associated to smart interventions to allow consumers to take informed decisions on the extent they wish to participate.

Preventing abuses

As a licenced operator we believe that there are robust controls in place on the network/system operators.

Question 41: Can you provide evidence demonstrating how smart technologies (domestic or industrial/commercial) could compromise the energy system and how likely this is?

A key system issue is rapid increases and decreases in demand. The system already addresses increases related to consumer behaviour before or after major events (e.g. people turning kettles on) which are predictable. Smart technologies theoretically create the risk of wider co-ordinated events that are difficult/impossible to predict. National Grid has indicated that ramp rates will continue to increase, meaning that fast, reliable actions are needed to be able to respond and maintain system stability. Robust cyber security of key smart technologies (e.g. EVs) and improvements to IoT devices should be encouraged to mitigate such risks.

Focusing on the perspective of the DSO, we recognise there's an increasing need to adapt and evolve cyber security measures to effectively manage the increased risks and attack surfaces provided by the pervasive deployment of smart technologies within our distribution networks. We consider the following scenarios as key areas of risk:

- The local IP connectivity of distributed generator owned and maintained SCADA equipment directly into the DNO's substations LAN or electrical apparatus;
- Either domestic or industrial smart devices being directly controlled and managed from the internet without sufficiently robust user access controls;
- A significant quantity of smart devices being remotely compromised by a threat actor, maybe due to a common vulnerability or management system, and these being maliciously operated to significantly adjust DSR within our distribution networks; and
- The tampering and malicious adjustment of critical messages between operators, consumers, aggregators or other participants resulting in modified generation and/or consumption patterns which cause a disruptive effect on electrical networks or market stability, operation and trust.

There are many factors, some of which are complex and interrelated in nature, that we feel will influence the likelihood of the above risks becoming of material concern such as:

- The critical mass of deployed smart technologies within our networks and the DSR capabilities and levels being supported;
- The cyber security maturity of the system design and development practices undertaken by smart solution providers, integrators and operators and their adherence to good practice cyber security measures and frameworks;
- The inherent resilience within the design of distribution networks and the diversity smart technologies deployed; and
- The sophistication and motivation of threat actors.

Designing, implementing and maintaining effective and proportionate levels of cyber security within smart appliances, data exchanges between the varied system participants and the resilience of critical supporting IT networks and systems are key to realising system security in a technology driven flexible energy system.

In these regards we consider the following approaches worthy of consideration by Ofgem and Government:

- Smart appliances and services will ultimately need to be intuitive to use and therefore have effective cyber security capabilities largely embedded into their construction and operation. Where consumers have settings and features at their control which could impact theirs or another energy system participant's cyber security, clear advice and effective agreements need to be in place to cover technical, procedural and contractual aspects to set acceptable tolerances of operation;
- Minimum cyber security standards through close collaboration between industry and government are to be established in relation to the build and operation of smart appliances supporting DSR;
- Above such minimum standards, energy system participants, including operators, aggregators and consumers, are given flexibility to use common good practice cyber security frameworks to take appropriate and proportionate 'risk' based cyber security measures;
- As the smart grid evolves with a flexible energy system playing a pivotal role in a secure, sustainable and low carbon energy supply, the need to understand and test the technology and data interdependencies between smart energy system participants is ever more vital. Again government and industry collaboration, driven through entities like the National Cyber Security Centre, can be used to undertake system level cyber assessments and attack simulation exercises to test system resilience and to drive a cycle of continuous cyber improvement in keeping with technology evolutions and cyber threats; and
- In order to effectively balance the needs of consumer flexibility and system reliability in the context of a smart energy system, further research and development of solutions to provide advanced cyber-attack detection capabilities (including unusual behaviours in IT systems and the devices or demands on the electricity system) are essential to support the adaptive management of electrical distribution networks and their supporting critical IT infrastructure and smart management components.

We believe that the cyber security risks arising from the transition to an increasingly flexible energy system are inherently manageable through the application of industry recognised good security practices, the development of minimum standards with all stakeholders where required and the continued healthy industry and government collaboration on cyber security.

To this end, in the last year we have:

- Undertaken a full review of our cyber security operating model against recognised global best practice to inform ongoing continuous improvements;
- Increased our level of investment in cyber security by 32%;
- Contributed extensively at industry and government information groups exchanges in support of Critical National Infrastructure Protection; and
- Taken on the chair of the ENA Cyber Security Forum to lead the future development of security standards and good practices as relevant to DNOs.

Question 42: What risks would you highlight in the context of securing the energy system? Please provide evidence on the current likelihood and impact.

We have set out the risks in our answers to the earlier questions on cyber security. There is current evidence that IoT devices have been co-opted to support internet denial of service actions and therefore are clearly vulnerable to cyber risks.

As IoT devices become more numerous a risk based approach to establishing the necessary system contingencies will be necessary.

4. The roles of different parties in system and network operation

This is a crucial section of the Call for Evidence and we are already utilising our portfolio of cutting-edge innovation projects to understand how our role is changing and are feeding this learning directly into our business. We are already displaying many aspects of the DSO role which is described in the Call for Evidence. We would like Ofgem to expand the current regulatory framework, in time for ED2, to provide the correct incentives across network companies to invest and deliver whole system benefits in the most efficient way. We also want to ensure that in meeting the immediate actions outlined in the Call for Evidence, we retain the flexibility to make changes to roles and arrangements in the future.

In response to the specific questions posed in the Call for Evidence we have set out the current situation on our networks, how this is likely to evolve in the future and where new roles and arrangements can help us maintain security of supply and deliver substantial whole system benefits.

Roles and responsibilities

Question 43: Do you agree with the emerging system requirements we have identified)? Are any missing?

We broadly agree with the emerging system requirements presented in the Call for Evidence and have provided examples in our response to question 44 of where we are already seeing evidence of the drivers for change on our networks.

The key priority for us will be to have visibility of the actions which others will be taking on our network and ensuring other parties have visibility of the actions we take. For example, we will need visibility of services provided from DERs, the SO and aggregators. Limited visibility may impact our ability to optimally manage the network and maintain system security in the future, as well as limiting the ability of the SO, generators and suppliers to operate efficiently. Again, we expand on this in our response to question 44.

Many of the aspects listed in the emerging requirements are already being implemented as business as usual. We have experienced rapid change in a number of our network areas, particularly with the high volume of DG and storage applications mentioned previously in this response. In addition, to ensure a resilient network we have undertaken bi-lateral work with National Grid to ensure that our connection contracts allow for emergency disconnection of DG when National Grid require it. We have also revised our process and procedures to manage a black start scenario.

In addition, we believe there are three important aspects which should be included in the emerging requirements.

- Forecasting of load and generation growth across the transmission and distribution networks. Accurate forecasting is a critical first step of network planning and important in enabling efficient system operation;
- The importance of providing transparent information to stakeholders. This includes where there is spare capacity available (through our heat maps) and also helping customers understand their potential DUoS charges under the EDCM and how they may vary depending on where they connect; and
- The need to start developing, advanced real time system-wide control. This will be a critical enabler of allowing the optimal operation of the networks (across transmission and distribution) to deliver whole system benefits. We are already embarking on the trajectory towards greater real time control through the TDI 2.0 project and we expand on this theme in our response to question 44.

Question 44: Do you have any data which illustrates:

- a) the current scale and cost of the system impacts described in table 7, and how these might change in the future?**
- b) the potential efficiency savings which could be achieved, now and in the future, through a more co-ordinated approach to managing these impacts?**

- a) the current scale and cost of the system impacts described in table 7, and how these might change in the future?

Table 7 in your consultation outlines three separate (if intrinsically linked) network impacts. We have looked at each of these in turn and where possible set out the costs and impacts in a qualitative and quantitative way.

Growth of Distributed Generation (DG)

The last few years have seen a rapid increase in not just the volume of DG connected but in the number of connection requests. We also have a substantial volume of DG which has accepted offers and are waiting to connect. We have set this out in Table 2 below:

Table 2: DG offers, contracted and connected

Category	Eastern Power Networks plc	South Eastern Power Networks plc	London Power Networks plc	Total
Offers issued (GW)⁴⁰	36	17	1	54
Contracted and waiting to connect (GW)	1.6	0.73	0.04	2.41
Connected⁴¹ (GW)	5.39	2.41	0.66	8.46

As a result of the above, our networks are becoming increasingly constrained. For example, in our Eastern region, a fifth of our GSPs could not accommodate a 25MW generator at EHV without reinforcement and over a tenth could not accommodate a 5MW generator at HV without reinforcement. As a consequence of these constraints we are offering flexible connections to customers, with ambitious plan to roll-out active network management across our Eastern and South Eastern networks by 2021.

As outlined earlier in our response, in addition to the DG connections, we have also received close to 12GW of applications from over 600 storage providers. This adds further complexity to assessing new connections as storage providers can be import and export. While we wait to see if storage providers accept a connection offer, we need to treat new connection requests on the basis that the storage providers accepts the offer. Therefore, new connection offers become interactive with those already issued. This is a difficult position to explain to customers and to keep an orderly interactive connection queue, particularly with 2.4GW of accepted offers to manage.

We have had to adapt our business and change the way we operate to deal with these connection volumes and the increasingly constrained nature of our networks. Specifically, we have:

- Increased the size of our network design teams to ensure a responsive service whilst experiencing a doubling in application volumes in the between 2012 and 2015;
- Introduced new policy guidance to support new market entrants such as storage providers and community energy groups understand the connection process;

⁴⁰ From January 2012 to November 2016.

⁴¹ To date

- Developed new processes to provide fair and equitable management of the interactive connection queues which have developed in the last three years;
- Increased our engagement and level of ongoing communication with connection applicants to ensure that they each understand explain the complex background to their connection request and received a bespoke service; and
- Deployed active network management across areas of our network to facilitate new connections in constrained areas without costly and time consuming reinforcement.

Exporting GSPs and whole system investment

We currently have several exporting GSPs across our networks. The impact of this is that all DG and storage connections above 1MW needs to be assessed by National Grid to understand what impact (if any) it will have on the transmission network. This is known as the statement of works process. It has resulted in considerable uncertainty for our customers in terms of the costs and timescales of connecting. In many cases where transmission network reinforcement is required, it makes the DG or storage project commercially unviable and the customer does not proceed with the connection.

We have been working with National Grid, both bi-laterally and through the ENA to try and improve the statement of works process. The aim is for National Grid to produce planning limits for each GSP which we can then use to provide better information up front to connecting customers on the time and cost of connecting. To date, it has proved very difficult for National Grid to produce these planning limits, given the complexity of the network and the constantly changing picture of DNO connection requests.

Co-ordinating local network management and system frequency requirements

The Call for Evidence correctly highlights the issues around co-ordinating local management of DG and storage with balancing actions taken by National Grid as the SO. We are currently rolling out active network management across large areas of our Eastern network. As stated above, we plan to have fully rolled out active network management across our entire Eastern and South Eastern networks (as well as where needed in London) by 2021. Therefore, co-ordinating the use of distributed resources for local and system wide benefits will become even more important in the future.

The scale of DNO active network management schemes, while ramping up, is currently low meaning that we have little evidence of actual conflicts with other services and their associated costs. However, we do have relevant evidence from the impact of National Grid's EFR tender. It was apparent that connecting customers who wished to bid for this tender were generally not interested in flexible connections for local network management. The feedback from these customers indicated that this was because the terms of the EFR tender did not lend themselves to being actively managed by the DNO.

We have been exploring these co-ordination issues through the ENA's Active Network Management group. This group has a specific work stream looking at where conflicts are likely to arise between local ANM and system wide balancing and how best to manage these conflicts. It is looking at the ownership of the ANM equipment where that equipment is used to resolve transmission and distribution constraints. The group are also looking at the process for managing the ANM scheme and the operational interface between SO, TO and DNO. As part of the strategic work stream, the ANM group is looking at whether the distribution network needs to leave some headroom for balancing actions or whether balancing and local constraints can be more optimally managed. The learning from our TDI 2.0 project will be important in informing future approaches.

Changes to cost in the future

We think there are two ways in which to look at how our costs may change in the future:

i) Network operation costs

Our forecasts (transposed from National Grid's Future Energy Scenarios) and set out in Table 3 below, are that under a high take-up scenario, we could have over two million active devices (such as EVs, DG and storage) connected to our networks by the mid-2020s⁴². These devices will not have regular consumption or export patterns and may be providing flexibility services elsewhere to the SO, suppliers or aggregators. To provide some context, the current number of active devices is in the low thousands and the flexibility markets to access these devices are only just developing. This will significantly increase the complexity of operating the system and the level of co-ordination needed between DSOs and National Grid.

Table 3: Take-up of low carbon technologies within UK Power Networks regions by 2030 based on National Grid Future Energy Scenarios⁴³ applied to UK Power Networks

Scenario	PV	Electric Vehicles
Now	2.6GW	0.016m
High	12.9GW	1.9m
Low	6GW	1.2m

To deliver decarbonisation at lowest cost, a paradigm shift is required in system operation. This will require investment in new IT and communications systems, along with the data and analytical processing to drive advance distribution management with strong co-ordination with National Grid. If we do not have the tools and remit to manage these devices, we will not be able to maintain the current levels of security of supply to our customers and it is also likely that the cost of decarbonisation will increase as we will be unable to optimise the use of resources on our network. As we outline in our response to question 45, it would be helpful if there was clarity of how the regulatory regime will treat the costs of investment in these areas and how transmission and distribution incentives will be aligned to ensure efficient delivery.

ii) Network infrastructure costs

We are already looking at the potential reinforcement costs associated with the Government's scenarios for the take-up of low carbon technologies in ED2. As part of our ED1 business plan we ran the Transform model⁴⁴ using our network data to provide a high level indication of potential reinforcement costs out to 2030. We ran the model across a range of scenarios based on the incremental use of the smart grid solutions. The model produced a range of potential reinforcement costs in ED2 of between £1.5bn (based on the core scenario we used in ED1) and £3.2bn (based on a 'high' take-up of heat pumps and EVs). We should emphasise that these figures are highly indicative but they are the best approximation available to us at present.

The figures emerging from the Transform model are supported to some extent by the work the ENA has undertaken for OLEV on the potential reinforcement costs for EVs. The ENA has estimated that the GB reinforcement costs of accommodating the anticipated eight million Electric Vehicles by 2030 and provided these to OLEV. We have assumed, based on the size of our network that around a third of these costs would fall to us between now and 2030.

⁴² This is based on the number of EVs, active DG and storage customers on our network, according to the figures in Table 3.

⁴³ <http://fes.nationalgrid.com/fes-document/>

⁴⁴ <https://www.eatechnology.com/global/middle-east-english/products-and-services/create-smarter-grids/transform-model>

The evidence above suggests we could need up to a four-fold increase in reinforcement allowances for ED2 (approximately £800m for the ED1 period), should the high take up low carbon scenarios emerge.

- b) the potential efficiency savings which could be achieved, now and in the future, through a more co-ordinated approach to managing these impacts?

We have split our response between savings available now and potential savings available in the future:

Savings available now

We have responded to the volume of DG connections through early deployment of our highly successful Flexible Plug & Play project, into the business as usual. We have expanded the trial zone and enabled 330MW of DG without the need for reinforcement. This has saved over £100m of reinforcement costs which would have otherwise made most of the DG schemes unviable. As outlined above, we are now planning an ambitious roll-out of the active network management infrastructure across our Eastern and South Eastern regions by 2021. Extrapolating the benefits against the current growth rate for Flexible Distributed Generation (FDG), we believe that this will allow in excess of 1GW of FDG generation/storage connect, saving customers up to £500m.

In addition, we are targeting the delivery of £43m of reinforcement savings (which are reflected in our ED1 business plan) through use of smart grid solutions, including flexibility.

Savings available in the future

It is difficult to estimate the level of potential savings with any certainty, particularly since the take-up of low carbon technologies is uncertain, along with the commercial and operational model for a more co-ordinated approach. We have looked at the evidence available to illustrate the wider system benefits as well as those which would accrue directly to our customers.

- i) Wider system benefits

The Call for Evidence cites the work undertaken by Imperial College for the Carbon Trust, which estimates the benefits of co-ordinated flexibility of £17-£40bn by 2050. We have engaged with Imperial College to help understand the assumptions made on the DSOs' role in delivering these benefits. Imperial College have been clear that a DSO role is crucial in delivering the vast majority of these benefits, given that the flexible resources will be connected to the distribution networks.

It is useful to look at where the savings delivered by a DSO can accrue across the system as shown in Figure 5 below:

Avoided generation plant: Imperial College's research shows that optimising the system operation at distribution level allows more generation to connect to the distribution network and avoids the need for more expensive, larger, generating plant to be built. This is a substantial proportion of the overall benefits (generation capex).

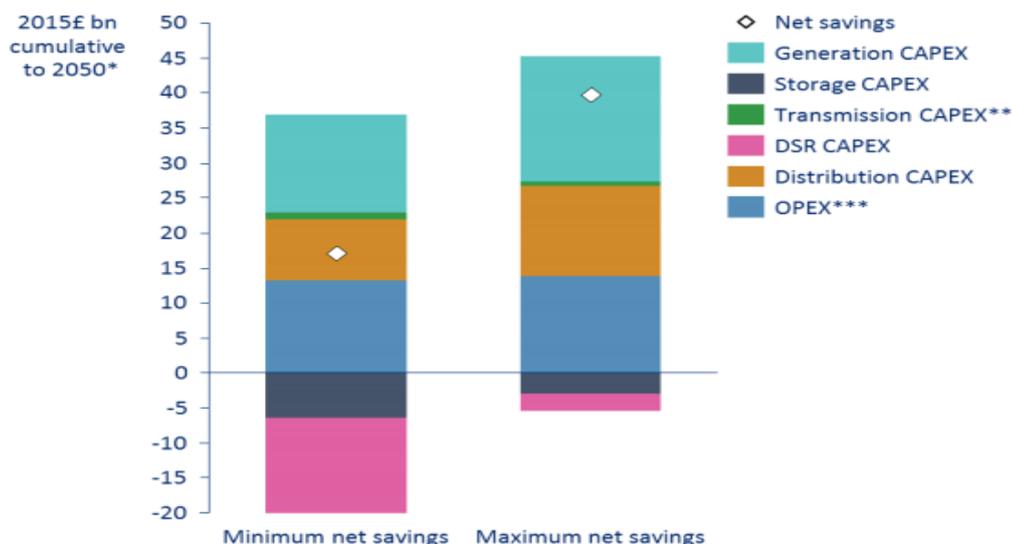

Avoided Transmission investment: Management of local distribution resources can avoid the need for transmission reinforcement. This is highlighted in the Imperial College work. We are actively trialling the delivery of these benefits through the TDI 2.0 project. National Grid has estimated that the benefits of the increased co-ordination being trialled will enable an additional 3.7GW of generation to connect to the system. National Grid go on to estimate that the total GB savings achieved through successful roll-out of the trial could be over £400m by 2050⁴⁵.

⁴⁵ https://www.ofgem.gov.uk/system/files/docs/2016/11/final_submission_tdi_2.0.pdf

More efficient balancing services: Access to DER for system balancing could displace the need for more expensive balancing options such as peaking plant. Again, this features in the work undertaken by Imperial College and Carbon Trust

Figure 5: Summary of flexibility benefits: An analysis of electricity system flexibility for Great Britain by the Carbon Trust (p5)⁴⁶

Chart 1 A breakdown of the minimum and maximum cost differences in scenarios with and without flexibility, cumulative to 2050

*Discounted back to 2015 using HM Treasury's Green Book social discount rate.

**Includes interconnector and onshore transmission CAPEX.

***Refers to variable OPEX (fuel and carbon costs). Fixed OPEX is included in CAPEX figures.

It is worth stressing that the regulatory framework does not currently allow any of the benefits to flow back to DNOs, despite our investment being needed to facilitate delivery of those benefits. Therefore, new incentives are needed to allow us to share in these benefits in order to fund the increased investment needed. We expand on this in our response to question 46 b).

ii) Distribution capex savings

Greater flexibility (and co-ordination of that flexibility by the DSO) can allow new connections to be accommodated without spending as much on reinforcing the distribution network. This can provide savings to the connecting customer, who avoid the need to pay for reinforcement and savings to wider customers who contribute to reinforcement costs through DUoS. Given projections of the take-up of low carbon technologies, these savings could be significant and account for around £8bn-£10bn of the savings cited by Imperial College. Many of the avoided connection costs will accrue to connecting customers under the shallowish connection charging policy.⁴⁷

We are already delivering some of these benefits today. We have £43m of reinforcement savings to deliver in our ED1 reinforcement budgets from use of DSR, as part of the wider smart grid benefits we are delivering. As highlighted above, we have ambitions plans to roll-out ANM across our EPN and SPN regions. Extrapolating the benefits against the current growth rate for FDG, we believe that this will allow in excess of 1GW of FDG generation/storage to connect saving the customers close to £500m.

⁴⁶https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/568982/An_analysis_of_electricity_flexibility_for_Great_Britain.pdf

⁴⁷ This requires customers to pay a proportion of reinforcement costs up front, with the remainder funded by DUoS customer. DNOs only receive these benefits

It is important to highlight that achieving the scale of benefits highlighted by Imperial College requires investment in IT and communications systems to provide real time visibility and network operation across transmission and distribution. As discussed further in our response to question 45, we are starting to trial this in areas (particularly through our TDI 2.0 project) but wider roll-out requires investment. We need a regulatory framework with aligned incentives across transmission and distribution to provide the certainty required to help attract this investment.

Question 45a): With regard to the need for immediate action, do you agree with the proposed roles of DSOs and the need for increased coordination between DSOs, the SO and TOs in delivering efficient network planning and local/system-wide use of resources?

We agree with the proposed roles of DSOs set out in the Call for Evidence and are already displaying many of these roles in our business operations. To fully respond to this question, we have set out the approach we have taken to developing our DSO capability, explained how this covers many of the roles outline in the Call for Evidence and highlight where further joint work is required by network operators to implement those immediate actions asking for greater co-ordination between parties.

Our approach to the development of DSO

We have been developing DSO capability since 2010 when we launched our Low Carbon London project⁴⁸. Our ED1 business plan included ambitious smart grid and innovation strategies aimed at ramping up our DSO capability⁴⁹. We have the largest and most successful portfolio of innovation projects across DNOs, which has helped us to trial and implement the foundation capabilities underpinning a DSO. We have also been active in following the innovation projects run by other DNOs to leverage the learning from them into our business.

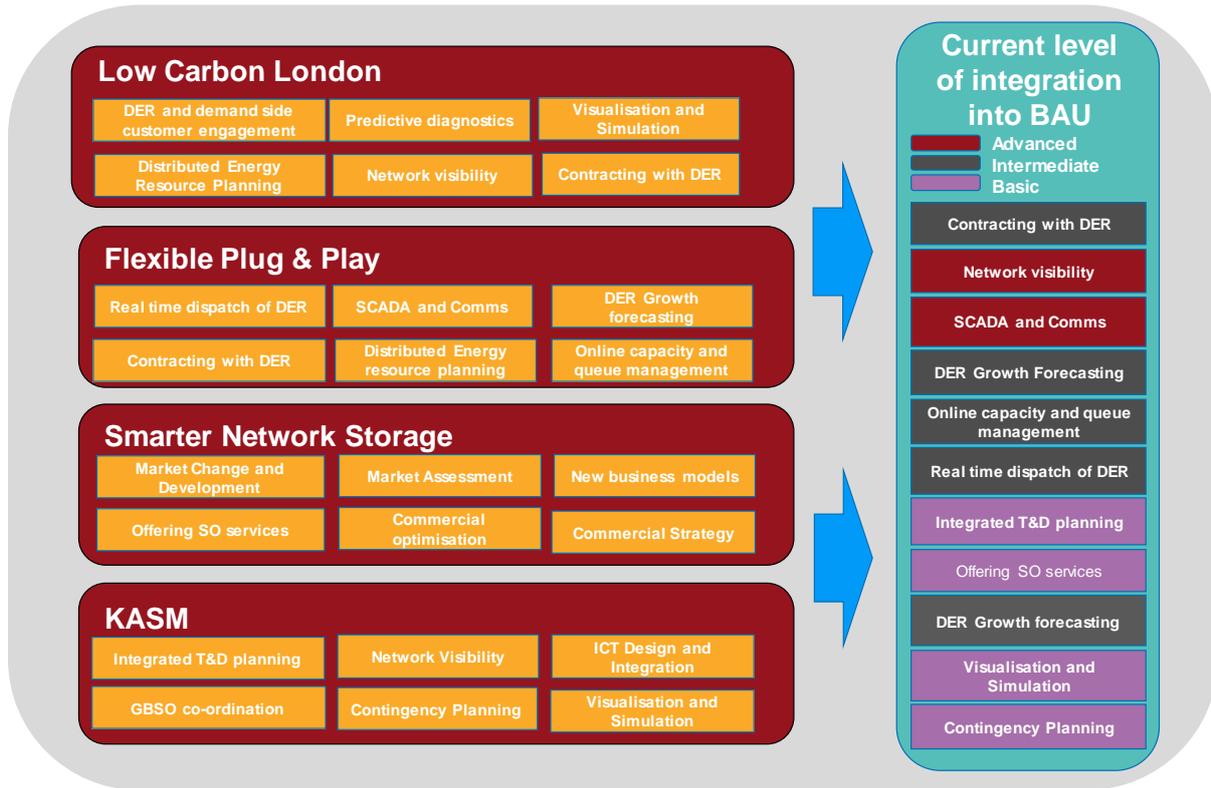

In response to the challenges we have seen on our network, we have started to deploy DSO capabilities as part of business as usual and are actively delivering over £200m of smart grid benefits within our ED1 business plan. We are actively developing other capabilities for deployment by the start of ED2.

Figure 6 shows how our innovation portfolio has defined and tested the building blocks of the DSO infrastructure. To ensure that these are deployed to provide benefits to our customers, we have restructured our business to support the delivery of the DSO capability in terms of technology, skills, data and systems that is required.

⁴⁸ [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-\(LCL\)/](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-(LCL)/)

⁴⁹ http://library.ukpowernetworks.co.uk/library/en/RIIO/Main_Business_Plan_Documents_and_Annexes/UKPN_Smart_Grid_Strategy.pdf and https://library.ukpowernetworks.co.uk/library/en/RIIO/Main_Business_Plan_Documents_and_Annexes/UKPN_Innovation_Strategy.pdf

Figure 6: DSO capability developed through some key innovation projects:

We are moving towards a new model of delivering system security which is less reliant on replacing and upgrading assets to maintain a certain level of redundancy, and more reliant on smart, real time operation of network assets. We believe that this is the most cost effective and efficient way to accommodate low carbon technologies to our network in order to deliver the Government's carbon reduction plans.

A full description of the work we have undertaken and that currently underway is set out below in Table 4:

We believe that we are actively meeting many of the immediate actions set out in the Call for Evidence and are incorporating them into our new DSO operating model. This looks to understand in depth the capabilities needed, their priority and the necessarily business change to build these capabilities. Consequently, we consider that we are advanced in terms of integrating the ability to run the network more flexibly into our central operations models, rather than have it running as a separate innovative trial which only works in some areas.

We acknowledge there is more work to be done in terms of implementing the joint industry processes around this co-ordination. This will involve learning the lessons from various innovation projects and trials and agreeing with other DNOs and National Grid how best to deliver a co-ordinated framework for planning and use of resources. We are committed to doing this but highlight some of the risks and challenges around these specific actions in our response to part b) below.

Table 4: Detailed description our integration of DSO capabilities into our business

Component	Examples
<p>1. Prioritising the DSO foundation capabilities, focusing on no-regret actions, that deliver customer and market needs.</p>	<ul style="list-style-type: none"> • We are prioritising investment in skills, particularly energy forecasting, power systems planning and ICT, energy markets and commercial analysis • We are creating a DSO function within our Information System department, focussed on delivering the software platforms, security and data architecture and DER management systems required for DSO transition • Network technologies that enable increased visibility and controllability of the network such as monitoring and automation at all voltage levels • We are actively developing cyber defence monitoring in order to ensure our more complex IT and communications systems remain secure
<p>2. Embedding successful innovation as business as usual to deliver customer benefits</p>	<ul style="list-style-type: none"> • We have created a 15 person strong dedicated team to enable the DSO transition for UK Power Networks. The team comprises of experts in programme management and change, power systems, ICT and commercial arrangements • We have the most network under active network control in mainland UK. Covering north Norfolk, we have enabled 330MW of DG capacity that may not have been viable saving over £100m for connecting customers • We have rollout plans to enable active network management across our Eastern and South Eastern networks by 2021 • We are planning to act as purchaser of flexibility through tendering for flexibility services to help avoid reinforcement and provide support during network outages • We have developed connections policy for large scale storage and domestic LV storage in response to market demand. We have published heat maps for demand and generation constraints • We are developing a comprehensive standard for the connection of EVs
<p>3. Working closely with the System Operator to improve co-ordination of network planning and operation</p>	<ul style="list-style-type: none"> • Working with National Grid to unlock capacity for further DG and Storage in our South Eastern region. This is examining how we can refine modelling assumptions, how the regional UK Power Networks Flexible DG scheme can coordinate with the transmission operator, how storage can be integrated and how distribution networks could offer solutions to transmission constraints • Our TDI 2.0 NIC project has been designed to develop and test practical co-ordination between T&D in order to resolve real constraints across both networks in the most efficient manner • Along with National Grid, we are co-developing the Regional Development Programme for the South Eastern region which focus on ANM, storage and network planning
<p>4. Developing Commercial Arrangements that inform future changes</p>	<ul style="list-style-type: none"> • We are developing market based development of more efficient curtailment mechanisms under NIA project⁵⁰ • Developing a commercial framework for joint SO/DSO procurement of flexibility under the TDI 2.0 project. The project is a world first DSO trial and tests the local balancing unit future model described in the Ofgem/BEIS Call for Evidence

⁵⁰ This is a potential NIA project which builds on the success of our LCNF project Flexible Plug and Play

Question 45 b): With regard to the need for immediate action, how could industry best carry these activities forward? Do you agree the further progress we describe is both necessary and possible over the coming year?

Further progress is necessary and possible over the coming year

If the projections on the future growth of DER are correct then it will be vital that we make further progress on the immediate actions and longer term models. These longer term models can not only reduce the cost of accommodating that DER but co-ordinate that DER in a way that maintains the security of our network. We expand on this concept in our response to question 46 a).

Some of the aspects listed in the immediate actions such as the formalised framework for whole system network planning and co-ordinating the use of resources require co-operation and clear allocation of tasks responsibilities between network operators. The premise in the Call for Evidence is that all the immediate actions can be delivered through current roles and arrangements. We agree but are concerned that this could 'lock in' current arrangements without a full debate and assessment of more fundamental changes. In this sense, we see delivery of these aspects of the immediate actions as intrinsically linked to the consideration of the future models outlined in question 46.

As an example, we are starting to see the SO co-operate with DNOs on its latest demand turn up service.⁵¹ Under the proposals trialled last year between National Grid and Western Power Distribution (and planned for roll-out in 2017), DNOs can access the distribution resources contracted for the demand turn up service through making a request to National Grid. National Grid then use the terms of their contract with the customer to procure the response required by the DNO. This is helpful in terms of sharing resources across SO and DNO. It starts to meet aspects of the immediate actions around co-ordinated use of resources. However, this is just one potential way of managing co-ordination and may not be the most efficient in the longer term (see Figure 7 in our response to question 46 a). We do not want to see systems and processes put in place to address the immediate actions which make changes to roles and arrangements more difficult as we move forward.

Best way to carry these actions forward

It is important that the immediate actions are implemented in a consistent way across network operators in order to provide a common set of processes and policies for our stakeholders. As such, we believe that the ENA provides the vital platform through which to share learning on how companies are addressing the immediate actions and agree how best to continue the co-ordination required. In addition, there will be some areas where it is helpful for individual network operators to work bi-laterally with National Grid to explore different options to help inform the policy debate. We are active in doing both of these to help address the immediate actions:

i) ENA work streams

We are using the knowledge gained from our innovation portfolio and practical experience of managing flexible connections to play a key role in the ENA's Transmission and Distribution Interface (TDI) work stream⁵². We chair the High Volts working group and have played a key role in developing the work programme for the Active Network Management and Statement of Works working groups. We recognise that progress across the TDI work streams have been mixed and we have supported plans to re-focus the work plan and accelerate delivery. It remains crucial to develop a common understanding of the issues and the mechanism to generate new common processes and procedures which can then be codified. Consequently, we believe that the ENA TDI work on TSO-DSO interface will develop a common roadmap which will provide a cohesive framework for DSO transition.

⁵¹ <http://www2.nationalgrid.com/UK/Services/Balancing-services/Reserve-services/Demand-Turn-Up/>

⁵² [http://www.energynetworks.org/electricity/regulation/transmission-distribution-interface-\(tdi\)-steering-group/transmission-distribution-interface-\(tdi\)-steering-group-deliverables.html](http://www.energynetworks.org/electricity/regulation/transmission-distribution-interface-(tdi)-steering-group/transmission-distribution-interface-(tdi)-steering-group-deliverables.html)

ii) Bi-lateral work with National Grid

To supplement the work through the ENA, we are working closely with National Grid to address whole system challenges. The close collaboration has been developing over the last three years with particular focus on the complex network of our South Eastern region. We have developed a joint work stream with National Grid on overcoming the whole system challenges in the South Eastern region with the following focus:

- Data exchange at interface and revision of T&D planning assumptions;
- Optimised ANM deployment;
- Integration of storage;
- T&D planning process; and
- Impact of ROCOF protection issues.

The outputs of this work will deliver additional capacity for connections at lowest whole system cost. The collaboration will be further accelerated through the TDI 2.0 project which will be starting with National Grid shortly. This will provide practical experience of how to share flexible resources between us and optimise their use for network operation and planning. It is also worth highlighting our KASM (Kent Active System Management) project. KASM will be delivering its final trials in 2017, demonstrating how the use of contingency analysis and increased visibility of the transmission and distribution network can reduce constraints for distributed resources⁵³.

Question 45 c): With regard to the need for immediate action, are there any legal or regulatory barriers (e.g. including appropriate incentives), to the immediate actions we identify as necessary? If so, please state and prioritise them.

The immediate actions identified around greater co-ordination in system planning and efficient use of flexible resources are both about extracting whole system benefits. As set out in our response to question 45 b), we are conscious that the actions needed to deliver them may need to be mindful of the longer term system operation models set out in question 46.

Our view is that alongside the work industry is taking forward on the immediate actions, there needs to be work undertaken on the supporting regulatory framework through which whole system benefits can be delivered. The current regulatory framework has been hugely successful in delivering safe, reliable networks which respond to customers' needs at an efficient cost. However, the framework was not designed with the delivery of whole system benefits in mind. We provide two examples below where this is the case:

i) Incentive for DSOs to invest for whole system benefits

As highlighted by research undertaken by Imperial College and the Carbon Trust, there could be £17-£40bn of benefits from optimal system operation by 2050⁵⁴. The vast majority of these benefits are obtained through optimising the use of resources at distribution level and therefore delivered by the DSO. Under ED1, the totex incentive mechanism encourages us to make investments where they reduce costs on our network but not where investments deliver cost savings elsewhere on the system. Equally, there is no current mechanism for us to share in the wider benefits which we could use to fund the necessary capability. We expand on these arguments in our response to question 46.

⁵³ <http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/kent-active-system-management/>

⁵⁴ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/568982/An_analysis_of_electricity_flexibility_for_Great_Britain.pdf

ii) Alignment of Transmission and Distribution price controls

A whole system planning framework requires a more joined up approach to assessing the costs (and associated benefits) across transmission and distribution. DNOs can provide some services directly to National Grid to alleviate constraints, as proven in Electricity North West's CLASS project.⁵⁵ However, some of the actions DNOs can take to provide lower cost solutions to transmission can impact on distribution network performance, for example, losses or customer interruptions.

The ED1 and T1 price controls were not set with delivery of whole system solutions in mind. We are uncertain if National Grid is funded to procure these types of solutions. We were not funded to do so and it is not clear how our provision of such services relates to the rest of the balancing market. In addition, our ED1 outputs do not take account of the impact of providing such services. Our performance is measured against our network outputs and not on the wider system benefits we facilitate. Therefore, even when it could be the most economic action, our regulatory framework does not provide us sufficient clarity over funding or the incentives to provide the services required.

Adapting the regulatory framework

We believe that the strengths of the current regulatory framework (totex benchmarking; outputs led with strong incentives) can evolve to encourage DSOs to enable the successful delivery of whole system benefits and achieve decarbonisation at least cost. We consider that there would also be merits in setting out a timetable for this work to provide the certainty that these issues will be looked at. This timetable could include a commitment from Ofgem to align the T2 and ED2 price control incentives.

As outlined in our response to question 46 below, evolving the current regulatory framework can place the correct incentives for industry to develop the commercial arrangements and specific roles needed to deliver whole system benefits.

Question 46a): With regard to further future changes to arrangements, do you consider that further changes to roles and arrangements are likely to be necessary? Please provide reasons. If so, when do you consider they would be needed? Why?

As and when more flexible resources (DER) connect to the distribution network, we believe that changes will be required to roles and arrangements in order to maintain current network reliability and to provide a framework through which to deliver whole system benefits. We also consider that DSOs need to play a central role in managing the resources on their network to maximise these benefits. Our knowledge of our networks and track record of delivery under a strong regulatory framework make us an obvious choice to take on a new role.

Why changes to roles and arrangements are likely to be needed

We consider there are two key reasons why we may need changes to current roles and arrangements.

i) Maintaining system security

We have highlighted earlier in this response how the anticipated increase in DER connecting to the network will vastly complicate the operation of the network. By the mid-2020s there could be up to two million DERs on our network which do not have regular consumption or generation patterns⁵⁶. The effective management of these devices, at lowest cost, will require DSOs to undertake a paradigm shift in system operation (enabled by advanced IT and distribution management systems). This will add significant complexity to system operation which will require co-ordination (and resolution of conflicts)

⁵⁵ <http://www.enwl.co.uk/class>

⁵⁶ See Table 3 under our response to Q44 a).

between DSOs and National Grid and potentially with other procurers of flexibility such as suppliers and aggregators.

Current roles and arrangements do not give us visibility of the actions of DER or the tools to manage potential conflicts over the use of DER by the DSO, SO, aggregators or suppliers. It is the inability to manage these conflicts, in a world where we will have vastly more complex system operation at distribution level which puts system security at risk. New roles and responsibilities and underpinning market frameworks will be needed to resolve this issue.

We are already concerned about this, hence our support to take forward greater visibility on the immediate actions. DNOs are the only party who are highly sensitive to the location of customers providing services. Consequently, given the more complex nature of system operation and the likely conflicts which will arise between parties on the use of DER, DNOs need to assume a new role as a neutral market facilitator of services from customers connected to their networks, in order to maintain system security. We are in a unique position to act as this facilitator, with a mandate to optimise the use of those resources for whole system benefits while maintaining the security of our network.

It is worth highlighting how co-ordination on use of DER based on current roles and responsibilities has the potential to be inefficient and compromise reliability. As briefly mentioned in our response to question 45b), the latest National Grid tender for demand turn up goes down to 1MW and generators of 0.1MW can contract with aggregators for the service⁵⁷. Therefore, it clearly reaches down into the distribution network. National Grid is trying to co-ordinate with DNOs, however, the only option available to DNOs is to contract for a response through National Grid when required. This has been trialled with Western Power Distribution and while it is a step forward in looking to co-ordinate efficient use of resources we do not consider it provides the most efficient medium or longer term option. This is an example of where we need to be careful in putting in place processes to address the immediate actions outlined which lock industry into a specific model.

Figure 7 below depicts how this co-ordination will work based on current roles and responsibilities. Figure 8 shows how co-ordination on use of DER could be more efficient with the DNO acting as a neutral market facilitator and procuring services from DER for the SO. Under option 1, the SO is contracting for all services on DNO networks without the visibility of how the DNO network is operating. It can lead to efficient procurement decisions and reliability issues. Figure 8 below shows option 2 where a DSO procures the services needed from its customers to the SO. It is a simpler process and avoids the reliability issues.

⁵⁷ <http://www2.nationalgrid.com/UK/Services/Balancing-services/Reserve-services/Demand-Turn-Up/>

Figure 7: Current roles and responsibilities with SO contracting party with DER

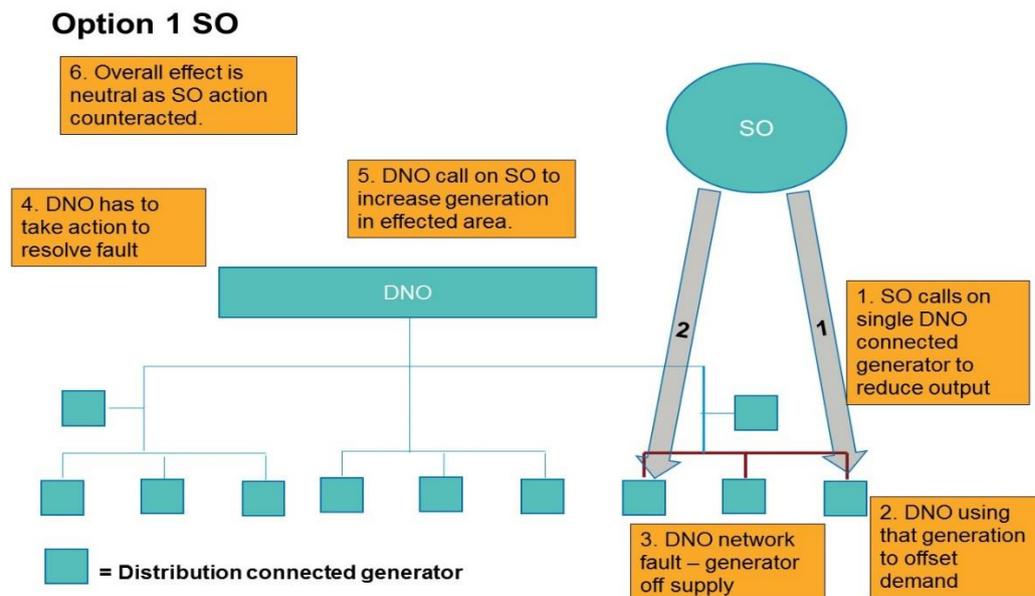

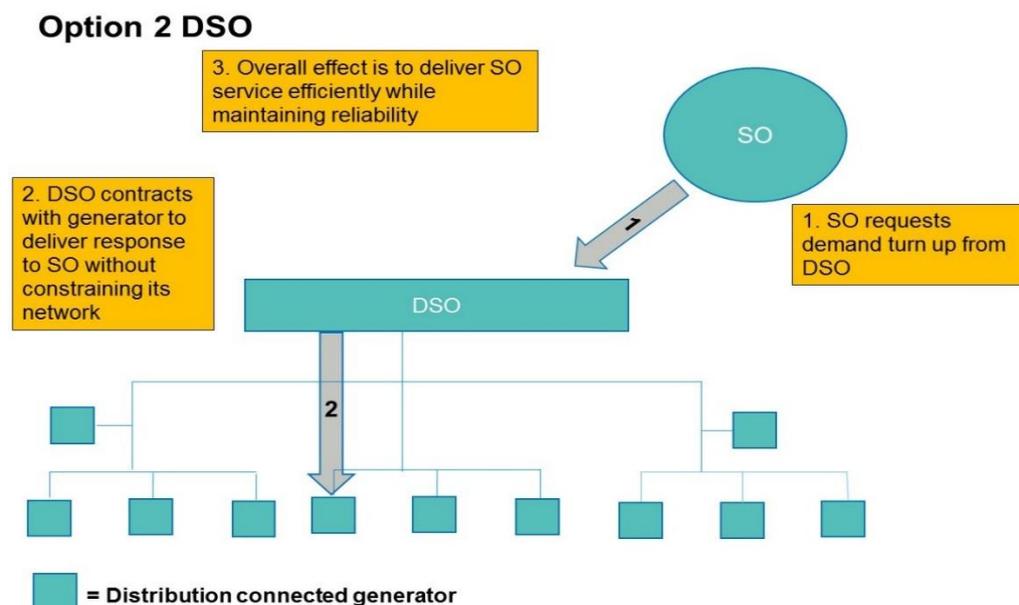

Figure 8: DSO co-ordination

ii) Delivering greatest whole system benefits

Analysis carried out in our Low Carbon London project demonstrated that the historical approach to designing distribution networks maybe suboptimal in the context of low carbon agenda⁵⁸. The analysis stated that what was required was a whole-systems approach – joining energy, emissions, ancillary services with infrastructure design covering local and national geographies. Again, DNOs are best

⁵⁸ Low Carbon London, “Novel commercial arrangements for smart distribution networks”, Report D5, Dec 2014, [http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-\(LCL\)/Project-Documents/LCL%20Learning%20Report%20-%20D5%20-%20Novel%20commercial%20arrangements%20for%20smart%20distribution%20networks.pdf](http://innovation.ukpowernetworks.co.uk/innovation/en/Projects/tier-2-projects/Low-Carbon-London-(LCL)/Project-Documents/LCL%20Learning%20Report%20-%20D5%20-%20Novel%20commercial%20arrangements%20for%20smart%20distribution%20networks.pdf)

placed to take a new role to deliver these benefits. The vast majority of flexible resources will be connected to DNO networks. DNOs can use the detailed knowledge they have from years of operating and developing their networks efficiently and safely to optimise the use of these resources, in a way that the transmission system operator cannot. As the number of DER increased dramatically (as predicted) we can use this knowledge to manage those resources to provide the following benefits;

- Optimise the revenue which DER can receive for providing services;
- Provide more efficient procurement of services for other parties (like the SO);
- Reduce the need for distribution reinforcement; and
- Maintain the high quality of system security.

The industry needs to be open to changes to current roles and arrangements, as well as have certainty over the regulatory treatment of the investment required in IT, communications and data processing, to deliver these benefits.

Why we are best placed to assume these new roles

In addition to our knowledge of the networks, we believe that we are well placed to take on a greater role in managing the flexible resources to our networks:

i) Strength of the current regulatory regime

The current regulatory regime has been hugely successful in delivering efficient, customer focussed networks. We think this could be adapted around an expanded DSO role to deliver whole system benefits. Such an expansion would incentivise network companies to work together to adapt roles and commercial arrangements at the pace and level needed to optimise the delivery of whole system benefits. The regulatory framework could also adapt over time as we learn more about fulfilling this role and the challenges involved.

ii) Our track record of delivering for customers

We have consistently delivered on our price control commitments and indeed gone above those to deliver for our customers. For example, we would highlight our track record of:

- Improving reliability, where we have reduced CMLs by 50% since 2010/1;
- Delivering improved customer service as demonstrated by our customer service scores which are now averaging 8.6 out of 10;
- Accepting and promoting competition in service provision in connections markets; and
- Delivering efficient totex outcomes for customers.

This demonstrates that we can be trusted to take on new responsibilities and deliver them for customers.

iii) Neutral market facilitators

We are completely unbundled from retail, generation or any other interest in the value chain. This means we are well placed to act as a neutral market facilitator for the flexible resources connected to our network. In addition, the totex approach under which we operate, means we are neutral to whether we choose a build or non-build option to meet our outputs. Consequently, we can be trusted to manage the flexible resources on our network in a way which optimises the wider system benefits they can provide to lower costs for customers.

Timing of changes to roles and arrangements

The timing on when changes are needed will be driven by the number of DER which connect to our networks⁵⁹. We have seen significant increases in DER in the last few years, particularly in our Eastern area. Experience to date shows that the volumes of connections are not uniform across GB and that changes to roles in some DNO areas may be needed before others. It remains to be seen if the pace of change will continue at its current rate, accelerate or decrease. This is largely dependent on factors outside of our control such as technological developments, market prices, consumer behaviour and Government policy, particularly around any incentives for EVs.

Our objective is to ensure that we are ready when changes are required and this is why we have invested heavily in our innovation programme. Our best view developed from our stakeholder engagement and experience on our networks is that we need to be ready to integrate the remaining DSO capabilities into our business for the start of ED2 to be in a position to manage the expected increase in DER at the lowest possible cost to our customers. We have a plan for how we continue to ramp up our capability to be in this position outlined in Figure 9 below:

Figure 9: Timeline for our ramp-up of DSO capability

DER take-up 		
2017-2019	2019-2023	ED2
<ul style="list-style-type: none"> • Flexible DG connections capacity exceeds 600MW • Initial flexibility tenders for reinforcement deferral/outage management completed • Commercial framework for DSO to SO services completed as part of TDI • Distributed Energy Resource Management Energy Software live as part of TDI • System monitoring enhancements underway 	<ul style="list-style-type: none"> • DSO trials underway in our South Eastern region (specifically on the South Coast) • DSO incentives development as part of ED2 consultation • Network support services contracts are widely used to defer reinforcement or minimise constraints • Revised framework for T&D planning at the interface • Introduction of market arrangements for constraint management • EHV ANM Capability fully enabled across our Eastern and South Eastern regions • Availability of smart metering data • IT DSO system implementation 	<ul style="list-style-type: none"> • Formalised DSO framework in operation • Distributed Energy Resource planning • Eastern and South Eastern regions operating as regional DSOs • LV visibility and automation • DSO commercial operations becoming core business capability • LV DER Dispatch • Extensive use data analytics • Creation of distribution level markets

We are conscious that it will take time to evaluate the options and implement new arrangements. Clarity on the regulatory framework for delivering whole system benefits will be crucial in empowering network operators to adapt current roles and develop the new commercial arrangements which are likely to be required.

⁵⁹ The Future Electricity Regulation paper provides an excellent overview of the evolutionary changes and different models required to respond to the stages of evolution:

https://emp.bl.gov/sites/all/files/FEUR_2%20distribution%20systems%2020151023_1.pdf

Question 46 b): With regard to further future changes to arrangements, what are your views on the different models, including:

- i) whether the models presented illustrate the right range of potential arrangements to act as a basis for further thinking and analysis? Are there any other models/trials we should be aware of?**

We have split our answer to this question into three sections to pick up each individual question separately:

Right range of models

The models presented represent the right range but it is important that the detail underpinning them is clear in order to properly evaluate them. We would also stress that in practice, there may need to be a hybrid of different models. Therefore, policy development should not be fixed on the three models presented in the Call for Evidence but consider aspects under each model.

Other models or trials

We think it is crucial to utilise the output of past and ongoing trials to develop the detail of the models set out in the Call for Evidence. We are already playing our role in this through the TDI 2.0 project which we are running in conjunction with National Grid. It will deliver the following outputs which can feed into policy design for the models needed:

- Commercial arrangements required to deliver a functioning local market platform for reactive and active power which can be used to resolve local constraints and transmission constraints;
- A full assessment of the costs and benefits of the local market platform and net benefit of extending the trial; and
- An assessment of the incentive framework used to make the market platform work and recommendations on an enduring incentive framework for an active DSO.

We are keen to work with Ofgem and BEIS to use learnings from the TDI 2.0 project as they emerge, to feed into the policy debate around the models and develop an evaluation framework through which to assess them.

There is substantial other work ongoing across GB, Europe and the USA as many countries wrestle with the same issue of how to coordinate the integration of DER triggered by a low carbon transition. Some of the studies worth highlighting include:

- Work by Elexon and Baringa on potential DSO models for GB in 2014/5⁶⁰;
- Centrica's Cornwall study on local energy market⁶¹;
- The European SmartNet project which is assessing the various models for TSO/DSO interaction⁶²;
- The European TSO/DSO platform work on data models⁶³; and
- The Californian ISO local margin pricing⁶⁴.

We have reviewed these models to help inform this response.

⁶⁰ https://www.elexon.co.uk/wp-content/uploads/2015/03/Active-Management-of-Distributed-Generation_March2015.pdf

⁶⁴ <http://www.caiso.com/pages/pricemaps.aspx>

ii) which other changes or arrangements might be needed to support the adoption of different models?

The key change to support any of the different models will be the development of the underpinning regulatory regime. The current regulatory framework does not provide the funding or incentives for us to make investments which deliver savings, where those savings do not flow back to us. As highlighted in our response to questions 45 c) we think that the development of the regulatory framework needs to be a key priority as it will also help with the delivery of some of the immediate actions. Figure 10 (see below), highlights how we think the evolution of DSOs to deliver wider system benefits can be hindered by the lack of a clear regulatory framework, along with the detailed design of the commercial model.

Our experience is that we are currently at stage 2 within Figure 10 in our Eastern and South Eastern regions. In these regions we are integrating DSO capability into our operating model to connect new customers through actively managing them. The focus for our deployment is on the network benefits which can be delivered as this is what we have the commercial tools to do and the incentives under ED1 to implement. Our innovation programme is starting to develop functionality for stages 4 and 5 – particularly through the TDI 2.0 project which will develop greater co-ordination between ourselves and National Grid on the use of flexibility resources on our network.

Figure 10: Potential evolutionary stages of DSO

To encourage development beyond stage 2 in the diagram, it would help to have a regulatory framework which provided the incentives for us to invest to deliver whole system benefits. The certainty such a regulatory framework could deliver would help to attract the investment required for the roll-out of the enabling technology. An amended regulatory framework can also place the correct incentives on network operators to develop the commercial framework to deliver DSO. At present, the misalignment of incentives and different commercial drivers between DNOs, TO and SO make this difficult.

Based on the predicted take-up of low carbon technologies (see our response to question 44) we think that a commercial model and associated regulatory framework need to be in place by the start of ED2. Given typical lead times to implementation, this means that clarity of the regulatory framework is needed in the next few years. This will allow industry to deliver the commercial framework in time for ED2 and provide a clear policy basis on which to start developing ED2 business plans in the early 2020s.

iii) do you have any initial thoughts on the potential benefits, costs and risks of the models?

As highlighted in our response to question 46 a), on the basis of the expected take-up of low carbon technologies, we will need visibility and an element of control of the flexible resources on our network in order to maintain system security. Based on the detail of the models presented (and we acknowledge they are high level) we think that the 'DSO/SO procurement mechanism' and 'Total DSO' models would best meet these needs. However, it is important not to think of the models presented in isolation – there may well need to be aspects of different models which need to come together. For example, based on our experience, we can see merit in contractual procurement of flexibility through a DSO model. If and when the number of flexible resources becomes so large, it makes management of these contracts too complex, it may be worth moving to a platform that is more based around marginal pricing. This should be seen as a potential future evolution and the focus in the next few years should be around the establishing arrangements for the efficient co-ordination of contractually procured flexibility.

We have used our experience to date to undertake a high level review of the costs and benefits of each of the models set out in the Call for Evidence. These are outlined in Table 5 below. We would be keen to develop the next level of detail around these models and use experience from trials to help undertake further assessment. Our TDI 2.0 project with National Grid will provide particularly useful insights into the DSO/SO procurement model and in particular the detailed interfaces required between ourselves and National Grid.

The main risks around the models are the level of complexity they could entail and how that is simplified to market propositions which are clear and transparent for our customers. We also need to be mindful of the considerable investment they could require in IT, communications and operational systems.

Evaluation of the models

We think it is important that, as an industry we start to develop an evaluation framework for these types of models (or aspects of the models). For instance, we feel that it would be important to consider the following:

- The simplicity of design and lead times to implement and have the flexibility to evolve over time;
- How the models will interface with other procurers of flexibility, such as suppliers and aggregators and take account of bi-lateral arrangements between DER to aggregate their output;
- Understand how the models will work alongside settlement processes, ensuring that suppliers are not out of balance as a result of flexibility actions taken by others;
- How the models can provide a framework for the coordination of planning and operation between TSO and DSO; and
- How the models interact with the connection process to give stronger signals to customers on where they can provide value for the local network.

Table 5: Costs and benefits of DSO models in the Call for Evidence

	DSO/SO procurement mechanism	Market signals and arrangements	Responsibilities in system operation	
			"Total TSO"	"Total DSO"
Costs	<ul style="list-style-type: none"> Requires effective DSO-SO coordination Potential conflicts between DSO and SO which will require a mechanism to resolve 	<ul style="list-style-type: none"> High levels of complexity Significant implementation overhead Requires fundamental change to charging arrangements which are typically slow May not provide certainty of income to service providers May not provide certainty of response required for network security 	<ul style="list-style-type: none"> SO will not necessarily have the right information and experience to make planning decisions at D level Adds significant complexity for SO to manage decisions at D level May not provide DNO with tools needed to maintain reliability 	<ul style="list-style-type: none"> Requires significant expansion of DNOs' current capabilities, over and above those for DSO/SO procurement model
Benefits	<ul style="list-style-type: none"> Allows party with best information to plan and operate own networks Should allow effective deployment of flexible resources Potentially supports most rapid connections process Provides DNO will a large degree of visibility and control over the flexible resources on its network 	<ul style="list-style-type: none"> Expansion of market signals Maximising competition Reduced requirement for monopsony residual balancers 	<ul style="list-style-type: none"> Reduces requirement for coordination between multiple entities 	<ul style="list-style-type: none"> Better ability to coordinate local solutions Provides for benchmarking and potentially competition between multiple DSOs Provides DNO will a large degree of visibility and control over the flexible resources on its network

5. Innovation

Question 47: Can you give specific examples of types of support that would be most effective in bringing forward innovation in these areas?

As we have set out in the Executive Summary, NIA and NIC funding has been successful in promoting investment in innovation, is broadly fit for purpose and continues to be required. Government could consider how NIA and NIC funding can be made compatible with other matched funding opportunities in areas such as smart vehicle charging and the development of flexibility platforms. We have encountered the need for clarity in our discussions with Open Utility in their application to the Energy Entrepreneurs Fund, which we supported.

We also support innovation projects having sufficient time to demonstrate value, and the framework should be developed to avoid NIC, NIA and price controls limiting energy sector involvement in longer term projects.

Question 48: Do you think these are the right areas for innovation funding support? Please state reasons or, if possible, provide evidence to support your answer.

We would generally support the areas identified. The key areas for ongoing innovation we have identified along with our ENA partners include:

- Supporting innovation that delivers value across the whole system and beyond individual network or system operator business scope as is being trialled in TD12.0;
- Supporting trialling of emerging commercial and market models and platforms, not just technology to be embedded into network/system operator operations;
- Facilitating cross-energy vector projects (e.g. Hydrogen or heat projects) and not just electricity in NIA/NIC;
- Supporting local energy (including community energy schemes) to ensure approaches exist to allow those least able to adopt smart flexibility technologies;
- Supporting the development of smart EV charging technologies and commercial frameworks to facilitate the development of interoperable standards and visibility of EV charging to network operators; and
- Supporting the development of vehicle to grid technologies with the UK automotive technology sector.

Annex 1: Stakeholder engagement

To help inform our response and to test that our messages help to deliver our stakeholders needs, we have engaged with a number of parties. We have listed these below for transparency:

- Two roundtable sessions with storage providers, to test our views on network charging and regulatory framework for storage;
- Cornwall LMP (local marginal pricing) to understand the project being run with Centrica;
- Goran Strbac from Imperial College to understand his work on the potential benefits of flexibility and the role of the DSO in delivering these benefits;
- Open Utility to understand its work on market platforms and peer to peer trading;
- Electron to understand its work on open source platforms and apps and how this technology can be used in energy sector;
- Lime Jump to understand their business model as a virtual power plant and how this relates to current market structures; and
- Innovate UK to understand the innovation funding landscape in the UK.

National Infrastructure Assessment - Call for evidence (October 2016)

Response by United Utilities

General Comments

United Utilities is the statutory water and wastewater service provider for the North West of England, responsible for planning, delivering, operating and maintaining vital water and wastewater infrastructure as well as providing water and wastewater services to more than 3 million households and businesses.

We welcome the proposals for an on-going collaborative, long term, cross sector and holistic assessment of the country's infrastructure needs and the development of coherent recommendations for addressing them. We welcome the focus on transparency so that all stakeholders can understand the impact of investment decisions on customers' bills, and the recognition of the role that the private sector plays in financing and delivering most of this investment.

Of particular interest to us is the requirement to ensure that water and wastewater services for customers in the North West remain resilient to hazards and trends including a changing climate and population growth. Management of our infrastructure to ensure that sites are protected, or can be recovered quickly in the event of impacts, must be at the heart of our business planning processes. The level of protection and acceptable risk to services should be aligned to national requirements or policy guidance and we see the formation of the National Infrastructure Commission as an opportunity to provide clarity around this at a national level. In addition, it should provide a mechanism whereby risk management authorities, regulators and other utility and service providers can ensure they undertake joined up resilience planning within a defined geographical area. In our view, there is still more to do to ensure that water issues are managed in an integrated way to get the best overall outcome for water quality, water resources and flood mitigation.

There are a number of common themes that come across in our responses to the questions, we would particularly welcome National Infrastructure Commission engagement in the following areas:

- **Flooding** - Like many parts of the country, the North West has experienced very significant flooding events over the last few years, driven by both long periods of exceptional rainfall and short intense storms in urban areas. Planning effectively for holistic flood management can be hampered by the disparate responsibilities that organisations have and the interaction of the different assets in their control. We believe that significant improvements can be driven in the planning and management of flooding by improving the planning system and through a systems thinking driven approach which integrates the use of assets, leverages data intelligence and employs new technology and work. In addition, the split in responsibilities and the focus on short term priorities is leaving the UK lagging behind other developed nations in the embedment in the use of more sustainable drainage systems (SuDS).
- **Catchment Management** - Linked to flooding, we have strong views that all water planning should be managed holistically at a catchment level. Planning for water quality improvements and management of water quantity (resources and flooding) will only be effective when considered together. Indeed, many of the natural measures now being promoted, such as upland restoration, slowing the flow and tree planting all have significant water quality and biodiversity benefits as well as reducing flood peaks. By thinking holistically costs can be reduced for customers. We are promoting the proliferation of natural solutions to achieve water quality improvements more cost effectively and sustainably.
- **Water Trading** - Long term climatic change is also forecast to bring longer periods of warm dry weather. This, coupled with increasing growth and housing development, means that we need to think about the management of our water resources nationally in a different way. At the moment all companies are working on their long term water resources management plans, which will be submitted to Defra in 2018. The

NIA Call for evidence: Response by United Utilities

assessment of long term water supply and demand will inevitably mean that consideration will be given around the country to the provision of new water sources in certain areas. We believe that water trading, a transfer of available resources from the North and West to the South and East, should be a fundamental part of these plans. This should be facilitated at a national level to enable successful implementation and to ensure that regulators and planners take a joined-up approach.

- **Resilience of our cities** - Over the last 12 months we have undertaken a comprehensive review of the resilience of our water and wastewater service, taking a structured approach and looking at likely hazards and the risk and consequence of failure of our systems. We have identified a number of areas where we are planning to invest over the next 10 years to reduce the number of potential single points of failure. Due to the nature of our water supply system many of our cities are supplied by water from the Lake District, Pennines and Wales many miles away from the point of use. We would welcome the opportunity to discuss our approach to ensuring the long term resilience of our city's supplies with you.

The governance and regulation of water issues can be improved to enable better decision making and a more sustainable outcome. We look forward to supporting the National Infrastructure Commission on these topics as they develop the first National Infrastructure Assessment.

Cross-cutting issues

Q1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

We have made a considerable investment in supporting the long-term sustainable growth of the North West of England since privatisation. A recent example is the completion of the West East Link in 2013 to enhance our ability to move water around our region to increase flexibility in droughts, enable us to take large trunk mains out of service for maintenance and make us more resistant to climate change in the longer term. We are also in the process of building a link from our Thirlmere reservoir to West Cumbria to replace local, environmentally sensitive water sources, increase the resilience of West Cumbria to short term droughts and provide additional capacity to support long term population growth. Over the last five years we have made considerable investment in wastewater infrastructure too including at Manchester Wastewater Treatment Works to achieve new environmental standards and to cope with the rapid and continuing growth in population. We are in the process of delivering substantial rebuilds of our wastewater treatment works at Blackburn and Oldham to meet new environmental standards and ensure our works are sustainable in terms of environmental performance but also in cost to customers.

As part of our business planning we are using new and even more sophisticated approaches to explore the resilience of our water supply systems to a range of hazards, from extreme drought to asset failure. To facilitate expected future economic and population growth, in particular with the potential for a Northern Powerhouse growth scenario in the North West, it is critical that there is enough supply to meet demand, and our systems have enough capacity and resilience both to meet the needs of society now and in the future. We expect that with higher expectations on the resilience of water supplies we will be promoting future investment to ensure that some of our major cities are less vulnerable to events that have a low probability of occurrence but the potential to have a significant consequence. Given the criticality of water to economic growth, this process could realise high value infrastructure investment. We are also examining the potential to undertake water trading (this could be imports, as well as exports) which would facilitate additional infrastructure activity in the North West, benefitting the regional economy (see our response to question 22).

Q2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

We have no evidence to offer to this question.

NIA Call for evidence: Response by United Utilities

Q3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

We have split our response to this question into two parts, the first covering wastewater disposal and particularly the management of surface water drainage and the second covering water efficiency and the importance of managing demand for water.

Surface water management

We would advocate a move towards more detailed, coordinated catchment level planning for surface water drainage. Whilst drainage is a matter considered in local plans and we welcome the commitments to sustainable drainage in the recently published draft Greater Manchester Spatial Strategy¹, we feel the current plans² are not sufficiently detailed in how surface water will be managed on a catchment by catchment, site by site basis to ensure that flood risk is sustainably managed in the face of the increasing trends from development and climate change as described in our 2015 Climate Change Adaptation report³. There is a focus on the flood risk to the development site but not whether that development will increase flood risk elsewhere. Responsibility for surface water management infrastructure is split between sewerage companies, local authorities, private land owners and the Environment Agency. This leads to a lack of leadership in making decisions about where investment is required to ensure that flood risk is managed in the most sustainable and cost effective manner for current and future generations. This split in responsibilities means that UK cities lag behind many of our European⁴ and international partners⁵ in the implementation of sustainable drainage systems despite being a relatively wet and densely populated country that has amongst the most to gain from more effective management of surface water in urban areas.

If done well, sustainable drainage systems are no more expensive than conventional systems to construct and operate (albeit some of the costs may fall on different agencies which is one of the issues blocking change). Some systems have the potential to reduce flood risk boost the aesthetic appeal of development (contributing to mental wellbeing), increase the potential for biodiversity and dampen heat island effects that will become more acute with climate change. Research has also evidenced the health and financial benefits of nearby nature and health⁶. Sustainable drainage systems like dry detention ponds can be integrated into developments and perform multiple tasks, not only are they a welcome open space but there are plenty of examples internationally of detention ponds that function as playgrounds⁷ or parking areas when dry. If implemented as part of an urban regeneration initiative, sustainable drainage can greatly increase the appeal of former industrial sites. The blue green infrastructure pilot in Newcastle⁸ is a great example of this, that we would like to see replicated in many of the former industrial areas of the North West.

In order to respond to the need to deliver additional housing in accordance with national government priorities, the UK planning system is increasingly identifying large sites for development. For example, the Draft Greater Manchester Spatial Plan⁹ proposes the release of a number of sites from the green belt. It has 37 sites which are capable of delivering more than 500 dwelling units and of these 37 sites, at least 20 are capable of delivering more than 1,000 units. Such large sites are often in multiple ownership and developed by a range of developers over a number of years and sometimes through the uncertainty of changing economic conditions. The delivery of infrastructure on these sites lacks the co-ordination that can be more easily delivered on sites in one ownership. We would welcome consideration of enhanced powers which are better able to ensure infrastructure is delivered in

NIA Call for evidence: Response by United Utilities

a co-ordinated manner and as part of site wide infrastructure strategies rather than the piecemeal approach dictated by differing land ownership boundaries.

Water efficiency

The Water Efficiency Strategy for the UK¹⁰, recently published by Waterwise for consultation, suggests introducing variable infrastructure charges for new developments to encourage water efficiency measures. The proposal is to use market incentives to reward developers for environmental improvements (e.g. using water labelled appliances and water efficient fittings) in order to enable them to improve environmental standards at no cost and with almost no administrative burden. Householders get higher quality fittings and lower running costs and there are benefits to the aquatic environment and improved water security. The offset is to be funded by the water company, but the idea is that all costs should be compensated by the generated water efficiency savings. This approach is currently being tested by Southern Water and if proved successful it could bring substantial reductions in both consumption and carbon emissions if rolled out across the UK, providing it is supported by appropriate promotion of water labeling in stores, on websites and linking it to building/procurement standards. This would significantly increase the market for water efficient appliances and fittings and would make these a more attractive purchase for all customers, not only developers.

Both the Water Efficiency Strategy and the Water Resources Long Term Planning Framework¹¹ recognise that although water efficiency in new developments has been improving, there are still opportunities to reduce water use further. This could be achieved by for example review of current policies for water efficiency and requirement for new dwellings to meet tighter Building Regulations (studies would have to be carried out to assess the achievable level of per capita consumption) and encouraging water neutrality partnerships i.e. homes, businesses, schools and hospitals in the area receiving a water efficiency retrofit to avoid an increase in overall demand as a result of new local development.

National standards

We will continue to work with developers to encourage the take up of sustainable drainage systems and the building of water efficient homes. However, we have limited powers to enforce any change in behaviour. Our customer research¹² shows that communities are concerned about the impact of development on their flood risk and environment. In our view developers stand to gain from developing water efficient houses and sustainable drainage to reduce local opposition and demonstrate their environmental and societal credentials and many recognise this and act accordingly. Unfortunately some developers see only an additional cost and are not willing to engage and as they can build, sell and walk away with no retrospective control, others (such as water bill payers) are left to deal with the long term consequences.

The government is understandably reluctant to maintain or strengthen standards on water efficiency and sustainable drainage as it is concerned about imposing any additional costs on developers in the light of the need for more housing nationally. But this is a short term view that doesn't take into account the wider societal and long term costs of high water consumption as well as surface water discharged to sewer and the consequences for flood and pollution risk downstream. An example of working differently towards wider societal benefits is from Business in The Community working with partners from The Water Taskforce¹³ and testing the concept that implementing SuDS on a school site could generate savings for a school, by reducing their hard-standing area and taking them down a charging band with their water supplier.

NIA Call for evidence: Response by United Utilities

We would support the National Infrastructure Commission in encouraging national standards for water efficiency and sustainable drainage systems that deliver a more sustainable and level playing field in the sharing of the cost of consequences in line with the polluter pays principle.

Q4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

We recognise the important contribution of demand management in achieving and maintaining an adequate water supply-demand balance in the North West. Demand management is an integral component of our strategy to balance supply and demand. Since privatisation of the sector in 1996, we have significantly reduced leakage helping to achieve and maintain a high standard of water supply reliability. Water efficiency promotion has been significantly enhanced since 2010 and overall water demand is at its lowest level for at least the last 20 years.¹⁴

Demand forecasts are complex and require many assumptions. The recently published water resources long-term planning framework¹⁵ models three scenarios, business as usual, extended and enhanced. The enhanced scenario considers the most ambitious savings that are feasible technically and economically over the next 50 years, but would come at considerable expense and/or require a significant change in legislation or regulation to enable their development. This scenario assumes extensive water efficiency activities (including greywater re-use and rain harvesting), high level of leakage management (including pressure management, active leakage control and maximum mains renewal) and most importantly a significant increase in customer metering. The relationship between demand management and cost savings is highly non-linear and is driven by the high costs of retrofitting for some measures (e.g. grey water re-use), leakage (e.g. mains renewals), and metering (incorporating difficult property installations).

We believe that increased smart metering is the way to maximise the potential for demand management. Better insight into customer consumption patterns will enable smarter, more appropriate targeting of water efficiency campaigns. It would allow for better quantification of the savings achieved and more robust cost-benefit analyses. Having more metered data would enable the development of new, more attractive tariffs financially benefiting customers from being more conscious and careful of their water usage. Increase in customer meter penetration will help in leakage management activities. As leakage is not directly measured, its accuracy depends on the accuracy of the components used in the leakage calculation, of which consumption is key.

The framework¹⁶ states that: “UK may achieve Per Capita Consumption (PCC) levels in line with the most efficient European countries over the next 50 years, through preferred metering programmes, sustainable house building and macroeconomic factors, though this is by no means assured”. In the extensive comparison carried by Ofwat¹⁷ the UK’s PCC is the highest (UK PCC 150 l/head/day, highest – Denmark 131 l/head/day, lowest – Belgium 107 l/head/day). By no means is the UK less developed or with significantly poorer infrastructure than any of these countries. The main difference is that in each of these countries’ meter penetration exceeds 90%, whereas in the UK fewer than 50% of domestic customers are metered.

Q5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

As our asset base has expanded both in size and complexity, maintenance and repair costs have increased. The increase in our asset base has been driven by:

- ever tightening industry permit standards due to the ongoing delivery of the Water Framework Directive and preceding environmental legislation in the UK;
- increases in population; and the

¹⁴ UU’s Water Resources Management Plan 2015 <http://corporate.unitedutilities.com/documents/WRMPMainReport.pdf>

¹⁶ Water UK, Water resources long term planning framework (2015-2065) [Report] / auth. Atkins Mott MacDonald, Nera, HR Wallingford, Oxford University. - July 2016.

¹⁷ [International comparison of water and sewerage service : 2007 report \[Report\] / auth. OFWAT. - 2007.](#)

NIA Call for evidence: Response by United Utilities

- increase in service level expectations from customers, businesses and regulators resulting in an even greater focus on the reliability of services.

The maintenance and repair of existing assets should be prioritised over the construction of new assets. A planned maintenance approach combined with repair when required is generally a lower cost approach through the lifecycle of the asset than construction of new assets. This is due to the tangible and intangible costs associated with construction such as planning, permissions, surveys and land acquisition before a new asset even starts to be built. Furthermore, a more systematic approach to maintenance focused on the criticality of that asset to the service system inevitably provides a greater level of service to customers.

The maintenance versus construction balance should be most effectively thought of as the decision to maintain and optimise the existing asset base, delivering reduced customer and environmental costs. However, the need to invest in the construction of new assets should be based firmly on the absolute necessity to construct new assets to meet future demands that existing assets cannot meet even with a well maintained baseline in place. In order to de-risk decisions around balancing maintenance and constructions to both utility providers and customers, being certain of the anticipated future demands on an asset or the regulatory requirement upfront is key.

Q6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

There is a significant opportunity for competition and collaboration within infrastructure services. Firstly, in terms of competition in the water industry, the potential for competition in retail services, water resources provision and sewerage sludge treatment and disposal, is being actively explored by the regulator. Ofwat is promoting this through the Open Water 2020 programme, opening up new markets across the sector and developing price controls. The purpose is to ensure the best deal for customers by promoting competition and innovation in the sector. The role of competition within the water industry is currently focusing on less tangible elements of infrastructure such as market testing of costs to serve customers, expanding on the element currently in place for project costs greater than £100m. As the industry progresses there may be further opportunities for competition in sub-services provision within infrastructure services.

Although collaboration in delivery of infrastructure projects is generally good, further opportunities lie in terms of feeding into regional strategic plans for developments; for example there could be further opportunity for delivering infrastructure needs in a collaborative way such as joint laying of water or sewers with fibre optical cables. There is the potential for collaborative working on resilience requirements for communities such as the re-use of decommissioned water industry assets for storage in the event of flooding.

Q7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The water industry is financed on a regional, five-yearly basis. It is funded by customers within each region who benefit from the infrastructure built within their area. To encourage the construction of inter-regional infrastructure, there is an opportunity to explore how companies could build infrastructure which doesn't directly, or solely, serve their customers. As many large inter-regional projects would take longer than 5 years to deliver and therefore impact more than one regulatory cycle, we would also need to examine a funding mechanism for water companies that would help to facilitate the delivery of large cross-boundary infrastructure where costs may be incurred in one region and most, if not all, the benefits in another.

United Utilities' region as a whole has sufficient water resources; this is in contrast to other areas of England which can be described as "water-stressed". Owing to how our industry is financially regulated (regional, five-yearly) there is currently no mechanism to encourage us to build infrastructure to transport this water to another, more water-stressed region. An example is the Thirlmere pipeline that we are building to link one area in our region with another which is more water stressed. Other options were considered (a pipeline from Northumbria Water's Kielder

NIA Call for evidence: Response by United Utilities

reservoir)¹⁸, which may have had a positive impact on national water resilience and infrastructure. However, national resilience was not a relevant driver when considering the options available in this project.

Q8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

In the regulated water industry there should only be an issue with financing if the project undertaken is non-appointed (i.e. the remit falls outside the regulated licence). It would therefore not attract funding through Ofwat's price review mechanism. In these circumstances we could not raise funding for the project from customers and would have to fund the project separately, finding the finance from someone other than through customer water bill receipts. An example of this would be building the infrastructure to enable water trading with another region. This would be a non-appointed activity because it would not directly provide water for customers in our region, but those in another region, under another licence. We would therefore not be funded through customer bills for such a project and would have to find the financing elsewhere, such as a national infrastructure funding pot or a third party fund.

Such infrastructure could typically take 10 years to be commissioned. The beneficiary of the infrastructure would usually pay in stages or in advance for this project. Alternatively, a third party could pay for this infrastructure to be built, later recouping the costs from the beneficiary water company once it is commissioned. This is unlikely to be the most cost effective option. Rather, should a funding mechanism be created to support such national infrastructure projects, the financing costs should be reduced and the obstacles to such projects diminished.

Q9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Regional and national forums for sharing resilience risk assessments should be developed to ensure the collaboration and sharing of best practice in managing resilience risks. ResilienceDirect is an online private 'network' which enables civil protection practitioners to work together – across geographical and organisational boundaries – during the preparation, response and recovery phases of an event or emergency¹⁹. This is a step in the right direction, however, the remit of ResilienceDirect and the associated existing regional and national groups for civil contingency response and management should be extended to accommodate the infrastructure investment capabilities within the various organisations responsible for delivering, managing, maintaining and operating key infrastructure. Clear responsibilities for each organisation to deliver and maintain resilience to defined levels for its infrastructure should become statutory requirements subject to cost benefit analysis to ensure efficient and affordable investment and maintenance.

Collaborative contingency planning should be actively encouraged with sharing of investment in mobile and temporary equipment across multiple parties; however this would need to include a clear protocol for access to the equipment in the event of an incident.

Q10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Water and wastewater infrastructure is critical for supporting population growth and economic development. However, the water and sewerage undertaker is wholly reliant on the planning system to ensure that the interests of existing bill payers are protected and that new development does not impose an unreasonable cost burden on current and future generations. The automatic right to connect water, foul sewage and surface water to the public sewer was established by the Water Industry Act 1991 (amended)²⁰. Whilst the right to connect for water supply and foul sewage is a public health issue and we fully support its retention, we believe the automatic right to connect surface water to the public sewer is outdated and offers no public benefit and indeed can be detrimental to the public if it results in an increase in flood and pollution risk elsewhere.

¹⁸ UU's Water Resources Management Plan p9 - <http://corporate.unitedutilities.com/documents/WRMPMainReport.pdf>

¹⁹ Cabinet Office, Resilient Communications - <https://www.gov.uk/guidance/resilient-communications>

²⁰ Water Industry Act 1991 - <http://www.legislation.gov.uk/ukpga/1991/56/contents>

NIA Call for evidence: Response by United Utilities

Our reliance on the planning system is insufficient given that drainage is only one of a number of factors that planning authorities have to take into account. Local planning authorities often have limited drainage expertise and certainly have limited resources to undertake the assessments required to determine the most sustainable approach to drainage. Lord Phillips' judgement in a landmark case (*Barratt Homes Limited v Welsh Water*) at the Supreme Court in 2009 stated that "more thought may need to be given to the interaction of planning and water regulation systems under the modern law to ensure that the different interests are adequately protected"²¹. We support this view and would welcome the opportunity to explore this further with the National Infrastructure Commission.

Rates of Surface Water Discharge

Since March 2015, the mechanism for determining the rate of surface water discharge from development sites has rested with the planning system. Prior to this there was an intention to create a separate approval process for determining the approach to surface water discharge. This was outlined in the Flood and Water Management Act 2010. The intention was to create sustainable drainage approving bodies, however, this approving process has never been enacted amidst fears that a separate approval body would lead to delays and increased costs for developers. We consider the current approach places an unnecessary burden on the planning process. We do not believe the planning system is the most appropriate arena for determining the rates of discharge to the receiving conduit for surface water discharge.

We recommend that the decision on rates of discharge should be part of a separate governance process directly determined by those organisations responsible for the receiving conduit/s, i.e. sewerage companies for sewers and lead local flood authorities for watercourses. On this basis, where there is a proposal to discharge directly to the public sewer, we believe it is important that powers are vested in a sewerage company to control the rate of discharge to the public sewer, especially the public combined sewer, as part of the normal technical drainage approval processes within the Water Industry Act 1991. We believe a change is required if we are to respond to the challenges of climate change and housing delivery whilst also reducing the burden on local planning authorities.

Point of Connection to Public Sewer

We believe there is merit in ensuring sewerage companies are able to exert more control over the point of connection to the public sewer directly under the Water Industry Act 1991. We acknowledge this would need to be reasonable and governed by a fair framework.

Right to Discharge to Waterbodies

We are concerned there is no predictable, transparent and fair framework for securing the right to discharge surface water to watercourses and canals even though these may be the natural receiving drainage catchment for the land in question. Currently, developers of land have to negotiate with the riparian owners of watercourses and canals to acquire the right to discharge. This introduces delay and uncertainty to costs in the development process. The automatic right to connect surface water to public sewers means that developers often prefer the certainty of discharging to public sewer rather than incurring the uncertainty of a connection to watercourse even if this is clearly the most sustainable solution. We believe the current uncertain framework for acquiring the right to discharge drives the wrong behaviours in the context of the delivery of sustainable drainage and the surface water hierarchy and results in delays to the delivery of development.

Q11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The growing awareness of the planet's vulnerability to human driven changes provides an opportunity to re-emphasize the multiple values of natural environment and the services that it provides. Protected areas, when integrated into land use plans as part of larger and connected conservation networks, offer practical, tangible solutions to the problems of both species loss and adaptation to climate change. Natural habitats make a significant contribution to mitigation by storing and sequestering carbon in vegetation and soils, and to adaptation by

²¹ Supreme Court judgement 2009, para. 58 - <https://www.supremecourt.uk/cases/docs/uksc-2009-0038-judgment.pdf>

NIA Call for evidence: Response by United Utilities

maintaining essential ecosystem services which help societies to respond to, and cope with, climate change and other environmental challenges. Many protected areas could be justified on socioeconomic grounds alone yet their multiple goods and services are largely unrecognized in traditional Cost Benefit Accounting (CBA) type approaches. The emergence of the concept of natural capital reflects the recognition that environmental systems play a fundamental role in determining economic output and human well-being. They can provide resources and services, and recycle emissions and wastes. It is for this reason that Natural Capital Accounting (NCA) or Ecosystem tools need to be used to better understand the various solutions that are available to any problem to determine the best long term societal approach.

Strategic decisions concerning infrastructure services are likely to be influenced by public authorities and policy makers in order to achieve their wider objectives, such as eliminating regional price disparities or cross-subsidising of other public services. Regulation is often also put in place to try and meet these aims, as well as to mitigate environmental impacts and to consider more cost effective approaches to infrastructure development.

Infrastructure should contribute, enhance and protect the natural environment by protecting and enhancing valued landscapes, geological conservation interests and soils and recognising the wider benefits of ecosystem services. Through minimising impacts on biodiversity (and providing net gains in biodiversity where possible) infrastructure could contribute to the Government's commitment to halt the overall decline in biodiversity or if this is not readily achievable, it may lead to the development of ecological networks that are more resilient to current and future pressures. To minimise impacts on biodiversity and the natural environment, infrastructure plans should consider biodiversity and promote the preservation, restoration and re-creation of priority habitats, ecological networks and the protection and recovery of priority species populations.

Consideration of more natural approaches to infrastructure development should aim to conserve and enhance biodiversity by applying the following principles:

- if significant harm resulting from a development/infrastructure scheme cannot be avoided (through locating on an alternative site with less harmful impacts), adequately mitigated, or, as a last resort, compensated for, then consideration for alternative approaches must be considered;
- proposed development on land within or outside a Site of Special Scientific Interest likely to have an adverse effect on it (either individually or in combination with other developments) should normally be limited;
- opportunities to incorporate biodiversity in and around infrastructure developments should be encouraged;
- planning permission should be refused for any development resulting in the loss or deterioration of irreplaceable habitats, including ancient woodland and aged or veteran trees found outside ancient woodland, unless the need for, and benefits of, the development in that location clearly outweigh the loss.

Q12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

CBA techniques need a more open approach with easily accessible information, particularly related to values used to measure costs and benefits. This could include a simplified manual or library explaining the theories behind the methodologies and how the CBA process is conducted. If easily accessible and open to the public, this could help increase transparency. Ensuring that CBA methods follow consistent principle-led frameworks such as the Natural Capital Protocol would add consistency and enable decisions to be made using consistent, trusted and credible information.

A major improvement would be standardised tools which are easy to follow and replicate. These would require consistent and clear baseline assumptions and some guidance to encourage all parties to use these standardised tools to develop consistent cost benefit assessments. If these are not in place, evidence gathering to improve assumptions (including peer-reviewed studies) should be explored. Provisions of a single set of data sources for key assumptions would be of great benefit, particularly for non-monetary qualitative values.

There is potential to make better use of statistical and probabilistic analyses to understand the robustness and of CBA scores and implication of results. Additionally, the evaluation of a broad range of alternatives or scenarios to support decision-making, exploring where possible, alternatives to new policies and regulations.

NIA Call for evidence: Response by United Utilities

CBA techniques are often tailored to a particular benefit for the sector driving it e.g. drinking water, flooding. There needs to be a more joined up approach to wider benefits, including consultation with key stakeholders, local residents and businesses to understand what benefits already exist and what is lacking. This has started to be demonstrated via a few Defra pilots of local action toolkits and Natural Capital, including an evidence review for Manchester²². Our infrastructure assets are located and interact with other systems such as the natural environment, other infrastructure and private assets. Understanding the costs and benefits of new infrastructure should consider how similar interactions might be affected.

Transport

As customers rather than providers of transport infrastructure, we have no evidence to provide in response to question 13 to 16. However, the resilience of the North West transport system is critical to the daily operational effectiveness of water and wastewater provision, particularly during incidents. The flooding and damage to road links in Cumbria and Lancashire in December 2015 had a detrimental impact on our ability to recover services quickly. We would welcome an improvement to the resilience of local transport systems and would highlight the need to prioritise links that benefit the recovery of critical services that flood affected communities are reliant upon, such as potable water supply.

Digital communications

Q17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

We have no evidence to offer to this question.

Q18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

The ever continuing development of technology creates a challenge to the expansion of digital connectivity with much of this focusing on 'Smart' technology with some level of artificial intelligence, the Internet of Things (IoT) and the link to big data and data analytics. All of these technological advances are prevalent and continually expanding.

Due to the highly contrasting nature of infrastructure coverage from densely populated urban areas to dispersed rural settlements, the level of digital connectivity differs vastly across our region. The poor coverage of broadband capacity in Cumbria is a major barrier to our ability to improve the remote monitoring and control of our assets in that area and puts us at a disadvantage in delivering efficient water and wastewater services compared to our peers in areas that are better served by digital technology.

There have been discussions about the potential to use our sewers as conduits to aid a more cost effective delivery route for new communications infrastructure. We are open to the concept but there are issues remaining around ownership and liability should the activities of one service have a detrimental impact on the other.

Energy

Q19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Decarbonising heat could be achieved through decarbonising the natural gas grid by replacing natural gas with a low carbon/renewable fuel, and/or utilising technology such as ground, air or water source heat pumps, or solar thermal, for space heating. Larger scale district heating networks could provide a means of decarbonising heat.

A future with relatively plentiful, cheap shale gas (wherever this comes from) will mean that decarbonisation technologies would need to be incentivised and/or natural gas needs to be heavily taxed, to provide an incentive to decarbonise. Sunk infrastructure costs in the existing gas grid, suggests decarbonisation of the existing gas network

²² DEFRA Pilot – Manchester http://urbanwater-eco.services/resources/Manchester_LAP_Evidence_Review_Final.pdf

NIA Call for evidence: Response by United Utilities

as perhaps being the most effective way to decarbonise heat. Where alternative private networks can be made commercially viable, these should be incentivised, but this isn't likely to be a solution for all heating requirements. Finding low carbon alternatives to natural gas and incentivising their use as a replacement to natural gas should be prioritised. The Renewable Heat Incentive (RHI) goes some way towards this, but this initiative could be made more secure for investors.

The water industry has significant potential to offer value in these spaces.

The production of biogas from sewage sludge provides a renewable and reliable source of gas. There are several uses of the biogas, it is widely used to produce heat and electricity for wastewater treatment processes. It may be possible that this approach could be extended to become part of district heating networks.

Recent developments in technology combined with financial incentives through the RHI has enabled the development of biogas clean up and injection to the national gas grid. These schemes decarbonise the existing natural gas grid. There is potential to significantly increase the quantity of biogas to grid if there is the right financial incentive for the market. Innovation in the water industry is at a very early stage in considering producing hydrogen that could be injected into the national grid network.

Heating (and cooling) requirements could be provided by using water source heat pumps alongside sewer flows. The opportunity for water companies to enter this space is perhaps difficult due to the financial risk around the loss of long term revenues from heat provision to a customer (i.e. will the customer be around for long enough for the initial capital outlay to be recovered). Developing the market and removing potential regulatory and financial barriers to this approach would be required to see this opportunity realised.

Q20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Energy efficiency will always be the first priority to reduce demand. An effective zero carbon power sector will need to be flexible, distributed and secure.

Flexible – We recognise that renewable generation will provide local and intermittent power and that energy storage technology will be needed to better match supply to demand. The power system will need to have inbuilt intelligence to respond quickly to price and balancing services signals. When there is a surplus, excess power can be put to productive use and when there is a deficit, non-essential power use can be curtailed. Incentives in the market to use energy when zero carbon sources are producing energy would support the right user behaviours.

Distributed – from households to businesses, more of the power required is generated and used locally. The transition to distributed and local systems means fewer people are paying for transmission and distribution networks.

Secure – a zero carbon power system must still provide secure supplies to critical national infrastructure, such as water and wastewater treatment plants. Back up supplies and local storage can play a part in this.

Q21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Low carbon vehicles could operate on electricity or hydrogen in the future. Low carbon electric vehicles present an opportunity to utilise excess electricity generation and store it for use at a later time in a productive manner. There is a need to develop a co-ordinated and organised grid of fast chargers across the country to enable the proliferation of this type of vehicle. Current charging opportunities are often linked to the motorway system and there is a risk this isn't developed in more rural or dispersed communities.

Hydrogen fuelled vehicles may become the preferred low carbon vehicle technology. However, this requires the development of infrastructure to provide the supply and distribution of hydrogen to the market. The water industry already has water infrastructure that could be used to supply the raw material for the production of hydrogen.

Water and wastewater (drainage and sewerage)

NIA Call for evidence: Response by United Utilities

Q22. What are the most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

There are long term water resources supply demand challenges, particularly surrounding climate change and population growth. In particular, it is widely known that the South and East of England face future acute shortages of water without intervention. There is no single most effective intervention to these problems, recognising in particular that demand side solutions are politically seen as preferential. Instead, the most effective intervention to ensure future demand needs can be met is likely to be a combination of a number of supply and demand solutions, and within the former category, the transfer of water between companies and regions has a key role to play. This view is consistent with latest 2019 Water Resources Management Plan guidelines and associated new methods, which strongly advocate exploring all options within an equitable and robust appraisal framework that takes account of future uncertainty in defining the optimal solution.

We have recently been involved in a collaborative Water UK led project entitled “Water resources long-term planning framework”²³ exploring the national water resources resilience outlook over a 50 year horizon, and examining the role of different option types to address those challenges. This was initiated in September 2015 in agreement with the Water Minister. The project complements the water companies’ own plans, but takes a higher more strategic view given the national scale. It used many of the techniques that a number of water companies are looking to apply in the next Water Resources Management Plan round. This concluded that most of the South East currently faces a 12% chance over a 25 year period of a drought severe enough to require standpipes for circa three months. The economic consequences of such an event are very high (£40-£120 per day per household) and provides a strong case to improve resilience at a cost of around £4 per customer per year. The current risk is lower in the north and west of England. This shows it is cost-beneficial to implement interventions to address this need, and that this is therefore in the economic interests of the country.

It was clear from this project, in line with our own views, that the most effective interventions would be a blend, termed a ‘triple-track approach’ of supply, demand and water transfer solutions. At a national level, resilience would be enhanced through greater national connectivity (such as from the River Severn to the Thames Water area, e.g. from Lake Vyrnwy). Further work is required to analyse the potential inter-regional transfers and consider the potable water quality and environmental risks implications on donor region resilience, and to ensure the regulatory, financial and operational arrangements can facilitate such transfers.

Other areas of the country face severe water resources challenges, and recognising the national importance we are keen to explore water trading in our plans. However, it should be recognised that there are long-term challenges in our own region such as climate change, and whilst the supply-demand options or interventions available to us are currently significantly greater than in other areas of the country, to facilitate transfers of water in our region requires additional interventions in our own region. We need to ensure that any proposals fully consider the effects on our own customers, stakeholders and the local environment. This is being completed as part of our next Water Resources Management Plan, with a focus on decision-making under future uncertainty (to define the best long-term solutions), resilience and ‘pathways’ in our plan where appropriate; this approach is in line with the recommendations from the Water UK project.

We are exploring water trading as a core part of our plan, and investigating all possible options (including those from third-parties) to define the best way to achieve a robust supply-demand balance for our own region, whether for our own needs or to facilitate the export of water. Our customers and stakeholders have strongly emphasised to us that they want water quality, resilience and the environment to be protected or enhanced from the activity, and/or that they would like to see financial benefits from any water exports. Recognising this, we advocate that further strategic level reviews and studies are completed after the next round of Water Resources Management Plans are developed, to further mature proposals that are generated as part of those strategic plans. Under such proposals, the need for a

²³ Water UK, Water Resources Long Term Planning Framework, <http://www.water.org.uk/water-resources-long-term-planning-framework>

NIA Call for evidence: Response by United Utilities

collaborative approach between government, regulators, companies and stakeholders is needed if the interventions are to be implemented and benefits achieved.

Q23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Demand growth from a sewerage perspective can be driven by:

- housing development and population growth
- changes in demand by existing households
- new commercial development
- increasing demand from existing commercial sites (led by expansion of the site or diversion of discharges from water course to sewer)
- infiltration (groundwater seeping into sewers through joints and cracks)
- urban creep (the increasing building over of permeable areas with impermeable, particularly in urban areas)
- climate change (increasing storm intensity and frequency)

Of these, the last two (urban creep and climate change) are by some margin the most significant medium to long term risks to sewerage and drainage capacity in North West England. The areas of demand growth have to some extent been mitigated by water efficiency activity including increasing numbers of metered households and the transition from a manufacturing (discharging trade effluent) to service sector (reduced volume and volatility of load) although the benefit from these trends is declining. Avoiding additional surface water being discharged to combined sewer is a priority to avoid future cost of collection and treatment and an increased environmental impact.

Surface water removal or detention during peak flows can be implemented at source or at other locations on the sewer network. This can be achieved through the prioritisation of surface water disposal to watercourse, increased take up of sustainable drainage solutions or more traditional storage solutions such as detention tanks. Retrofit SuDS into existing areas can be costly but should be explored when redeveloping previously industrialised areas and could reduce the impact in combination with other interventions. Installation of SuDS as standard at new developments (where surface water removal is unachievable) would also contribute to a reduction in peak flows maintaining the resilience of the receiving sewer network.

We have inherited a legacy of watercourses culverted into sewers with complex interactive upstream catchments of ditches, highways and land drainage. These were typically tapped into the sewer for a specific local reason at the time, when management of sewers and watercourses fell under the same local authority and environmental impacts of overflow discharges were not a high priority. The impacts and flows vary across our region but can produce significant peak flows that reduce capacity of the sewer network. A joined-up approach to returning flows back to their natural paths wherever feasible should be explored further.

The increase in demand from growth in population can usually be managed effectively, provided it is a foul only flow as these flows are an order of magnitude smaller than the surface water contribution. Whilst the growth in population in the North West is not projected to be as significant as in the South East, there are pockets that are significant particularly around Manchester and its associated commuter belt and the Mersey gateway. We actively engage with local authorities in developing their local plans particularly in relation to the management of surface water from new and re-development sites. The spatial location of development is more difficult to influence as our concerns are just one of many that planners need to take into account. We try to encourage development in areas where there is existing drainage and sewerage capacity and away from areas where environmental capacity for wastewater discharges are constrained and cannot be achieved without incurring considerable cost. In practice, such is the constraint on planning sites, we are rarely able to have a significant impact. Population growth means an increase in the load received at our wastewater treatment works and with the focus on maximising the benefit from this load through energy production and fertiliser products, demand growth does not just represent a downside risk but also a potential opportunity to increase output in these areas, increasing income and reducing costs for customers. This is another reason why our supply demand emphasis is on removal of surface water flows from sewers. We believe surface water is best managed on the surface and sewerage assets should preferentially focus on the collection and disposal of foul flows.

NIA Call for evidence: Response by United Utilities

Q24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Alongside the Environment Agency, Greater Manchester Combined Authority, the Rivers Trust and Natural England, we are a partner in “Natural Course”, a 10 year LIFE Integrated Project (IP)²⁴. The project strongly supports a whole catchment approach and is working towards better implementation of plans under the Water Framework Directive by working in a more integrated way with project beneficiaries and stakeholders to address the barriers, gaps and shortcomings preventing Good Ecological Status being achieved by 2027. Two of Defra’s Pioneer projects to test various aspects of their 25 year environment plan are located in our region, an urban focus in Manchester and a catchment focus in Cumbria. We will play our part in delivering these projects as our operations make a significant contribution to the environment in both areas, we are also one of the largest owners of catchment land in Cumbria (and the largest commercial land owner in the UK). Working in partnership is fundamental to effectively delivering a whole catchment approach to manage water, wastewater and flood risk.

A whole catchment approach allows us to develop joined-up thinking and strategic planning across our water supply, wastewater and flood risk management systems. We have been advocating for some time that there needs to be a more joined-up approach to water quality, water resources and flooding planning at all levels of governance and regulation on a catchment by catchment basis. Within government departments and regulators, responsibility for these different topics tends to sit with different teams and there is often a lack of joined up thinking in plans and initiatives. We welcome recent steps to get greater alignment between river basin management plans and flood risk management plans but there is some way still to go to get to a truly integrated catchment approach.

We created an Integrated Catchment Strategy team in March 2015 to take a look at how environmental and service targets could be more cost effectively delivered through a catchment approach. Our strategy has switched the focus from our assets to the river itself and we are aiming to achieve targets through the most efficient approach which may not be through investment on our own assets. We have been testing this approach with local stakeholders on the River Ellen in West Cumbria and are planning a more detailed catchment pilot on the River Petteril in North Cumbria. The River Petteril is a good test catchment as it not only has issues with phosphates from both point and diffuse pollution sources but the river was also a contributor to the flooding experienced in Carlisle in December 2015. We think that by working with farmers and landowners in the catchment we can deliver water quality objectives at lower cost to water bill payers and potential deliver a benefit to flood risk too as the objective of reducing or slowing run off from farmland has benefits for water quality and flood risk reduction.

In summary, taking a catchment approach would enable water resources, water quality and flooding to be managed in a more sustainable, resilient and cost-effective manner, giving us the opportunity to:

- Take a holistic, risk based approach by addressing the wider drainage issues, as well as surface water flooding and water quality issues in the catchment;
- Involve key stakeholders and work in collaboration with other organisations, such as local authorities, highways agencies, the Environment Agency and housing developers;
- Target and develop integrated solutions to: reduce flood risk, protect local communities, improve water availability and quality, improve our assets, and enhance the natural environment and urban areas;
- Deliver more for less: aligning resources and efforts through a partnership can deliver interventions which may not be achievable or affordable if individually tackled. Combined resources also means that more benefits and savings can potentially be achieved by the partners; and
- Deliver multiple benefits: integrated solutions can reduce localised risk as well as influence and impact on other issues in the catchment. For example, sustainable drainage solutions which combine water management and green infrastructure, can deliver a multitude of benefits such as: reducing water runoffs from urban developments, but also improve water quality by intercepting pollution from runoffs, mitigate flood risks, increase biodiversity and amenity value.

Through the LIFE IP project and other engagement with stakeholders we are endeavouring to bring about a change towards more integrated planning. Defra’s introduction of the Catchment Based Approach (CaBA) aims to embed

²⁴ Natural Course (LIFE IP) – <http://www.naturalcourse.co.uk>

NIA Call for evidence: Response by United Utilities

collaborative working at a river catchment scale to deliver cross cutting improvements to our water environments²⁵. Defra's view is that over time collaborative catchment working will become self-funding, unfortunately the reduction in government financial support in this area has in our view come too soon, before this point was reached. As a result, most CaBA hosts are underfunded and insufficiently empowered to bring about such a fundamental change in approach. We believe a reinvigoration (with appropriate funding) of the CaBA framework is the best vehicle to achieve a more effective whole catchment approach rather than creating a new structure, new bureaucracy or new initiatives.

Flood risk management

Q25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

It would be helpful for there to be a defined national minimum standard for flood resilience. This would help infrastructure providers to plan to meet at least a certain level of protection which could then be enhanced subject to local conditions, customer support and willingness to pay. Flooding is understandably an emotive issue and a horrific experience for those who suffer flooding of their homes. After flood events there is often an expressed desire to ensure "this can never happen again" or an expectation that we will protect assets to ever higher standards without any consideration of the cost or the relative risk of flooding compared to other hazards to service. When developing investment plans that includes assets with long lives, knee jerk changes to expectations on risk exposure lead to inefficient investment and unnecessary costs to water bill payers.

The Pitt Review 2008 considered that "for the purpose of building resilience in the critical infrastructure a minimum standard of 1 in 200 annual probability would be a proportionate starting point" but this was never incorporated into any official guidance.²⁶ The National Flood Resilience Review²⁷ led by Defra asked infrastructure providers to consider risk to sites serving more than 10,000 people from flood based on the "Extreme Flood Outline" and to procure temporary flood barriers to protect vulnerable sites in the short term with the aim of providing more permanent protection in the longer term. It is not clear to what extent these requirements now constitute official standards or what the basis for setting standards at this level was.

Building upon the National Flood Resilience Review, it would be appropriate for there to be different levels of resilience requirements for different levels of criticality of infrastructure assets, coupled with a suitable and affordable timeframe for their implementation. It would be sensible to align the requirement to the Environment Agency's currently published flood risk zones, although it would be beneficial for additional modelling to be undertaken to assess the impact of climate change on those return periods and flood extents. This would require agreement on appropriate climate change scenarios to be used for such assessments to avoid excessive cost through adoption of an extreme condition.

Flood resilience is not just about protecting sites from flooding with barriers, we need to ensure that other approaches to the provision of flood resilience get equal consideration including the decision to allow sites to flood and interrupt service but to have robust response and recovery plans to get sites back on line as quickly as possible once the flood subsides. This aligns with the principle of the 4 R's of resilience planning: resistance, reliability, redundancy and response/recovery as advocated by the Cabinet Office "Keeping the Country Running".²⁸ We would

²⁸ Defra, Keeping the Country Running, 2011 <https://www.gov.uk/government/publications/keeping-the-country-running-natural-hazards-and-infrastructure>

NIA Call for evidence: Response by United Utilities

be happy to work with the National Infrastructure Commission to assess how appropriate national flooding standards could be set in the context of finding the appropriate balance between risk and cost.

As well as being an infrastructure provider, we are also a customer of other infrastructure providers on which our service relies, particularly electricity, telecommunications, transport and flood protection. Any standards should apply equally to other infrastructure sectors (albeit adjusted based on criticality) as a failure in service standards in any one of these sectors could adversely impact on our service levels. Resilience to flooding is necessary for all infrastructure irrespective of whether it is provided through general taxation or private infrastructure providers.

We are impacted by flooding but others are also potentially impacted by flooding from our assets, particularly sewers. We have reduced the number of sewer flooding incidents considerably in recent years but there is still more to do to reduce the risk even further. Sewer flooding can be caused by a lack of hydraulic capacity or due to a blockage in the pipe. Most hydraulic capacity issues have already been addressed and those that remain are extremely costly to resolve on a cost per property basis. There is a debate to be had as to how much it is reasonable to invest to prevent flooding to an individual property. Our focus in recent years has been to address the most common cause of sewer flooding, blockages. It is considerably more cost effective to tackle this problem through operational activity and through customer education to prevent the misuse of sewers, for example, the disposal of wipes, fats, oils and greases down the drain. The industry is currently engaged with trading standards about the use of the word “flushable” on products that cause problems with sewer blockages and lead to flooding and environmental pollution.

Q26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Natural flood risk management (NFRM) covers a wide range of actions and land use types. Whilst NFRM can only be part of the solution to flood risk we believe it can make a good contribution and offers many wider benefits than traditional hard engineering. Many different measures can act as NFRM, encouraging the retention of water within a catchment and, through that, enhancing the natural functioning of the catchment. They contribute to a reduction in flood risk through regulating the flow and transport of water so as to smooth peaks and moderate extreme events. Measures can include riparian planting, reinstating flood plains and restoring meanders. They can support biodiversity conservation and restoration and they are more resilient to climate change as they are not generally designed to cope with a flood of a fixed severity but provide a benefit in all conditions.

As the largest commercial land owner in the UK with 57,000 hectares of land including large upland areas supplying our key reservoirs in Cumbria and the Pennines, we are well placed to support the proliferation of natural flood management schemes. Our Sustainable Catchment Programme (SCaMP) has been operating since 2005 restoring damaged peatland on our catchments primarily to provide a water quality and biodiversity benefit. We also expect our programme to provide a benefit to carbon sequestration by leading to an increase in the rate of peat development and a flood benefit by slowing the rate of flow off the uplands. This has been achieved by controlling stock levels, blocking grips and re-seeding bare peat that has been damaged by air pollution, overgrazing and historic drainage to increase agricultural output. Alongside this we have been undertaking an extensive monitoring programme and we believe this monitoring data is the longest continuous record of the benefits of a re-naturalisation of uplands in the UK. We are starting to see a slowing down in the deterioration of colour in the water draining from SCaMP catchments and the consultants undertaking the monitoring programme are undertaking a review of the impact on peak river flows downstream, early indications are that there is a considerable impact on peak flows during storm events.

We are involved in river restoration work with the Environment Agency and other partners. A project to restore a historically straightened section of Swindale Beck immediately upstream of our intake at Truss Gap was completed in September 2016. The project has resulted in a new sinuous channel measuring 891m in length, replacing a straightened reach 750m long. The new channel is better connected to the flood plain with a wider and more gently sloping profile, helping to slow the flow of water through the valley. The sinuosity of the channel has meant that natural in-river features (gravel bars, riffles and pools) have all formed rapidly after connection, resulting in much greater habitat diversity than in the straightened route. The old channel was in-filled and reseeded using brush

NIA Call for evidence: Response by United Utilities

harvested seed from the surrounding SSSI hay meadow, resulting in an increased area of species rich hay meadow. The project was funded by the Environment Agency, Natural England, United Utilities, Cumbria Waste Management Environment Trust and RSPB and was project managed by RSPB. The work took six months to complete and cost £205,000.

There are difficulties with the implementation of NFRM including those around the need to align with multiple stakeholders and legal issues around the liability from less certainty around the level of protection provided. However, better computer models are enabling us to process the many strands needed to design and create a built environment with water at its heart particularly within ungauged catchments where we have no historic flow data. The implementation of NFRM and evidence gathering around its effectiveness takes time. There is still a high level of uncertainty and there is difficulty in monitoring dynamic catchments, there is potential for new approaches e.g. use of time-lapse cameras and drones to aid our understanding and communication technologies are enabling us to introduce computer activated controls into our water management systems.

In winter 2015-16, flooding caused widespread disruption and damage in several areas of the north of England. As a consequence, Defra is investigating a range of flood alleviation options. One of these options is to consider case studies of impounding reservoirs used for water supply purposes operating in a way that may assist with the alleviation of downstream flooding: this is not a new concept as several examples exist already where arrangements are in place for this purpose. Yorkshire Water, United Utilities, Environment Agency, Ofwat and Defra are working together to understand the potential benefits and risks and identify the potential for wider application. Reservoirs within Yorkshire Water's and United Utilities' areas are currently being screened to identify suitable case studies. It is anticipated that agreements may be reached to test further reservoirs to determine whether flood alleviation benefits can be realised without adverse consequential impacts and without compromising the reservoirs' principal purpose of the long-term provision of reliable drinking water supplies.

Solid waste

Q27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Our wide ranging business activities lead to a variety of waste streams, each requiring different approaches and business processes to optimise the management of wastes. In total, we produced 730,313 tonnes of waste in 2015/16, which was made up of the following waste streams:

- Construction waste 43.6%;
- Treated wastewater sludge 35.1%;
- Network excavated material 8.4%;
- Water sludge 6.2%;
- Grit and screenings 3%;
- Ash 2.2%;
- Office waste 0.6%;
- Hazardous waste 0.6%; and
- Operational site waste 0.3%.

Of this waste, 94.5% was diverted from landfill and we have set ourselves a target to divert 95% of waste to beneficial use. Our high level of waste diversion demonstrates that current financial and regulatory incentives are sufficient in driving us to manage the sustainable disposal of our waste and contribute to UK recycling targets.

In 2015/16, we diverted 100% of ash produced from landfill, compared to 0% diverted from landfill in the previous financial year. Ash is now blended with other end of use wastes for further use as aggregates and in concrete block manufacture. To support better ways of managing our ash waste, we have formed an internal working group with

NIA Call for evidence: Response by United Utilities

the aim to provide alternative long term sustainable solutions for the disposal and application of ash. Options considered include use by civil engineering suppliers and/or use within our supply chain. Alongside this we frequently provide samples of ash to businesses and researchers to explore the recovery of phosphorus and/or precious metals. Regulations to amend Annex III of the Waste Framework Directive (2008/98/EC) as regards the hazardous property HP 14 ('Ecotoxic'), could potentially cause the reclassification of ash from non-hazardous to hazardous. For United Utilities, this would result in a reduction in diversion from landfill and could significantly increase disposal costs if ash is classified as hazardous and is subject to a higher rate of tax under the proposed landfill tax changes.

Wastewater sludge is a large contributor to our total waste volume and a key feature of our sludge strategy is to maximise the beneficial reuse of sludge, by recycling to agricultural land as the Best Practicable Environmental Option in line with EU and UK Government requirements and policy. In order to sustain this recycling outlet, we will seek to maximise farmer uptake rates and reduce the exposure to changes in supply-chain sentiment by improving sludge digestate quality and engaging agricultural and food industry stakeholders. We participate in research, both independently and collaboratively, to promote the beneficial use of sludge in agriculture and technologies that will help secure the long term sustainability of our recycling activities. We are supporting the development of the Biosolids Assurance Scheme, which is a quality protocol for sludge treatment and disposal, to reassure stakeholders that the use of treated sewage sludge is safe and beneficial. Maintaining an outlet for sludge disposal to land is crucial. Therefore, any legislation that inhibits this would be detrimental and have a financial impact on our customers due to the high costs associated with disposing of sludge by incineration.

Q28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Waste regulation is complex and differentiated by waste types entering the treatment process. Current regulations often specifically exclude the reuse of wastewater and sewage sludge from the circular economy and this must change to enable the water industry to support national circular economy goals. Recovery from wastewater and sewage sludge has the potential to play a significant part in a circular economy, providing a wide spectrum of opportunities including water, nutrients (notably phosphorus), plastics, as well as generating renewable electricity and gas. We recommend that circular economy regulations should set out criteria that describe the quality of the final product, without limiting the input material from which it originates.

The circular economy regulations must support the recovery of phosphorus from wastewater and sewage sludge. Phosphorus is one of the essential nutrients for plants, animals and humans and is therefore crucial for all life on the planet. The limited availability of phosphate rock as well as Europe's high dependency on imports made it part of the revised list of Critical Raw Materials in May 2014. There is enough phosphorus in wastewater that if recovered, could provide a significant sustainable contribution to agriculture and food security, whilst also delivering environmental benefits to the natural environment through cleaner watercourses.

Currently, phosphorus recovery from wastewater or sewage sludge is not economically feasible. Market opportunities for recycled phosphates are essential for closing the cycle and should be broader than the fertilizers industry only. Legislative frameworks could better support the development of cost-efficient and optimal solutions. Incentives for phosphorus recovery would focus actions to the most promising and cost effective solutions. However, at the moment it is not clear what raw materials or processes are the best for phosphorus recovery and more research is needed.

National Infrastructure Assessment Call for Evidence

Submitted by [name redacted] and [name redacted], School for Social and Community Medicine, University of Bristol

Cross-cutting issues:

1. Investment in walking infrastructure is the best value for money of all road infrastructure types.

Walking infrastructure has potential to reduce the large national health burdens of physical inactivity and air pollution while also increasing transport network capacity, strengthening community cohesion, local spend in high streets, and equitable access to jobs.

Physical inactivity and air pollution are two of the great health challenges of our times - both are clearly linked to leading causes of premature death including cancers, heart disease and dementia¹. Physical inactivity is estimated to cause 17% of deaths in the UK² and costs the nation £20 billion per year³. The mortality burden of outdoor air pollution is estimated at 40,000 deaths per year, with social-economic costs of £20 billion per year⁴. Walking is known to be the single most equitable form of physical activity across gender, age, ethnicity and categories of deprivation⁵. As such, walking is a unique form of transport which can reduce both health and job access inequalities.

3. Walking infrastructure needs to be safe, enjoyable and convenient for everybody.

Walking is currently not safe in the UK, but is poor in both absolute and relative terms of traffic risk. The rate of killed or seriously injured (KSI) per billion miles is almost 20 times higher for pedestrians than car occupants (484 vs. 25 respectively)⁶. These rates are 3 to 10 times higher than absolute traffic injury rates of European counterparts such as Sweden, Denmark and the Netherlands, and up to 19 times higher when comparing rates for children⁷. Even allowing for the methodological limitations of traffic injury rates per distance travelled, this international data clearly suggests that our national traffic safety ambitions can be improved. The need for improved road safety is consistently identified across scientific literature as a key determinant of children's travel by walking or cycling to school⁸, meaning there is a double negative impact in the resulting low levels of active travel to school. Countries and cities across the world are adopting zero KSI targets for pedestrians⁹.

Evidence from the UK indicates that walking infrastructure should be enjoyable, pleasant and convenient, with connections to public transport to facilitate walking uptake and maintenance¹⁰.

A previous National Infrastructure Commission report identified that population projections show that we have a growing and ageing population¹¹. It is essential to recognise that we spend a large part of later life in poor health¹², and that this is related to the accumulation of non-communicable disease across the life course¹³ and unsustainable treatment costs¹⁴. Older adults gain some of the greatest health and wellbeing benefits from walking. There is a strong cost rationale to ensuring that walking infrastructure is safe, enjoyable and convenient for older adults for it to achieve full health and economic potential at scale.

Transport:

13. Daily walking needs to be built-in.

Walking needs to be built in to travel patterns to ensure that the Chief Medical Officer's recommendation of 150 minutes of moderate-to-vigorous physical activity per week are met on a population scale. Research from the UK shows that a daily 15 min walk at 3mph to work or local public transport interchange would achieve this¹⁵ – a spatial radius of 0.75 miles. Up to 1.5 miles (30 mins) radius would be ideal from a public health point of view to counteract the effects of prevalent sedentary work patterns. Imagining scenarios of flexible home working, the importance of local density of housing with walking scaled spatial relationships to shops, schools and services has increased importance.

Flood risk management:

26. Blue-green infrastructure can help maximise flood protection and upgrade walking infrastructure.

An example of this is investment in walking and cycling infrastructure in Copenhagen co-financed through climate adaptation and flood protection measures.

The following statement was provided by Ramboll Denmark:

"In response to extreme urban flood events in 2011 and 2012, legislative changes were made to allow the municipality to upgrade service requirements to be delivered by water utility companies. This decision was based on allowing for both a 30% increase of precipitation over the next 100 years and management of larger storm events e.g. 1-in-100 storms based on cost-benefit risk analysis. Legislative changes further enabled water utility companies to take out loans and increase revenues through rate increases in order to invest in capital projects to deliver this

new level of flood and stormwater management. In addition, water utility companies were given the legal right to co-finance urban renewal projects which achieve these new urban hydraulic performance targets together with both municipalities and private investment companies.

The volume of expected investment is equivalent to over £2 billion (20-25 billion DKK) over the next 20-25 years. Based on initial project work, an estimated 50% of this will be spent on surface infrastructure systems – termed blue-green infrastructure - which improve hydraulic performance and flood capacity while upgrading for example pedestrian and cycling environments and recreational areas. From 2017, typically utility companies will finance 75% of investment and municipalities 25%.”

LOCATION, LOCATION AND LOCATION

Getting best value from investment in infrastructure

This paper responds to question 3 in the consultation by the NIC on carrying out the National Infrastructure Assessment. It amplifies evidence sent in by the Royal Society of Arts' Sustainability Network. An attachment, originally prepared for the Call for Ideas, suggests testing out Multi-Criteria Analysis (MCA) and Land Value Capture in different types of situation where difficult choices have to be made. The aim of this particular paper is to show how housing and infrastructure should be linked together to get better value from public investment.

The real challenges

Achieving the NIC's aims, including fiscal responsibility, require the UK to adopt better methods for devising, assessing, and financing major infrastructure projects. The huge bill for updating our infrastructure systems set out in reports by McKinsey and Company and The Policy Exchange makes strategic phasing critical.¹ As infrastructure is a necessary, but not a sufficient condition for economic growth, it also needs to be located in the right places. Every surveyor learns that there only three things that matter in property: location, location and location. Yet government has been criticised for being 'spatially blind'; short-term political pressures make it hard to focus public investment where it will yield best long-term value.² This means producing not just simple short-term economic benefits, but also balancing social and environmental impacts.

The report of the Mayor of London's infrastructure plan provides some useful data on the expected capital expenditure in London alone over the next three decades.³ Leaving out health, still requires capital expenditure of £1.3 trillion. Significantly housing accounts for 41% closely followed by transport at 35%, while energy trails behind at 11%. Studies in both Milton Keynes and Cambridgeshire found similar orders of magnitude.⁴ So there is no escaping the realities that government objectives such as doubling housing output or raising

¹ Dieter Helm et al, Delivering a 21st Century Infrastructure for Britain, Policy Exchange 2009

² See for example case studies in Sir Ivor Crewe and Anthony King, The Blunders of our Governments

³ The Mayor of London, London Infrastructure Plan 2050

⁴ Nicholas Falk, The Steps to Quality Growth: towards a new business model for house-building, Cambridgeshire Horizons 2101

productivity depend on mobilising much greater levels of investment that we have achieved in past decades.

The task is made more complicated by five facts of life:

- Much of the opposition to development, especially house-building in the South, stems from concerns over impact on congestion (and related pollution)⁵
- Private developers and institutional investors will not fund major projects without assurances that infrastructure will be in place
- Utilities are reluctant to commit until spatial growth plans have been agreed
- Infrastructure projects in the UK take many years to plan and implement (Crossrail was initiated in the 1940s)
- There is little public appetite for raising taxes to fill the gaps, or trusting in Commissions of Inquiry.

How housing and infrastructure interact

Despite the obvious truism that economic growth and housing are inter-related, there is surprisingly little clear research on how far one shapes the other. Much of the work on ‘urban form’, while interesting, has been inconclusive.⁶

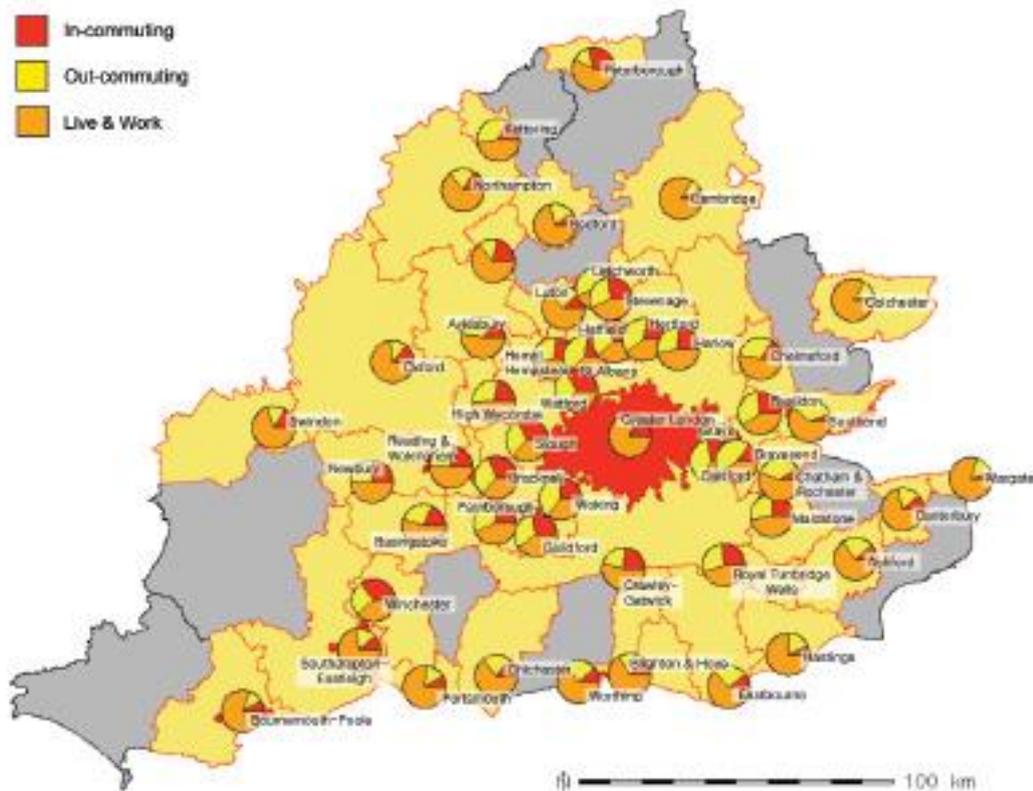

However there is evidence of significant differences between types of town:

- Much of the congestion on the roads and railways is caused by more people commuting ever further to work: paradoxically improved transport capacity tends to lead to people living further away from work.⁷
- Outside London and the South East, where most people take well over an hour to commute into Central London, commuting times are often quite short. The chart below from Peter Hall’s research shows that the smaller the town, the more people tend to commute outside to work, using cars for the most part. It is the larger university towns that are most self-contained.

⁶ Katie Williams on Shaping our Cities for the Future of Cities Foresight 2014

⁷ David Metz, Travel Fast or Smart? A Manifesto for an Intelligent Transport Policy, London Publishing Partnership 2016

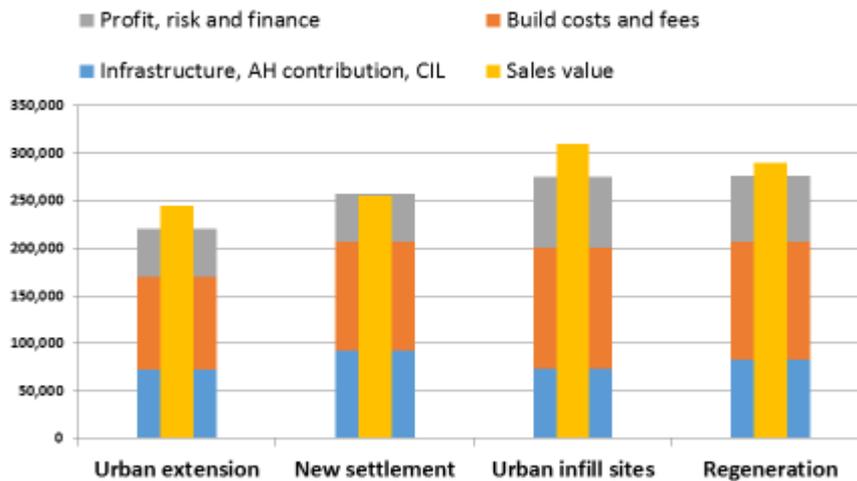

- House prices determine land values, with huge differences across the country; thus in Cambridgeshire, land in Cambridge City (which is 45 minutes from Kings Cross) is valued at £5.7 million an acre, compared with £1.0 million in East Cambridgeshire, and only £370,000 in Fenland.
- House prices are affected by travel times to work, with a clear gradient as distances from major sources of employment such as London increase.⁸ Much of the impact of improved transport is therefore lost in higher house (and land) values.
- Even within a relatively well-served conurbation, such as London, differences in accessibility can trap people in disadvantaged areas, and may explain why low-paid jobs are filled by immigrants. As the public transport system is largely radial, most use cars to make orbital journeys to get to work in many parts of Outer London, and clog up poorer town centres.
- Very different returns on investment are possible from urban infill or extending areas with infrastructure capacity compared with developing new communities from scratch (which require substantial subsidies).⁹ The

⁸ A useful web site from Anna Powell-Smith shows this graphically for 2,500 stations

⁹ The analysis for URBED's Wolfson submission was prepared by Pete Redman of Trade Risks, who calculated that land value uplift from development on the edge of Oxford was sufficient to build the first stage of a tram system

residual land value is the difference between the sale receipts and the cost of construction, including fees, and urban infill sites involve lower costs and risks.

Transport models such as SATURN, are typically used at great cost to evaluate single projects or options, and little seems to have been done to assess the interrelationship of alternative growth scenarios and transport systems. Local authorities no longer have the staff or budget to explore the options properly. Yet improvements in GIS and mapping techniques have revolutionised the possibilities.

- Transport for London has just upgraded its online planning tool WebCAT which shows how well connected locations are in terms of transport as well as journey times¹⁰
- The Centre for Advanced Spatial Analysis(CASA) at UCL has been backed by Innovate to develop better software which brings all the environmental constraints together, and allows development impacts to be assessed at a sub-national or city region level¹¹
- URBED’s work in Central Oxfordshire, following on from winning the 2014 Wolfson Economics Prize, has identified options for making better use of rail, and the need to change the way we plan for strategic growth if we are to realise the benefits and avoid waste.¹²
- Work on major national infrastructure projects such as High Speed 2, and also the Oxford/Milton Keynes/Cambridge links has highlighted

¹⁰ <https://tfl.gov.uk/info-for/urban-planning-and-construction/planning-with-webcat/webcat>

¹¹ An overview is available from Prospective, the company developing the software

¹² Nicholas Falk, Planning for Posterity, Town and Country Planning, September 2016

the importance of ensuring that local linkages are in place if the benefits of increased rail usage are to be secured.¹³

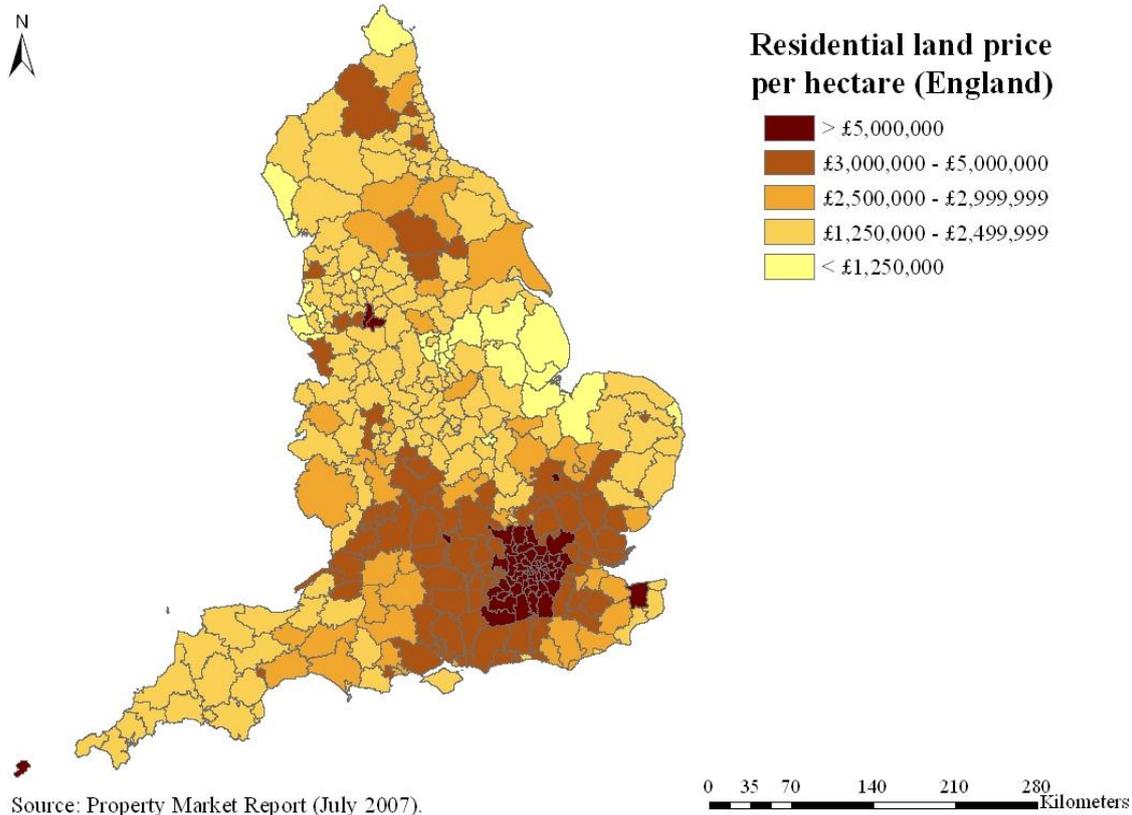

But cities are not the simple ‘engines’ or ‘drivers of growth’ that they are sometimes called. Comparisons between British and Continental cities show that while London is in a class of its own, as a ‘World City’, our provincial cities lag behind their Continental counterparts in many aspects.¹⁴ However most studies fail to take sufficient account of the wider Travel To Work or Functional Urban Area in which skilled staff and managers live: some of the most dynamic employers such as Dyson in Malmesbury or Renishaw in Stroud are now based far from the cities where they may have originated.

Not only is it important to compare like with like, but also to distinguish between different types of location. Crudely a distinction can be made between Growth and Regeneration Areas based on land values, where regeneration areas require public subsidy before development is viable, while growth areas have high enough land values to attract private investment not just in house building, but also providing enabling infrastructure. The map below sets out land values from a CLG report, and £3 million a hectare should provide enough land value uplift not just to build private houses for sale, but also to meet social and environmental obligations.

Pete Redman of TradeRisks, (who specialise in raising bonds and produced the calculations in our Wolfson Economics Essay,) is cautious about how much could be secured from capturing land value uplift. He thinks the UK government is already spending large amounts on infrastructure renewal and improvement; we need to spend about £88 billion a year, of which half should be private investment, whereas actual expenditure is a little over £60 billion. The private contribution is only about half of what it should be. He reckons we could squeeze another £2.5 billion a year, or double the current contribution from the private sector. As Ministers are keen to keep public expenditure down, something has to give.

¹³ See for example the reports of the Independent Transport Commission High Speed Rail and Connected Cities: Accessible Places for Growing Economies , 2016

¹⁴ EU State of the Nations 2016 , Centre for Cities Competing with the Continent: how UK cities compare with their Continental counterparts.

A further distinction also needs to be made according to the size or role of the city, with Metropolitan Cities or Junctions having quite different needs and potential. Thus it is the larger or Core Cities where metro or tram systems are viable, and cities such as Leeds should expect to be compared with cities such as Lille in France or Leipzig in Germany. It is these ‘Metro cities’ where the returns from upgrading local infrastructure should be greatest if the impact on social and environmental capital is properly assessed. Finally it is often helpful to distinguish between Central, Inner and Outer or Rural areas, and different types of urban form, such as Linear or Connected Cities, which lend themselves to quality public transit, such as Swift Rail. www.connectedcities.co.uk While this may not suit the way UK statistics are collected, when it comes to planning major transport and development projects it is essential.

Where we can learn from

As well as learning from the places that have failed to ‘join-up’ transport and development, the NIC should also be learning from cities that have used different approaches with greater success. In *Good Cities Better Lives*, Sir Peter Hall and I selected a range of Continental cities that could serve as models for

how the UK might achieve better growth.¹⁵ We picked French cities for the chapter on transport, but similar approaches are used throughout Europe as the following examples of ‘smarter urbanisation illustrate¹⁶. I have chosen examples below of what might be classed as ‘regeneration’ areas that have lost industrial jobs, and therefore which are most similar to typical British major towns and cities:

- The conurbation of **Lille** not only succeeded in attracting a station on the High Speed line from London to Paris, but also upgraded its local transport system at the same time. In what was known as the Metropolitan Compromise, implemented through a kind of ‘City Deal’, some 80 communes support the Mayor of Lille in return for upgrades to local transport.¹⁷ This included a driverless Metro linking up the old industrial towns of Roubaix and Tourcoing, an upgraded tram to Roubaix, and an integrated quality bus system that knitted the whole agglomeration together. This was helped through the Versement Transport, a charge on the payroll of those with more than ten employees. The French planning system of Aménagement de Territoire starts with the ‘bigger picture’.
- The ‘shrinking’ city of **Leipzig**, in East Germany, a former textile city which lost 90% of its manufacturing jobs after reunification, has reversed its decline in a relatively short period. Major transport projects have put a long-distance line under the central city, and upgraded the tram system to make it easier to use public transport. At the same time, the major employer of BMW was persuaded to open up its new manufacturing and research facility by the commitment to build a new motorway around the edge of the city, to ensure components get to the factory without congestion. The City planned its future by working closely with the universities and major employers, and is able to draw on finance from the state investment bank KfW and also local savings banks or Sparkasse, who fund business growth. As a result Leipzig has become known for its creative cluster of artists and businesses.
- In **Rotterdam**, the old port area of Kop Von Zuid has been transformed with stylish housing, connected up by the iconic Erasmus Bridge, and river taxis.¹⁸ The splendid new Central Station symbolises the city’

¹⁵ Peter Hall with Nicholas Falk, *Good Cities Better Lives: how Europe discovered the lost art of urbanism*, Routledge 2013

¹⁶ Nicholas Falk, *Smarter Urbanisation and Rapid Growth*, *The Planner* February 2017

¹⁷ Lille is also a case study in URBED’s report for Joseph Rowntree Foundation, *Regeneration in European Cities*, 2008i, and is compared with Bradford and Leeds

¹⁸ Rotterdam forms another case study in URBED’s report for the Joseph Rowntree Foundation, *Regeneration in European Cities: making connections*, and is compared with Southwark

renaissance as a cultural city to rival Amsterdam, and as well as local Metro and tram services, the whole Randstad area (equivalent to Greater London) is connected together with Swift Rail type services. Dutch planning is a model for how to integrate transport and development, with higher densities promoted around the most accessible locations. As an example, Rotterdam was not allowed to build a new business park by its airport until the one at Amsterdam's Schipol had been completed, while South Amsterdam provides one of the best models of how to integrate transport with mixed high density development.

Joining up investment plans

Difficult choices have to be made if the constraints on the growth of areas with real economic potential, such as Oxford and Cambridge or West London around Heathrow are to be relaxed. Similarly efforts to regenerate older industrial areas such as in Stoke or Bradford cannot be accomplished with major investment in transport. But making decisions by ranking all transport projects together and applying relatively crude Benefit Cost Analysis (BCA) is simply stupid, even if the WebTAG process has tried to take account of different factors. The studies for corridors like Oxford to Milton Keynes are a good start, but only effective if they grapple with the problems of Intra-City, as well as Inter-City transport, and succeed in linking development with infrastructure projects.

There is, alas, no simple answer, and politicians have a key role in weighting priorities or values. But this should come AFTER options have been sketched out or scoped, and in the light of broad estimates not just of likely costs and usage, but also of risks. As in the example of Cambridge Futures, some clear thinking early on, bringing the main stakeholders together, can produce a clear enough vision to allow major infrastructure investment decisions to be taken, and quality growth secured. It looks as if techniques such as Agent Based Modelling could offer a way forward, and certainly deserve consideration: https://en.wikipedia.org/wiki/Agent-based_model . So too does Policy-led Multi Criteria Analysis, as set out in UCL's Omega 3 report, which was explored in a seminar on Trams for Oxford.¹⁹

While it may be over-ambitious to think that the UK as a whole will adopt Land Value Rating, and start to hypothecate the uplift in land values from development towards local infrastructure, at least a start could be made by considering land values in making investment decisions, such as where to locate

¹⁹ See paper by Robin Hickman in the report Trams for Oxford, www.oxfordfuture.org.uk and paper by Fiona Ferbrache on the economic impacts of light rail, both of whom are linked to the Transport Studies Unit at the University of Oxford.

a new generation of Garden Cities or Sustainable Urban Extensions.²⁰ Indeed, there could even be support in some areas for going further and requiring major housing developments to contribute to the cost of upgrading local transit systems where that will relieve congestion for all and help support property values.²¹

The NIC, through its role in assessing major projects and infrastructure capacity, could hold the key. Thus Multi Criteria Analysis in a historic city like Oxford might consider not just at time savings, but the impact of different transport investments on the growth of private sector jobs and housing investment, and also on the employment prospects and earnings for people living in the poorer parts of East Oxford, and possibly on pollution and health more generally.

Conclusion

Tackling the challenges the UK faces in upgrading its worn-out infrastructure are technically and politically complex. They are also critical if the country is to respond to the likely loss of confidence and community wellbeing after Brexit. This requires more than just a few grand projects; instead it means enabling a range of small projects to go ahead that will release local constraints and support plans that mobilise private investment and community enterprise.

A separate report prepared with transport and planning experts for the NIC's Call for Ideas, suggests how 'smarter growth' might be achieved. The RSA's Inclusive Growth Commission, and bodies such as the New Economics Foundation, are also working on proposals for land value capture. The time could be ripe for a break-through in achieving the three E's by which all strategic planning should be judged²²:

- **Effectiveness:** does it work (and produce desired results)?
- **Efficiency:** is it being delivered economically (and minimise waste)?
- **Equity:** is it fair to all concerned (and does it help social inclusion?)

**Viessmann response to
National Infrastructure Assessment Call for Evidence**

Response submitted by: [name redacted] [email redacted]

Executive summary

About Viessmann

*The **Viessmann Group** is one of the leading international manufacturers of heating, industrial and refrigeration systems. Founded in 1917, the family business maintains a staff of approximately 11,600 employees and generates 2.2 billion Euro in annual group turnover.*

With 22 production divisions in 11 countries, subsidiaries and representations in 74 countries and 120 sales offices around the world, Viessmann is an internationally orientated company. 56 percent of sales are generated outside Germany.

As a family-run company, Viessmann sets great store by responsible conduct with a long-term vision. Sustainability is already firmly embedded into the company's guiding principles. For Viessmann, the practice of sustainability means reconciling cost efficiency, ecology and social responsibility throughout the entire company to enable us to meet our current needs without compromising the ability of future generations to meet theirs.

As an environmental pioneer and technology leader in the heating industry, Viessmann has been supplying minimal emission, energy-efficient heating systems for oil and gas for decades as well as solar thermal systems, wood combustion systems and heat pumps. Many Viessmann developments are regarded as milestones in heating technology.

Answers to questions:

We have provided answers to questions 1, 4, 5, 6, 7, 12, 19, 20 and 21.

Cross Cutting Issues	
1.	What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?
As a general comment Viessmann would support the message being made by trade associations such as the Sustainable Energy Association that energy, including heat and power generation and demand reduction should be treated as an infrastructure priority. We welcome the recognition of energy as a workstream by the National Infrastructure Commission. Having buildings suitable for purpose for both domestic and commercial use can have wide-ranging benefits such as improved health of UK citizens from living in warmer homes and on the UK economy through more manageable fuel bills.	

<p>4.</p>	<p>What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?</p> <p><i>Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.</i></p>
<p>Viessmann is supportive of demand management in energy consumption as an effective way to reduce energy use; cutting carbon and lowering fuel bills. In particular, we support the approach ‘system plus’ which can apply to existing boilers and renewables in future. The approach ensures that boilers and heating systems are installed and operated optimally. This can be achieved through robust regulation in the heating sector applying many of the principles outlined in the ‘Each home counts’ review which targets renewables but the approach is applicable across the sector to ensure installation best practice and consumer protection.</p> <p>Alongside this, cost-effective technologies such as boiler controls, weather compensation and hydraulic balancing ensure a system is operating optimally. This ensures system efficiency with minimal human input but also no loss of comfort, which mitigates many behavioural constraints related to demand reduction. Payback periods are also relatively short for these technologies and intervention points such as a gradual strengthening of building regulations could increase their use. More details on hydraulic system balancing and system plus are provided below.</p> <p>In relation to rebound effects, most private end users adjust their heating in response to variations in their thermal comfort, driven by the typical start/stop performance of a boiler operating as heat generator for a high temperature heating system, coupled with room thermostats that traditionally have a high tolerance of +/- three to five degrees C. In our scenario of a balanced and weather compensated heating system, modulation of the flow temperature and integration of a digital thermostat ensures that heating comfort is improved and internal temperature delivery is stabilised to a much smaller thermal tolerance, therefore, it is anticipated that adjustment of heating circuits will in fact decrease and there will be very minimal rebound effect as the root cause has been marginalised.</p> <p><u>Hydraulic balancing and system plus in detail</u> <u>Hydraulic balancing</u></p> <ul style="list-style-type: none"> ▪ Hydraulic balancing of a heating system is necessary to ensure that all heat emitters in the system are supplied with the same level of heat at the same time. ▪ This requires the flow rates in the heating circuit piping, the output of the circulating pump and the heating curve of the heat generator to be adjusted very precisely. Subsequently, it is ensured that no room is under- or oversupplied with heat and that the energy is used in the most efficient way. 	

- Hydraulic balancing, as part of a package of measures such as advanced controls, has the potential to reduce energy consumption of a heating system by up to 15 percent – therefore hydraulic balancing can fundamentally maximise efficiency and reduce CO2 in the long term.
- However, unlike commercial installations, hydraulic balancing is often not done in domestic properties because it is perceived to be a complex procedure and requires a lot of time as well as expert knowledge. However, significant progress has taken place over the last few years with several developers, including Viessmann, developing automated or simplified hydraulic balancing processes that render it easier for installers to implement.
- An innovative solution is provided by these automatic hydraulic balancing systems which are already being used in the market. The Viessmann solution, Vitoflow, simplifies and accelerates the execution of hydraulic balancing and is a precise and reliable method of balancing the heating system. Other novel systems are also available developed by Grundfos, Danfoss and Schneider amongst others. Simpler manual options for hydraulic balancing are also available that do not require specialised equipment.
- Legislation should aim to incentivise hydraulic balancing in all interactions installers have with consumers including regular maintenance visits, spot checks, or radiator and pump replacement. The Energy Company Obligation (ECO) scheme also presents another intervention opportunity and including hydraulic balancing as a proposed and eligible measure helps support the aims of the scheme.
- In Germany, the benefits of hydraulic balancing are already recognised¹ and in August 2016 a scheme was launched to support hydraulic balancing².

Advanced system controls – weather compensation

- Weather compensation should be a necessary component of boiler installation. It is a proven, low cost, non-disruptive technology developed by all key market participants and mandated in other leading markets like Germany. Weather compensation is also necessary for regulatory changes to lead to real change in heating system operating efficiency by allowing boilers to operate in lower operating temperatures and condense fully.
- Weather compensation is delivered via a small temperature sensor located on the outside of the building, on a north facing wall. This is wired to the internal controls of the boiler and information about the outside temperature is sent to the boiler controller constantly. When the outside temperature changes the boiler responds to either increase or decrease the central heating water flow temperature to compensate.
- Modulating flow temperatures in this way means building inhabitants do not experience a change in temperature. The boiler output is sized to meet the coldest

¹ <http://www.deutschland-machts-effizient.de/KAENEF/Redaktion/DE/Standardartikel/Dossier/B-hydraulischer-abgleich-2.html>

² https://ec.europa.eu/energy/sites/ener/files/documents/DE%202016%20Energy%20Efficiency%20Annual%20Report_en.pdf (see page 4).

conditions, and therefore the boiler can reduce energy consumption for the majority of the year, increasing system efficiency and reducing wear and tear on the boiler. This results in lower fuel bills and also fewer breakdowns which is also of benefit to fuel poor customers.

- Weather compensation is one example of advanced system controls that can provide energy efficiency benefits. Viessmann has commissioned Salford University to undertake research to assess in real life the performance of boilers with weather compensation; the research concluded that weather compensation can deliver immediate energy savings in excess of 7% and enhanced room temperature consistency by preventing overheating. This equates to savings of approximately £65 per annum. The average cost to the end user of an outside temperature sensor for weather compensation, when installed alongside a boiler, is just £33³. Meaning payback under this scenario is achieved in just one year and savings continue for the system lifetime. In a retrofit scenario costs would be around £100 for weather compensation and an additional £100 if installed alongside hydraulic balancing. Meaning costs are still very modest compared to the savings achieved, with a short payback period of just over three years. Potential future smart development could see delivery of hardware-free weather compensation which would come as part of a package included in a smart control upgrade requiring no additional installation cost beyond the smart control.
- Viessmann consider these improvements as part of a pathway approach to achieve improvements in efficiencies in heating systems delivering long-term benefits. Recognition of weather compensation in policy interventions such as ECO not only supports the aims of the scheme but also sends a signal regarding the importance of boiler efficiency improvements such as this.

5.

How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Building regulations are a primary opportunity to improve the standard of energy efficiency in the UK's building stock. However, Building Regulations do not yet go far enough to improve the energy efficiency of new buildings. Updates to Building Regulations could ensure that low flow temperature heating systems and system plus measures are installed in all new builds. This would ensure the UK is not left with a further legacy of buildings which require costly retrofit to improve their energy efficiency. In addition, installation of low-carbon heating in the future would be easier because the heating system would already be enabled for this. Where new build can be improved through regulation, subsidy can then be directed towards existing buildings that require retrofit heating systems through schemes such as the Renewable Heat Incentive (RHI). Overtime such schemes should enable cost-reduction to deliver a self-sustaining market for renewables and low-carbon technologies. The pathway to zero carbon should be reinstated.

³ See policy paper 2 'Developing tailored support for "boiler plus" solutions' for more details

6.	<p>What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?</p>
<p>The power, heat and transport sectors are becoming ever more interrelated; electricity is increasingly destined to heat building as well as power them (such as heat pumps or combined heat power systems in place of fossil fuel boilers) and energy from buildings is used to power a growing number of electric vehicles. Ensuring collaboration and avoiding inconsistencies across these sectors will be important to the supply of infrastructure; In particular, where inconsistencies may discourage investment or job growth. For example, installers can become deterred by high training costs or lack of information on new technologies, causing fewer to enter new sectors instead opting to stick to the status quo. This limits the number of installers delivering low carbon or renewable measures. Similarly, consumers can also be deterred, for example if not enough information is available on a new technology or if there is too much information on several technologies. This can limit their interest in installing low carbon measures. Ensuring installers are equipped with the right information to share with consumers can help to overcome this.</p>	
7.	<p>What changes in funding policy could improve the efficiency with which infrastructure services are delivered?</p> <p><i>Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.</i></p>
<p>With regards to funding policy it is important to carry out thorough market research into which methods will motivate consumers to make changes whilst at the same time ensuring robust methods for managing budget. This will help minimise scenarios where a scheme is under-utilised because it doesn’t provide enough incentive or where a scheme is closed rapidly because it is over-subscribed (typically called ‘boom or bust’).</p>	
12.	<p>What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?</p> <p><i>Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions</i></p>
<p>We would support more recognition of the longer-term wider benefits of improvements to energy in buildings. As outlined in answer to question 1, having buildings suitable for purpose for both domestic and commercial use can have wide-ranging benefits such as improved health of UK citizens from living in warmer homes and on the UK economy through more manageable fuel bills. These benefits should be recognised when carrying out cost-benefit analyses.</p>	
<p>Energy</p>	

19.	<p>What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?</p>
<p>Decarbonising heat is strategic priority for government. One of the most important points in achieving required levels of decarbonisation is to ensure industry and investors are given clear signals on policy direction. Under previous governments schemes have been developed setting a direction and industry has been quick to develop approaches and supply chain for delivery. However, frequent changes such as to the Renewable Heat Incentive (RHI) or scrapping of schemes such as the zero carbon homes regulations mean industry and investors quickly lose confidence. Without a steady and growing supply chain in the low-carbon, renewables and energy efficiency sectors longer-term targets will be harder to achieve.</p> <p>A long-term direction should be set that considers a mix of technologies appropriate to the various types of buildings and their uses in the UK. This includes renewables and low-carbon technologies such as biomass, CHP, gas heat pumps and fuel cells and energy efficiency measures such as boiler controls, weather compensation, system balancing. Government should provide subsidy for strategically important technologies to support commercialisation and to bring technology costs down to achieve self-sustaining markets. At the same time technologies that are already cost-effective such as boiler controls and system balancing can be implemented through a gradual tightening of regulations.</p> <p>It is also worth noting that the majority of the installation network is familiar with gas boilers and very little else. To effectively implement de-carbonisation, installers need to be part of the solution, as they provide the initial options to consumers and without their support the adoption of low carbon solutions will not be realised. Therefore, the construction of separate regulation and certification requirements for installers to bring their skills up to date, should be carefully planned and costs to the installer minimised.</p>	
20.	<p>What does the most effective zero carbon power sector look like in 2050? How would this be achieved?</p> <p><i>Note: the “zero carbon power sector” includes the generation, transmission and distribution processes</i></p>
<p>The Committee on Climate Change (CCC) provide a pathway to low-carbon heat in the UK in their 2016 document ‘The future of heating in UK buildings’. We are broadly supportive of the proposed illustration of how UK heating could look in 2050. This includes; ‘in rural areas buildings not connected to the gas network could switch to biomass or heat pumps’ and ‘buildings connected to the gas network could switch to ... heat pumps, while some others could continue to use gas/biomethane. Low carbon heat networks could be built and extended’.</p> <p>In order to achieve this, as outlined in answer to question 19, there needs to be a clear and consistent policy pathway which provides confidence to industry and investors regarding the outlook for the zero carbon power sector. Subsidy will be required to ensure commercialisation of some technologies whilst the use of other technologies which are already cost-effective can be increased through gradually tightening of regulation.</p> <p>However, regarding the CCC recommendations for hydrogen, power-to-gas is a more realistic and proven route to decarbonisation, whereas hydrogen, as CCC point out, requires further feasibility and public acceptability to be proven. Power-to-gas can also</p>	

rely on renewable sources, does not need carbon capture and storage, or the mass storage of hydrogen, or the wholesale conversion of the gas infrastructure or the replacement of existing gas appliances.

To create synthetic methane gas (CH₄) for injecting into the grid, power-to-gas uses excess wind and solar electricity to split water into hydrogen and oxygen by means of electrolysis. The hydrogen is then mixed with carbon dioxide from a biogas system and converted, using a microbiological process, into methane gas. The methane may then be fed into the natural gas grid or stored. In addition, there is also a process for upgrading technology for raw biogas supplied by biogas and sewage plants. As a scalable technology, power-to-gas can provide almost unrivalled energy storage capacity - an advantage over hydrogen, which is voluminous and expensive, and over electricity, which suffers standing losses.

The synthetic methane can be used for gas heating as a low carbon heating solution, or used to generate electricity through combined heat and power (CHP) units. As a fuel, it can be stored and transported with minimal impact.

An example of where this technology has been proven is at Viessmann's head office at Allendorf in Germany, where the methane produced by power-to-gas is being fed back into Germany's natural gas grid. This is a major part of a combination of measures, known at Allendorf as Efficiency Plus, which has reduced the consumption of oil and gas by 60 percent and cut CO₂ emissions by a massive 80 percent.

The biological methanation process at Allendorf runs under a moderate amount of pressure and at relatively low temperatures. It directly processes the carbon dioxide contained in the raw biogas, meaning the CO₂ doesn't need to be present in high concentration or purified form. This is significant because it opens up new procurement paths. Smaller sewage treatment and biogas plants, in which no biogas purification is performed, can now also be considered as CO₂ sources. This is an additional benefit as it increases our capacity to capture CO that would be produced by natural plant decomposition and use it constructively.

As outlined power to gas is already proven and has potential in the UK. Minimal incentives and support can bring forward more projects in the UK and support with delivery of a cost-effective route to decarbonisation.

21.

What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

As outlined in answer to question 20 we consider power-to-gas an important strategic technology in the heat and power sector. The benefits of power-to-gas are relevant to the growth in use of low carbon vehicles as the power, heat and transport sectors are becoming ever more interrelated; electricity is increasingly destined to heat building as well as power them (such as heat pumps or combined heat power systems in place of fossil fuel boilers) and energy from buildings is used to power a growing number of electric vehicles.

Dealing with a whole systems approach instead of dealing with sectors in silos will prove more effective in meeting renewables targets in the long-term.

Virgin Trains East Coast: submission to the NIC's National Infrastructure Assessment (NIA) consultation.

February 2017.

1. About Virgin Trains East Coast

- 1.1 Stagecoach and Virgin are working in partnership to operate the East Coast inter-city route under the Virgin Trains brand.
- 1.2 We launched the new East Coast franchise in March 2015 and are investing £140 million aimed at improving the passenger experience which has already seen the refurbishment of our entire existing fleet.
- 1.3 May 2016 saw the launch of 42 additional services (22,000 extra seats) per week between Edinburgh and London.
- 1.4 We will shortly see the launch of 65 new Virgin Azuma trains providing 12,000 extra seats for a new and expanded timetable, increasing capacity into King's Cross by 28% during peak time and enabling Edinburgh-London journey times to be cut to around 4 hours.
- 1.5 We have been running the West Coast franchise for 20 years in which time we have more than doubled passenger numbers, cut journey times, expanded our timetable and grown our passenger satisfaction scores.

We currently run 157 weekday services on the ECML and 111 Saturday/Sunday services with a grand total of 1,009 trains per week.

This will increase further from 2018 with the launch of our 65 new Azuma trains and expanded timetable increasing services to existing destinations as well as bringing direct services to other towns and cities for the first time.

21.1 million journeys were made on Virgin Trains services on the ECML in 2016.

2. Executive Summary

- 2.1 Britain's railway network is vital for economic growth, to create jobs, support UK businesses and to enable housing development.
- 2.2 Passenger numbers on the UK's rail network have doubled over the last 20 years.
- 2.3 The East Coast Main Line (ECML) is a vital rail artery which already generates more than £300 billion to UK plc. The long-distance high speed services generate significant premiums for the Government, accounting for approximately one third of farebox income.
- 2.4 The ECML connects local and regional economies with each other, the national economy and to Europe on routes totalling over 936 miles from northern Scotland all the way down to London.
- 2.5 Our ECML services support local and regional economies across the 'Northern Powerhouse' in Yorkshire, Nottinghamshire, Lincolnshire, Durham and Northumberland. The ECML is a vital tool therefore in supporting the Government's Industrial Strategy.

- 2.6 The ECML however has not seen the level of investment seen on the West Coast Main Line (WCML) meaning that key infrastructure assets on the ECML, such as signalling and wiring is over 30 years old and reaching the end of its design life.
- 2.7 This is having a negative impact on services, hitting punctuality and thereby undermining UK productivity and economic growth.
- 2.8 Stretching from Inverness down to London via the north east, Yorkshire and the east midlands, the ECML has a key role to play in helping rebalance the UK economy.
- 2.9 An investment of between £2 billion - £4 billion over a 10 year period as recommended by Network Rail would help would unlock the ECML's currently restrained potential and bring significant economic benefits both locally and for the national economy.

Independent research compiled in 2016 for the East Coast Main Line Authorities (ECMA) – which represents the local and combined authorities along the ECML route - shows that an investment of £3 billion starting from 2019 will generate £9 billion of benefits for the UK economy.

This investment in the ECML would maximise the benefits of HS2, with an extra £5 billion being unlocked for the UK economy initially, then rising to £9 billion when combined with the benefits of the eastern leg of HS2.

3. The current challenge

- 3.1 The ECML is currently restrained by infrastructure assets which, having being installed during the modernisation of the line in the 1980s, are naturally reaching the end of their design life.
- 3.2 These include signals, cabling, power supply equipment and overhead wiring.
- 3.3 The biggest issue from a performance point of view is overhead wiring.
- 3.4 Passenger numbers on the ECML have more than doubled since the 1980s modernisation programme.
- 3.5 This means the strain on this infrastructure is having an increasingly noticeable impact on passenger journeys.
- 3.6 Disruption caused by faulty infrastructure hits not only passengers' onboard experience but hits the UK economy and of course the revenue returned to the DfT.
- 3.7 In congested areas on the route, there's a significant need for additional tracks, grade separated junctions, removal of level crossings, and lengthening of platforms in strategic locations.
- 3.8 While HS2 will be useful in providing lots of extra long distance capacity, HS2 will not alleviate the many bottlenecks and weaknesses in the current infrastructure.

Over the summer of 2016 services on the ECML suffered from significant delays due to faulty overhead wires at Ranskill, near Retford in Nottinghamshire.

As a result of the Ranskill dewirement, over the period from 6th September to 11th September, we handled over 24,000 Delay Repay claims from delayed passengers which equated to around £1.5 million.

4. Boosting economic growth both locally and nationally

- 4.1 The ECML already links communities and economies across many different counties and regions, linking smaller towns to nearby cities as well as providing a long distance inter-city connection.
- 4.2 From 2018, our planned expanded timetable for our 65 new Azuma trains will not only increase the services to existing destinations such as Leeds, York and Bradford, but also bring direct services for the first time to Huddersfield and Middlesbrough.
- 4.3 This will bring more services, more seats and reduced journey times, on both existing routes but also connecting certain economies directly with each other for the very first time.
- 4.4 This will support the Government's ambition to drive economic growth in every region of the country and boost UK productivity through better connectivity.
- 4.5 However, investment and improvements are needed now to ensure the benefits of these services are delivered and built upon in the coming years as passenger numbers increase further. If we cannot make the basic infrastructure more resilient then upgrades will not be able to deliver the full benefits expected.

For its size Middlesbrough currently has the poorest rail service to London of any city in the country apart from Bradford. However, Virgin Trains will be introducing direct Middlesbrough-London services from 2021.

Independent research by the local authority has found that the introduction of a direct Middlesbrough to London service every 2 hours could generate upwards of £5.8million per annum in additional GDP.

5. Unlocking the ECML's potential through investment

- 5.1 With the introduction of our 65 new Azuma trains from 2018 and the increase in the number of electric trains on the ECML (increase in Govia Thameslink traffic and replacement of Hull Trains' and TransPennine Express's diesel trains with electric/bi-mode trains) the overhead line infrastructure on the ECML needs to be more resilient.
- 5.2 Resilience is the most important issue to be addressed to improve punctuality and performance and unlock the true potential of the ECML.
- 5.3 Replicating the investment seen on the WCML would help bring about this improvement.
- 5.4 The 2008 upgrade of the WCML at a cost of £8 billion removed bottlenecks and increased line speeds through four-tracking and extensive re-modelling along with renewal of existing assets such as the power supply.
- 5.5 This enabled Virgin Trains to deliver a new high frequency timetable, increasing capacity and line-speed which enabled us to increase services to places including Manchester, Birmingham, and Chester and up to Scotland along with new services to places such as Wilmslow.

An investment of between £2 billion - £4 billion is required on the ECML.

To replicate the benefits seen on the WCML as a result of the 2008 upgrade, Network Rail estimates that an investment of between £2 billion - £4 billion is required over a 10-15 year period from 2019.

5.6 As part of this investment, the following schemes should be delivered which would significantly improve performance, reliability and cut journey times:

- Full closure of all level crossings on the ECML.
- Full portalisation of the overhead line equipment, and renewal of life-expired overhead line components.
- Palisade fencing along the full ECML (replacing post and wire fencing) to eliminate the many instances of trespass and animal incursion onto the high speed railway
- Grade separation at Newark flat crossing to cut ECML journey times and provide capacity to increase east-west service frequencies.
- Increase in linespeeds from 125mph to 130mph-140mph in targeted locations, to enable Newcastle-London journey times to be cut to under 2h30 and Leeds-London to under 2h00 (taking advantage of our new Azuma trains which have both ERTMS Level 2 and 140mph capability).
- Other grade separation such as from the West Riding to the ECML north of Doncaster on the Up line (towards London).
- Increasing linespeeds between Doncaster and Leeds to cut journey times.
- Through routing of trains through Darlington enabling them to make a quicker approach
- **Digital Railway** – VTEC are very supportive of the need to develop a digital railway infrastructure and believe it is vital to solve the issue of capacity and remove restrictive signalling logic.
- This requires the delivery of the Digital Railway systems, especially ERTMS (European Rail Traffic Management System) Traffic Management and C-Das with Full ERTMS Level 2 throughout ECML.
- This will allow VTEC to enhance its train services through: timetable planning to the second rather than to the minute; more effective management of the mixed traffic on the ECML; and making on-the-day, real-time changes to our train plan that are effective and are communicated to our customer systems, improving reliability and recovery from delays. (This is affected however by the delay in delivering ERTMS in control period 5 - as originally planned – having now been deferred to control period 6).

6. The role of the National Infrastructure Commission

- 6.1 Virgin Trains welcomes the opportunity to submit to the NIC's first consultation.
- 6.2 We acknowledge the value in the NIC providing impartial, expert advice on major long-term infrastructure challenges.
- 6.3 Investment in the ECML will not only benefit existing passengers in the short-term but it will also drive long term growth and productivity in the regions it serves.
- 6.4 With rail passenger numbers set to grow across the whole rail network, it is important that one of the longest and busiest intercity routes in the UK is fit for purpose.
- 6.5 We believe that the NIC would be a powerful advocate for investment in the ECML.
- 6.6 The Department for Transport is currently evaluating the investment priorities for rail Control Period 6 and an influential voice, like the NIC's, will further strengthen the case for investing in the line.

National Infrastructure Commission call for evidence

- 1) **Water UK is pleased to respond to this call for evidence.** We are a membership organisation which represents a range of water service providers, including all major statutory water and wastewater companies in England, Scotland, Wales and Northern Ireland.
- 2) **We appreciate the call for evidence is by its very nature, cross cutting, and there are questions that are not relevant to the water industry.** We have therefore grouped our responses, with the relevant question number in brackets.
- 3) **The supply of water and waste water services are critical to our economic, social and environmental wellbeing. We have a good track record but lots still to do meet future needs on water and waste water, using demand and supply side measures** (1, 4, 22, 23)

Companies in England and Wales have invested more than £130 billion since privatisation in 1989, and have ensured safe, reliable drinking water supplies, efficient wastewater and water recycling services, and improvements in the environment.

However, the challenges to come are significant. Water UK's recent long term water resources report¹, which we have shared with the NIC, suggests there is a significant and growing risk of severe drought impacts arising from climate change, population growth and environmental drivers - pressures that will also be suffered by waste water services.

Challenges associated with existing drought risk (resilience) and reductions in available water to protect the environment are immediate and need to be addressed over the next 10 years. Beyond that, increasing populations and hotter temperatures will drive up demand for water. The hotter temperatures will increase evaporation during spring and summer and, although the impact of climate change on rainfall is uncertain, the possibility of more prolonged dry periods cannot be excluded.

Work has been continuing on long term water resources to understand better the gaps that still remain, including the extent to which companies are using adaptive planning methods in their draft Water Resource Management Plans. A brief paper covering this is attached as Appendix 1.

Water UK's Water resources long-term planning framework explored the extent to which demand management could form part of the sector's solution to the growing gap between supply and demand. Demand management has a fundamental role in providing a greater level of resilience, and to reduce the potential risk of investment that might be regretted at a later stage.

The report recognised the case for considering more extensive programmes of demand management, and, as you might expect, there is a range of views amongst companies,

¹https://dl.dropboxusercontent.com/u/299993612/Publications/Reports/Water%20resources/WaterUK%20WRL%20TPF%20Final%20Report_FINAL%20PUBLISHED.pdf

depending on size, structure and geographical location, about the most effective way of achieving reductions this way.

In some companies' view, programmes of measures need to strike a balance between a level of ambition that provides more significant savings than those realised at present, and a recognition of the risks associated with an over-reliance on projected savings that rely on wider factors.

Issues to note include the extent to which some of the more ambitious strategies identified in the report rely on significant behavioural change, as well as significant future innovation to reduce costs below their current levels to make the options economically feasible. For these to be realised, they would also rely on significant regulatory and policy support – for example, in mandating high levels of water efficiency in new build homes.

A variety of conditions exist within the sector, with a significant difference between the wetter north and west, and the drier south and east which, as an area classified as one of severe water stress by the Environment Agency, is one where compulsory metering is an option companies can consider. Companies' differing levels of headroom, coupled with differing growth projections mean that, while some companies can offset projected growth through demand management measures alone, this is not possible for others. In the Thames Water region, for example, demand management can offset up to half of the high levels of expected growth. In some cases, therefore, while demand management remains a central element of companies' response to the supply demand deficit, supply-side measures will be essential to bridge the gap.

Some of our smaller companies, feel that the market is able to deliver far more robust and cost-effective embedded demand-side measures, particularly with new build properties, the majority of which will be built in the water resource critical areas of the South and East of England. For example, Albion Water says it has clearly demonstrated that it is possible to create embedded demand-side measures into these new communities, using water for toilet flushing and external use, potentially reducing potable demand to 80 litres per head per day with no loss of service and no financial penalty to customers (usually a benefit). These structural solutions, Albion says, reduce peak demand on potable systems considerably, thus improving network asset utilisation, as well as addressing local drainage and sewerage challenges.

In terms of the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand (Q23): Water UK has led a sector wide initiative in this area, 21st Century Drainage, and had the opportunity to present the work to the Commissioners last year. We outline the work of the Programme in more detail later in this submission. We have worked very hard to ensure the programme covers all administrations, and we have support from the governments, economic and environmental regulators of all four nations of the UK.

4) A more holistic, joined up and outcomes-based approach is key to future success (3, 6, 9, 10, 11, 24)

The pressures we have already identified around population growth have led to another primary priority for successive governments – housing growth. Sufficient housing is imperative for a functioning society, but often, planning for new housing developments come first, and infrastructure is considered afterwards – it should be the other way around. There is a significant potential for community level infrastructure that both saves water and reduces flood risk - e.g., communal rainwater harvesting for garden use, permeable paving, green roofs for community buildings, front lawns and community green spaces – these should be the first and default options for proposed developments. However, while water companies are exploring their ability to play a much greater role in one aspect of this, namely, SuDS adoption, it remains a matter of regret that the more integrated approach of Schedule 3 of the FWMA 2010 was never implemented.

It is clear for both water resources and wastewater and water recycling services that we will need all the “tools in the box” – and many incremental improvements will, cumulatively, make a significant difference to the overall pressure on resources.

It has become increasingly clear to many companies that integrated catchment management, dealing holistically with the problems of too much and too little water, is a sensible method of planning for the future given the uncertainties of climate change and population growth. According to the consultancy, Indepen, an estimated 13 billion pounds per annum is spent on supporting the environment and agri-environment schemes:

Catchment spending by purpose

Annual spending on England's catchments (£m) - by purpose				
Purpose	Total England (£m)	Total Southern Water region (£m)	Total South West Water region (£m)	Total Wessex Water region (£m)
Pollution control and enhancing natural capital of land	7,883	827	533	496
Rural land management	2,444	361	292	167
Water company - sewage treatment	1,277	174	100	116
Pollution control	1,231	157	60	111
Green infrastructure	761	67	24	45
Conservation management	354	35	31	30
Catchment regulation	302	30	18	25
Green growth	84	4	8	3
Flooding, drainage and raw water for supply	5,699	453	113	287
Water company - drinking water collection and initial treat	1,389	59	63	46
Flood damage	1,280	112	39	74
Water company - sewers and drains	1,196	134	55	66
Drainage and irrigation	931	78	25	53
Inland flooding- capital	412	31	24	17
Inland flooding- operations	230	24	12	17
Research	165	14	5	10
Inland waterways	97	-	-	3
Grand Total	13,353	1,280	755	783

The money is often used in a piecemeal and disjointed way, with catchment schemes sometimes working against each other. A key blocker has often been the regulatory system itself, which can discourage collaborative working - for example, the pooling of resources to achieve outcomes that are desirable to all parties in a catchment, thus making

the most effective use of finite resources. Often, catchment operators have had to find ways of working around the regulations, rather than being empowered by a regulatory structure which supports and encourages collaboration.

The policy work presently being undertaken by government to provide an alternative to CAP could present an ideal opportunity both link water and agricultural policy and to support more catchment based collaboration. Without this, such solutions are always difficult as they may well breach the “polluter pays” principle. A new, effective regime will require all parties to agree a different style of outcomes and investment approaches; one whose compliance assessment is flexible, and where existing controls of diffuse pollution are developed further developed so as to be effective and then enforceable.

5) For both water supply and drainage, the key now is how the available evidence is used in the forthcoming regulatory processes (22, 23,24)

Within a regulated industry such as the water sector, delivery of long term outcomes for customers and society are heavily influenced, and in many cases determined, by regulatory processes.

In England and Wales, companies will be incorporating and building on the evidence from the long term water resource report in their next 25-year Water Resource Management Plans. These plans will also form a key foundation of companies’ business plans for the next periodic review by Ofwat of price and service levels in England and Wales, PR19 – business plans which will also incorporate the latest available evidence from the 21st Century Drainage programme.

Through different mechanisms – for example for England and Wales via the Strategic Policy Statements due to be consulted on shortly by the UK and Welsh Governments respectively – the UK and devolved governments have the opportunity to provide a strategic steer on the short, medium and longer term priorities for the sector.

6) For drainage, the key is better capacity assessment and simplified accountabilities (22,23,24)

Wastewater planning has some catching up to do to achieve the sophisticated approach companies employ in water resource planning (hence the 21st Century Drainage Programme), and this may take more than one AMP to achieve, but the water industry is both ambitious and confident that the work being done through the 21st Century Drainage Programme will lay solid foundations upon which to build in future years.

The water industry has an excellent record of achievement so far, which we detail in the 21st Century Drainage Communications document:

<https://dl.dropboxusercontent.com/u/299993612/Publications/21st%20Century%20Drainage/21st%20Century%20Drainage>.

If those responsible for urban drainage systems are expected to take further control they should be given powers to control the entry of surface water, plastics etc., into the system. To do that the ownership and accountability / responsibilities for urban drainage need to be reviewed to simplify the landscape and ensure there is a single controlling mind to

investigate, understand and then direct solutions. As so many parties are currently involved in the drainage landscape, it has sometimes been difficult for companies to ask customers meaningful questions about flood resilience and water companies' role in this.

7) We have identified that water supply measures are affordable but have more to do on waste water (5, 8, 23)

While we recognise that consumers will face a range of potential pressures due to investment in essential infrastructure, the investment needed to increase resilience of water supplies is relatively modest compared to the cost of drought.

In most areas the additional costs of becoming resilient to 'severe' drought events are less than £4 per household customer per year, if the right measures are taken early enough. Bill impacts would not be immediate: they will take effect gradually as investment in demand reduction and supply options are delivered. The 'central estimate' of the benefit, that is, of the value customers place on avoiding severe restrictions, is ten times more than this cost, and is still four times greater than the cost even if low case estimates of the benefits are assumed.

As already mentioned, Water UK has led a sector wide initiative in this area, 21st Century Drainage

The Programme has commenced with two prioritised main projects:

- Firstly, a strategic urban drainage planning tool, not dissimilar to that used for determining the long term water resource needs of water companies. A key project underway within the scope of the Programme is that of drainage capacity management. The project aims to better understand the linkage between current and future pressures on available hydraulic capacity and in turn on outcomes, to facilitate the development of optimal long term interventions by:
 - Reviewing and developing high level methods for the assessment of the available capacity of sewerage systems;
 - Assessing the uncertainties around future pressures;
 - Developing an associated framework that utilises the above information to facilitate long term (25 years +) and contextualise the associated interventions, and
 - Developing effective visualisation techniques to inform relevant stakeholders.
- Secondly, we are developing new design guidance for storm overflows which prioritises investment at an affordable pace.

We are also commencing a piece of work to define and agree a set of wastewater resilience metrics to ensure that we, as a sector, can track progress effectively.

These projects will provide the basis for water companies to cost the AMP7 (2020 to 2015) investment requirements for their drainage assets within the context of the longer term resilience needs of catchments. The first two projects are jointly led with the Environment Agency and promise real benefits to the sector's customers as well as to the

environment. The first conclusions should be ready for both projects in early spring; we will of course share any findings with the NIC as soon as possible.

Further projects have been outlined for delivery over the next two to three years in what will inevitably be an iterative process. The important principle has been to prioritise this Programme to ensure that we deliver the long term planning tools first. Subsequent projects will focus on, for example; innovative solutions, identification of impediments to change, enablers, how best to nudge customer and business behaviour, and evidence gathering to support the need for policy change..

We are in a better place now that organisations with responsibilities across the drainage landscape have joined together to work collaboratively on this 21st Century Drainage Programme. We look forward to embedding long term planning within the sector and enhancing the resilience of the UK's drainage infrastructure such that we are able to effectively manage the challenges of climate change and population growth for people and the natural environment.

A factor that could have an impact on the affordability of both water and wastewater services is the future availability of finance from the European Investment Bank.

The European Investment Bank (EIB) is currently the largest single lender to the UK water industry, with EIB debt being around 13% of gross outstanding debt at March 2016, and over £6.5 billion borrowed by the ten water and sewerage companies in England and Wales over the period 2005-2016.

Companies currently borrow from the EIB for several reasons, including the flexibility of being able to readily borrow in a variety of formats (fixed rate, floating rate or index-linked) and to vary the timing of drawdown of loans for minimal costs, and the ability to raise substantial amounts of index-linked debt.

The primary benefit of EIB lending to water companies, and their customers, however, is the lower rates that lending is provided at compared to other sources of debt financing.

At this point, it is unclear whether the EIB will be able to maintain its role as a provider of finance the UK water industry following the UK's withdrawal from the EU; if it does not, then other things being equal, costs to customers will be higher.

8) We have made progress on resilience but have plenty still to do (23, 24)

The industry is actively involved in several areas which are providing more detail to our understanding of resilience:

Water UK led the formation of Water and Wastewater Resilience Action Group. Its objectives are:

- o To define qualitative standards for resilience across England and Wales.
- o To share best practice where appropriate.
- o To engage widely with relevant stakeholders.

Water UK NIC call for evidence submission

- o To identify and provide support for individual proposals for research especially where such support will act as a catalyst in encouraging further funding from other sources.
- o To actively seek ideas for research in areas of members' needs but which do not have sufficient funding available from elsewhere.

The group has already started work on defining some metrics for resilience, in preparation for the 2019 Price Review. The work on wastewater is being led by the 21st Century Drainage Programme.

We have also worked closely with Defra on the National Flood Resilience Review, assessing the resilience of critical infrastructure to flood events. Companies have undertaken lengthy reviews, investing where necessary.

We would be happy to expand on any of the topics covered in this response in greater detail.

APPENDIX 1: APPLICATION OF ADAPTIVE PLANNING THROUGH THE STATUTORY WATER RESOURCES MANAGEMENT PLANNING PROCESS

Introduction:

In response to increasing levels of future uncertainty, the water industry has modified the way in which it plans future resilience and investment to mitigate risks to supply during drought events. As part of the preparation for the 2019 round of statutory Water Resources Management Plans (WRMPs), UK Water Industry Research (UKWIR) commissioned two sets of guidance that are intended to support better planning in the face of uncertainty, namely; ‘WRMP 2019 Methods – Decision Making Process Guidance’ and ‘WRMP2019 Methods - Risk Based Planning’. These are referred to by the Environment Agency WRMP19 Water Resources Planning Guidance (WRPG), so the principles of resilience testing, links to operational drought measures and flexible methods for planning future investments in the face of uncertainty now form a core part of the WRMP19 process.

Because of the potential need for large scale inter-regional solutions to water resources needs in the future, the Water UK ‘Long Term Water Resources Framework’ identified a need for ‘adaptive planning’ across the water industry, possibly with a requirement for a national level adaptive plan to complement the WRMP19 process. However, following the release of that study, and as a result of the new focus of the WRMP19 WRPG, it is now apparent that those companies and regional organisations that are facing significant future risks to water resources resilience have started to adopt ‘adaptive planning’ type methods themselves as part of the WRMP evaluation process. This has two key advantages over a national level approach:

1. The analyses are carried out to a greater level of detail than could be achieved by a national level plan using methods that are targeted specifically to each region and water company.
2. Water companies are able to liaise with their own customers to understand what level of risk they are willing to face and how they would prefer the water company to adapt to future uncertainties.

Based on this, Water UK therefore considers that the WRMP process remains the best way to adapt to future risks and uncertainties. Evidence relating to the nature of the adaptive planning that is being undertaken, and the best approaches to dealing with any remaining gaps in the planning process, are provided below.

The Industry Approach to Adaptive Planning.

The fact that WRMPs are updated every 5 years means that the WRMP process was already, to a certain extent, an inherently ‘adaptive’ planning process before the new methods were introduced. However, previous WRMPs generally relied on a Net Present Value (NPV) type economic optimisation approach that used a single estimate of the future supply/demand balance to determine investment. This meant there was a risk that investment in water resources would not represent ‘best value’ in the face of future uncertainties. Water companies also tended to plan for a single level of drought risk (a ‘drought design scenario’), which was represented by the data available in the historic record.

Under the new WRMP19 guidance, water companies are now adopting a mix of methods for decision making and the management of risk, which are geared towards the particular nature of the pressures and uncertainties that each company faces. The UKWIR guidance notes

incorporate a specific ‘problem characterisation’ process that allows water companies to review the risks and uncertainties in their own water resources plans and adopt an approach that is suitable to their own situation. In some cases the exact approach is still being developed by some water companies, but a general summary of the methods that have been selected for use in WRMP19 is provided in Table 1.

Table 1: Summary of ‘Extended’ Planning Methods Being Adopted for WRMP19.

Type of Approach	Description	Reason for Adoption	Number of Companies adopting
System-simulation	Methods that use a simulation model of the water resources system to examine how different investment options perform across a defined range of drought severities and futures (particularly climate change futures) to determine which approach represents ‘best value’ in the face of uncertainty	In most cases these methods are being adopted because the <i>resilience</i> of potential future investments varies depending on how climate change and demand develop over time. Companies may also need to evaluate supply risks to customers using a number of different, water storage related, metrics.	>10 (includes WRSE and WRE regional modelling efforts, plus at least 3 companies outside of those regions) ²
Aggregated ‘real options’	Methods that use simpler representations of future supply and demand in economic models, but concentrate on identifying the ‘least regrets’ approach to near term investment in the face of very large future uncertainties. The ‘tactical’ timing of investment is particularly highlighted under this approach.	Companies adopting these methods generally face the largest range of uncertainty in the future supply/demand balance, in particular as a result of uncertainties over the amount of license that is at risk because of the need to protect the aquatic environment. The water resources benefits of investments that are being considered are generally less uncertain, but there is a large risk of inefficient investment if the wrong shorter term plan is adopted.	1-2
Hybrid methods incorporating ‘true’ adaptive planning	WRMPs that incorporate both of the above types of modelling, and represent future investment strategies as adaptive plans that include monitoring and trigger points to allow the plan to be adapted as the identified future uncertainties are resolved.	Companies that are adopting this approach tend to face large near term investment needs and very large future uncertainties, including technical uncertainties over the benefits of new schemes as a result of future hydrology and drought patterns under climate change.	2

² WRSE – ‘Water Resources in the South East’; WRE – ‘Water Resources in the East’

Both the WRSE and WRE initiatives include regional level system-simulation models that are being used to investigate the ‘best value’ investment approach across a number of water companies for a range of futures and drought severities. There are some differences in approach (for example, WRE is multi-sectoral) and the decision making methods do differ between the two initiatives, but the basic principles are very similar. The water companies that lie within those two regions are either using the data and findings from those studies to carry out their own, more detailed, ‘best value’ analyses for the WRMP19 investment plans, or are carrying out complimentary studies using their own system simulation or ‘real options’ type approaches.

Possible Gaps in the New WRMP Process.

In the ‘Long Term Water Resources Planning Framework’ document, Water UK identified that there is a risk that regional scale investments (e.g. large inter-regional transfers) could be difficult to identify and promote unless national level co-ordination is adopted. However, the water industry has actively taken this on board through a combination of bilateral negotiations and discussions between the regional groups and those companies that could potentially provide raw water transfers to those regions. In addition, the WRPG requires that all companies assess the capability of their resources and drought intervention measures across a range of drought severities, so water companies are now better able to compare like with like when they are planning for transfers. It therefore appears that this risk is now being addressed through the statutory WRMP process.

The ‘Long Term Water Resources Planning Framework’ document did identify one further adaptive planning type risk that is unlikely to be captured by the new WRMP process. Under some futures resources can start to become so constrained that demand management measures need to be introduced across those areas that are not currently water stressed in order to allow sufficient transfers to the most water stressed regions. Because such measures would require national level policy intervention, it is difficult to see how this would be captured within the WRMPs or regional studies without some form of national level monitoring and review. This is important, because *the levels of demand management that were contained within the WRLTPF included an assumption that such measures would be used if necessary*. If this strategy is not available then excessively costly resource development or demand side measures may be required under the more adverse futures. Similarly, if the large scale transfers described within the WRLTPF are found not to be viable through the WRMP process, then this will need to be flagged to policy makers as a potential risk to future supplies.

Water UK therefore considers that there is still a need to monitor how drought resilience, climate change and demand are changing at a national level to determine if such a policy risk is materialising. However, because such risks will take some time to materialise, and because all of the relevant data are contained within the WRMPs, it would appear that the most efficient way to do this would be through a high level review that is carried out after each set of final WRMPs is published. Any need for adaptation beyond the current statutory regime could therefore be reviewed once every 5 years following the WRMP process.

A Water Efficiency Strategy for the UK – Consultation

November 2016

Waterwise 180 Piccadilly, London, W1J 9HF

Foreword

Recent evidence shows that we will see increased demand for water from all sectors, and reduced supply because of changes in weather patterns leading to natural water shortages and also because the legislative response to these shortages will restrict water abstraction and potentially, water use. At the same time, we will see greater stress on the water supply networks from extreme weather events and increased demand.

So how will the UK water sector be resilient in the face of these challenges?

This was the question addressed by the recent Water UK report Water Resources Long Term Planning Framework (2015-2065). One of the key conclusions from this work was the need for a greater focus on demand management and water efficiency. This strategy responds to the Water UK report and looks at how water efficiency can be delivered and considers the policy and regulatory changes needed to achieve the extended and enhanced water efficiency scenarios in the Water UK report.

The Water UK report, the upcoming Periodic Review of water company plans, the opening of the water sector to greater competition, the UK exit from the European Union and the increasingly obvious effects of climate change make this a good time to take stock and develop a strategic approach.

A broad range of issues are discussed in the strategy, including:

- Water and energy efficiency in homes – new rebate schemes and enhanced product labelling, large scale retrofit programmes to deliver lower water consumption, reduce household bills and cut emissions
- Water, people and communities– large scale behaviour change and communications programmes to establish a water saving culture
- Water and urban developments – incentives for developers and joined up blue and green infrastructure, that gives greener homes without increased costs and provides healthy resilient spaces and places for people and nature
- Water and the circular economy – tools for water and wastewater reuse, to extract the maximum value out of our use of water
- Water technology, innovation and jobs – citizen science projects, better links between academia and the water sector, an incubator for water efficient products, leading to jobs and economic growth

This strategy outlines the changes to policy and practice that would enable water efficiency to deliver these things. It is a UK Strategy but recognises the differences between the countries that make up the UK. This version of the strategy is the consultation phase and we welcome input from everyone in shaping the final strategy document.

Appendix A – Water efficiency strategies and plans across the UK.....	30

Introduction

The UK faces a number of water challenges. Climate change will lead to increasingly erratic weather patterns, this means less certainty over river flows and rainfall, leading to more floods and droughts. This also casts doubt on the assumptions around the reliability of traditional water sources like groundwater abstraction or reservoirs. Climate change will also mean that the UK will be required to produce more food, as other parts of the world become less suitable for agriculture, and this will require more water use in the UK for irrigation. At the same time, increased population will mean that there will be a greater demand for public water supply.

The extremes of weather and the changes in demand will put an increasing strain on water infrastructure. The links between water and energy will also become more critical, because water is required for power generation and fuel production and at the same time energy is also used to pump, treat and heat water. There will also be issues relating to the interrelationship between water supply and the natural environment. Summer river flows will be significantly lower in the coming decades, and there will be competition for water between public water supply abstraction, power station cooling and agricultural irrigation. Furthermore, lower river levels will cause issues for effluent dilution.

Water efficiency can play a significant role in addressing the challenges faced by the water sector and beyond. Water efficiency is one of the few tools that can address both climate change mitigation and climate change adaptation, it can help the UK meet its climate targets and make the country more

resilient to droughts and floods. It can reduce pressure on infrastructure and it can offset the need for new infrastructure. It can help reduce water and energy bills for households and businesses. It can create skilled jobs and it can offer export opportunities for British innovation. It is at the interface of engineering, social science and ICT and is a modern high-skills sector that could create jobs.

Waterwise is an independent, not for profit organisation with the vision that water will be used wisely, everywhere, every day. We are supported by water companies, product manufacturers, consultancies and others working in managing demand for water. We have developed this consultation with our supporters and input from government and regulators.

Recommendations are provided in **bold, italics and underlined** throughout the document.

Please complete the consultation response form at this [link](#) or email responses **by 31 January 2017** (info@waterwise.org.uk).

Waterwise will be meeting directly with stakeholders over this consultation period also. The final strategy will be launched in Spring 2017 and will include an action plan based on the recommendations in this consultation.

Why do we need to become more water efficient in the UK?

In September 2016 Water UK released their Water Resources Long Term Planning Framework (2015-2065) report ([Water UK, 2016](#)). New modelling techniques and a 50 year planning horizon help to consider the impacts of climate change, population growth, environmental protection measures and trends in water use on water availability. This identified that we are facing longer, more frequent droughts and more acute droughts in future than previously thought. The difference between supply and demand could be significant by the 2040s.

Based on the latest long term national water resources planning research by Water UK – without significant innovation and increased water efficiency we will need expensive large water transfer schemes and new supply options to be built. The report outlines extended water efficiency practices (smart metering, tariffs, retrofitting 65% of properties, new home standards 105 litres per head per day and reduced leakage through active leakage control and pressure management) as well as enhanced water efficiency (all new homes achieve 105 litres per head plus extensive retrofitting, large-scale mains replacement for leakage). The report also highlights significant policy and regulatory support to achieve cost effectiveness to deliver the ‘extended’ demand management strategy.

If we do not take action the impacts of water scarcity will be wide ranging, from impacts on river flows and biodiversity to constraints on economic development, power shortages,

reduced food production and stresses on social cohesion. Yet despite the diverse impacts of water scarcity, these are not widely understood beyond government, regulators and other organisations that are directly involved with managing water resources.

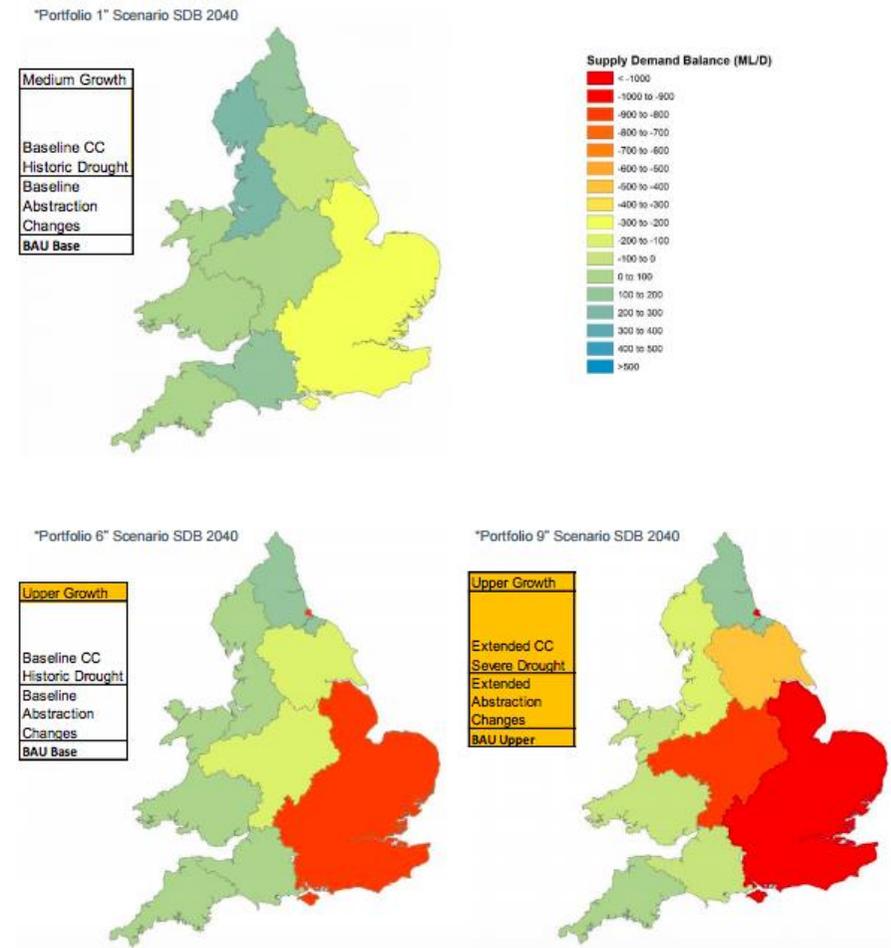

Figure 1 Supply demand deficits project to the 2060s (Water UK, 2016)

Q1. Do you think that water scarcity is a serious threat to the UK?

Q2. Do you think that there needs to be greater consideration given to the impacts of water scarcity and if so by whom?

Q3. Do you think that increased water efficiency is a legitimate response to the threat of water scarcity?

Water energy nexus

Heating water in homes for cooking, personal washing and cleaning produces 5% of the UK's greenhouse gas emissions and a quarter of CO₂ emissions from homes – it is the second biggest use of energy in homes, after space heating, and before gadgets and appliances. By wasting less hot water in homes – through more efficient fixtures and fittings and more efficient use of hot water from taps and showers - these can impact positively on carbon targets. Wasting less hot and cold water will reduce the carbon footprint of the water industry, which would as a result need to pump and treat less water and wastewater (and in turn make the sector more resilient to climate change). The water industry produces 1% of total UK greenhouse gas emissions and Scottish Water is Scotland's largest user of electricity. In short, wasting less hot and cold water cuts carbon emissions, decarbonises the economy and support the creation of new green jobs and technologies.

- ◆ Energy efficiency and fuel poverty retrofit/ advice programmes should include water efficiency measures

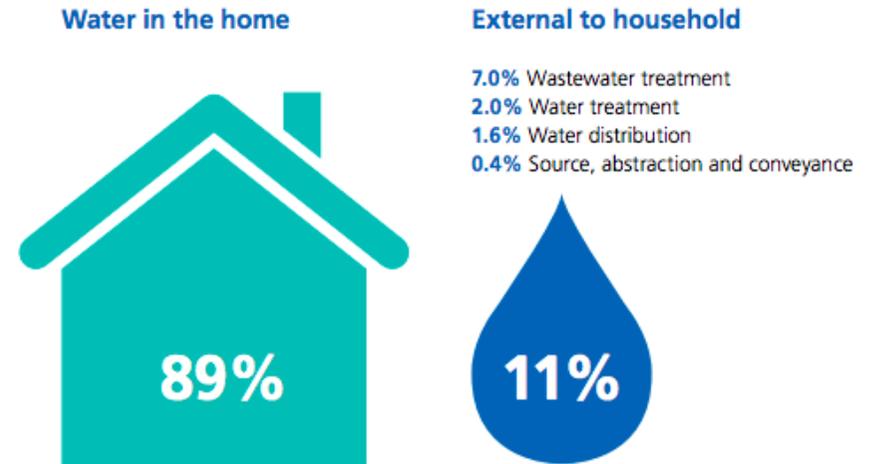

Figure 2 Proportion of carbon emissions from heating water in the home, excluding space heating (*Environment Agency and Energy Saving Trust, 2009*)

Q4. How can we better integrate water and energy efficiency programmes?

How far are we from best practice?

There is currently no agreed definition of delivering best practice water efficiency, however there are many approaches emerging and these are being investigated by the International Water Association. An international assessment released in May 2016 ranked **London 34, Birmingham 28, and Manchester 26 out of 50 major cities** for water efficiency (Copenhagen ranked first). These low scores reflect the progress that needs to be made on metering, water reuse and innovative water charging schemes ([Arcadis, 2016](#)).

The latest assessment of water company performance by the Consumer Council for Water identified a slight increase in water consumption over the past year. Their key findings include ([CCWater, 2016](#)):

- Over the past five years, there has been a downward trend in the amount of water that households are using each day, although fluctuations can be seen throughout the years. However, in 2015-16, there was a slight increase in the amount of water that customers use each day (Figure 3)
- Unmetered households use more water (around 30 litres per person per day more) than metered households

Figure 3 Per capita consumption 2010 to 2015 (CCWater, 2016)

Water UK have developed a dashboard called “[discover water](#)”. This now includes water consumption and leakage data at the individual water company level. There is an opportunity for this dashboard to combine data from several indicators in order to index companies on their water efficiency performance.

- ◆ **The Water UK dashboard and future resilience indicators within this should reflect best practice water efficiency**

There are many international water efficiency examples that could be considered as best practice; parts of Spain and Denmark have managed to reduce per capita consumption of water to 100 litres, without the use of greywater recycling or large-scale rainwater harvesting (IWA, 2016); places like Denver USA or Singapore have developed mass public engagement programmes either through government intervention or marketing; Israel has implemented circular economy principles with 100% reuse of wastewater for agriculture; Singapore has developed closed loop wastewater to driving water systems and Japan has implemented wide scale rainwater harvesting through legislation.

The Water UK long term water resources planning framework developed a water resources zone based approach to per capita consumption targets in their scenarios. This recognised the variation within and between companies and how water efficiency could be achieved. Figure 4 illustrates how a target that reflects the initial consumption could be applied rather than a flat target for all water resource zones. In the US approaches that assess best practice water use/ water budgets at a household level have been used and there has been nationwide and state-wide comparative assessments.

- ◆ Develop indicators/ targets around per capita consumption and best practice

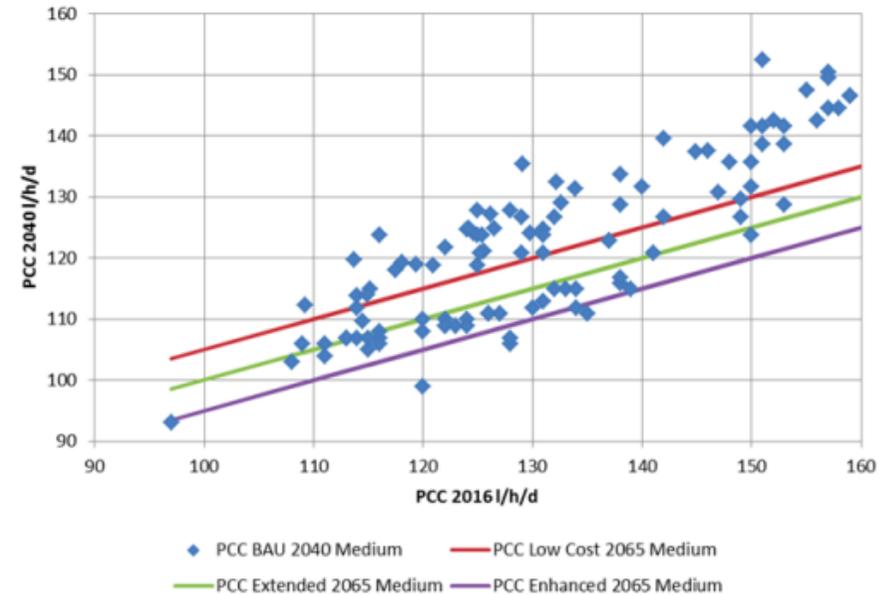

Figure 4 Developing water resource zone based per capita consumption targets (Water UK, 2016)

Q5. How can we better measure and monitor best practice water efficiency in the UK? Is per capita consumption the best indicator?

Q6. Could the UK match international best practice and achieve a per capita consumption of 100 litres? And if so how?

Q7. What other indicators or approaches could be used to help monitor progress or set targets towards greater levels of water efficiency?

What is water efficiency and what is our vision?

For the purpose of this strategy we will use the following definitions:

- Water efficiency involves ensuring the maximum value of water by reducing waste, effectively doing more with less.
- Water conservation involves restricting water use, effectively doing less with less
- Demand-side measures include water efficiency, water conservation, metering and leakage reduction (as opposed to supply side measures such as new reservoirs in water resources planning)

Being water efficient is using the minimum amount of water required to carry out the specific task. By improving water efficiency less water is wasted and the economic, social and environmental value is maximised. Water efficiency has an important role to play in the green economy, an inclusive society and a thriving environment. Water reuse and rainwater harvesting also have a strong role to play in efficient urban water management.

Water saving is something we can all be a part of everyday as shown in the themes for Water Saving Week (Figure 5), held annually in March.

Our vision for this strategy is:

‘A UK in which all people, homes and businesses are water efficient, achieved through smart technology, and regulatory and legislative frameworks for water, energy and housing sectors that complement each other’

Question 8: Do you agree with our definition and vision for water efficiency in the UK?

Figure 5 Water saving week themes

Water, people and communities – changing behaviours

There is a growing and identified trend in the UK towards resource-efficient behaviour. In recent years advice programmes and incentives have targeted energy efficiency, but Waterwise research indicates that households are also keen to be more efficient with water (see some of the key messages from our tracker survey in Box 1).

Box 1: Key findings from Waterwise and Ideal Standard Water Efficiency Annual Tracking Survey in Great Britain (GB) (2016)

- Only 14% of GB adults that pay for their water via a fixed rate bill don't take any actions to specifically reduce their water usage. This reduces to 6% among GB adults with a water meter.
- 82% of GB adults with a water meter reduce their water usage in order to save money, whilst only 30% of those with a fixed rate bill save water for the same reason.
- In 2015 70% of respondents answered yes when asked if they personally take actions to try and save water, in 2016 88% said that they take action.
- There appears to be a lack of communication regarding water efficiency with 62% (in 2015) and 67% (in 2016) of respondents reported having had received no help, information or free water saving devices in the past year. This is highest in Wales, where 85% have not received this. Further, 18% of those that do not take any action to save water did so

because they “had not thought of saving water before”

There is a need to generate a water saving culture throughout the UK. This could be achieved through a large scale combined communication campaign, which would need the involvement of water companies, government and other key stakeholders in order for it to be delivered effectively. This would also require continuous local communications, regularly, for reinforcement of the message.

A recent research project by Kings College London (Lewis, 2016) has identified that there is a lack of awareness of the range of behaviour change methods and a need to build skills/capacity in water companies to deliver this. Of greatest importance is improving the capacity and confidence of water companies to properly evaluate behaviour change programmes. Waterwise are developing a new social science for water network for water to help address this. We are also writing a behaviour change handbook that directly addresses the concerns identified.

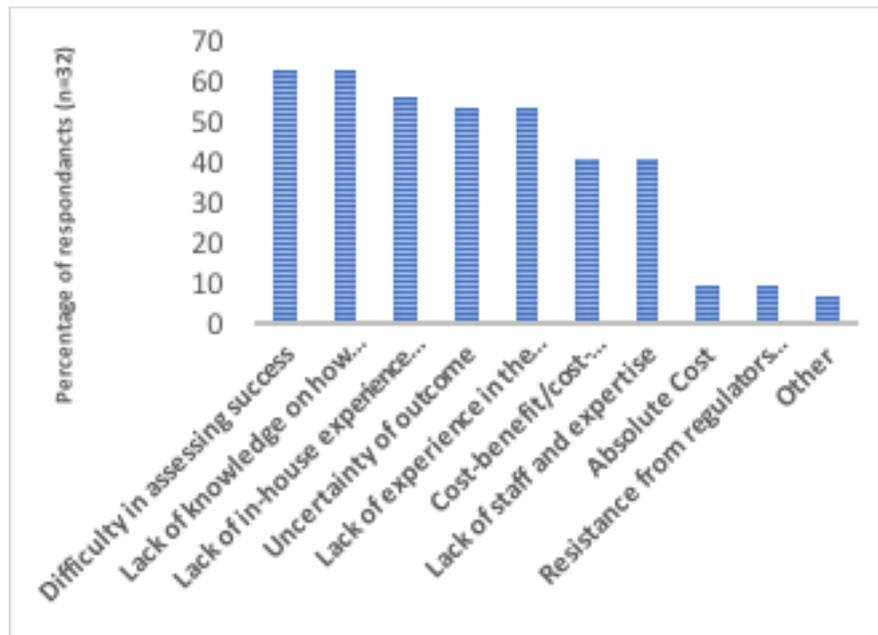

Figure 6 Water utility responses on behaviour change (Lewis, 2016)

There is a lack of consistent messaging and little co-ordinated joint action between water companies and this may become even more difficult as competition is introduced for non-household customers in April 2017 and potentially household customers in the future. The 2012 drought highlighted the importance and benefits of having joined up messaging, however it also demonstrated issues around a lack of awareness and understanding in the community on water resources issues such as supply and groundwater. Findings from Australia ([Turner et al., 2016](#)) indicate that as watering restrictions and communications are removed consumption can increase.

The 2012 drought was the first time that a new range of Temporary Use Bans were implemented. A project for UK Water Industry Research was undertaken to understand the impacts of these restrictions on water use both qualitatively in terms of customer views and quantitatively in terms of water use. Although the impacts of water use were hard to statistically support due to the timing of the implementation with heavy rainfall and flooding, there was a clear message from businesses and households that they'd like better communication in the run-up to a drought. Earlier communication around the drought led to some water company customers having a better understanding of the issues, which possibly supported reduced consumption.

A [UK Drought Portal](#) is now being produced using various standardised indexes of precipitation, evapotranspiration, streamflow and groundwater levels. These enable communication of drought at a higher resolution and easier comparison between different parts of the country. There is also a need to communicate water demand and water storage for each water company to help raise awareness of water resources amongst the general public. The Water UK Discover Water dashboard could be extended to include this.

[SaveWater South East](#) is a partnership of six water companies in the South East, the Environment Agency and Waterwise. It was set up to increase the awareness of water as a finite resource and create a water saving culture by working together via joint communications and projects. It is also looking to work together with other stakeholders interested in water efficiency. The outcomes from this

partnership could help inform wider regional or national water efficiency programmes.

- ◆ *Recognise that developing a water saving culture is a shared endeavour and should not be seen as purely a job of the water industry*
- ◆ *Develop a national water efficiency communication platform as a partnership between Government, the third sector and Water companies*
- ◆ *Behaviour change approaches should be further refined to support water companies in broad communications and integrated with retrofit or metering programmes*
- ◆ *The water companies and the Met Office, CEH, EA, NRW, SEPA should combine resources to provide a water information system for the UK that includes drought and water supply to inform customers and policy makers*
- ◆ *Future guidance on implementing Temporary Use Bans during drought should include considerations beyond the water sector and include more involvement from product developers*
- ◆ *Government should provide guidance for local councils on how they should interpret their water efficiency duties (Water Act 2003)*

Q9: Do you agree with the recommendations for building a water saving culture?

Q10: How can we bring together partnerships to deliver this wider level of awareness?

A water efficiency framework for competition

Through retail competition for water, customers are/will be free to change from their existing monopoly water company to another water supplier. This is really about the “customer-facing” services including billing customers, handling payments, reading meters, and taking calls from customers about network related issues. It does not include water resources management, water and sewerage treatment, or management of water or sewerage networks. These are referred to as upstream competition (Figure 7).

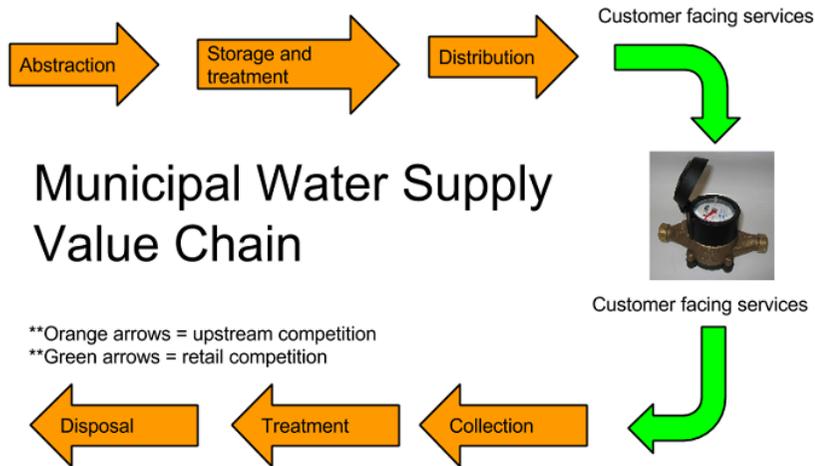

Figure 7 Retail competition elements of the water value chain highlighted in green

Traditionally water companies have a limited relationship with their customers, focussing only on billing or repairs when something goes wrong. Several companies have delivered targeted programmes to businesses, but in general it has been limited to water efficiency services supplied in terms of

online audit checklists or audits for large/ key customer groups only.

Non-domestic retail competition

From April 2017 1.2 million businesses and other non-household customers in England will be able to choose their water retailer. In Wales only businesses using more than 50Ml/year can choose their supplier. This has been possible in Scotland since 2008. In 2014 Business Stream reported saving customers £43m through water efficiency, 20 billion litres of water and 34,000 tonnes of carbon dioxide emissions since 2008 in Scotland ([Business Stream, 2014](#)). The public sector in particular in Scotland is projected to save £36m over four years.

As retail competition is introduced for non-households there are several challenges for water efficiency. These include:

- Capacity to deliver water efficiency services
- Customer awareness of competition and water efficiency services
- Some water companies have outcome delivery incentives from Ofwat linked to non-domestic water efficiency that need to be delivered in this price review period (before 2020)
- Water Resources Planning and access to data to support forecasting
- Bundling water as the cheapest service along with others such as telecoms and energy with higher margins – this would reduce any price signals towards water conservation.

Domestic retail competition

Ofwat have identified disruptive technologies as a potential opportunity with competition. These include improved customer engagement around billing and smart metering. Introducing more smart technologies into homes such as leak monitors or point of use devices such as shower monitors could enable behaviour change. Smart metering in particular is a key innovation that could help customer engagement and behaviour change to reduce water consumption. Ofwat's emerging findings of the costs and benefits suggest that retailers may find innovative ways to lower metering costs, including installation of smart metering with more innovative tariffs and water efficient products ([Ofwat, 2016](#)).

The emerging findings on the costs and benefits of residential competition suggest that water efficiency could have a net benefit of between £98m and £398m. This along with the £177 potential metering benefit would make a large impact on the less innovative and competitive scenarios.

Although Ofwat are only beginning to analyse the costs and benefits of domestic competition, many challenges are similar to non-domestic competition and water efficiency delivery is at the heart of this. Potential concerns outlined by Ofwat and in discussion with stakeholders for this strategy include:

- Customers who don't have access to technology (e.g. internet) can be significantly disadvantaged and are less likely to switch supplier.
- Water Resources Planning – reduced access to customer data due to communication restrictions on wholesalers

- Significantly reduced benefits if water efficiency measures are not implemented
- During drought without clear and consistent communication between retailers there will be much less effective implementation of temporary use bans (watering restrictions) and behaviour change to reduce consumption
- A race to the bottom based on prices – The latest research from CCWater suggests found that 44% of households would need to save over £40 a year before switching retailer, which is unlikely given the margins possible.

A framework for water efficiency in retail competition

Retail competition has the potential to improve water efficiency through:

- Billing and metering
- Water audits and water efficiency measures
- Alternative water sources

To achieve the above outcomes, we need to raise awareness of retail competition and water efficiency services, develop and run training programmes to increase skills and capacity in water efficiency services, and develop an effective comparison approach to help businesses choose retailers based on these services. There also needs for more consideration of how to ensure that all members of the water sector promote water efficiency as the sector fragments, this would include non-regulated participating such as Third Party Intermediaries (TPIs). Ofgem define these in the energy sector as “switching websites, energy brokers and energy efficiency advice providers who interact with energy

consumers” ([Ofgem, 2016](#)). TPIs can offer advice and products to assist with a range of functions including water procurement, efficiency and management.

- ◆ *Develop a water efficiency framework to support new retailers in delivering water efficiency, identify capacity gaps, and provide an independent assessment against the framework to inform consumer choices*
- ◆ *Ensure that as the sector fragments all parties in the water sector deliver water efficiency, this should include non-regulated elements of the sector (e.g. TPIs)*

Q11: Do you agree with the opportunities and challenges outlined for water efficiency from greater retail competition for water?

Q12: Do you agree with the recommendations for developing a framework for water efficiency in competition?

Q13: How can we ensure that non-regulated members (e.g. TPIs) of the water sector help to deliver water efficiency?

Water Sensitive Cities – improving water efficiency in our urban environment

Social Housing

Social housing stock still makes up a significant proportion of properties across the UK, on average of 18% across the UK in 2012 ([ONS, 2014](#)). Local Authorities and Housing Associations regularly run retrofit programmes and there is an opportunity to procure water efficient devices to help reduce water and fuel poverty. Waterwise research (for the Greater London Authority) revealed that 80% of social housing has baths but not showers – this is in part because much of the stock was constructed before showers were considered a standard fitting, and in part because social housing standards such as Decent Homes do not require installation of showers as part of refurbishment ([Waterwise, 2009](#)). This is significant as an average bath uses 80 litres of hot water compared with 32 litres for four minute shower with a water efficient showerhead.

In Wales “Guidance on water and associated energy efficiency for the Welsh Housing Quality Standard for retrofit programmes” was published in 2012 ([EST and EA Wales, 2012](#)). The guidance set out the key reasons for saving water in social housing and detailed what providers can do in procurement and retrofit programmes. It was estimated that if every social housing property in Wales had water-efficient taps, a toilet, and a shower retrofitted then combined energy bills could be reduced by a staggering £3.5 million a year. Similar guidance could be developed for the Scottish Housing Quality Standard or the Decent Homes Standard in Northern Ireland.

- ◆ **Water efficiency should be included in social housing standards (i.e. Decent Homes and Welsh Housing Quality Standard). Any refit or upgrade of existing social housing should include the installation of showers in homes where there is only a bath. Develop voluntary guidance and partnerships with water companies.**

Water Efficiency in New Developments

Although water efficient fixtures and fittings are often no more expensive than inefficient products there is still a perception that it costs more for developers and affects marketability of homes. An opportunity to address this is through an incentive related to the infrastructure charges posed by water companies on new developments (provided for in the Water Act 1991). A variable infrastructure charge linked to the installation of labelled water efficient fittings and fixtures would incentivise greater water efficiency in new developments. Ofwat and Water Companies can agree on the specifics of these approaches with developers. Additionally, there is the potential for part of the developer cost saving to be put towards a fund for water efficiency behaviour change in those homes or delivering wider water neutrality in the area.

Waterwise are trialling this approach with Southern Water in Eastleigh. Developers in Eastleigh are being offered a 50% discount in their water infrastructure connection charge for new builds if they use fittings rated A or B under the European Water Label. The incentive is simple and easily verifiable and uses market incentives to reward developers for environmental improvements. It means that developers can improve environmental standards at no cost and with almost no administrative burden, householders get higher quality

fittings and lower running costs and there are benefits to the aquatic environment and improved water security. The discount is funded by Southern Water but this should be offset by the water efficiency savings generated. This trial is a good example of public, private and third sector organisations working together to develop solutions that work for everyone. This is a truly sustainable approach.

This is the first time this type of approach has been tested and the results will be fully evaluated and the potential for wider roll-out will be assessed. Other water companies are working on similar approaches for water efficiency or water reuse and there is an opportunity to share knowledge in this area.

- ◆ **Variable infrastructure charges to be implemented for new developments to encourage water efficiency measures**

Water efficiency in new developments has been improving, however there are still opportunities to reduce water use and a need to understand actual vs reported water use figures. Changes to Part G of the building regulations in 2010 required that the water use of a home (calculated using the Water Efficiency Calculator for New Dwellings) is no more than 125 litres per person per day. The [Housing – Optional Technical Standards](#) in the National Planning Policy Framework also set out how local planning authorities can set out Local Plan policies requiring new dwellings to meet the tighter Building Regulations optional requirement of 110 litres/person/day.

The Building Research Establishment's Environmental Assessment Method BREEAM development accreditation scheme is the most commonly used assessment of water efficiency for non-households. The [water component](#) provides

up to five credits towards an overall score for a building. A potential limitation with this approach is that it doesn't currently require products to meet an approved standard (e.g. based on a water label) and this in turn doesn't help transform the market for water efficient products and appliances beyond the non-household sector. BREEAM assessment is often a local planning requirement.

- ◆ **Water efficiency standards need to be linked to water labelling and incentives**
- ◆ **Develop a training programme to support new water retailer and also facilities managers in delivering water efficiency services**

New planning frameworks with an increased role for local communities should take forward water neutrality partnerships – with homes, businesses, schools and hospitals in the area receiving a water efficiency retrofit to avoid an increase in overall demand as a result of new local development. For example, Neighbourhood Planning in England gives communities powers to set such policies through a neighbourhood plan and when they grant planning permission through Neighbourhood Development Orders and Community Right to Build Orders for specific development.

Local Area Agreements should require water efficiency in local planning policies. Pilots and incentives should be developed to provide community-scale water provision and sustainable urban drainage – building resilience to flooding and scarcity. Severn Trent Water and a range of partners are trialling physical changes (homes and streets), behaviour

change, and independent testing facilities in their Urban Demonstrator Project ([Severn Trent Water, 2016](#)).

- ◆ **New planning frameworks with an increased role for local communities should take forward water neutrality partnerships**
- ◆ **Local Area Agreements should require water efficiency in local planning policies.**

Retrofits

With less than 1-2% of the total building stock each year being new build, 70% of total 2010 building stock will still be in use in 2050 ([Retrofit2050, 2014](#)). The built environment is currently responsible for over two thirds of total carbon emissions and a majority of public water supply use.

Waterwise research suggests that a partnership approach to water efficiency is the most cost-effective. Partnership retrofitting and behaviour change campaigns tend to show greater uptake, greater engagement and greater water, carbon and financial savings, and to be more innovative than solo approaches. There is a role for social enterprises, co-operatives and community organisations to work together with Government and the water sector to deliver water efficiency. The establishment of partnerships and trusts for resource efficiency could also deliver social and economic benefit to local communities.

Water closet (WC) leakage has been identified as a major issue in the UK. Recent research on around 300 toilets concluded ([Ballinger and Gilbert, 2015](#)):

- On average, approximately 4.1% of WCs were found to be leaking.

- Average leakage rates of 215 litres/toilet/day (based on the sample mean) and 72 litres/toilet/day (based on the sample median) were derived from the study
- Total wastage from WC leakage is estimated to be 397 Ml/day (based on the sample mean) and 133 Ml / day (based on the sample median)
- The overall contribution of WC leakage to the average per capita consumption is between 1.65% and 4.63%.
- New properties (post-2000) are most likely to have leaks and 81% of these are associated with flush valves
- ◆ **The government to work with water companies and other partners to develop large-scale water efficiency retrofit schemes across the UK, including through establishing partnerships**
- ◆ **Raise awareness of the need for compliant products among retailers and suppliers, plumbers and the customers. Further customer and stakeholder education is also required regarding compliance. This could be achieved through the provision of advice and information.**

Tools like the Royal Institute of Chartered Surveyors (RICS) SKA refurbishment guide should drive greater water efficiency retrofitting and we would like to see the building sector adopting these type of approaches as standard.

Q14: How can we improve water efficiency in social housing across the UK?

Q15: What further incentives and standards are required to increase water efficiency in new homes?

Q16: How can we increase the number of water efficiency retrofits being undertaken?

Q17: What further incentives and standards are required to increase water efficiency in new non-domestic buildings?

Products and labelling

An effective water labelling scheme is essential for transforming the market so that consumers can purchase water efficient devices. The UK currently has the European Water Label and Smart Watermark to help identify water efficient products. As of 2015 the Water Label had 88 registered brands and 8,000 registered products. Although there has been some increase in use of the label in stores and online, it is not widely visible. The links with building standards and the Waterwise/ BMA water calculator have driven use for new developments. We can learn from experience in Australia and the USA to further develop and strengthen water labelling the UK.

Figure 8 The European Water Label

The Water Efficiency and Standards Labelling (WELS) scheme in Australia calculated a saving of 70,000 ML/year

water (Figure 9), 5.5 MT/year of carbon dioxide, and AUD\$520m/year in household utility bill savings. The labelling scheme has been combined with a range of wider programmes including rebates on efficient product and appliance to help transition the market.

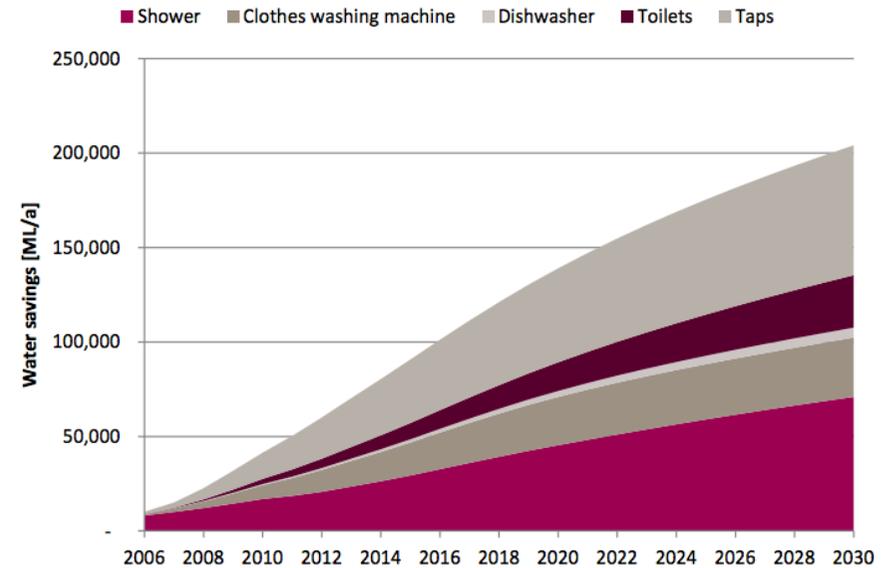

Figure 9 Historical and projected water saving from water labelling and increased water efficiency in Australia (ISF, 2015)

The US Environmental Protection Agency's Watersense labelling scheme has saved more than 1.5 trillion gallons of water since 2006 (approx. 6.8 million megalitres), 78MT of carbon dioxide, and USD\$32.6 billion in savings in consumer water and energy bills. In 2015, 16,110 labelled produced were available (USEPA, 2015). The programme also extends to labelling of new homes and through social media and

drought communications is well integrated into overall water efficiency programmes.

Strengthening adoption of the Water Label

A labelling scheme on its own isn't the end goal. We need further uptake of the label and promotion on products, in stores, on websites and linked to building/ procurement standards. Incentive programmes that require the label, such as reductions to developer charges or rebate programmes, can also help this market transformation.

Rebate schemes have been essential for driving market transformation and the uptake of the Water Efficiency and Standards Labelling scheme in Australia. For example, the rebate scheme in Western Australia was funded by the State Government and delivered through the water company and resulted in 170,000 new water efficient washing machines being installed. The number of Perth households installing dual flush toilets increased from 36% in 1992 to 84% in 2006 and front loading washing machines increased from 7% to 25% (Marsden Jacobs Associates, 2009). Rebate programmes run by water companies in the UK could better support a market transformation than current free giveaways. This would enable consumer choice, which is especially important where homeowners are refurbishing their kitchens/ bathrooms.

The government in Northern Ireland is considering amending the Water Supply (Water Fittings) Regulations (Northern Ireland) 2009 to include a performance rating for water fittings. This could be linked to the Water Label to support changes in other parts of the UK. This effect was seen with the plastic

bag charge implemented in Wales, then Scotland, Northern Ireland and England.

- ◆ *Undertake an independent review of the effectiveness of The Water Label*
- ◆ *Water companies should be incentivising the use of water efficient devices and fittings, through rebates similar to those used in the USA and linking eligibility to the European Water Label.*
- ◆ *Northern Ireland to consult on mandatory water efficiency standards*
- ◆ *Link public sector water standards to the water label to encourage manufacturers to use the label and produce more efficient products*
- ◆ *Review BREEAM accreditation and link the water components to the Water Label to help support a wider market transformation*
- ◆ *Water efficient devices listed in the HMT/Defra ECA Green List being zero rated for VAT, which should be possible after the UK leaves the EU*

Q18: Should water companies incentivise the uptake of water efficient devices and fittings through rebates and other financial levers?

Q19: Should the UK Government give water efficient devices a zero VAT rating?

Water Calculator

Waterwise and partners produced [The Water Calculator](#) to link the Water Label with Part G of the building regulations and the Code for Sustainable Homes. The calculator has won awards and is used daily by a range of architects and other building industry professionals.

There is a need to modernise the calculator so that it reflects the latest water efficiency technology, changes to building standards, and opportunities to link with incentive schemes around water company developer charges and public procurement. The calculator could also be extended to provide a portal for new non-domestic water retail companies to provide water efficiency options for their customers.

- ◆ **Waterwise will revise the water calculator linked to the Water Label in line with the latest standards and communicate this further with stakeholders**

Figure 10 Screenshot of The Water Calculator website

Rainwater harvesting and greywater reuse

Rainwater harvesting and greywater reuse have been implemented with mixed experience in the UK. A report on the carbon implications of these systems in 2010 suggested that due to pumping and treatment they are often more carbon intensive than the public water supply ([Environment Agency et al., 2010](#)). Additionally, the payback periods can be long on some systems.

Since that report there has been advances in technology around pumping and sensors to better link with wider objectives such as reducing flood risk. However, there remains a gap in research, skills and accreditation for these systems compared with countries such as the USA and Australia. The WATEF Network has attempted to address some of these issues, however there is still a need for more industry and academic research to inform labelling and standards. Issues include:

- Water regulations and water quality
- Public acceptance
- Ownership and maintenance models
- Land availability for installation of community scale rainwater and greywater reuse systems
- ◆ **Undertake further research on the costs and benefits of rainwater harvesting and greywater reuse**
- ◆ **Assess accreditation and training standards for installation of rainwater harvesting and greywater reuse**

Product Innovation

The products being supplied by water companies in retrofit programmes to households have changed little since the first

mail-out of devices in response to Ofwat Water Efficiency Targets in 2011. The UK has a long history of innovation in manufacturing and includes several technology hubs that could be utilised to develop smart water products including point of use measurement and behaviour change feedback devices. With climate change leading to more extreme weather and drought internationally we can also export products.

A range of new products and technologies include:

- Smart point of use water measurement devices – showers etc.
 - Smart rainwater butts that empty when needed for stormwater attenuation
 - Airflush toilets
 - Ultra-low flow products
 - Improved customer engagement displays and devices
- ◆ *Develop a water product incubator programme based on an Innovate UK funding challenge*
- ◆ *Use the Waterwise bi-annual water efficient product awards to promote and stimulate research and innovation*

Figure 11 Range of retrofit devices and innovations available for retrofit programmes

Q20: How can we strengthen the Water Label to transform the market towards more efficient products?

Q21: What other options are there for product innovation in water efficiency for the UK and how can we incentivise these?

Water company delivery and regulation

Metering

The UK is one of the few countries in the developed world not to have either full water metering or a clear programme to implement universal metering. At present 50% of households in England and Wales are metered and this is projected to increase to 61% over the next five years ([CCWater, 2015](#)). In England, the policy position on metering is that water companies can compulsorily meter customers if they have been designated as being in an area of water stress (by the Secretary of State based on evidence from the Environment Agency). In Scotland there are some meter trials but the current level is close to zero, whilst in Wales the Welsh Government is looking at the benefits of smart meters.

However, the Southern Water Universal Metering Programme (UMP) has shown that domestic metering can save 16.5% ([Ornaghi and Tonin, 2015](#)). If people do not pay for the amount of water they use, there is no financial incentive to use water efficiently. For unmetered customers, it is important to seek alternative ways to incentivise the efficient use of water.

- ◆ **Freedom for water companies to introduce full metering for benefits beyond water stress status**
- ◆ **All homes in England and Wales to be fitted with water meters by 2020, supported by tariffs to protect vulnerable customers. Supported by a political commitment and based on a wider cost-benefit analysis**

Tariffs

Metering with appropriate tariff structures - such as the rising block tariff (wherein the unit charge rises for progressively higher volumes of water is taken by customers), or a seasonally-varying or aridity-indexed tariff (wherein water costs more per unit when it is less plentiful) – has the potential to be a major incentive to water efficiency in the future. In their latest water resources plans, a number of water companies have announced substantial selective metering programmes that are predicted to generate considerable reductions in consumption. There should be support for appropriate and smart metering to manage the demand for water; however, the social and economic implications of such an approach need to be properly factored into policy and practice, with appropriate provisions being made for the disadvantaged.

Some companies are also thinking outside the usual range of tariffs towards incentives. Gamification and discounts/ prizes linked to reduced consumption at a household or community scale are an example of this.

- ◆ **A new round of tariff trials linked to smart metering and the potential for retail competition to be supported by Ofwat and Water Companies**
- ◆ **Evaluation and dissemination of new incentive approaches**

Improving delivery of large scale domestic retrofit programmes

With universal metering programmes including home visit programmes for water efficiency there has been an increase in the total number of visit undertaken. In the current water company delivery period, there are hundreds of thousands of

planned home visits. However, there is wide variation in the level of water saving achieved and the quality of delivery. We can learn from the range of approaches and their level of uptake and water savings achieved.

The evidence base for water efficiency, developed by Waterwise and the industry, has been used as an essential resource in many water resources management plans and the Water UK long term water resources planning framework report. However, there is a need to collate up to date figures. This will help understand variation between companies and programmes.

- ◆ *Increase roll out of Waterwise Water Efficiency training to water companies across the UK*
- ◆ *Provide a database of companies that have trained staff or use trained contractors to provide assurance to Ofwat and the general public about the efficiency and reliability of delivery in water efficiency programmes*
- ◆ *Update the water efficiency evidence base*

Q22: Do you agree with the recommendations on metering and tariffs?

Q23: From your experience in delivering or receiving home visit linked to retrofit programmes, how can the industry support improvements and knowledge sharing?

Q24: How can we improve the evidence base for water efficiency to better share learning on the latest large scale water efficiency programmes?

Integrated water management and resilient infrastructure

The Ofwat resilience task and finish [group](#) defined resilience:

Resilience is the ability to cope with, and recover from, disruption, and anticipate trends and variability in order to maintain services for people and protect the natural environment now and in the future.

Although water efficiency was not included as a direct recommendation it is implicitly part of recommendations: increasing public engagement and education; ensuring clear routes for funding legitimate resilience investment; ensuring coherent planning at both a regional and national level; improving the understanding of risk and failure; ensuring water services are resilient under different water sector structures; developing benchmarking, standards and metrics; and, ensuring existing plans are stress tested.

Integrated Water Management

There are many different names and definition for integrated water management. In this strategy, we are referring to a holistic whole water cycle approach to managing water resources, water quality, and flood risk management. Water efficiency is often seen as one part of a silo (water resources) and there is a need to join up retrofit and behaviour change projects with water company programmes on sustainable

drainage and catchment management. Box 2 outlines an example of a more integrated approach to water management implemented in Sydney, which could also be applied under the competition and regulatory regime in England and Wales. Through multiple instances of semi-autonomous systems such as Central Park nested in a city we can balance decentralised and centralised infrastructure.

Box 2: Upstream competition case study: Central Park Sydney

This innovative new development is served by [Central Park Water](#), servicing 4,000 residents and 15,000 workers and visitors daily. The world's largest membrane bioreactor system, with ultraviolet and reverse osmosis treatment in the basement of the building, provides water to 50-70% of non-potable uses including toilet flushing, washing machine use and garden/green wall irrigation.

Figure 12 Central Park Sydney showing green walls (Photo: Hans Veneman, Creative Commons, Flickr)

Water sources include:

- Rainwater from roofs
- Storm water from impermeable surfaces/planter box drainage
- Groundwater from basement drainage systems
- Sewage from an adjacent public sewer
- Sewage from all buildings within the Central Park community
- Drinking water from the public water main

Wider benefits stated by Central Park Water include lower infrastructure charges for developers, quicker land release speeds for development and lower bills for customers. Central Park Water also supply recycled water to surrounding buildings, including the Institute for Sustainable Technology.

A range of similar schemes are developing in New South Wales, including an additional eight communities and more than 25,000 dwellings. As of April 2015, the economic regulator IPART reported 28 current licences under the Water Industry Competition Act 2006 are supporting these developments.

By joining up sustainable drainage programmes with water efficiency programmes, behaviour change and retrofits of homes can be more effective. A major supply deficit is

projected for London by Thames Water, and we are also facing sewer capacity issues due to surface water inflow. There is the potential to consider the city as a water supply catchment through water capture and reuse. A similar situation exists in our other large cities.

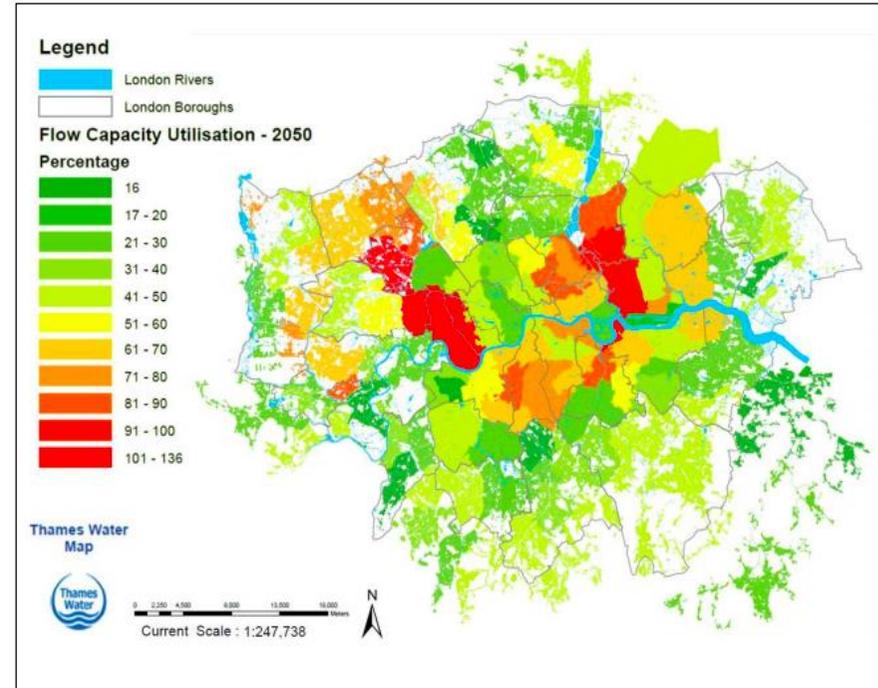

Figure 13 Sewer flow capacity in London (GLA, 2016)

Competition isn't the only option. An alternative community model is taking shape in the South West of England. This is called [RainShare](#) and involves connecting those with excess water, including roof runoff, with those who need water. The first example of this will be between householders and an adjacent allotment for growing vegetables. In the UK,

innovative approaches on water reuse have been implemented by water companies in the North West Cambridge development and at the Olympic Park in London. Both schemes required innovative thinking from water companies and clear partnerships with the developer, the University for Cambridge and the London Legacy Development Authority in London respectively.

- ◆ **Retrofit sustainable drainage (SuDS) and Water Sensitive Urban Design (WSUD) projects should include water efficiency**
- ◆ **Identify opportunities for water efficiency within distributed infrastructure systems to provide nested semi-autonomous areas within cities and improve resilience**

'Smarter' water infrastructure

There is increasing recognition of the need to better utilise Big Data such as smart metering information and the Internet of Things (e.g. sensors) to better manage water. These technology trends can potentially revolutionize the Water sector, by providing highly detailed data and actionable insights throughout the water lifecycle; from production and distribution, through to consumer engagement. Low-cost internet of things (IoT) based sensing devices (e.g. flow, pressure, quality) monitoring, analysing and transmitting data throughout the water network (from a well to a household) can have a significant effect on the entire water value chain. The technology-driven pollination of water data with other data sources (e.g. weather, energy) and systems (e.g. smart home, Cleanweb, open data) can further increase opportunities for extracting value from the data. Such benefits are apparent in the Energy sector, a perfect example of the application of Big

Data technologies. Energy utilities enjoy state-of-art Big Data systems to monitor, analyse, and automate energy production, management, and demand. At the same time, they have joined a growing ecosystem of consumer-centric products and services for energy monitoring and automation that provides them with further data, capabilities, and insights.

There is a need for a debate within the water sector about the amount of open data. More open data would enable greater public engagement with water and the development of more ICT solutions, which could aid water efficiency. However, there is also a need to protect privacy and consider the ethics of data collection and use.

The level of metering in the sector has grown dramatically in the past ten years and companies are now starting to install smart meters. These should provide information that will aid network optimisation and customer facing information to drive water efficiency. But there needs to be more work on the use of smart rather than big data. Water companies need to focus on what data is needed and how this should be gathered. Metering is not the only option and neighbourhood meters for network optimisation combined with in-home sensors that can provide data directly to customer's smart phones in one approach that can provide an alternative.

- ◆ **Support innovation and wide-scale adoption of big data analysis and the internet of things to support greater understanding of demand and behaviour change in water efficiency programmes**
- ◆ **Review the data needs of the sector, assessing what data is needed and how it should be collected and used**

- ◆ **Increase availability of Open Water Data, including anonymised information on water demand and outputs from water efficiency pilot projects**

Q25: Do you agree with the recommendations for improving water efficiency in cities and urban developments?

Q26: What are your views on data collection and accessibility?

Conclusion and next steps

Climate change and population growth are placing increasing pressure on water resources in the UK. Growing demand and the need to protect the environment are pushing water companies to deliver greater levels of water efficiency.

There is a need for a coordinated approach to delivering water efficiency in the UK and our initial review of stakeholders has identified key brokers in this. We also recognise that a country specific and region specific approach is also required in delivery to engage with water customers and change behaviours.

This consultation document sets out a range of key issue areas developed with Waterwise supporters. The aim of the strategy is to provide the evidence to support government action in this area and for water companies and other stakeholders to reference as they develop their next round of plans. We also set out a range of actions for further research and collaboration and are seeking input on these. Additionally, we would welcome any input on research and evidence to further support this strategy.

Through this strategy we are also seeking to deliver against the International Water Association’s 17 principles for water-wise cities (Figure 14). In particular, water-wise communities.

Please complete the consultation response form at this [link](#) or email responses by email **by 31 January 2017** (info@waterwise.org.uk).

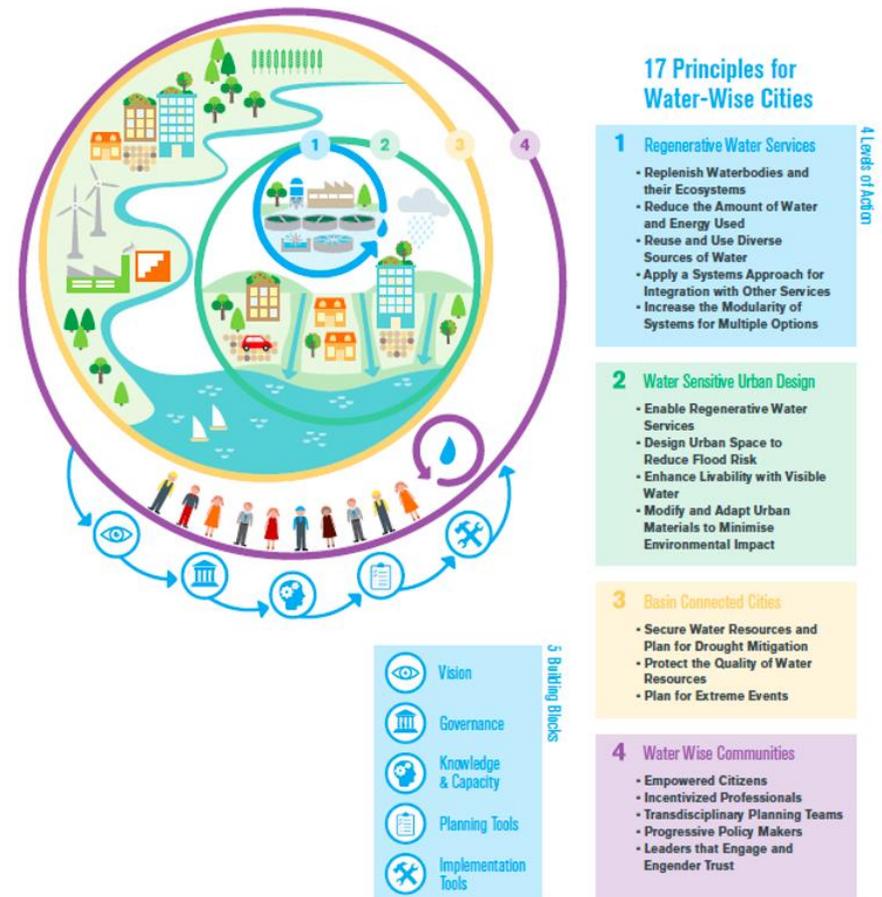

Figure 14 Principles for water-wise cities (IWA, 2016)

Summary of consultation questions

The consultation questions are listed below and you can respond to these by email (info@waterwise.org.uk) or our online [form](#).

Q1. Do you think that water scarcity is a serious threat to the UK?

Q2. Do you think that there needs to be greater consideration given to the impacts of water scarcity and if so by whom?

Q3. Do you think that increased water efficiency is a legitimate response to the threat of water scarcity?

Q4. How can we better integrate water and energy efficiency programmes?

Q5. How can we better measure and monitor best practice water efficiency in the UK? Is per capita consumption the best indicator?

Q6. Could the UK match international best practice and achieve a per capita consumption of 100 litres? And if so how?

Q7. What other indicators or approaches could be used to help monitor progress or set targets towards greater levels of water efficiency?

Question 8: Do you agree with our definition and vision for water efficiency in the UK?

Q9: Do you agree with the recommendations for building a water saving culture?

Q10: How can we bring together partnerships to deliver this wider level of awareness?

Q11: Do you agree with the opportunities and challenges outlined for water efficiency from greater retail competition for water?

Q12: Do you agree with the recommendations for developing a framework for water efficiency in competition?

Q13: How can we ensure that non-regulated members (e.g. TPIs) of the water sector help to deliver water efficiency?

Q14: How can we improve water efficiency in social housing across the UK?

Q15: What further incentives and standards are required to increase water efficiency in new homes?

Q16: How can we increase the number of water efficiency retrofits being undertaken?

Q17: What further incentives and standards are required to increase water efficiency in new non-domestic buildings?

Q18: Should water companies incentivise the uptake of water efficient devices and fittings through rebates and other financial levers?

Q19: Should the UK Government give water efficient devices a zero VAT rating?

Q20: How can we strengthen the Water Label to transform the market towards more efficient products?

Q21: What other options are there for product innovation in water efficiency for the UK and how can we incentivise these?

Q22: Do you agree with the recommendations on metering and tariffs?

Q23: From your experience in delivering or receiving home visit linked to retrofit programmes, how can the industry support improvements and knowledge sharing?

Q24: How can we improve the evidence base for water efficiency to better share learning on the latest large scale water efficiency programmes?

Q25: Do you agree with the recommendations for improving water efficiency in cities and urban developments?

Q26: What are your views on data collection and accessibility?

Appendix A – Water efficiency strategies and plans across the UK

A number of strategies and plans already exist or are in preparation that can help deliver water efficiency. These are outlined below:

- Final Water Resources Planning Guideline ([Environment Agency and Natural Resources Wales, 2016](#)) – the 2016 guideline requires water company plans to be: “Demonstrating how you will fulfil your obligation to promote water efficiency and your plans for increased customer metering, thereby reducing abstraction and its impact on flows and groundwater levels”
- Water White Paper ([Defra, 2011](#)): We must use water more efficiently and be careful to avoid pollution in using our drains. We will encourage and incentivise water efficiency measures, for example under the Green Deal. We will encourage voluntary water efficiency labelling to enable customers to choose more efficient products. We will also collaborate on a campaign to save water and protect the environment, working with water companies, regulators and customers to raise awareness of the connection between how we use water and the quality of our rivers.
- Defra 25 Year Plan – In response to the National Capital Committee’s third State of Natural Capital report, the Government has committed to producing a 25 year plan for a healthy natural economy ([link](#))
- National Infrastructure Assessment – the National Infrastructure commission announced in May 2016 that they will be developing an assessment with a 30 year timeline and this will include water, sewerage and flood defences ([link](#))
- Water Strategy for Wales ([2015](#)): will assess and consult on options for encouraging reduction in water consumption. “This will include working with the water companies and other interested parties to encourage and incentivise engagement and action on water usage; to challenge perceptions; to promote the benefits of water efficiency; and carry out further investigation into the costs and benefits of metering.”
- Scottish Water – Water Efficiency [Plan](#) 2011-2015: The strategy sets their three key areas around engaging with customers, improving assets, and working with stakeholders.
- Sustainable Water - A Long-Term Water [Strategy](#) for Northern Ireland (2015-2040): Progress delivery of difficult crosscutting policies such as water efficiency, surface water management and water and sewerage funding and regulation; Managing water consumption by improving water efficiency in homes and businesses; The long-term target is to reduce average water consumption from 146 l/h/day to 130 l/h/day.

- Continue to invest in education and public awareness campaigns to promote water efficiency and the value of water, supported by continued work of the Water Bus and school visits, and other educational means.
- Develop and implement a public awareness campaign highlighting the benefits of water efficiency and how it can lower energy bills
- Consider regulatory options in which all future residential development is water efficient and aims to achieve a maximum consumption figure of 130 l/h/day. Carry out pilot projects to test and compare the cost effectiveness of different water efficiency / reuse technologies (for both retro-fitting and new build). Consider amending the Water Supply (Water Fittings) Regulations (Northern Ireland) 2009 to include a performance rating for water fittings. Develop and implement policies in respect of retro-fitting water efficiency/ recycling measures in homes and businesses.
- Draft Mayor of London Water Strategy ([2011](#)): The Mayor believes that Londoners should have a secure supply of water that is affordable, safeguards the environment, and a water infrastructure fit for a world-class city.
 - Point 1. Improve the water efficiency of London's existing buildings through retrofitting simple cost-effective measures. This saves Londoners money and offsets the demand for water from new development.
 - Point 2. Ensure all new development is super water efficient. This reduces residents' bills (all new development is metered), the need for new water resources and the impact on the environment.
 - Point 3. Raise Londoners' awareness of the financial benefits of increased water efficiency – many Londoners would be able to save money by being more water efficient and even having a water meter.
 - Point 4. Increase the number of homes that have a water meter. Paying for the volume of water consumed is the fairest way to pay for water, yet less than a quarter of London's 3.2 million homes have a meter. Having a meter helps consumers be aware of how much they are using and provides information to help control their bills.
 - Point 5. Change the way Londoners pay for their water. The current system does not encourage or reward water efficiency, nor sufficiently protect those who cannot afford to pay
 - Point 6. Continue to tackle leakage. A quarter of our water is lost in leakage – this is water we pay for but never receive. A one per cent drop in leakage would provide enough water for 47,120 people.

The National Infrastructure Assessment: Call for Evidence

Wessex Water Services Ltd Response, February 2017

Introduction

Wessex Water is the regional water and sewerage business serving 2.8 million customers across the south west of England including Dorset, Somerset, Bristol, most of Wiltshire and parts of Gloucestershire and Hampshire.

Within this Call for Evidence paper, we have focussed our response on the Water and Wastewater and Flood Risk Management questions; however, we have also provided information associated with the crosscutting themes and other topic areas. We believe that the infrastructure that we provide cannot be understood in isolation. There are wider infrastructure challenges that are representative of the area we serve and have impacts on our ability to operate. Therefore, we have provided some insights into current challenges around energy and digital communications.

We welcome the opportunity to share our ideas and challenges and to provide evidence to support the success of alternative approaches. Within this response there are five core themes, which are common across many sections, these are:

- The need for more integrated infrastructure planning and delivery across sectors and political boundaries- we are leading the way in this area through the production of an Adaptation and Resilience Plan within the Bristol Avon Catchment
- Recognition of the need for multi-functional greenspaces within developments to provide drainage, amenity and therapeutic spaces, delivering better living and working environments
- The need to change legislation around the 'right to connect' surface water to foul sewerage systems to ensure appropriate drainage solutions at a local level
- The need for good data in order to change behaviours and enable demand management options to succeed, we have provided evidence on the work we have done around wastewater measurement and demand management measures for public water supply.
- Operating at a hydrological catchment scale enables more holistic planning for drainage and flooding aspects, however this often requires operating beyond political boundaries that can be challenging despite the duty to co-operate between local authorities. Our Adaptation and Resilience case study highlights the advantages associated with this new and, we think, better way of working.

In terms of energy, as a water company this contributes to a significant proportion of our ongoing operational costs. Due to government policy and rising non-commodity cost elements of power bills, there will be a marked increase in our costs next year. For context, there will not be a commensurate increase in consumption levels due to our on-going commitment to energy efficiency across our operations. For example, next year's electricity bill will be >£2M more than this year due to these non-commodity costs. One in particular, the capacity market will add approximately £0.75M to our bills simply due to increased costs being levied on consumption between 4 and 7pm on winter weekdays.

With respect to digital communications, our activities are increasingly becoming more automated with the opportunity to monitor and manage treatment works remotely. In order to maximise these opportunities, in a way which would be better for our customers - in terms of incidence responses and lower staff time to travel and work on sites- we need good digital and telecommunication systems. Wessex Water operates across a largely rural area where 3 or 4G communication systems are not available or sufficiently reliable, reducing the opportunities for more remote solutions.

Question	Response and supporting evidence
<p>1) What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?</p>	<p>Water and sewerage infrastructure is essential to enable economic growth, to enable housing developments and industrial expansion whilst protecting public health and the environment. We operate within a region with a strong growth agenda, particularly in the West of England. Between 2001 and 2011 the population of the West of England grew by 9%, and by 2025, a further increase of 19% is anticipated.</p> <p>Sustainable water and sewerage services are essential to enable this growth.</p> <p>It is also essential that the planning and provision of this infrastructure are integrated with the longer term development plans to ensure that the assets are sustainable, constructed in the most cost efficient manner and are also resilient to future pressures such as a changing climate and economic variation.</p>
<p>2) How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?</p>	<p>N/A</p>
<p>3) How should infrastructure be designed, planned and delivered to create better places to live and work?</p>	<p>Wessex Water is leading a pioneer project bringing together the two Local Enterprise Partnerships (LEP) and two Local Nature Partnerships (LNP) within the Bristol Avon catchment to develop an Adaptation and Resilience Framework to enable further economic and housing growth. Further details are included in Appendix 1.</p>

<p>How should the interaction between infrastructure and housing be incorporated into this?</p>	<p>It is our aspiration that there is collaboration with other providers and strategic planners to develop a single infrastructure plan that delivers the needs of the catchment over a 25-year time horizon, taking account of development, transport and drainage needs in a sustainable, joined up way. The delivery and funding of such a plan would be collaborative to maximise the skills, expertise and commercial advantages of the individual organisations to deliver efficiencies to customers.</p> <p>Infrastructure needs to be designed, planned and delivered through a holistic systems approach with greater understanding of the risks and opportunities across sectors and political boundaries at the appropriate scale (hydrological catchments). This includes housing, transport, flooding, public health, green and blue infrastructure to enable the most beneficial solutions and efficiency delivery. The integrated approach means that infrastructure is planned with consideration to upstream and downstream constraints, opportunities and receptors, rather than in isolation.</p> <p>The Adaptation & Resilience Framework for the Bristol Avon Catchment is a pilot project that begins to address these issues by bringing greater integration between sectors and organisations around spatial planning at a catchment scale by building up evidence at a sub catchment scale. The project provides a vehicle for multiple organisations (Environment Agency, the four West of England Unitary Authorities and Wiltshire County Council, West of England LEP and Swindon LEP, Wessex Water and Bristol Water, Wildlife Trusts, Catchment Partnership and Highways England) to plan for better-integrated solutions to shared risks.</p> <p>We recognise the wide value of more integrated and sustainable drainage solutions. The use of more sustainable solutions, integrated with green and blue infrastructure, can provide multi-functional spaces within developments enabling space for amenity and recreation, alongside drainages, flood attenuation and water treatment.</p> <p>Albion Water (which is 51% owned by Wessex Water) has been working with developers to enable improved water, waste and drainage planning at the early stages of the development. This results in more sustainable solutions and reduced bills for the homeowners. This also enables provision for multi-function space within the master planning to enable sustainable drainage and green spaces to improve amenity and recreation.</p> <p>https://www.albionwater.co.uk/developers/our-projects/upper-rissington-gloucestershire</p> <p>There has been much research that highlights the benefits of nature and greenspace to health and wellbeing, e.g. Marmot Review, Royal Society of Wildlife Trusts and MIND, have all commissioned research to evaluate the benefits provided.</p>
---	---

<p>4) What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?</p>	<p>Demand management for water supply services</p> <p>A key aspect of our Water Resources Management Plan is to reduce the demand for customers: https://www.wessexwater.co.uk/waterplan/</p> <p>We aim to continue to reduce demand and leakage by accelerating metering in our region by installing meters in households when customers move house and by providing enhanced water efficiency services to help customers reduce their water use further.</p> <p>We have been increasingly making the link between water efficiency and affordability for customers. We offer free combined water and energy efficiency home visits to customers who are struggling to pay, and promote water meters where we think this will help.</p> <p>Our customers consume on average 143 litres per person per day and just over half of households have a meter.</p> <p>Perceptions about our climate and leakage mean customers are often sceptical about the need to become more water wise. Almost all, however, are interested in ways that they can reduce their bill – or in other ways that they or their community can be rewarded to use less water. Customers typically feel they have little knowledge of, and control over, their water use and bill.</p> <p>While a majority of customers support an acceleration of metering there remains a vocal minority of unmetered customers who do not. Customers are generally in favour of smart meter technology, mainly because they believe it will enable them to make bill savings.</p> <p>However, we recognise that there needs to be a twin track approach between demand management and the provision of supply side interventions.</p> <p>Demand management for sewerage services</p>
---	--

	<p>Demand management is seldom used for sewerage/drainage services due to a lack of measurement technology that is affordable, accurate and reliable. However, at Wessex Water we believe it can be with the advent of new technology.</p> <p>Without measurement, it is not easy to send out demand management signals. To address this, Wessex Water have been behind the development of a unique wastewater meter that has the ability to be used for fiscal charging purposes at a domestic/business level. With this sort of measurement, price signals can be more easily used to encourage demand management. Whilst this technology is still in its infancy, its potential nationally is massive.</p> <p>http://www.dftl.co.uk/in-the-press/leicester-mercury.html</p> <p>https://www.instituteofwater.org.uk/news-post/wessex-water-wins-the-institute-of-water-national-innovation-award-2015-sponsored-by-mwh/</p>
<p>5) How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?</p>	<p>Decisions about maintenance levels are usually driven by risk and delivery is about cost effectiveness whilst maintaining levels of service.</p> <p>Decisions about construction of new assets is usually driven by the requirement to meet higher standards of service or resilience.</p> <p>Within a finite pot of funding, we believe priority should be given to maintenance. New assets should only progress if demonstrably cost-beneficial for the bill payer or environment.</p>
<p>6) What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?</p>	<p>Competition between suppliers generally results in lower costs of delivery. Ofwat, the economic regulator of the water industry, recognises this and it has developed policies that are intended to facilitate the development of new markets in water trading and bioresources (sewage sludge).</p> <p>Government policies could encourage the development of new markets for drainage and flood defence infrastructure, with water companies bidding (alongside each other and all other potential suppliers) to provide solutions at a local and regional level.</p>

Companies exposed to broader objectives (such as the provision of drainage and flood defence infrastructure) will need to be compensated for investments undertaken, particularly if these social objectives are not funded through a regulated price control. Water companies are required to reduce internal and external flooding through outcome delivery incentives, which form part of their regulated income because these outcomes are directly related to customer service. Were water companies to bid for work in the supply of drainage and flood defence infrastructure, the income from this work would be unregulated but if the solution offered, were in the same catchment area, customers of the water company would, no doubt, benefit directly from the reduced risk of flooding.

Collaboration between utility companies might provide opportunities to improve the supply of infrastructure services. For example, the delivery of a new road might allow for additional infrastructure (mains water pipes, telecoms cable laying, etc.) but this would require better information sharing and an understanding of proposed investments across the area.

The integrated strategic infrastructure plan referred to in question 1, could provide a higher-level view of maintenance requirements and enable the opportunity to work with other infrastructure providers to identify co-ordinated approaches. For example, working more closely with the Lead Local Flood Authority and the Environment Agency around the repair and maintenance of local drainage or flood defence assets could identify efficiencies by planning and undertaking the required work at the same time. We are beginning to work in this way in Wiltshire by co-ordinating our flood risk efforts within one combined team in Wiltshire Council, co-funded by Wessex Water.

Leading on from a combined infrastructure plan, a maintenance plan could be developed. It should be noted that there are many assets that require the same skill sets to maintain, whether that is mechanical and electrical skills, pipe cleaning or rehabilitation/replacement or grounds maintenance work (e.g. maintaining parks and SUDs). In some instances, this could be shared amongst relevant delivery partners and co-funded, for example, drainage and flood defence assets operated by water companies, LLFAs and the Environment Agency.

We strongly believe in advocating collaborations and partnership approaches to delivering innovative and shared solutions. This is demonstrated through our strong support of the Dorset and Bristol Avon catchment partnerships. More information is available here:

<https://www.wessexwater.co.uk/dorset/>

<https://www.wessexwater.co.uk/bristolavon/>

	<p>These Partnerships enable the wider discussion and understanding of shared issues to develop more innovative solutions, such as the Bristol Avon Adaptation and Resilience Framework and the EnTrade nitrogen offsetting platform which we have developed in Poole Harbour:</p> <p>https://www.entrade.co.uk/Content/4869%20EnTrade%20leaflet.pdf</p> <p>EnTrade is a nutrient-trading platform, which enables business-to-business transactions between farmers and the water company to reduce nitrogen leaching into groundwaters, therefore negating the need to provide expensive and unsustainable water and wastewater treatment systems.</p>
<p>7) What changes in funding policy could improve the efficiency with which infrastructure services are delivered?</p>	<p>We believe that the current funding policies enable a non-regulated part of a water company to bid to deliver infrastructure services for other providers, such as Environment Agency or Local Authority flood defence structure construction should it wish to.</p> <p>The current Grant in Aid mechanism for flood defence provision precludes a regulated water company from bidding for these construction contracts but this is not the case for non-regulated construction or maintenance businesses that have been established.</p>
<p>8) Are there circumstances where projects that can be funded will not be financed? What Government interventions might improve financing without distorting well-functioning markets?</p>	
<p>9) How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increased</p>	<p>Greater integration across sectors in planning, operational and maintenance plans outlined at a catchment and sub catchment scales would bring a greater awareness of shared risks and opportunities to mitigate against risks upstream and downstream in individual catchments and across the whole catchment. Collaborative working aligning</p>

interdependence across sectors?	plans would bring a greater understanding of the weak points in the system the interdependent risks. Refer to earlier question & case study.
10) What changes can be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?	<p>The current planning system is insular and constrained by political boundaries.</p> <p>We believe that by planning at a wider scale, such as at hydrological catchment scale, it would enable more holistic solutions to be developed and promote a better understanding of the in-combination upstream and downstream effects of developments. For example, the knock-on impacts of housing developments further up the catchment can lead to greater flood incidents further downstream, or not recognise opportunities for more natural flood management systems for flood attenuation much further up the catchment. This is a key theme addressed through our Adaptation and Resilience Framework (Appendix 1).</p> <p>The planning system and infrastructure governance done at a catchment and sub catchment area with greater integration across sectors would bring awareness of how upstream activities can affect downstream assets etc. Decisions with an understanding of the wider identified risks, costs and routes to delivery would result efficient delivery of infrastructure.</p>
11) How should infrastructure most effectively contribute to protecting and enhancing the natural environment?	<p>Climate change impacts mean that infrastructure may become increasingly more reliant on the ecosystem services provided by the natural environment in terms of reducing flooding and impacts from high temperatures. Holistic master planning with opportunities for low carbon transport adjacent to well-connected green spaces that connect the natural environment both inside and outside urban areas can provide multifunctional landscapes, which can address multiple risks. Water, climate and health sensitive urban design should lead the design of infrastructure.</p> <p>The ‘right to connect’</p> <p>A key issue that continues to exacerbate adverse environmental impact from new development is the continuing ‘right to connect’ enjoyed by developers. Whilst the Government’s original plan was to remove this under the Floods and Water Management Act 2010, Schedule 3 of the Act has never been enacted in England (whereas it has been in Wales). The right to connect enables developers to connect surface water run-off from new development into combined sewers on affordability grounds i.e. if they consider it too expensive to send surface water to a surface</p>

	<p>water receiver such as a ditch or watercourse or to ground, then they have a right to connect to a nearby public foul sewer.</p> <p>The consequence of this is a cost avoidance from the developer, which is passed onto the existing regulated sewerage customer, greater combined sewer overflow spills and increased risk of downstream sewage flooding.</p> <p>This is unsustainable development as the development is not paying for the cost that it incurs.</p> <p>Whilst we do not believe there is a need to remove the right to connect new foul sewers to existing public foul or combined sewer network nor indeed surface water from surface water sewers (the sewerage company has a duty to provide this additional capacity). However, it is critical to prevent surface water from new development to be allowed to connect into combined/foul systems due to ‘affordability of development’ issues. See recent article from experts supporting this view: http://wwtonline.co.uk/news/separation-of-stormwater-‘key-to-health-of-sewer-networks-3386#.WJH1Q01vhD8</p> <p>As mentioned previously, we believe that greater provision of sustainable drainage systems, natural flood management and nutrient / biodiversity trading platforms have the potential to address many of these issues at source and promote a better environment as a result. Typically, these options will be less expensive to operate over the longer term. Further details on the application and advantages of sustainable drainage systems can be found at:</p> <p>CIWEM report on SuDS susdrain website CIRIA SuDS Manual</p> <p>Albion Water is currently demonstrating more sustainable options for water and waste management on new developments. (Question 3). This includes the provision of greywater and rainwater harvesting as an integral part of development planning. Integration of these options at an early stage reduces the environmental impact of the development.</p> <p>A good example of how infrastructure investment across different companies can lead to enhancement of resilience of supply services as well as enhancement of the environment can be found in Appendix 2.</p>
12) What improvements could be made to current cost-	

benefit analysis techniques that are credible, tractable and transparent?	
22) What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?	<p>The water sector already has an effective mechanism through the Water Resources Management Plan. However, we recognise that 5-year investment plans can be a blocker to larger supply side options, e.g. an additional resource in the Thames Water area. High investment supply side projects tend to be delayed in the hope that small scale demand management options can fill the gap in the interim. Wessex Water was unusual in having a Water Supply Grid funded over an 8 year (2 AMP period), further details are available in Appendix 3.</p>
23) What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?	<p>Our experience is that new development is often placed ahead of sustainably drained new development. This is because drainage matters and the cost consequences for ensuring that satisfactory arrangements have been made for sustainably drained new development are often considered too late in the planning process. Sustainable drainage often (but not always) requires more space and can sometimes require greater investment to ensure the right infrastructure is provided.</p> <p>If, however, recognition of these needs are not made early on at the viability stage of new development, shortcuts and non-ideal solutions are often made to shoehorn drainage provision in as more of an onerous afterthought and costly inconvenience rather than an integrated and often value-adding element of a new development.</p> <p>Recent changes in governance have enabled greater consultation and discussion amongst responsible bodies but there is still limited joined up delivery on the ground.</p> <p>One body responsible for drainage functions would be an improvement- recommendation from Environment, Food and Rural Affairs Committee.</p>
24) How can we most effectively manage our water	<p>Planning, operational and maintenance plans across sectors done at a catchment and sub catchment scale. This can bring greater awareness of risks/faults in the systems, which may affect other infrastructure providers or other</p>

<p>supply, wastewater and flood risk management systems using a whole catchment approach?</p>	<p>organisations, which could be resolved more efficiently by others or by pooling budgets with multiple organisations. More integrated master planning that create water, climate and health sensitive places can have multi-beneficial solutions beyond water and flood risk management systems. Appendix 1 details the work in the Bristol Avon Catchment.</p> <p>Wessex Water is the first water company to trial an innovative Catchment Permitting option for reductions in phosphorus discharges from our sewage treatment works at a large geographical scale. This solution has enabled phosphorus removal to be delivered under the water Framework Directive. Due to the disproportionate cost exemptions within the Directive a traditional solution at individual sites would have failed the cost benefit assessment. This catchment scale solution delivers the required phosphorus reductions at a cost of £20m less than the traditional approach: https://gis-services.wessexwater.co.uk/storymaps/environment/stour/documents/Investigations/4688.pdf</p>
<p>25) What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?</p>	<p>Wessex Water has managed flood risk using a risk matrix approach for a number of years. See diagram below.</p> <p>It works on the principle that where impact/consequence of flooding is higher, acceptable standards of protection should be higher.</p> <p>All properties/areas that have experienced flooding and lie above the line of acceptable risk form part of the prioritisation process for investment to reduce risk. Company targets are set based on a total risk score, which is made up of the sum of all the risk scores from each part of the risk grid.</p>

Flooding Risk Matrix: Number of Properties / areas				Impact					<table border="1"> <thead> <tr> <th>Nr of Properties /areas above the line of acceptable risk</th> <th>Total Risk Score</th> </tr> </thead> <tbody> <tr> <td></td> <td>51509</td> </tr> <tr> <td>407</td> <td>10943</td> </tr> <tr> <td>662</td> <td>14864</td> </tr> <tr> <td>432</td> <td>12232</td> </tr> <tr> <td>607</td> <td>11590</td> </tr> <tr> <td>188</td> <td>1880</td> </tr> </tbody> </table>		Nr of Properties /areas above the line of acceptable risk	Total Risk Score		51509	407	10943	662	14864	432	12232	607	11590	188	1880

Probability	Very High	5	2:10yr	19	31	196	133	28	407	10943														
		4	1:10yr		45	368	189	61	662	14864														
		3	1:20yr			13	44	375	432	12232														
	Very Low	2	1:30yr				69	538	607	11590														
		1	1:50yr					188	188	1880														

Example of Flood Risk Grid used by Wessex Water to visualise and prioritise flood risk and investment prioritisation.

Such an approach could be adopted more widely than sewage flooding risk, and extended to be used for pluvial, fluvial, groundwater, coastal flooding risk.

Using a single approach to flood risk across the country and across the flood risk management organisations, could bring a cohesive and joined up approach to prioritising flood risk reduction investment across the UK.

26) What are the merits of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Greater communication, planning, and management between sectors is needed to address increasing climate change risks. Understanding of the upstream/downstream impacts allows us to plan more intelligent solutions which can be incorporated into the public realm and create better-designed spaces.

Natural Flood Management (NFM) may have a role in reducing peak flows or slowing down flows as we become more aware and begin to factor in ecosystem services provided by natural capital wider more integrated urban design

	solutions that address water, climate and health impacts should become more mainstream in the design of our infrastructure.
--	---

Case study: market approaches to resilience (Bournemouth resilience supply)

In the south of our region we have worked with Bournemouth Water to improve have improved the interconnection between our water supply networks, allowing up to 20 MI/d to be transferred in either direction should one company have an issue affecting the resilience of their supplies to customers. A significant improvement has been achieved in resilience by making each other's water infrastructure available for use by the neighbouring company should that be necessary.

Case study: smart abstraction licences – reducing the impact of abstraction on river flows while maintaining resilient water supplies

One of the key objectives of our water supply grid project is to reduce the amount of water we are allowed to abstract from the Hampshire Avon catchment. Detailed studies between 2005 and 2010 showed that if we were to abstract at our full authorised rate there would be a significant effect on the river flow and its environment. The reductions in authorised abstraction, 25 MI/d, will be implemented in April 2018 following the grid's completion.

However, as originally planned, these reductions would locally have reduced the resilience of our supplies. We would not have been able to use existing infrastructure to deal with short-term operational outages or rising nitrate levels at sources which are not subject to a reduction to improve river flows.

To maintain and improve resilience against these threats we developed revised abstraction licence conditions with the Environment Agency, which allow us to maintain abstraction for short periods to deal with operational outages and for longer periods when nitrate levels (and river flows) are high. While these revised abstraction licence conditions are very complex, they ensure that the environment is protected at the same time as ensuring that we avoid stranding assets that would make water supplies less secure.

Case study: The water supply grid

The water supply grid is an eight-year project to improve the security of supply for customers. New pipework is connecting areas of our region with a water deficit to areas with surplus water. This will allow us to continue meeting demand for water during drought periods as well as in normal weather conditions. It will also help us reduce the water we abstract as required in some places to improve river flows and protect their ecology.

The project comprises more than 25 new schemes across Somerset, Wiltshire and Dorset, involving more than 150 km of pipeline, 30 new pumping stations and 11 new storage tanks. The diagram shows the main new links, including a major north-south pipeline running from north of Poole to the centre of our region, and a number of smaller connections and extensions. By joining up our main supply pipes in this way, we are able to do a number of things at once: meet demands for water, deal with groundwater sources suffering from higher nitrate levels, and deliver environmental benefits without developing new water resources or providing additional treatment.

Careful construction is very important as our region is environmentally rich, containing many protected species and a variety of designated sites including Sites of Special Scientific Interest (SSSIs), County Wildlife Sites, World Heritage Sites and Areas of Outstanding Natural Beauty (AONB). We intend to build the new pipelines in ways that cause minimum disruption to local communities and minimise construction traffic movements.

So, we carry out comprehensive environmental and engineering surveys, which help us understand and address environmental and community considerations, both during design and construction. We use construction techniques such as trenchless technology to pass under sensitive river locations, railways and major roads, and we re-use excavation and construction materials where feasible.

We are consulting local interest groups and members of the public to ensure their views are incorporated into pipeline routes and the design of new buildings. The project, which began in 2010, will be completed in 2018, with some elements finished in 2013.

The project comprises more than 25 new schemes across Somerset, Wiltshire and Dorset, involving more than 150 km of pipeline, 30 new pumping stations and 11 new storage tanks.

The National Infrastructure Assessment: Call for Evidence - West of England Response

Summary

The West of England (WoE) is a significant driving force for economic growth in the UK. Growth has exceeded the national average over the past 15 years, productivity is highest of all core cities and the **region is a net contributor to the UK economy**. The region has a strong track record on innovation and knowledge-intensive industries, a growing workforce with high levels of skills, growing high value-added industries and considerable strength in export-heavy industries. The motorway, rail, air and port infrastructure make this a **truly super-connected city region** and this connectivity facilitates a high proportion of local businesses competing internationally.

However this success cannot be taken for granted. Recently productivity growth has dipped, growth has not translated into jobs post-recession and jobs created across growing industries have failed to offset big job losses in other areas. Crucially, the region's infrastructure is under strain:

- Housing availability is increasingly constrained, house prices in the West of England are the highest of any core city relative to median earnings
- Congestion and reliability of public transport is a growing problem; levels of congestion are amongst the highest in the UK, public transport plays a much smaller role than in other areas - only 6% of residents of the West of England use public transport to get to work.
- There is significant variation of broadband speed and connectivity across the region.
- And the workforce is set to grow a further 5.2% over the next 10 years, adding to the pressure.

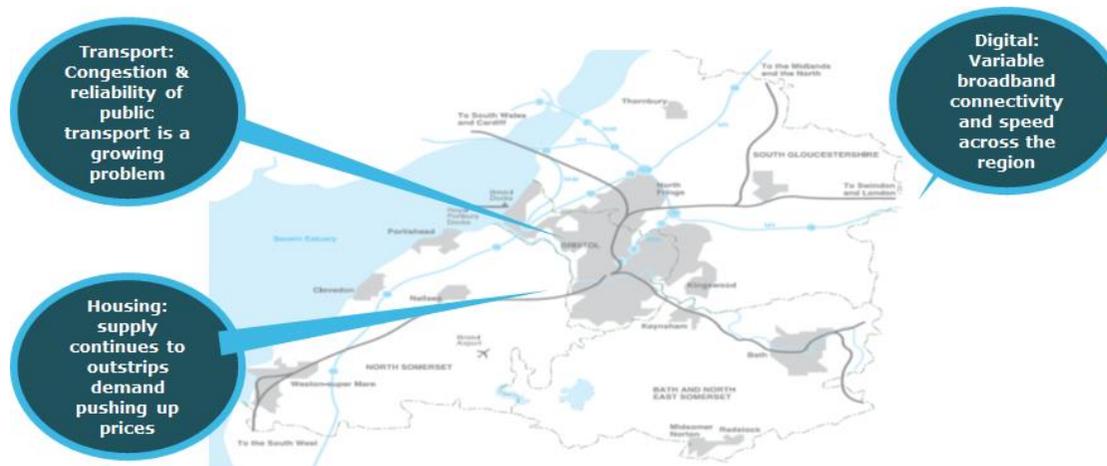

Figure 1: WoE Challenges

The West of England position as a transport hub means that problems on the region's road and rail network have knock on effects for neighbouring regions.

The West of England authorities are working together to address these challenges with **a strategy to plan transport infrastructure and houses together** – the first of its kind in the UK. This 'Joint Spatial Plan' (JSP) will be a Statutory Development Plan document that will provide a strategic overarching development framework for the West of England to 2036. Along with the parallel 'Joint Transport Study', these plans will allow strategic decisions to be made to deliver integrated housing, employment and transport opportunities so we can build sustainable, diverse communities which are well connected to job opportunities. The new West of England Combined Authority will play a crucial role in driving the strategic delivery of a high skilled, competitive local economy that facilitates inclusive growth for a diverse population and in which quality of life and prosperity is protected for future generations.

As an international gateway, a net contributor to the Treasury and a City-region with a new devolved governance, the West of England offers huge potential to test innovative and ambitious proposals to deliver effective infrastructure and identify the productivity and economic uplift arising. We are determined to ensure that the West of England continues to play its role as a key driving force for growth in the UK. We would like to work with the Infrastructure Commission on a focused piece of work to explore the potential for;

- **A funding pool to make our own strategic decisions** (arising from national and local strategic planning)
- **Building upon existing relationships and partnership work** e.g. Wessex water, HE funding into the Joint Transport Study, EA engagement with Avonmouth/Severnside and JSP
- **Piloting projects to test solutions locally;** some examples of possible projects are set out below but we would like to explore the options with the Commission.

As highlighted in detail in the Core Cities response to the NIC call for evidence, for places to work effectively it is crucial that infrastructure is seen in a holistic way. This is critical to avoiding the knock on effects that are obvious at a local level; such as the health and social care implications of vulnerable households living in inefficient homes that they cannot heat or power; or the economic and health consequences of a failure to invest in low carbon transport systems. It is vital that consideration of future infrastructure provision has regard to:

- Resilience – to climate change, geo-political events, etc.
- Efficiency and sustainability.
- Environmental & social standards – investment in infrastructure offers an opportunity to build high environmental and social standards in to the tender and design specifications, potentially building a competitive advantage in building low carbon infrastructure for the UK
- Interconnectedness of the regulatory system.

Background

The West of England covers the four unitary authorities of Bath and North East Somerset, Bristol City, North Somerset and South Gloucestershire. Centred around the cities of Bristol and Bath, the West of England City Region forms its own unique area with a history of global trade and connectivity, diversity of people and jobs, strong productivity, high-value employment, and a skills base to match with a proven track record of success. With an economy worth some £31.7bn, the West of England is a net contributor to the UK economy.

The West of England is a super-connected region both nationally and internationally. It is a motorway intersection serving the M4 corridor enabling powerful economic relationships through to Swindon, Oxford, Cambridge, London (East) and Newport, Cardiff, Swansea (West). Likewise the M5 connects the South West and the nationally significant energy projects at Hinkley and Oldbury and offers access to the Northern Powerhouse via the West Midlands.

Bristol Airport and Bristol Port offer growing international connectivity and both have significant growth plans, with the Airport seeking expansion from 10m to up to 20m passengers per annum, and additional deep water container capacity proposed at the Port. However, despite **Bristol Airport being named the UK's best performing airport** in January 2016 for a second consecutive year; plans to increase passenger numbers are constrained by the surrounding infrastructure, and the productivity growth of the Port risks being curtailed by the withdrawal of the rail electrification proposals.

The UK Government's recently published "Industrial Strategy" recognises that ports are hubs for employment and it suggests that improving connections to ports can help to promote trade and create jobs. **Bristol Port deals with imports and exports from almost every continent** and its West-coast position, close to the centre of the UK, makes it extremely attractive to customers seeking to move goods to and from the Midlands and M4 corridor. The Port is a multi-modal transport hub providing storage and processing facilities within its secure estate.

It remains crucial that Bristol Port's links by sea, road and rail are not compromised by conflicts with passengers and commuters and that congestion on the transport networks is addressed to maintain the Port's competitive advantages associated with rapid movements of cargoes to and from the Port.

Publication of the Hendry Review has been welcomed and its conclusion that any tidal lagoons in the Severn Estuary must not impact established commercial organisations such as the Port of Bristol, but we would caution against the conclusion that Tidal Lagoon Swansea should be seen as proof of concept. The Port of Bristol's potential sensitivity, as nationally significant infrastructure, to the future cumulative effect of massive lagoons in the Estuary, needs to be understood fully.

As a city-region **we would urge that developments further into the Severn Estuary are not permitted to proceed until the impacts on the Estuary are understood fully, and mitigation developed.** The unregulated development of Tidal Lagoons will have devastating effects on the environment and established users of the Estuary.

The West of England faces a huge congestion challenge with no resilience, which poses a significant threat to productivity and an increasing threat to air quality. Infrastructure provision through to 2050 increasingly needs to contribute to a modal change away from car dependency and supporting both public and low carbon transport. Delivering that modal shift requires a public transport system is reliable and an attractive alternative.

The region-wide Joint Transport Study undertaken by the 4 Authorities has already identified a **transport infrastructure deficit of more than £7.5bn** to meet the region's existing and future development needs to 2036, at least twice as much as the West of England Councils are currently spending on building transport schemes. The emerging Joint Transport Plan will need to address a compelling congestion challenge by expediting arterial and radial routes in and across the city region so as the local population can access local employment. Whilst funding can be sought through partnerships with the likes of Network Rail and Highways England and funding from developer contributions through the planning system, there will still be a significant deficit. Opportunities for financial incentives and financial approaches to demand management will need to be considered, such as built in charging mechanisms (e.g. car parking). The region will also look to further opportunities through devolution for local accountability of budgets and assessment of transport priorities. The establishment of a West of England Combined Authority for example and an annual Investment Fund of £30m will afford some **transport projects to be expedited with dedicated local funding** that was previously subject to costly and prolonged competitive national pots. Devolution is a significant opportunity to match expedited delivery with local accountability and one that the region would like to maximise.

Rail and rapid-transit offer the most ambitious opportunities for the region but also the most expensive and often with greatest risk. We have therefore provided below some very specific ambitions for rail in the region and **invite the Government to explore the West of England as a pilot region for an innovative new approach to the funding and delivery of local rail schemes**. Critical to the sustainability of the region will be the delivery of the electrification of the mainline, the redevelopment of Temple Meads Station and the delivery of our MetroWest Phases 1 & 2.

We are therefore working together with a range of strategic partners across the public and private sectors to tackle this infrastructure and investment deficit. The devolution of powers and money to the region from central government means we have responsibility for a local transport budget and a new Key Route Network of local authority roads that will be managed and maintained within the region and an investment fund to be informed by a robust and integrated statutory planning framework.

Affordability of homes in the West of England is also a critical issue with average house prices being between 7-9.5 times the average earnings across the Authorities. This is not an issue confined to the West of England but it is particularly acute here. Ensuring that our workforce has access to appropriate range and type of affordable homes in the right places to access employment opportunities is critical to ensuring sustainable economic growth. The JSP will provide the framework to deliver up to **105,000 net additional new homes between 2016 and 2036** of which, around 32,200 (30%) should be affordable homes. The four authorities' existing Core Strategies make provision for some 66,000 dwellings meaning there are up to 39,000 additional dwellings that

need to be planned for through the JSP spatial strategy. We need to explore the mechanisms for delivery and how to address the shortfall of delivering affordable homes in particular social rent products that can help to provide housing opportunities for all of our workforce.

The distinctive regional geography also offers opportunity, with the expansive Severn Estuary already subject to two nationally significant **nuclear projects set to provide 12% of the nation's energy**. The Estuary also affords opportunities for **innovative energy solutions, combined with flood defence schemes** that can open economically viable areas of the existing floodplain.

Case Studies & Specific Proposals

The rest of this submission sets out some examples of the sorts of case studies that we would like to discuss with the Commission. These highlight some of the key infrastructure issues faced in the region where involvement from the infrastructure commission could provide support to unblock progress.

1. Commitment to support for the delivery of the infrastructure to relieve the £7.5bn deficit identified by our Joint Transport Study.
2. Create a pilot with the WoE that looks at funding alternatives linked to the delivery of local rail schemes, to create an equal risk and reward framework that will encourage more third party investment in the rail network.
3. A national infrastructure approach to the provision of heat networks; energy efficient investment in UK homes supported by a zero carbon approach to planning policy and building regulations; single infrastructure budgets to deliver place-based solutions; national research into maximising energy demand management; additional revenue support for innovative energy projects; development of demand-side measures on the local electricity networks
4. Resource to deliver a water drainage strategy which meets new demand and fulfils drainage, health and environmental issues collectively
5. Create an Integrated Catchment Management approach with all key stakeholders to create an Adaptation and Resilience Framework that enables greater awareness of the integrated risks between sectors. Complemented by expansion of an innovative catchment based social prescribing demonstration project to improve the public health, water quality and amenity provision across a large geographical area.
6. A package of digital infrastructure measures to enable the region and the country to compete internationally

Transport case study: Better aligning the risks and rewards of investment in rail improvements

The rail network in the West of England has the potential to provide a catalytic change in travel behaviour, provide a focus for urban redevelopment around existing and new stations and be better linked to other modes to enable a truly multi-modal transport network. The West of England has carried out extensive modelling to define the first set of improvements (Metrowest Phase 1 & 2) in partnership with Network Rail and is continuing to plan for the future with Network Rail as part of the West of England Joint Transport Plan.

Unlike other forms of infrastructure, the planning and delivery of new and improved rail infrastructure is more complex and more difficult to link to financial beneficiaries in order to generate private sector contributions to new schemes. Equally the relatively short return periods used when calculating economic benefits suppress BCR and tend to favour other modes when attracting DfT funding.

The West of England rail network also serves as a strategic cross roads for rail at a national level and the interaction of local and national services results in the infrastructure upgrades required to expand local services, having to fund signalling and permanent way improvements on the 'national corridors'. While this is not unreasonable, the additional benefit to Train Operating Companies in increasing passenger supply for national routes is not factored into or recycled back to fund the scheme. These issues make Local Authority funded rail improvements difficult to deliver with all risks placed on the promoter and no financial upside should the scheme be successful.

It is clear to us that change is needed to how third parties and in particular local government, channel investment in the national rail network. The current arrangements all too often force local councils to be the sole promoter of a scheme, exposing the council to all the costs and all the risks in a context of a network that is owned, regulated and operated entirely separately from the councils. The result of this is the promoting council has very little control of the cost and the risks of the scheme and is reliant on Network Rail to develop the scheme and manage the design development. Clearly local councils are not best placed to be the sole promoter of a rail scheme, but they do have a role to make worthwhile investments in the network. One of the key recommendations of the Shaw Report 2016 was that Network Rail need to lever in more investment in the network from third parties including local government. However **the current system places 100% of the cost and risks upon the third party promoter, which in our current experience is difficult to manage given the lack of control and input we have into the delivery process.** The current model will probably not deliver the scale of investment from third parties, advocated in the Shaw Report. The model needs overhauling to **maximise the potential for leveraging in third party investment, where costs and risks are shared between the third party and Network Rail.**

- What is the proposed remedy?

In order to overcome this the NIC should consider how the funding and delivery of Local Rail schemes can be speeded up and developed to create **an equal risk and reward framework to encourage more third party investment in the Rail Network**. Equally the ability within the **planning system to link the funding of the scheme to direct and indirect beneficiaries of the scheme** would accelerate delivery. Using our experience as third party promoter of rail schemes over several years, we have set out in **appendix 1**, a mechanism for how costs and risks could be shared between the third party and Network Rail. Ultimately the rail industry must be structured in such a way to deliver projects on time and on budget.

- How does this fit with the national context?

Many other City Regions have similar transport infrastructure issues to resolve and rail has the ability to provide long term sustainable solutions that would create a significant behavioural change. When looked at in a multi-modal context, **rail is normally the preferred mode for medium and long distance journeys** due to its ability to move large numbers of people quickly to a single point.

- How does this address the objectives of the National Infrastructure Commission (i) support sustainable economic growth across all regions of the UK, (ii) improve quality of life

Future employment growth is likely to be focused in city centres, major towns and in sector clusters out of town, the expansion of the local rail network to **move people quickly and with resistance to congestion over the long-term**, to these locations, supports sustainable growth.

- What will the benefits be locally?

Metrowest Phase 1 & 2 have been designed to **reduce the use of private cars on existing transport corridors to free up road space for bus rapid transit and cycling and crucially reduce some existing congestion hotspots on the strategic road network**. Proposals for further targeted expansion of the local rail network would aim to increase this impact further.

Energy case studies

- What is the issue?

The energy infrastructure of the UK is currently experiencing radical change as it continues its journey from a centralised system reliant on fossil fuels to a **decentralised and embedded energy system, with more intermittent renewable generators and fuels for power, heat and transport**. In addition the

effects of smart digital technological advances experienced by other industrial sectors e.g. high street retail, have yet to be implemented within the sector, but will undoubtedly transform the provision of energy services within the UK.

The West of England has long been recognised as being a centre for the new sustainability and environment entities established in the later quarter of the 20th Century, along with being a leading UK centre of excellence for digital technologies (e.g. SetSquared). It is the collaboration of knowledge-based and innovation companies within the region that will drive the new business arrangements and opportunities within the energy sector, which the region is attempting to capture through **the development of sustainable energy, growth and digital infrastructure**. The WoE is doing this because it reduces carbon emissions, increases local wealth, reduces the social and health impacts of a fossil fuel energy system (e.g. air quality, fuel poverty), increases the security of supply thereby attracting industry and commerce and improves the quality of life for our residents, thereby making our region more attractive for inward investment.

- What is the proposal?

There are a number of principal infrastructure and policy interventions that can make a significant difference to the provision of sustainable energy and growth for the region. These are as follows;

a) Heat networks

The development of infrastructure should be considered in the context of efficiency and the delivery of heat, which represents 45% of the final UK energy demand. **The WoE would like to see a national infrastructure approach to the provision of heat networks**. These allow delivery of heat to be undertaken in the most efficient and low carbon manner, while improving the overall efficiency, resilience and capacity of the UK energy system through the increased use of combined heat & power plants on heat networks. In Bristol we are currently developing two heat networks within the city centre either side of the floating harbour, while at a regional level we are currently investigating the development of a heat network in Avonmouth that would bring waste heat from our industrial processes to the City centre via the new developments in South Gloucestershire around the former Filton Airport to the north of the city.

b) Energy efficiency

The WoE strongly support the UK Green Building Council's well evidenced response to the NIC's call for evidence in autumn 2015 for a wide-scale and deep retro-fitting of energy efficiency measures to homes. We suggest that **energy efficiency investment in UK homes** should be seen as an infrastructure investment.

In addition to retro-fitting, a clear and strong policy decision is needed now regarding **zero carbon planning policy and building regulations** as they are impacting on current building stock and currently acting as a barrier to zero carbon solutions. Current building regulations and design standards are also resulting in building stock which will constrict the extent to which zero carbon solutions can be delivered over the next 50 years.

c) Regulatory change

The UK currently has a silo approach to infrastructure from regulators whether government or OFregulators. For example: Bristol is seeking to develop holistic cross-discipline infrastructure solutions to build a resilient and 'future city', the prime example of this being the Temple Quarter Economic Zone (TQEZ), where the Council is interlinking local and national transport, city physical and economic development; research and academic capacity and utility heat and superfast broadband infrastructure, to build an economic zone which creates sustainable, future resilient economic growth over this century. However, this is against a backdrop of regulation which is established to achieve economic efficiency within its "silo" rather than economic efficiency across a programme of place-based infrastructure. **The WoE strongly advocates place-based single infrastructure budgets / programmes to enable holistic and efficient development of placed-based infrastructure.**

In addition, the WoE assert that local authorities should be a statutory consultee to other utility and infrastructure entities investment plans to ensure that these investment plans overlay and interlink with the economic development and growth plans of the region.

d) Smart systems

The UK is well behind its international competitors in the delivery of full fibre infrastructure to the premises. Portugal and Spain has 60% coverage compared to 2% in the UK. This is already impacting on our reputation as digital leaders and in the medium to long term, will impact on international inward investment decision making unless it is addressed. The recent NESTA Digital City Index confirmed none of the UK cities surveyed scored highly on digital infrastructure because of this.

In this context, the WoE would welcome **opportunities to accelerate investment through the Government's Digital Infrastructure Investment Fund**, whilst recognising the £400m funding allocation for the whole of the UK is relatively small compared with the size of the task. It will therefore likely have to be targeted at Cities to deliver the best return on investment. Further investment will be needed in fibre moving forward in order for WoE to remain competitive with peer cities in Europe. The public sector has an important role in facilitating this through aggregation of demand.

In terms of the energy system specifically, the WoE would suggest that the maximum potential for demand management is yet unknown. As a country we have yet to fully integrate advanced software in terms of the internet of things and also in behavioural demand response. **We would strongly advocate a**

range of quick separate research lines of enquiry across a range of academic disciplines into the potential. It should also be noted that many of these possible interventions in the demand side will be at the local level and will require involvement of local government in a number of capacities, there is significant risk to this as public sector finances across the country are under increasing strain.

However, the introduction of smart meters in the domestic market has provided the ability to understand usage and enable utilities to understand consumption, thus allowing the potential to change payment processes/structure e.g. to 30 minute pricing. This facilitates moving consumer demand to high cost and low cost, thus pricing can be used as a mechanism to shift energy consumption to more appropriate times of the day e.g. less demanding times. Through smart metering we may encourage residents to be more energy efficient e.g. turn off lights.

e) Funding allocations

The WoE would assert that there are a considerable number of **energy infrastructure projects and programmes that are “stuck” in the development pipeline due to the human resource capacity constraint in terms of skills, numbers and experience** within both the public and private sector. The principle area of difficulty is in the pre-feasibility / development phase of any programme. To that end we advocate that public sector funding, or funding to the public sector should include small elements of **revenue funding to unlock the pipeline** based on a five to ten leverage factor i.e. for every £1 of public sector grant would leverage five to ten of project value, which could be both public/private funded projects. **A combined grant and pre-agreed / authorised loan facility would enable projects to be enacted quickly.**

In addition to any new interventions, government energy policy needs to stabilise as energy projects in particular are struggling to secure investment as **policy uncertainty around subsidies etc. means investors are not willing to commit to long term projects.**

f) Demand-side

The WoE recognise that we can play a significant positive approach to assisting **the development of demand-side measures on the local electricity network** and increasing the take up of embedded generation systems.

Demand side management and embedded generation will be key to a flexible and robust electricity system in the future. **Micro generation at the local or community level will form part of the energy mix** underpinned by a centralised base load of gas/nuclear generation when required. Wherever possible embedded generation linked to energy storage will be able to increase the length and frequency of demand side management, allowing the National Grid to increase the flexibility of the energy system.

The WoE would strongly advocate that **all the scales of demand side response are appropriate for future energy storage technologies**. Technologies employed at the transmission and distribution levels will provide additional levels of redundancy and contingency scales and allow the Grid to balance the energy mix at times of stress. The domestic scale will be able to benefit hugely from localised energy storage, which depending on type – battery, hot water or phase change materials – will allow householders to have a level of energy independence which when aggregated nationally can be used to shave peak demand where required. We have already installed batteries at the domestic scale linked to embedded generation.

- How does this fit with the national context?

Without a fundamental change in the energy system across power, heat and transport then sustainable growth will not be attainable and will ultimately lead to the UK missing its greenhouse gas emission targets. On a global scale it will be a small-scale contributor to the acceleration of climate change and the resulting economic, social and environmental impacts.

- How does this address the objectives of the National Infrastructure Commission (i) support sustainable economic growth across all regions of the UK, (ii) improve quality of life

The provision of the locally embedded and decarbonised energy systems linked to smart digital systems support the provision of sustainable economic growth and improved quality of life for the residents and businesses of the WoE. In addition, it continues to **support the region's leading edge industries** and entities within this region.

Water supply and demand case study: Resourcing Water Drainage Strategy alongside the Joint Spatial Plan

- What is the issue?

The West of England has ambitious growth plans as set out in the emerging Joint Spatial Plan (JSP). A key objective is to ensure that new development is properly supported by and aligned with the necessary infrastructure in a timely way. This includes both water supply and drainage. Discussions with infrastructure providers have indicated that **substantive network improvements are required to support the scale of development proposed**. This is particularly an issue for urban extensions and new settlements which will require significant network development. Bristol & Wessex Water are responsible for the delivery of water supply and sewerage treatment in the West of England, and like all utility companies, they are required to produce **5-year business plans** for approval by OFWAT. This **short time horizon is not helpful** in the context of JSP / planning for growth and providing certainty to the development industry over 20 years

- What is the proposed remedy?

The West of England UAs are preparing an Infrastructure Delivery Plan (IDP) to accompany the JSP and address the issues raised above. **Additional resource to address the water drainage part of the IDP would be beneficial.** This would enable formulation of a water drainage strategy which meets new demand to enable the timely progression of development in an innovative way. This approach would enable **a plan for the expansion of the water drainage network to support the growth locations in an efficient way.** This could include;

- the establishment of a multi-disciplinary agency to strategically oversee the management of water and waste water (such as the Dutch Water Boards¹) to bring together the currently fragmented stakeholders and silo operations. the closure of some treatment plants which would help enhance the viability & good planning of some locations and the expansion of other plants which would facilitate the most efficient operation of network
- Inclusion of multifunctional drainage mechanisms which help to mitigate climate change & provide green infrastructure (eg SuDs), which facilitates active travel modes & recreation
- Improvements to the water drainage system embedded in the new strategy for growth which is robust for the very long term to avoid the needs for ongoing, expensive ad hoc interventions with reduced maintenance costs and long term reliance.

- How does this fit with the national context?

This plan would help to **deliver economic growth and accelerate the provision of new housing** as well as facilitating preventative health objectives, for both physical and mental health.

- What will the benefits be locally and how does this address the objectives of the National Infrastructure Commission? (i) support sustainable economic growth across all regions of the UK, (ii) improve quality of life

¹ Dutch Water Boards levy their own taxes (through pollution) and receive central government finances. They are responsible for quality of surface water (canals, lakes, ponds and streams), policy making, planning and building, issuing permits and treatment of sewage.

The supply and affordability of housing in the West of England is one of the key challenges facing the city-region. A multi-disciplinary and longer term approach to water drainage will enable the provision of new housing and maximise development viability which facilitates the support that can be given to achieving the optimal development outcomes and enhances the quality of life for existing and new residents

Catchment Area Planning Case Studies: Adaptation and Resilience Framework Pilot and Social-Prescribing Pilot

- What is the issue?

To improve efficiency and reduce duplication, infrastructure should be designed, planned and delivered through a holistic systems approach with greater understanding of the risks and opportunities across sectors and political boundaries. **The UK Climate Change Risk Assessment (July 2017) has identified Flood Risk and Heat Stress as the two high risk issues that need to be addressed in the next five years.**

Adaptation measures are required to protect infrastructure from loss of capacity, or failure, as a consequence of increased risk from flooding and heat stress. Such measures could include **increased investment in green infrastructure in key locations** to provide multi beneficial solutions and a related pilot is underway to tackle the growing threat of pharmaceuticals in the riverine environment. This 'social-prescribing' pilot will be dependent on well-planned, accessible green infrastructure.

Spatial planning done at this scale and with greater integration across sectors enables an understanding of the interdependent impacts of upstream land use changes on downstream assets. Stronger integration between sectors in strategic planning, as well as ongoing asset management and maintenance, can help mitigate against failure of multiple infrastructure systems.

Surface Water Flooding is currently the responsibility of unitary authorities resulting in different levels of technical understanding of the issues, data and possible multi-beneficial solutions as well as different levels of capacity and financial resources to address the issues. A catchment scale approach enables a coherent plan to be developed where expertise and resources can be pooled across unitary authorities and more targeted consultancy services can be brought in. The recent flood resilience review highlighted that there are gaps in how the business case for flood risk is made paying little attention to the transport, digital communication, and energy network corridors between properties.

- What is the proposed remedy?

The Adaptation & Resilience Framework for the Bristol Avon Catchment is a pilot project that begins to address these issues by bringing greater integration between sectors and organisations around **spatial planning at a catchment scale** by building up evidence at a sub catchment scale. The project provides a vehicle for multiple organisations to plan for better integrated solutions to shared risks.

The Adaptation and Resilience Framework enables a greater awareness of the integrated risks between sectors and at different levels within individual organisations, from strategic planning to asset management on the ground. It improves **sharing of data and mapping, enabling pooling of budgets to deliver collaborative and multi-functional solutions**. It enables issues to be addressed at source rather than by end of life costly solutions.

An integrated Catchment Management approach allows all parties to have sight of the competing demands for the provision of roads, cycle ways, pedestrian footpaths, on street parking and green infrastructure. This project does not require a significant overhaul of organisational responsibilities but rather facilitates improvements between organisational communication and planning and more efficient expenditure of resources. **Additional resource to pilot this approach across the catchment would enable tangible benefits to be demonstrated which could then be rolled out nationally** and through the Adaptation and Resilience Framework multiple organisations can begin to understand and plan for the wider risks from climate change.

The wider costs and potential solutions could be captured through existing planning processes such as the Strategic Flood Risk Assessments (SFRA) (stage 1 and 2) for new developments. By surface water modelling upstream from development sites as part of the SFRA, evidence can be built up to locate where the most appropriate areas for green infrastructure provision to protect development sites should be. It also provides a mechanism for developer to understand and contribute to investment in green infrastructure to protect development sites from surface water flooding.

Embedding principles around Green Infrastructure and sustainable urban design can address issues of heat stress and flooding through incorporating integrated water, climate and health sensitive urban design.

Green Infrastructure also has a critical health role. Wessex Water is working with B&NES Public Health department, the University of Bath and a number of NGOs to test the effectiveness of social prescribing to improve societal health by offering alternatives to pharmaceuticals for those at risk from lifestyle conditions (e.g. Type-2 Diabetes, Obesity). The study is a snapshot covering a maximum of 70,000 people within the most deprived areas of Bath, working with three GP practices, over a four-year period. Without intervention, pharmaceuticals will continue to pass through to river systems through the sewerage network.

Social prescribing includes options such as walking, gardening, green gyms as well counselling, art groups and integration projects to offer exercise, social inclusion and support as an alternative to the prescription response. Strategic planning of green infrastructure is therefore hugely complementary to delivery. There has been much research from organisations such as Mind and the Marmot Review (2010) demonstrating the benefits of access to the

environment on societal health and wellbeing. However, in order for social prescribing to be effective receptors are required, these include the support networks, education and amenities which make access to greenspace easy and non-threatening to the public. In the WoE we would like to trial an innovative catchment based social prescribing demonstration project to improve the public health, water quality and amenity provision across a large geographical area. **A demonstration of this scale would cost £2.5m to deliver** and would link with a potential 'Innovative Catchment Trial' as part of the PR19 Water Industry National Environment Programme, described in the Environment Agency's Draft Chemicals Strategy.

By way of alternative, Wessex Water has identified that in order to broadly achieve the Environmental Quality Standards for pharmaceuticals across the Bristol Avon catchment, **approximately £550m capital investment would be required at sewage treatment works** serving more than 10,000 people. This would increase the average water bill by £200 per year, putting additional strain on customers and potentially driving an increase in anxiety and depression. It should be recognised that these end of pipe treatment technologies are energy and chemically intensive processes.

- How does this fit into the national context?

Planning at a Catchment scale is in line with the future direction of DEFRA outlined in the 25-year plan for the environment which is due to come out later this year and may become a recommendation in the National Adaptation Programme. This is also in line with the Climate Change Act 2008 where local authorities need to proactively plan with their partners Adaptation measures and is in line with many of the recommendations that came out of the recent Flood Risk review. It aligns with Defra's direction to water companies advocating the Catchment Based Approach.

Support for innovative social and early interventions can significantly reduce the expense of infrastructure resilience required to tackle the threats to river systems and catchment areas through the likes of pharmaceuticals.

- What will the benefits be locally and how does this address the objectives of the National Infrastructure Commission? (i) support sustainable economic growth across all regions of the UK, (ii) improve quality of life

The catchment based strategic planning alongside the JSP will enable co-ordinated local approaches to flood risk mitigation that supports the supply of land for housing and employment growth and for sustainable development of physical and green infrastructure that delivers a quality of life, addressing the emerging challenges to society.

Digital Case Study: Package of Interventions

- What is the issue?

Variable connectivity currently limits sustainable economic growth and the quality of life for residents in the West of England. An accelerated transition to ultrafast speeds and widespread availability of full fibre (fibre-to-the-premises FTTP) connectivity is required for its future prosperity, and to improve choice and competition in the market.

Improved connectivity has the potential to transform public services, such as tele-health, and **reduce public expenditure in the future**. The West of England has a strong knowledge-based economy which needs excellent connectivity to compete with developed economies currently making the transition to ultrafast and full fibre. Businesses across the wider economy in the region need good connectivity as the norm in order to invest and grow.

Within the West of England as a whole, OFCOM 2016 Connected Nations data shows:

Local authority	Super Fast Broadband % availability	% Indoor 4G coverage	Ultra Fast Broadband % availability
Bath and North East Somerset Council	83	55	0%
Bristol City Council	93	97	1%
North Somerset Council	82	62	0%
South Gloucestershire Council	92	77	1%

A significant amount of the West of England is rural and this is reflected in the data. However, even within the urban areas, significant connectivity issues exist for residents and businesses. The West of England has a growing alternative network sector specialising in full fibre connections, however the city-region's broadband infrastructure is still dominated by BT and Virgin Media. Many homes and businesses lack a choice in provider, particularly away from

our urban areas where BT Openreach dominate. Investment decisions by incumbent operators have been selective which has led to many business parks / trading estates being poorly served. **Market failure in SFBB provision has resulted in several thousand SMEs only able to access superfast speeds through an expensive, dedicated lease line.** These are often slow to install, subject to long contracts and have a high monthly cost. They therefore lack choice and competition in their business broadband offer. With the trends of cloud computing and the ongoing shift of processes online, connectivity is vital to the future prosperity of the city region's economy, our ability to attract future inward investment and retain existing sectors, e.g. digital and creative, many of whom are dependent on faster connectivity.

Digital connectivity plays an important role in social and economic inclusion. Approximately, 18k residents in Bristol alone lack access to superfast broadband, with many more across the West of England. Digital exclusion in turn leads to additional need for other infrastructure, such as transport infrastructure as people are unable to work from home, or from peripheral locations.

Public services can also benefit from improved digital connectivity, the West of England has been successful in transferring many services online and delivering efficiency savings. Research projects in the region are demonstrating the potential of a new generation of services which offer the potential to transform public service delivery. These services require a step change in connectivity and a universal service to avoid further exclusion for vulnerable groups with high service needs.

The West of England is already **a leader in the research and development of smart city solutions** – such as connected and autonomous vehicles, smart electricity grids and the internet of things. These emerging areas are being tested on the City Region's research and development testbeds, such as the Bristol Open Network. This enables businesses to develop and test new commercial services in a safe environment. However, it is likely that the **real world connectivity, speed, reliability and general quality of connections will need to improve if the economic, social and environmental value of this research is to be realised.**

- What is the proposed remedy?

A package of interventions could help the city-region address its connectivity issues and facilitate this transformation. We are already developing some of these as part of a strategic approach to connectivity across the West of England but require national action to deliver others.

- Ensure the whole of the West of England is covered by a Broadband Delivery UK (BDUK) partnership, currently Bristol City Council is not included. This restricts funding and connectivity provision within the city.

- Ensure that new developments are built with UFBB and fibre as standard and a 2nd choice of BB infrastructure provider to help develop a more competitive market. This will require support through revision of the National Planning Policy Framework.
- Full fibre voucher scheme (FFVS) for businesses and residents to help stimulate demand and create new market opportunities.
- Provide infrastructure subsidies for upgrades in areas of the City-region experiencing market failure with no superfast broadband offer and to ensure key infrastructure has been upgraded e.g. BT Telephone Exchanges.
- Community wi-fi concessions focussed on areas of high footfall and district centres. On-street wi-fi is known to help the economy to grow.
- Ensure the City-region's business parks and small trading estates have a FTTP offer and competition between providers. Extend the use of council-owned ducts to full fibre providers to raise revenue for councils and help them extend their networks.
- The West of England has exceptional research and development expertise in our universities and businesses and we have created a world class testbed in the Bristol Is Open (BIO) network which is currently being extended to create an Open Programmable City Region (OPCR). Continued investment in this testbed and in projects which can exploit it fully is needed.
- Investment in 5G is needed and the West of England presents a good opportunity for pilot projects exploiting the BIO/OPCR infrastructure to create a 5G wireless city centre and replicate this in other urban centres in the WEST OF ENGLAND.

In addition, this could be supported by

- Better use of existing national fibre networks e.g. Highways England, JANET and Network Rail to improve choice and competition in our local connectivity market by making better links to national backhaul networks.
- How does this fit into the national context?

The UK as a whole faces a productivity challenge; improved digital connectivity will result in **productivity gains for businesses**. It will also improve the **attractiveness of the UK as a location for inward investment**.

- What will the benefits be locally and how does this address the objectives of the National Infrastructure Commission? (i) support sustainable economic growth across all regions of the UK, (ii) improve quality of life

Improved digital connectivity will have a positive impact on sustainable economic growth within the West of England improving the quality of life for residents and the potential for the transformation of public services, with the **potential to reduce public expenditure in the future**.

Dear Sir John

WEST OF ENGLAND REGION

Thank you to you and your colleagues on the Infrastructure Commission for visiting Bristol and for meeting with South West colleagues and with colleagues from the West of England region.

As West of England, we will be following up with evidence to your commission in the New Year but we wanted to reinforce the message that the West of England region should be considered as the centre of a highly productive economic region rather than as a part of the South or South West.

The West of England forms its own unique area with a history of global trade and connectivity, diversity of people and jobs, strong productivity, high-value employment, and a skills base to match with a proven track record of success second only to London. Yet, despite these attributes, possibly even because of them, successive governments have overlooked its promise with the risk that the region will plateau losing further growth for the benefit of all, and we're starting to feel the effects. A lack of investment into key infrastructure projects threatens to close the gate on growth at a time when the UK needs it most. We believe that it's time for policymakers to stop looking over our shoulder to the distant South West or to see our City Region as an outlier of the M4 corridor. We have a unique offer to the country and a significant role to play. Put simply, it's time to invest to put the Great Western Gateway on the map to help ensure Britain has a place on the global stage.

Our strategy to achieve this is simple and compelling. We are working together – the authorities of Bath and North East Somerset, Bristol City, South Gloucestershire and North Somerset, along with our Local Enterprise Partnership – to make the best case for investment so as to develop our strained infrastructure which holds us back from ever more success. We have created an integrated housing and transport plan so we can build sustainable, diverse communities that want to live and flourish here and contribute to the success of the West of England. We are attracting knowledge-rich businesses to invest here creating more jobs, more prosperity and more opportunity for people that live and work

in our region and for the country as a whole. We are integrating all of this with our universities to ensure we have the skills that meet the needs of our region and the needs of the employers that come here.

This seems so obvious. Yet it is unique. Other areas require heavy investment to regenerate and to get them to the starting blocks. Some have not come together for the benefit of their communities and are advancing disparate, poorly formed ideas. Some haven't even turned their attention to the importance of investment for growth. It is only the West of England that has a track record of success, a plan for delivering even greater opportunity, a united set of partners with a clear, consistent vision, and the geography required to trade [REDACTED]. The evidence in support of the West of England is overwhelming.

In [REDACTED] contribution to the UK has outperformed the national average: we generated £3,900 per person above other regions of England, making us one of the highest contributing Core City areas. That kind of performance has not happened by chance. Our region boasts one of the highest skilled workforces in the country owing to four universities that develop top talent, and our ability to attract and grow industries that keep our graduates in the area. The West of England has become an incubator for high-value sectors including advanced engineering and aerospace. Nearly a third of employees working in the area are employed in knowledge-based industries and tech manufacturing. Productivity in our City Region is the highest in the UK outside of London, and our region is far more than big business. SMEs born in the West of England have the highest survival rate in the UK.

Undoubtedly, ours is an area where highly-skilled people work, but it's also a region that a diverse population of people call home. The West of England continues to attract and retain residents who recognise our cities and towns as a gateway to a thriving art scene, an established creative industry and a reputation for bringing in the latest music talent: ours is a place where communities are forged as much through common interests as by proximity. These things combined have meant that Bath and Bristol regularly top national surveys identifying the best and coolest cities in the UK.

However, success is not without its challenges. Between 2001 and 2011, the population grew by 9%, more than in any other City region. By 2025, we expect our population to increase again by 19%. As the population grows, so too does the strain on our transport networks, housing supply and broadband connectivity. The effects are showing. Bristol ranks 6th of 17 cities on congestion, while house prices in the region are the highest of any Core City relative to median earnings.

The region is truly international with 56% of its business with annual turnover over £1m having subsidiary officers overseas and many businesses are connected to the world through Bristol Port and Bristol Airport allowing them to compete internationally. Now, more than ever, we want to make sure the gateway to international trade remains open, to the benefit of both our region and our country. Undoubtedly, ours is an area where highly-skilled people work. But it's also a region that a diverse population of people call home.

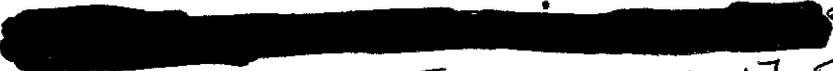

With the right investment and commitment from policymakers, we have the foundations in place so that, through the next decade, we can become the most prosperous region outside of London, and connected to the rest of the world.

The West of England looks forward to working with you and your colleagues in your important work for the Infrastructure Commission and we would be delighted to meet or speak again in the near future to discuss how we might work together to develop the infrastructure vision and plans for the West of England forward.

Yours sincerely

National Infrastructure Commission National Infrastructure Assessment Call for Evidence Submission from The Wildlife Trusts

1.0 Introduction

- 1.1 This submission has been developed by The Wildlife Trusts in response to the Commission's call for evidence to support the development of the National Infrastructure Assessment.
- 1.2 There is a Wildlife Trust caring for wildlife and wild places near you. We have a shared mission to create an environment rich in wildlife for everyone. We know that a healthy natural environment is the source of our prosperity and our wellbeing. We want to inspire people about the natural world so that they value it, understand their relationship with it and take action to protect and restore it. We are actively engaged in the planning system, promoting opportunities to improve the natural environment and review more than 60,000 planning applications a year. We have more than 800,000 members including 150,000 members of our junior branch Wildlife Watch. Every year we work with thousands of schools and our nature reserves and visitor centres receive millions of visitors. Each Wildlife Trust is working within its local communities to inspire people about the future of their area: their own Living Landscapes and Living Seas.
- 1.3 *A Living Landscape* is a recovery plan for nature championed by The Wildlife Trusts since 2006 to help create a resilient and healthy environment rich in wildlife and to provide ecological security for people. In *A Living Landscape* habitats are restored and reconnected on a large scale with the local community closely engaged. The vision is a primary objective of The Wildlife Trusts and builds on a groundswell of landscape-scale activity at a county level. The Wildlife Trusts have a long track record of delivering landscape-scale conservation. Across the UK there are now more than 150 Living Landscape schemes covering an area of more than four million hectares. These are being delivered in partnership with many different individuals and organisations, including farmers and landowners, water companies, land-based industries, local authorities, other NGOs, statutory agencies, local communities and volunteers.
- 1.4 We have an interest in this inquiry because any assessment of National Infrastructure must address nature and biodiversity considerations if planning is to fulfil its objective of achieving sustainable development¹.

¹ DCLG (2012) National Planning Policy Framework, Para 6

2. Key recommendations

By working with nature and not against it, the National Infrastructure Commission has a real opportunity to create a positive legacy by contributing to a healthy, sustainable and nature-rich future, which delivers multiple benefits for people, society and the economy. In achieving this, The Wildlife Trusts recommends:

- The commission's recommendations are founded on the five principles of sustainable development as set out in Government's UK Sustainable development strategy.
- Natural Infrastructure is recognised within the National Infrastructure Plan as a vital part of our national infrastructure and a priority for restoration alongside other infrastructure needs.
- Nature is incorporated into all major infrastructure development sectors and recognised as central to the decision-making processes of all developments.
- Infrastructure development is strategically and spatially planned, with local Ecological Network Mapping at the heart - to avoid damage to important natural assets and to maximise opportunities for natural solutions, restoration and enhancements.
- Rebalancing investment in flood defence and climate change resilience towards more sustainable natural solutions throughout the country.
- Greater levels of investment to support environmental retrofits to the existing road network are allocated in Roads Investment Strategy 2.
- Integration between the National Infrastructure Plan and local plans for housing to ensure new developments are well connected to essential services, transport and green space.
- The design of all new housing developments to incorporate green infrastructure and natural solutions that collect and capture water. With the nationally identified Garden towns and villages being exemplars of environmental sustainability and green infrastructure provision.
- All major infrastructure developments to:
 - have a visionary Green Infrastructure Strategy which sets out a measurable approach to achieve net gains for nature.
 - use the most up to date, locally relevant, ecological data and any survey data collected during development projects to be shared with local data providers.
 - have strategies for long-term monitoring of development impacts and mitigation/compensation requirements.
 - have strategies and funding for long-term management of green infrastructure.

3. General comments

- 3.1 This Government aspires that we will ‘*be the first generation to leave the natural environment in a better state than it inherited.*’ Achieving this, demands that the natural environment is seen as a thread of responsibility running through the activities of all Departments, not just Defra, and that all interested parties (Government, Business and civil society) work together in a new and focused way.
- 3.2 In the future, the pressures on land and the environment will continue to grow as the need for new housing, infrastructure and other development increases. Yet the growing population will also require clean water, space for food production, high quality soils and pollinators to support agriculture. It will also call for homes and communities to be protected from flooding during times of high rainfall through better catchment management and reduction in water flows from the land. The imperative for planners and decision-makers at all levels of government, will therefore be to ‘enable’ development to take place whilst also ensuring that the benefits and services we all receive from the natural environment are nurtured and sustained into the future.
- 3.3 Unfortunately, our actions as a society over the past century have undermined nature’s ability to support us – just as our need for that support has increased. Recent decades have seen steady declines in almost all UK species and natural habitats on land and sea, despite the fact that nature is our life support system. These declines affect how our environment soaks up extreme rainfall, absorbs carbon, and provides clean water. It affects the health of our soils, fish stocks and pollinators. It affects how we can adapt to climate change, the liveability of our cities and the productivity of our countryside. Nature has become more remote from us and less present in our daily lives. Over the same period, conditions such as obesity, diabetes, heart disease and depression have increased. **We need to halt and reverse trends and bring nature back. We need to invest more time, energy, commitment and money into nature’s recovery – because wildlife and wild places need it, and because our health, wellbeing and prosperity depend upon it.**
- 3.4 Government’s Natural Environment White Paper² recognised that environmental and economic goals are complementary and that long-term economic growth relies on services provided by the natural environment. The Economics of Ecosystems and Biodiversity study (2010)³ showed that protected natural areas can yield returns many times higher than the cost of their protection. A recent report by the Institute for European Environmental Policy⁴ likewise estimated that the economic value of ecosystem services from across the EU from the terrestrial “Natura 2000” network alone is worth between €200 and €300 billion per year. There are also multi-million pound opportunities

⁴ See IEEP (2011) “Estimating the Overall Economic Value of the Benefits provided by the Natura 2000 Network”. Available at http://circa.europa.eu/Public/irc/env/financing_natura/library?l=/benefits_natura_2000/estimating_benefits/project_reports/2000_benefits_main/_EN_1.0_&a=d and ‘Assessing Socio-economic Benefits of Natura 2000 – a Toolkit for Practitioners’ (September 2009 Edition) http://ec.europa.eu/environment/nature/natura2000/financing/docs/benefits_toolkit.pdf

available from greener goods and services, and from markets that protect nature's services.

3.5 The National Ecosystem Assessment⁵ calculates that the wrong kind of economic growth between now and 2060 would cost the UK £20.7bn per year because of the damage it would cause. By contrast, putting nature at the heart of development would save £33bn per year. Well managed and wild natural places provide lasting and substantial benefits to the economy and are ultimately the root of all our productivity – by tackling a wide range of health problems; reducing the severity of droughts and floods; improving our food security; absorbing carbon dioxide emissions; and making the UK a better, more inspiring place to live.

3.6 We need to move away from the Natural Environment being viewed as a barrier to development and economic growth. Instead we should be looking to create 'win wins' and in so doing, moving beyond polarized situations in which the choice is either development or the environment. How decisions are made now, across a range of government policy areas will leave a legacy for years to come. This legacy can be positive – and result in a healthy, sustainable and nature-rich future – if policy makers, planners and other decision-makers work with nature and not against it, to ensure it thrives and delivers multiple benefits for people, society and the economy. **The National Infrastructure Commission has a real opportunity to steer this positive legacy.**

3.7 **Natural Infrastructure is a vital part of our national infrastructure and should be recognised within the National Infrastructure Plan as a priority for restoration on a level footing with other infrastructure needs.** We recognise the Commission has a specific remit for transport, digital communication, energy, water and wastewater, flood risk management and solid waste. However, we urge it to consider the interdependence of these sectors with our natural world by **placing nature at the heart of how decisions are made on all infrastructure developments** and by doing so, taking forward the recommendation of the Natural Capital Committee that *'The national infrastructure plan should incorporate natural capital into each of the main infrastructure sectors, following the mitigation hierarchy for managing impacts. An investment programme for natural capital should also explicitly feature within the National Infrastructure Plan.'*

3.8 The remainder of this submission focuses on specific questions posed by the consultation under cross-cutting issues and flood risk-management. However, these are based on the vital role of our natural environment in delivering and supporting our strategic infrastructure needs, as set out in points 3.1 – 3.7 above.

4. Cross cutting issues

4.1 The comments below should be considered in response to questions 3 and 11 of the consultation.

Planning sustainably

4.2 With climate change presenting a significant and serious long-term threat to biodiversity and societies worldwide, it is vital to get infrastructure right – this means the right type,

⁵ See <http://uknea.unep-wcmc.org/>

the right location and in the right way. It should be driven by a sustainable, future-proof, approach that will be good for people, good for the environment and good for the economy in the long-term. One of the objectives of the commission is to ‘support sustainable economic growth’. In achieving this objective, **we urge the commission to ground its recommendations on the five principles of Sustainable Development**⁶ of living within the planet’s environmental limits; ensuring a strong, healthy and just society; achieving a sustainable economy; promoting good governance; and using sound science responsibly.

4.3 Understanding the need for infrastructure across the country, is a crucial starting point. It should:

- be informed by up to date local data, which evidences societal, environmental and economic needs. Long-term economic growth will not be achieved and maintained in a sustainable way if these elements are not integrated into the decision-making process.
- Be integrated. For example, transport and energy infrastructure should be integrated at national, sub-national, county/unitary and local levels; new communities/developments should be well-designed and located and connected with transport routes (including active travel), services, green space.
- avoid harm to the highest value environmental sites, such as SSSIs and Local Wildlife Sites and seek opportunities on and off site to enhance them through careful choice of location and design.
- engage stakeholders, communities and experts from the outset.

4.4 When planning new infrastructure, serious consideration should be given to retrofitting the infrastructure we have. The natural environment has become increasingly fragmented by roads and other development and a strategic approach is urgently needed to identify where natural connections can be made for people and wildlife over existing linear transport routes. There are also places throughout the transport network where areas of woodland, wetland, and grassland can be better managed to increase size, improve quality or re-establish links by creating new areas of habitat that can clean run-off, create sound barriers, capture particulates and absorb carbon dioxide. Road side verges, rail embankments etc, can be managed to provide wildlife corridors, which reach into and connect our towns and wider countryside.

4.5 The Wildlife Trusts welcomed the inclusion of designated funds within the Roads Investment Strategy 1 (RIS1)⁷ and believe these offer a chance to start fixing some of the deep-seated environmental problems created by past decisions, while also helping to maximise the environmental performance and value of the network into the future. Most of the projects benefitting from the funds are still in early stages. But two of those receiving funding are:

- The A38 / Stover Country Park in Devon - the designated funds are being used to treat highway runoff into Stover Lake as part of a wider project to restore historic assets and habitats.

⁶ HM Government (2005) Securing the future delivering UK sustainable development strategy

⁷ Department for Transport (2015) Road Investment Strategy: for the 2015/16 – 2019/20 Road Period https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/408514/ris-for-2015-16-road-period-web-version.pdf

- M5 Titford Pools – the designated funds are being used to restore water quality, reduce future contamination, improve and encourage the biodiversity value of the site; and improve its recreational value to walkers, cyclists and lake users.

4.6 Funding of this nature is extremely important and its **continuation at a greater level of investment into RIS 2 would be a welcome recommendation of the National Infrastructure Commission in its assessment.**

Planning strategically and spatially

4.7 Once the need is established, **infrastructure should be strategically and spatially planned, with Ecological Network Mapping at the heart.** Having a spatial understanding of where nature exists, where it needs to be restored and created, the benefits it currently provides, and how and where investment in nature can leverage multiple benefits should be an essential component of infrastructure planning (For more on Ecological Network Mapping, see annex1).

4.8 Used as the basis of planning, development and land-use decisions, ecological network maps can ensure that development is planned and designed in a way that both avoids and mitigates damage to our natural infrastructure through the targeted enhancement of local ecological networks. It is also a vital tool in understanding and considering the cumulative impacts of national infrastructure developments.

4.9 When combined with other environmental information (eg soil, water quality, flood risk), the resultant maps can unlock practical and pragmatic win-wins, where nature can be an integral part of the solution to pressing public policy issues, such as flooding and the need for access to nature near homes. For example, water companies interested in producing clean water through sound catchment management, can use these maps to identify where particular habitats, which play a part in filtering water (eg wetlands) could be enhanced or created. Ecological network maps have also been used to identify where habitat creation or restoration can re-establish naturally functioning floodplains and, thereby, provide flood control and enhanced protection for settlements downstream (see specific example under section 5.8 on Devon’s Culm Grassland).

4.10 The National Planning Policy Framework includes some positive policies on ecological networks, but it does not provide sufficient policy guidance for those involved in planning and development. **The National Infrastructure Commission could provide a strong steer to government to ensure ecological networks are properly mapped at the local level and fully embraced in Major Infrastructure Planning and design.**

4.11 Fundamental to the mapping of ecological network maps and decision making is access to ecological expertise and well-resourced, up to date, locally informed ecological data. It is not enough to rely on national datasets. Local Environmental Records Centres (LERC) and other local data providers should be seen as the ‘go to’ organisations by developers for pre-existing local ecological data (the value of this data is recognised in Highway’s England’s Action Plan⁸). In turn, developers should be encouraged to share with the LERC, any data gathered as part of the project (eg surveys for EIAs, SEAs/ HRA. **This data sharing would ensure that projects are informed by the most up to**

⁸ Highways England (2016) Our plan to protect and increase biodiversity. See: https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/441300/N150146_-_Highways_England_Biodiversity_Plan31o.pdf

date, locally relevant data and should be established as a standard operating practice for the National Infrastructure Commission.

Planning design and delivery

- 4.12 Natural Infrastructure should be integrated into the design of all hard infrastructure development at the outset, with the aim of achieving a genuine net overall gain for wildlife, both on and beyond the development. This should include robust adherence to the mitigation hierarchy and avoidance of high value sites, habitats and species in the location and design of the development. Where damage to existing natural assets is unavoidable, compensation measures should create more than is lost (net biodiversity gain).
- 4.13 Many infrastructure companies, including LiNet⁹ members, have (Network Rail and Highways England) or are considering (Transport for London) adopting policies for securing ‘net gain’ from development. Net gain projects deliver quantifiable and measurable benefits for biodiversity as well as providing a range of wider environmental enhancements, such as flood risk mitigation, enhanced air quality and opportunities for public engagement with the natural environment. **If the National Infrastructure Plan were to advocate the adoption of ‘net gain’ outcomes as ‘business as usual’ across all infrastructure projects it would be more likely to secure significant environmental benefits.**
- 4.14 **We recommend that each development is informed by a Green Infrastructure Strategy.** These strategies should be visionary and identify the opportunities to incorporate and enhance the surrounding natural environment with the aim of achieving multiple benefits and ultimately a net gain for nature. Strategies should be under-pinned by ecological network map(s) relevant to the development area and informed by a wide range of local experts with a knowledge of ecology, hydrology, technical design, pollution management etc. The earlier the natural environment is considered in the design process and the more key stakeholders are engaged, the more likely the development will maximise multiple benefits. This will make construction easier and more cost effective and help avoid any unnecessary and unexpected delays.
- 4.15 In 2014 The Wildlife Trusts produced a challenge report for HS2. *‘A greener vision for HS2: Ideas for large-scale nature restoration along the HS2 proposed route’*¹⁰. The report highlighted the environmental damage likely to occur as a result of construction of a High Speed rail link from London to Manchester and Leeds. But it also put forward an ambitious vision for large-scale nature restoration along the proposed route - creating and restoring large areas of habitat and providing new access to nature for people. The vision was well received by the HS2 Hybrid Bill House of Commons Select Committee and the likes of Costain and LFM.
- 4.16 The proposed vision was for a 1km ribbon of wildlife-rich landscape either side of the line – planned, established and run by a partnership of residents, landowners and local and expert groups. Recreated and naturally regenerated habitats would buffer, link and provide ‘stepping stones’ between wildlife sites. In time, there would be new meadows, woodlands and wetland expanses to explore, alongside existing farmland, communities

⁹ LiNET is an informal group of linear asset owning/managing sectors, with a shared aim to promote, embed and mainstream the use of green infrastructure (GI) as a tool for enhancing the resilience and reducing the whole life costs of national and local linear infrastructure assets.

¹⁰ The Wildlife Trusts (2014) HS2: The case for a Greener Vision <http://www.wildlifetrusts.org/HS2reports>

and housing. Green bridges, pathways and cycle tracks would reconnect communities cut through by the proposed line. This would spread the benefits of HS2 to many people along the route, rather than just those near its few stations. Funding for ongoing maintenance would be part of the HS2 legacy.

- 4.17 With just 1% of the HS2 budget (£130m plus c.£10m annual maintenance and rent), we believe this vision offered a firm commitment to the environment by achieving the creation of c.15,000ha of new/reconnected habitat; 120 miles of new foot and cycle paths. With the potential to provide net gains for wildlife and added value to people and communities from a relatively small proportion of any major infrastructure budget, **visions such as this should be a key requirement for all major infrastructure projects.**
- 4.18 Developers should give early consideration to the long-term management of green infrastructure in and around the development and how this will be undertaken once the development is complete. **Developers should plan and provide appropriate funding secured by a legal agreement at outline application stage for the long-term management of natural infrastructure.**
- 4.19 Clear **proposals should also be agreed for long-term monitoring** in relation to both the impact of the infrastructure development and the enforcement and implementation of any mitigation/compensation measures undertaken. Ensuring that the outcomes of such monitoring are used to inform and adapt future design and transport development.
- 4.20 With regards to housing and infrastructure, **there needs to be clear integration between the national strategy for infrastructure and local housing plans**, so that new housing developments are of a scale appropriate to their location and appropriately served by transport routes, services and green space. **Green infrastructure and nature should be at the heart of all new housing developments.** As a baseline, they must meet national access standards, provide a net gain for biodiversity and respect the existing landscape character. Developers should start by identifying existing habitat features and using them as the building blocks for the network of green spaces. The design of our buildings, towns and cities should recognise the value of natural solutions that collect and capture water, such as green roofs and walls, sustainable drainage systems, green space and gardens. These features all help to absorb the run-off from development, filtering pollutants and supporting flood prevention.
- 4.21 We would expect the nationally identified ***Garden towns and villages to be exemplars of environmental sustainability and green infrastructure provision***, in order to reflect the true principles of the concept. The prefix ‘garden’ must mean, truly sustainable and healthy places to live, not simply greenwash. The UK Green Building Council’s guide on Demystifying Green Infrastructure¹¹ includes several examples of housing developments that have sensitively incorporated Green Infrastructure throughout the development.
- 4.22 Gardens can do much to act as sponges and help stop water flowing too fast and overwhelming rivers. But evidence shows that flooding in our built-up areas is increasing because of the loss of garden space in favour of new development and hard standing. A

¹¹ UK Green Building Council (2015) Demystifying Green Infrastructure. See <http://ukgbc.org/sites/default/files/Demystifying%20Green%20Infrastructure%20report%20FINAL.pdf>

report¹² by London Wildlife Trust in 2011, revealed the scale of the capital's garden loss was at a rate of two and a half Hyde Parks per year. Hard surfacing (including decking and paving) increased by over 25 per cent in the hundred-month study period. In January 2014, 90% of the severe flooding in parts of West Sussex was believed to be coming from surface water run-off. In response, a local scheme (Arun and Rother Connections) was established to promote measures such as rain gardens and Sustainable Urban Drainage Systems to help prevent future flooding in the Arun and Rother river catchments.

4.23 There are many examples of where major developments have effectively contributed to protecting and enhancing the natural environment that could be extrapolated to major infrastructure works. Two such examples are Abberton Reservoir and Lorton Valley Nature Park.

Case study: Major development of Abberton Reservoir, Essex

Abberton Reservoir, owned by Essex & Suffolk Water, is situated 8km southwest of Colchester and is one of two water storage reservoirs. Covering 485 hectares, it supplies drinking water to one and a half million people in Essex and holds 46 billion litres of water. Its recent enlargement and enhancement transformed the site into a spectacular natural wetland, leaving a legacy to be enjoyed by future generations. Development included: raising the main dam by 3.2 metres; increasing the storage volume by 58%; building a number of smaller col (earth) dams around the edge of the reservoir; relocating the Essex Wildlife Trust Visitor Centre to a larger site; diverting the B1026; and modifying the causeway.

As a wetland site of international importance, it was essential that the environment was protected before, during and after construction. Much of the success of the scheme relied on early engagement with all community parties to ensure everyone had a say, so that everyone was happy with the outcome.

Case Study: Lorton Valley Nature Park. Dorset

Over many years, the extent of wildlife habitats and open space within the Lorton Valley had been reduced through development of a landfill waste site, drainage of the wetland and the construction of the Weymouth Relief Road on the western boundary.

The designation of the sailing venue for the London 2012 Olympic and Paralympic Games at Weymouth and Portland in Dorset provided a catalyst for wider investment in green infrastructure. By integrating existing nature reserves, ancient woodland and land secured through environmental mitigation for the new relief road, a new Nature Park was established in the Lorton Valley to the north of Weymouth town centre. The benefits involved reconnecting and enhancing biodiversity habitats; improving local landscape character; expanding local recreation and volunteering opportunities; supporting learning and play, especially for children; enhancing physical and mental health and wellbeing; and contributing to the local tourist economy.

¹² London Wildlife Trust, GiGL, Greater London Authority (2011) London: Garden City? Investigating the changing anatomy of London's private gardens, and the scale of their loss. See: <http://www.wildlondon.org.uk/sites/default/files/files/London%20Garden%20City%20-%20full%20report.pdf>

By taking a strategic approach to green infrastructure delivery, the work of various partners has been combined to establish a far greater environmental legacy from the Olympic and Paralympic Games than would have been achieved by organisations working separately. Existing sites have been improved and are now connected to provide a wider network of publicly accessible nature areas across Weymouth and Portland.

The consolidation of the landholding across the valley became feasible through the revised alignment of the Weymouth Relief Road that helped to unlock the delivery of the Nature Park. Detailed negotiations between Natural England and Dorset County Council resulted in a net increase in biodiversity over the long term. Greater support for wider environmental projects has now been established through policies set within the emerging Weymouth and Portland Local Plan.

Pooling expertise between all partners has helped to secure a mix of funding that may not have been accessible to individual organisations. The Nature Park has benefitted from coordinated investment, using existing resources of the various partners, the funding of mitigation measures from the County Council, Environmental Stewardship for enhanced landscape management from Natural England, and a successful joint bid for funding from the National Lottery. With added impetus gained from the Olympic and Paralympic Games, a quantum of investment has been combined to accelerate the establishment of the Nature Park for the benefit of local communities and visitors. (For more information see full case study¹³).

5. Food Risk Management

The comments below should be considered in response to questions 25 and 26 of the consultation.

- 5.1 Storms and flooding have caused significant damage across the UK, and climate change is likely to increase the frequency of such extreme weather in the future, costing Governments and taxpayers millions, and devastating communities and businesses. Heavy rain will always occur, but the effects in today's built-up areas are directly related to land-use upstream and our inadequate urban drainage systems. Inappropriate developments can change the hydrology of large areas, removing peat, culverting rivers and preventing the land from storing water - creating a real danger of further flooding downstream.
- 5.2 Much of the water that causes flooding runs off the hard surfaces of our roads, and hard infrastructure, rather than being absorbed by the earth. Drainage systems cannot cope with the volumes of surface run-off and the water quickly inundates homes and businesses. These impacts are all exacerbated where homes and businesses have been built in the natural floodplains of rivers and streams.
- 5.3 Engineered and “hard” flood defences are constructed in an attempt to protect vulnerable communities from flooding, and in some areas they are the only solution. But building and maintaining flood defences is expensive, running to hundreds of millions of pounds and it can only do so much. When a river is cut off from its floodplain by man-made flood defences, its natural spreading room is not available and it ceases to function naturally.

¹³ Natural England (2013) Lorton Valley Nature Park; Green Infrastructure Case Study (NE388), <http://publications.naturalengland.org.uk/publication/5269657?category=49002>

5.4 Many of our rivers are now disconnected from the land. Consequently, we have lost large areas of marshlands, reedbeds and wetlands that would help store water and filter out pollutants. Instead, the water, held in its artificial channel, moves straight through any built-up areas. Continual rain fall in the uplands, causes the river to burst its banks or overtop the flood wall.

5.5 **The Wildlife Trusts welcome the Commission's consideration of natural flood risk management in its first National Infrastructure Assessment and believe it is essential that Government prioritises investment in this area.** Wilder landscapes can provide the natural solutions to help prevent flooding in the future. Habitats such as upland bogs and moors, woodlands, wetlands and species-rich grasslands act as giant sponges, absorbing and holding water and slowing down water run-off into rivers, thus reducing the effects and ultimately the cost of flooding to society. We can also mimic these natural processes in urban areas, weaving water-holding habitats into the urban fabric - installing more green roofs on our houses, more permeable surfaces in our towns and cities and more sustainable drainage systems to capture excess water. And along the coast, natural habitats can be created that reduce the force of tidal surges elsewhere.

5.6 Flooding needs to be addressed through a range of solutions, but working with nature rather than against it is the key to a more flood resilient future. **Working with nature will reduce our vulnerability to the impacts of flooding and climate change and increase resilience in the future. It is cost effective and delivers many other benefits: creating niches for wildlife, increasing people's wellbeing and benefiting tourism and local economies.** We need to:

- Make the land work more effectively as a sponge by restoring water retaining habitats over large areas
- Create more places where flood waters can be held back or stored. These places often become recreational areas for people too
- Make more space for rivers
- Design into our buildings, towns and cities, places that collect and capture water, such as green roofs, sustainable drainage systems, rather than it torrenting off hard surfaces into rivers
- Create places on farmland which will store floodwaters and protect the best areas for food production - giving water room - eg create small flood storage areas on parts of the farms that are less productive - protecting a larger areas from extreme weather

5.7 There are already some excellent examples of how restored landscapes have made space for water, for example, in upland areas where old drainage ditches have been blocked and overgrazing reduced. This allows vegetation like sphagnum mosses and heather to regenerate, helping to hold water in the hills for longer and reducing peak flows downstream during high rainfall events.

5.8 Across the UK Wildlife Trusts are working on large-scale habitat restoration schemes which slow down water and reconnect rivers with their floodplains, making space for water. **We need these kind of approaches to be significantly extended across the country. This can only happen if investment in flood defence is rebalanced towards these more sustainable solutions.** There are many examples of natural

solutions and outcomes (see The Wildlife Trusts website¹⁴). But three have been highlighted below:

Case Study: Culm grasslands, Devon

Ecological network maps have been used to identify where habitat creation or restoration can re-establish naturally functioning floodplains and thereby provide flood control and enhanced protection for settlements downstream. Devon Wildlife Trust is working with farmers to deliver this. When restored, this habitat acts like a sponge to hold water following rainfall and release it slowly over time, helping to prevent flooding downstream.

Early results from a recent study of the hydrology of these grasslands undertaken by Devon Wildlife Trust in association with the University of Exeter show Devon's Culm grassland provide an extra 20% carbon storage compared to agriculturally improved fields. They also have four and a half times the water storage capacity - indicating that species-rich grasslands may be better at preventing downstream flood risk than intensively managed grasslands or grasslands that have scrubbed-up or developed mature woodland cover.

Case study: Slow the Flow – Pickering

Pickering in North Yorkshire was flooded four times in 10 years. This has had a big impact on communities. It is in an important landscape with multiple stakeholders. The aim of the Forestry Commission's Slow the Flow project was to demonstrate how the integrated application of a range of land management practices at a catchment scale can help reduce flood risk, as well as deliver wider multiple benefits for local communities.

The majority of the catchment area is owned by three land owners (Forestry Commission, the North York Moors National Park and Duchy of Lancaster). This was advantageous as it meant they could cooperate and work in partnership. Durham University helped with the science and evidence. They began by identifying which tributaries needed interventions in order to have the desired effects. This involved working out what was happening to the water.

Interventions considered and implemented to slow the runoff from the Public Forest Estate included riparian woodland, floodplain woodland enhancement of natural flood storage using large woody debris dams and timber mini bunds. Further downstream moorland gullies were blocked with heather bales to reduce rapid runoff. These are relatively cheap and easy to install. Part of the project involved harder flood protection measures for Pickering. Around 50% of these were funded by the District Council.

This approach isn't anything new - in 1928 'The Question of Forestry in Britain' was already talking about forestry solutions to flooding. But the Forestry Commission is now using the Pickering scheme as an example of best practice and promoting its approach elsewhere.

Case Study: The Nene Valley

The Wildlife Trust for Bedfordshire, Cambridgeshire and Northamptonshire is working in The Nene Valley on large-scale habitat restoration and creating functioning ecosystems as an integral part of land management – such as putting back river meanders. The aim is

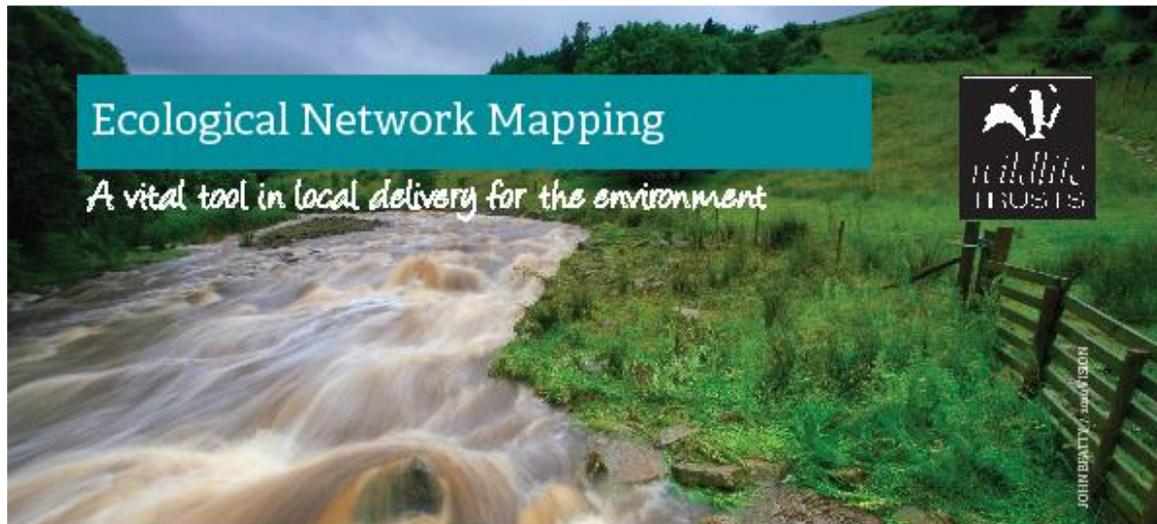

¹⁴ <http://www.wildlifetrusts.org/tacklingflooding>

to reap the benefits that natural support systems provide such as flood-prevention, waste management and cleaner air.

Part of this work includes a 16 mile long stretch of six restored sand and gravel quarries. The reserve stretches from Earls Barton in the south to Irthling borough and Stanwick, and has been linked by footpaths and waterways to create one of Europe's newest Special Protection Areas for vulnerable bird species. The site lies at the heart of the Wildlife Trust's 'Living Landscape' for Northamptonshire, and is located in one of the first Nature Improvement Areas. The nature reserve replaces a landscape of intensive farming with a progressively restored and managed river-floodplain wetland, which brings huge biodiversity benefits and habitat connectivity. It also enhances the river - making it a feature of ecological and landscape benefits, in addition to providing a drainage channel.

The Wildlife Trusts
10 February 2017

Annex 1 Ecological Network Mapping

Spatial blueprints for investment in nature

Wildlife Trusts across England have pioneered locally-driven approaches to ecological network mapping for several years. The maps have helped to guide their own landscape-scale conservation activities. They have also been a mechanism for engaging local people, landowners, planners and developers in taking positive action to protect and restore the natural environment.

When spatial ecological data is combined with other environmental information (e.g. soil, water quality, flood risk), the resultant maps can help to identify 'win wins' where nature can be an integral part of the solution to pressing public policy issues such as flooding and the need for access to nature near homes.

The maps, when integrated into the local planning process, can be used to identify how mitigation for housing and other infrastructure development can enhance local ecological networks – and more generally will ensure that nature is at the heart of strategic decision making and local 'place making'.

They can also provide the local basis for investment in natural capital, ensuring that public and private investment in nature is aligned where it will deliver multiple benefits for people, the economy and the natural environment.

My Wild City - mapping habitat creation opportunities in Bristol

What is ecological network mapping?

It is a powerful, strategic tool to identify where habitat protection, creation and restoration is required to retain or enhance a local ecological network and to secure nature's recovery.

'Establishing a resilient and coherent ecological network across England has been recognised as the strategic way in which to conserve biodiversity and ecosystem services while also making efficient use of scarce land and resources.' (Lawton et al. 2010)¹

Mapping an ecological network requires the best available spatial data from national and local sources. This should include information on core wildlife-rich areas such as SSSIs, Local

Wildlife Sites and all other priority habitats. Once these are mapped, it is possible to identify opportunities for habitat creation and restoration to achieve more, bigger, better and joined-up sites within a functional, coherent and resilient ecological network.

The maps can be created at a variety of local scales (e.g. catchment, local authority area, NIA) and if designed collaboratively across boundaries, can be used to identify where cross-boundary landscape-scale interventions may be needed to establish ecological networks across the country.

Dear Sir / Madam

Re: National Infrastructure Assessment – Call for Evidence

The Swindon and Wiltshire Local Enterprise Partnership's (SWLEP's) Strategic Economic Plan (SEP) (<http://www.swlep.co.uk/strategieconomicplan.pdf>) sets out that Swindon and Wiltshire's competitive advantage is based on:

- A pivotal central southern location with geographic proximity to major economic centres including London, key airports, and coastal ports;
- A dynamic, knowledge-based economy with nationally important clusters in life sciences, advanced manufacturing, financial and professional services, digital and information and communications technology (ICT) and land-based industries;
- A resilient and attractive rural economy with world class landscape, heritage and visitor attractions;
- An economically significant military presence;
- Strong small and medium sized enterprise (SME) growth with high levels of innovation and business survival; and
- A vibrant economy with a skilled workforce and low unemployment.

Reflecting the above, we want to build on our economic opportunities (as set out in the SEP and Swindon and Wiltshire Economic Assessment 2016 - <http://www.swlep.co.uk/resources/document636067576937666000.pdf>) :

- Exploit our potential to attract further inward investment and support the development of SMEs in high value sectors to balance growth in the South East.
 - The Business Location Index 2015 prepared by Local Futures, in partnership with the Municipal Journal, shows both Swindon and Wiltshire to be amongst the top 5 business locations in England.
- Extend our reputation as a hub for specialist sectors in Life Sciences, Advanced Manufacturing; Financial and Professional Services; Digital and ICT and Land Based Industries

- Employment in knowledge-based industries increased by 15% between 2012 and 2014 to 65,600, nearly twice the growth experienced nationally (8.2% across Great Britain).
- The number of patents granted per 100,000 residents over the five-year period 2007-11 averaged 19.4 patents per 100,000 residents. This was more than double the rate found across England as a whole over the same period. Swindon and Wiltshire is ranked 8th in terms of business enterprise research and development (R&D) expenditure per full-time employee and the level of R&D spend is more than double the national average.
- Rapid population growth
 - The pace of population growth is fast. Swindon and Wiltshire have seen the fourth highest level of population growth in the country with an increase of 10.6% since 2004.
- Strong jobs growth forecast
 - Total employment in Swindon and Wiltshire is forecast to rise between 7-8% between 2015 and 2030. This equates to between 27,000-29,000 additional jobs over the period.

There are, however, economic challenges.

Competitiveness has been in decline. Taking the period 2001-2013 England experienced growth in nominal Gross Value Added (GVA) of 61.7%. In contrast Swindon and Wiltshire saw growth of just 50%. While Swindon GVA per head is above the national average (£30,900), it is below average in Wiltshire (£19,800). And, Wiltshire's UK competitiveness index score (UKCI) for 2016 of 96.6 is significantly below the UK average and has fallen from 97.4 on the 2013 UKCI, resulting in its ranking position falling by 10 positions from 122.

The type and quality of the housing in an area can have a significant impact on the health and wealth of local economies and the ability to attract and retain people depends on good housing and attractive and inclusive neighbourhoods. Between 2015 and 2026 there is a residual requirement for 42,480 new homes to be built across Swindon and Wiltshire; 23,171 of which are required between 2015 and 2021. In Wiltshire, however, housing affordability is a significant issue. In 2014, the median house price in Wiltshire was £217,500, 34% higher than the figure for England and Wales. The ratio of median house prices to median gross annual salaries in the county in 2014 was 10.5 compared with 8.8 in England and Wales.

Our strategic location and connectivity is both a strength and a weakness. It is no coincidence that the peaks in our historic economic growth coincided with the arrival of the Great Western Railway in the 19th century and the M4 five decades ago. A similar step change in transport investment is now required to deal with the area's inadequate transport infrastructure and to support our growth plans and opportunities. Of particular relevance in the context of this call for evidence, are a number of supra-regional transport infrastructure issues and requirements.

There is significant investment (£2.8 billion) underway for the electrification of the line between London Paddington and Cardiff via Swindon and Bristol Parkway, and the associated introduction of the Intercity Express Programme (IEP) trains from 2018. These investments will improve rail links between Swindon and north Wiltshire and London, reducing journey times to 45 minutes, but the Government decision to defer investment in the electrification of the railway line into Bath and Bristol Temple Meads will mean that the full benefit of this investment will not be realised. The completion of the full electrification project is therefore a priority for the region.

On the Strategic Road Network, it is essential for the economy of the South West, and especially that of Gloucestershire and Swindon, that the current studies into the dualling of the A417 'missing link' south of Cheltenham is translated into action through the delivery of this scheme as part of Highways England's Road Investment Strategy (RIS) 2 programme. This will particularly boost the motor manufacturing sector at Swindon, and will improve strategic connectivity between the West Midlands, the South West and the South East.

Looking eastwards, the Government commitment to investment in the East – West Rail project linking Oxford and Cambridge, and in the parallel Oxford to Cambridge Expressway, is welcomed, but opportunities to maximise the benefits on this investment should not be overlooked. Specifically, these include the potential to operate rail services between the West of England and Oxford, Milton Keynes and Cambridge utilising the new railway line. This would connect Bristol, Bath, Chippenham and Swindon with destinations in the South Midlands and East Anglia without the need to travel into London and change trains there, thereby freeing up capacity on the Great Western Line. These rail services would also help facilitate new rail stations at Corsham (where there is a cluster of high tech businesses centred around the significant digital infrastructure investment in the Global Communications Centre at MOD Corsham) and Royal Wootton Bassett (which is near to the Defence School of Electronic and Mechanical Engineering at Lyneham) in Wiltshire. A report commissioned by the Council (Corsham Rail Station Initial Feasibility Report, December 2015¹) included a high level assessment of a new train service from Bristol to Oxford based on one train per hour (12 services per day) calling at Bristol Temple Meads, Bath Spa, Chippenham, Swindon and Oxford. This assessment indicated the following demand and revenue outcomes: 330,000 journeys; £2.73m in base year rail revenues; and £4.112m of user benefits. With new stations at Corsham and Royal Wootton Bassett, the base year rail revenue figure increased to £3.781m.

Similarly, connectivity between Swindon and Oxford (and the M4 and the Oxford – Cambridge Expressway) would be greatly improved through the dualling of the A420 route connecting the two. This has specific benefits for the economies of both Swindon and Oxford, with manufacturing industry such as BMW having bases in both communities. The improvement of the A420 would also provide congestion relief for the M4 into London and the A34 South of Oxford, freeing up capacity on these routes for their core roles of providing strategic connectivity to the South East and the South Coast ports respectively.

Therefore, the next generation of NIC work needs to examine the potential for strengthening the strategic connectivity between Swindon, North Wiltshire and the West of England (acting as a gateway to the South West) and Oxford.

¹ <http://www.wiltshire.gov.uk/council/howthecouncilworks/plansstrategiespolicies/transportpoliciesandstrategies.htm>

Connectivity is also poor on the north – south axis within the 'Wessex' area that covers Dorset and the coastal ports in the south, the whole of Wiltshire, Bath and the intersection with the M4 corridor to the north. Wider economic benefits are being foregone due to this poor connectivity: the A46 / A36 corridor is constrained by having to pass through parts of Bath city centre; there are bottlenecks and capacity restrictions on the A350; and the rail corridor from Southampton through Wiltshire and on towards Bath, Bristol and Swindon has relatively long journey times. Better connectivity will help close current 'productivity gaps' in the area. Improved north-south connectivity will also benefit long-distance traffic, especially commercial vehicle movements, from the Midlands into the area and on to the south coast. Other economic benefits will be the 'unlocking' of much needed new developments, especially new housing sites at strategic locations. In recognition of the above issues, Wiltshire Council, Dorset County Council and Bath and North East Somerset Council have commissioned a 'Wessex: North to South Connectivity (Executive Summary attached)'. This study effectively forms an initial evidence piece to better enable Highways England to consider including options for improvements that could be taken forward as part of its RIS2 process. The NIC should help support this work as part of its National Infrastructure Assessment process.

I hope the above is helpful and I look forward to seeing the conclusions of this process in your Vision and Priorities document to be published in the summer.

Yours faithfully,

National Infrastructure Assessment Call for Evidence

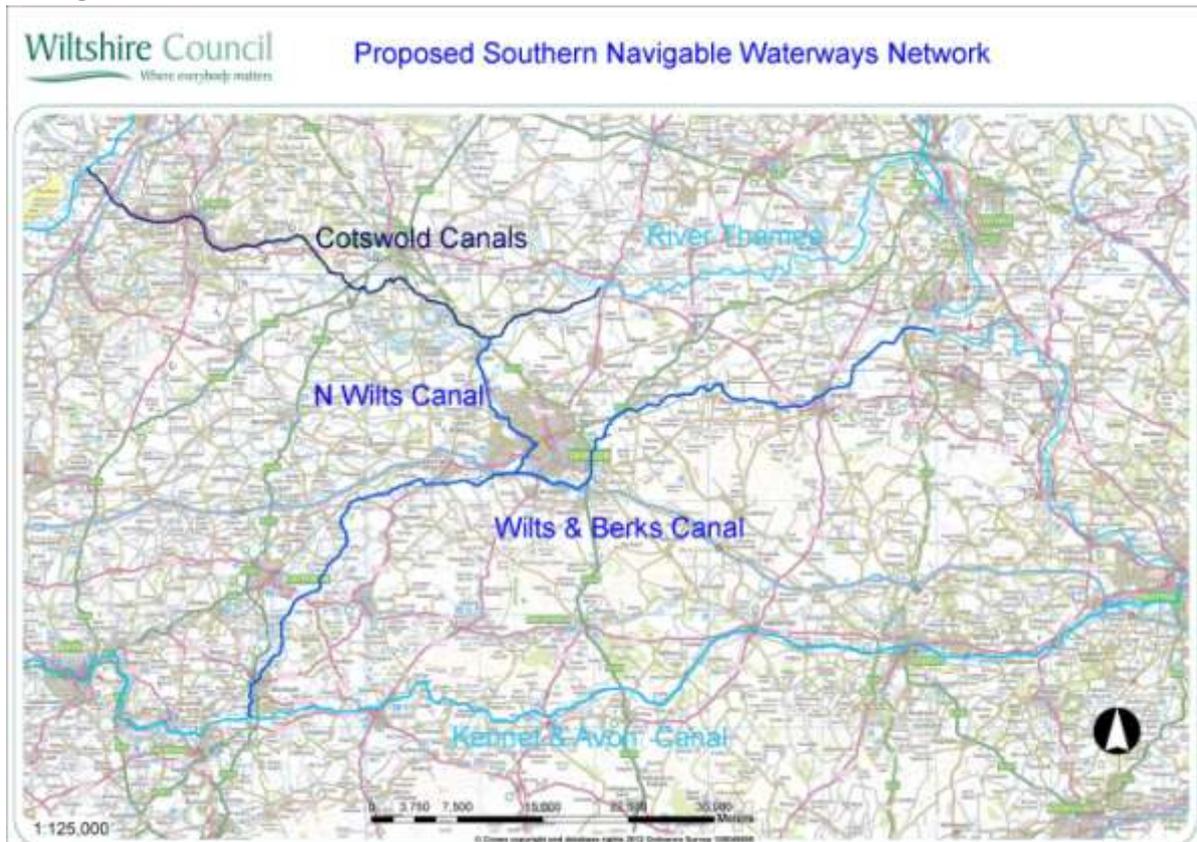

Restoration of the Wilts & Berks
Canal
Wiltshire Swindon & Oxfordshire

This evidence is submitted by [Name redacted] on behalf of the Wiltshire Swindon & Oxfordshire Canal Partnership.

Project	Southern Waterways Network – Wilts & Berks Canal
Client	

Revision	Date	Issued for/Revision details	Revised by
Draft 1	22 December 2016	First draft for WBCT comment	KWO
Draft 2	18 January 2017	Rewrite with additional information	KWO
Final	25 January 2017	Reviewed by WBCT Exec	

Background

Currently there is a large missing section of the former navigable waterways in southern England.

The restored routes of the Wilts & Berks, North Wilts and Thames & Severn Canals would produce at least £100m p.a. into the rural tourism economies of Wiltshire Oxfordshire and Gloucestershire based on the economic impact study of the Kennet and Avon Canal restoration. Added to this would be the transformational place changing effect on Swindon at the core of this network, and many regeneration opportunities in towns and villages along the route. Planning work on restoration of these canals is well advanced and significant sections have been, or are currently being restored.

The contribution to local life, healthy living (walking/cycling), volunteering, heritage, biodiversity, place setting, and flood management adds to the cumulative impact of these schemes.

The project team recognise that this may not be most obvious infrastructure for the Commission to consider but would suggest that the significant positive impact if the scheme's proposal merit further investigation especially given the likely return of fund invested.

This evidence is submitted by the Partnership delivering the Wilts & Berks & North Wilts canals so of necessity concentrates on these waters but there has always been close working with the Cotswold Canals project and the Commission are invited to view this report in an holistic way taking into account the whole southern waterways network.

This is an extract from the current restoration strategy for the waterway:-

- **The restoration of the Wilts & Berks Canal is supported by the Canal Partnership to deliver a community asset and green infrastructure linking Wiltshire, Swindon and Oxfordshire.**
- **The plans conform with national and local policies and plans and the Partnership seeks to continue the protection from development of the canal route for the life time of the current Local Plans**
- **Economic and social benefit will be significant which will be demonstrated in a Business Plan for each of the proposed programmes.**
- **Sources of funding for the project will be demonstrated in the Business Plan.**
- **A clear strategy for ownership of the canal corridor will be developed.**
- **Funding will be sought from third party sources wherever possible including substantial enabling development where relevant and possible.**
- **The delivery of the project will be over a number of years and be substantially completed in the period 2025-2031.**
- **Opportunities to use the waterway for local flood control schemes will be investigated and implemented where practical.**
- **The Partnership has already made accessible over 30% of the main canal route and the top priority is to complete landowner negotiations and obtain agreements to open all the towpath by 2018.**
- **Swindon is recognised as the hub of this restoration and the proposed Southern Canals Network. Waterfront Swindon will be developed as an urgent priority and will be connected to the national network at the earliest opportunity.**
- **To gain maximum public and environmental benefit at the earliest opportunity, discrete sections of the waterway will be restored to work as isolated and viable sections.**
- **Sustainability will be built into the plans to allow long term maintenance of the operational waterway.**
- **Community and volunteer participation are vital elements in both restoration and maintenance and they will be streamlined and**

accentuated to be a beacon of community empowerment and achievement.

- **During the Masterplanning phase, considerable emphasis will be placed upon use of new technologies in construction, harvesting of renewable energy and flood defences in clear demonstration of a fully sustainable national asset.**
- **The economic social and environmental value of the restoration and regeneration of the Wilts & Berks Canal has not to date been fully assessed and quantified. The Partnership will seek as a matter of urgency to fully define at a Programme level the likely Gross Value Added (GVA) and employment created by the restoration of the canal**

In preparing this document the questions posed by the Commission are used as headings for the relevant areas where the Canal Partnership believe this project can have positive impacts

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Investments required for the Southern Canals Network

Wilts & Berks Canal Rural	£400m
Wilts & Berks Canal Swindon	commercially funded
North Wilts Canal	£ 50m
Cotswold Canals	£300m
	£750m
Contingency	£150m
Total	<u>£900m</u>

These figures exclude current active projects

We would expect a project of this nature to be delivered over 20 years making an annual funding requirement of £45m

The immediate call on funding would be in the order of an estimated £25-30m to secure the land for the project via an Order under the Transport & Works Act

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

There is no specific research looking at this issue. Scottish Canals recognise that iconic structures like the Kelpies and Falkirk Wheel create specific tourism destination visits

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The place making opportunities for towns like Swindon on the route with a revival of a town centre community are exactly what a waterway restoration can achieve creating a 'heart and soul' and acting as a catalyst for further improvements and developments . Examples are scattered throughout the existing canal network:

- Brindley Place Birmingham
- Gasworks development St Pancras London
- Paddington Arm London
- Queen Elizabeth Park London
- Salford Quays Manchester
- Oracle Reading
- Banbury
- Stallybridge

This is small sample of waterway restorations and associated regeneration that have transformed inner city/town areas . All have the waterway have a core of mixed used with associated housing creating a hub for communities centred around a waterway.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

In the context of canal restoration most of the work will be required to build new infrastructure- the majority of the canal route still exists in derelict form

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by "funding", the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

The aim of bringing this infrastructure project to the attention of the Commission is to demonstrate that third party Government funding to guarantee the viability of the scheme (eg the securing of the land via a Transport & Works Act Order would underwrite the security of investment for third parties (both commercial and grant giving). Delivery of the rural section will need to be funded from non-commercial sources but the current business plan for the Swindon will fund the canal from development opportunities.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that "can be funded" but "will not be financed" refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The project needs to use the Transport & Works Act to secure the route of the canal and to be the means for governance of the operation waterway – a swift and efficient implementation of an Order under this Act would efficiently deliver the land required to implement phases of the project in multiple locations. Permissions will be required from a number of Agencies and cross-Agency co-operation and working will be required to deliver the scheme (eg Environment Agency Natural England Local Authorities).

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

There will be significant opportunities to increase biodiversity and connectivity. The project has already identified the ecological and environmental issues that will need to be addressed in the form of mitigation. The scheme will deliver a significant net positive contribution to biodiversity and habitat creation.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent? Note: "credible" improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. "Tractable" improvements are those that can generate usable quantitative outputs. "Transparent" improvements are those that do not rely on 'black box' modelling and assumptions.

While some quantitative benefits are easily defined, others are not- for example public health where the opportunity to exercise in a safe, free to use, and pleasant location will without doubt increase walking and healthy pursuits but the actual net benefit of this healthy living is very hard to define. This issue was partially addressed in the 2009 Jacobs Report *The Benefits of Inland Waterways* however there is no easy formulaic way to define this and other benefits in a particular location. A further issue is the traceability of the actual benefit of the restoration as the restoration is often the catalyst to create new businesses which in turn generate employment and tax revenue etc.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

Local walking and cycling routes are easily created in urban areas.

There are further opportunities for freight by water for materials such as aggregate or bulk waste.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

Towpath cycling opportunities can add benefits to create travel patterns that do not involve use of cars and therefore can help in reduction of air pollution
Some urban locations are suitable for creation of waterbus services.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

Longer distance cycling for inter-town commuting + leisure cycling and walking on suitably constructed towpaths

16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?

Digital communications:

17. *What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?*

The linear nature and town to town connection of the waterway make the towpath an ideal opportunity for ducting for utilities and for extending the fibre optic network. Mobile communications masts can also be placed in the canal corridor.

18. *Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?*

Note: the existing "regime" refers to the current market, competition and planning frameworks. "Digital communications" includes both fixed and mobile connectivity.

Energy:

19. *What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?*

The water body of canal used for local heating (heat pumps)

There are limited opportunities for hydro-power and linear location for solar panels

20. *What does the most effective zero carbon power sector look like in 2050? How would this be achieved?*

Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.

21. *What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?*

Water and wastewater (drainage and sewerage):

22. *What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?*

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Water transfer using the Cotswold Canals under active consideration by Thames Water for Severn-Thames transfer.

23. *What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?*

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

The restored canals can be designed to be part of attenuation schemes or for flood water transfer.

24. *How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?*

Flood risk management:

25. *What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?*

26. *What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?*

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials

As response to Q 22 – the canal and off line storage can provide attenuation and retention of water in upper catchments.

Solid waste:

27. *Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?*

28. *What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?*

Note: A "circular economy" is an alternative to a traditional 'linear economy' (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process

Appendix

Economic & Social Impact of the restoration of the Kennet & Avon Canal 2010 Update

Executive summary

The Kennet and Avon Canal runs for 87 miles, linking the River Avon at Bristol with the River Thames at Reading. The canal was restored to through navigation in 1990 and the restoration was eventually made secure through further work, completed in 2002 and supported by £25 million funding from the Heritage Lottery Fund (HLF).

Following the restoration, two phases of economic evaluations were undertaken to review impacts, carried out by Ecotec in 2003 and 2005. The present study, undertaken by the Economic Development Unit, British Waterways, updates the 2005 study to 2009, through:-

- Assessing the economic benefits delivered by the Kennet & Avon Canal for the local economy, arising from increased tourism and leisure activity;
- Determine and quantifying where possible the ecosystems services delivered by the Canal.

As far as possible, both sets of impacts are broken down by local authority area.

Where possible, impacts are compared with:-

- The pre-HLF project baseline in 1995, taking account of the fact that the canal was navigable throughout at this time, all be it with restrictions;
- An assessment of what was forecast would happen if the canal reverted to 30% cruiseway status, undertaken as part of the economic appraisal for the HLF project by Coopers & Lybrand in 1995.

Local economic impact

The study estimates that around 11.2 million tourism, recreation and functional visits were made to the canal in 2009. This compares with 7.7 million visits in 1995, a growth of 46%. Visits to the canal have continued to grow since the HLF project was completed in 2002. These visits generated some £42 million gross direct expenditure in the local economy by visitors to the canal in 2009. This rises to £55 million if indirect and induced spend is added.

This expenditure supports some 1,306 leisure & tourism-related jobs in the canal corridor. This has grown from 815 jobs in 1995, pre-restoration. The original economic appraisal supporting the application for HLF funding stated that a high proportion of these jobs would be lost if the canal reverted to 30% cruiseway. So the net jobs supported by the canal in its current navigable state are 1,230, compared with the situation if canal maintenance was reduced and navigation largely ceased.

In summary, direct and total visitor spend, plus annual visits and jobs supported, by local authority in 2009 was:-

Reading

Direct visitor spend	£664,000
Direct, indirect & induced spend	£863,000
Visits p.a.	188,000
Jobs supported	20

West Berkshire

Direct visitor spend	£12,293,000
Direct, indirect & induced spend	£15,980,000
Visits p.a.	3,491,000
Jobs supported	386

Wiltshire

Direct visitor spend	£14,459,000
Direct, indirect & induced spend	£18,796,000
Visits p.a.	3,344,000
Jobs supported	444

Bath & North East Somerset

Direct visitor spend	£14,698,000
Direct, indirect & induced spend	£19,107,000
Visits p.a.	4,193,000
Jobs supported	455

Total

Direct visitor spend	£42,113,000
Direct, indirect & induced spend	£54,747,000
Visits p.a.	11,216,000
Jobs supported	1,306

Additionally the Ecotec 2005 study found that between 1995 and 2005 there had been some £375 - £435 million private and public sector investment in canalside properties. (This work hasn't been updated in the present study.) Many of these were residential, but around 2,700 jobs were supported in commercial canalside developments, particularly in Reading. These jobs aren't necessarily directly related to the canal, but are supported by developments focussing on the regenerated canal corridor.

Impact on ecosystems services

It is recognised that inland waterways make a valuable contribution to people's quality of life. They provide recreation, transport and land drainage. They act as a focus for the regeneration of waterside areas. They provide an important environmental, landscape and heritage resource. In this study, such quality of life benefits have been expressed and analysed in terms of ecosystems services delivered. Unlike the expenditure by visitors and the resultant employment generated, these ecosystems services represent real increases in people's welfare, rather than a spatial redistribution of benefits.

In this analysis, relevant ecosystems services have been identified and the benefits quantified where possible. It hasn't been possible to place a monetary value on all identified impacts, although the major benefits have been captured. Therefore the values will underestimate the actual benefits delivered. The analysis has been made (at 2009 values) against three scenarios:-

1. The current position (2009);
2. The position prior to the HLF project (1995);
3. The position if the canal reverted to largely un-navigable (ie. 30% cruiseway) status.

The following annual benefits have been identified:-

Ecosystem service	Value 2009 (£s)	Value 1995 (£s)	Value – Un-navigable (£s)
Provisioning services			
Business creation & employment		Not applicable	
Property value enhancement (capital)	£150.9m	£150.9m	£65.7m
Cost effective transport		Not quantified	
Water supply		Not quantified	
Volunteering		Not quantified	
Regulating services			
Carbon saving – sustainable transport & renewable energy		Not quantified	

Land drainage	£2.1m	£2.1m	£0.0m
Waterway habitats	Included elsewhere		
Cultural services			
Recreation	£10.7m	£6.9m	£3.5m
Waterway heritage, landscapes & environment	£1.0m	£1.0m	£1.0m
Outdoor learning	Not quantified		
Cross-cutting services			
Health & well-being	Not quantified		
Wider tourism & regeneration benefits	Not quantified		
Total – annual value	£13.8m	£10.0m	£4.5m
Total – capital value	£150.9m	£150.9m	£65.7m

Note:-

1. All values are shown at 2009 prices, for comparison purposes
2. No change is assumed in property value enhancement between 1995 & 2009, although some growth can be anticipated because of improvements in the quality of the canal environs.

This shows a growth in benefits delivered of at least £3.8m per year since 1995. If the canal was to revert to largely un-navigable status (30% cruiseway) some £9.3m benefits per year would be lost, together with a fall of around £85m in the capital value of properties. These benefits compare with an annual cost of maintaining the canal of £2.5 million in 2009/10.

The estimated split of benefits and costs by local authority is:-

Bath & North East Somerset

Ecosystem service	Value 2009 (£,000s)	Value 1995 (£,000s)	Value – Un-navigable (£,000s)
Property value enhancement	£54.1m	£54.1m	£37.3m
Land drainage	£155k	£155k	£0k
Recreation	£3,983k	£2,590k	£1,295k
Waterway heritage, landscapes & environment	£189k	£189k	£189k
Total – annual value	£4.3m	£2.9m	£1.5m
Total – capital value	£54.1m	£54.1m	£37.3m

Wiltshire

Ecosystem service	Value 2009 (£,000s)	Value 1995 (£,000s)	Value – Un-navigable (£,000s)
Property value enhancement	£47.3m	£47.3m	£0.0m
Land drainage	£1,100k	£1,100k	£0k
Recreation	£3,177k	£2,065k	£1,033k
Waterway heritage, landscapes & environment	£464k	£464k	£464k
Total – annual value	£4.7m	£3.6m	£1.5m
Total – capital value	£47.3m	£47.3m	£0.0m
Annual maintenance cost			£1.4m

West Berkshire

Ecosystem service	Value 2009 (£,000s)	Value 1995 (£,000s)	Value – Un-navigable (£,000s)
Property value enhancement	£35.8m	£35.8m	£14.7m
Land drainage	£756k	£756k	£0k
Recreation	£3,316k	£2,155k	£1,077k
Waterway heritage, landscapes & environment	£319k	£319k	£319k
Total – annual value	£4.4m	£3.2m	£1.4m

The National Infrastructure Assessment – Call for Evidence

About the Woodland Trust

The Woodland Trust appreciates the opportunity to respond to the National Infrastructure Commission call for evidence. Given the overriding importance of green infrastructure in the delivery of sustainable development we would like to take this opportunity to reiterate our call for green infrastructure to be considered as part of the NIC's remit. Notably, this was a key recommendation in the Natural Capital Committee's 4th State of Natural Capital Report¹. We hope that our submission will show the Commission that green infrastructure, particularly irreplaceable ancient woodland and newly planted woods and trees need to be a key component in the Commission's considerations on long term infrastructure provision, as per the Government's manifesto promise to 'protect your countryside, green belt and urban environment'.

As the UK's leading woodland conservation charity, the Trust aims to protect native woods, trees and their wildlife for the future. Through the restoration and improvement of woodland biodiversity and increased awareness and understanding of important woodland, these aims can be achieved. We manage over 1,250 sites across the UK, covering around 23,000 hectares (57,000 acres) and we have 500,000 members and supporters.

Questions and Answers

We have only answered the questions that fall within our charitable remit.

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

The Trust cannot comment on specific geographical priorities. But we would like to raise the issue of the importance of considering the natural environment from the outset. Whilst the Trust recognises that the development of infrastructure is critical, we ask that it is done with due consideration of the natural environment. The Trust believes the natural environment – both its protection and enhancing its ability to deliver vital ecosystem services to society - should be a starting point for all decisions on infrastructure provision. This is essential to delivering the current government's manifesto commitment that 'we will build infrastructure in an environmentally sensitive way'.

The Natural Environment White Paper (NEWP) published in 2011 must be at the heart of all infrastructure decisions. It outlines the Government's vision for the natural environment over the next 50 years and informs key areas of policy development in relation to conservation and

biodiversity. This includes a Government commitment to “providing appropriate protection to ancient woodlands.” In addition the NEWP confirms that “Departments will be open about the steps they are taking to address biodiversity and the needs of the natural environment, including actions to promote, conserve and enhance biodiversity.”

The NEWP also says “We will move progressively from net biodiversity loss to net gain, by supporting healthy, well-functioning ecosystems and establishing more coherent ecological networks.”

The evidence on which the Government has based these key policies in the Natural Environment White Paper is found in the Lawton Review. This recognises the importance of habitat networks, and reducing fragmentation of habitats. The review also stated that the government must “provide greater protection to other priority habitats and features that form part of ecological networks, particularly Local Wildlife Sites, ancient woodland and other priority BAP habitats”.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Green infrastructure is critical to creating better places to live and work. Woods and trees have the ability to deliver multiple benefits. Planting schemes should be bespoke to fit the needs of both the site and the community. Woodland creation can do everything from build resilience to flood risk and climate change to helping to instil an understanding and respect for the natural environment in children. Green infrastructure can play a critical role in softening the interface between hard infrastructure and housing.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Natural infrastructure should be integrated into the design of more traditional infrastructure and retrofitted into maintenance and renovation projects. Additionally, it is important to consider whether a natural infrastructure approach could meet the objective, as opposed to hard infrastructure or using a combination of both.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

All funding mechanisms must ensure that any green infrastructure created is accompanied with appropriate legal agreements assuring it will be maintained and enhanced in perpetuity.

Careful ecological assessments and planning at an early stage can minimise damage and ensure that the required infrastructure and mitigation works are as effective as possible in enhancing biodiversity and public access.

It is also worth turning the question around to consider what happens if we don’t invest in certain infrastructure now. The NIC’s own research paper on population recognises that rising congestion

and pollution have the potential to stifle London's growth. This is backed up by a very robust evidence base, for example a report from the Royal College of Physicians states:

Each year in the UK, around 40,000 deaths are attributable to exposure to outdoor air pollution which plays a role in many of the major health challenges of our day. It has been linked to cancer, asthma, stroke and heart disease, diabetes, obesity, and changes linked to dementia. The health problems resulting from exposure to air pollution have a high cost to people who suffer from illness and premature death, to our health services and to business. In the UK, these costs add up to more than £20 billion every yearⁱⁱ.

This current work is an opportunity to mitigate this on-going challenge and to mitigate its impact in the future. As such the Trust seeks assurances that the Commission is taking these considerations into account at the earliest possible stage.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The importance of protecting existing high value habitats and species should be considered as a primary concern for any infrastructure project. Linear infrastructure such as transport and energy corridors represent a significant risk to habitats such as ancient woodland. Yet careful ecological assessments and planning at an early stage can minimise damage and ensure that mitigation works are as effective as possible in enhancing biodiversity and public access.

The Trust would like to make particular reference to the importance of protecting ancient woodland. Ancient woodland is defined as an irreplaceable natural resource that has remained constantly wooded since AD1600. The length of time ancient woodland takes to develop and evolve (centuries, even millennia), coupled with the vital links it creates between plants, animals and soils accentuate its irreplaceable status.

Our ancient woodlands are quintessential features of England's much-loved landscapes – irreplaceable, living historic monuments which inspire us and provide us with a sense of place and history in an increasingly frenetic world

These are not The Trust's words, but taken from the government's own Keepers of Timeⁱⁱⁱ, written as a statement of policy to better protect and value ancient woodland. The Government Forestry and Woodlands Policy Statement (2013) confirms the Government's commitment to Keepers of Time by stating protection of our trees, woods and forests, especially ancient woodland, is our top priority.

Natural England's (NE) standing advice for ancient woodland and veteran trees (6 April 2016) recognises that ancient woodland is irreplaceable and that development of adjacent land, not just its direct damage can have a significant negative effect on ancient woodland. The Trust seeks assurances that the Commission is taking these considerations into account at the earliest possible stage.

Water and wastewater (drainage and sewerage):

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

We believe that a catchment approach to water management, integrating management of supply, waste water and flood risk, is hugely important. We welcome this question as its inclusion shows recognition of the need to consider water management at a wider landscape scale rather than simply considering hard infrastructure measures in isolation. Whilst man-made solutions (e.g. flood walls and water treatment plants) will continue to play a substantial role in many schemes, it is increasingly accepted that natural approaches to water management can also offer significant benefits. What is clear is that both approaches need to be looked at in tandem, to address both short and long term risk and to ensure that more affordable and appropriate options are considered alongside costly capital schemes. We would recommend the Woodland Trust report ‘Stemming the Flow – The role of trees and woodland in flood protection^{iv}’ for more information.

Flood risk management:

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

A joint publication by Forest Research and Confor – The Role of Productive Woodlands in Water Management^v (March 2015) – states that:

‘Society is increasingly threatened by flooding, while the water environment remains seriously impacted by a range of human pressures, including diffuse water pollution. There is strong evidence to support woodland creation in appropriate locations to help manage these issues....There is a strong case for further investment in well-targeted woodland creation to help meet a wide range of environmental and social goals, including contributing to the Floods Directive, Water Framework Directive, Biodiversity 2020, Greenhouse Gas reduction, climate change adaptation and growing the rural economy’.

Trees and woodland can reduce localised flooding and alleviate the effects of larger floods in a variety of ways, including:

- Water penetrates more deeply into the woodland soils (higher infiltration rates) leading to less surface run-off.
- Trees, shrubs and large woody debris alongside rivers and streams and on floodplains act a drag on flood waters, slowing down floods and increasing water storage.
- Trees protect soil from erosion and reduce the sediment run-off, which help the passage of water in river channels, reducing the need for dredging.
- The greater water use of trees can reduce the volume of flood water at source.
- Trees slow the speed at which rain reaches the ground, with some rain evaporating into the atmosphere - even in winter native deciduous trees intercept up to 12% if rainfall.

Dear Sirs

I am writing on behalf of Worcestershire Local Enterprise Partnership to provide a specific response to Question 1 of the Call for Evidence ie “ What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

Working in partnership with LEPs, landowners, local authorities, train operating companies, Network Rail, MPs and others, Worcestershire is in the process of implementing 2 major rail infrastructure schemes to support the growth of our economy in line with the Strategic Economic Plan for the County (<http://www.wlep.co.uk/assets/WLEP-Final-SEP-310314-V-1-1.pdf>). These being the development of Worcestershire Parkway Station (<http://www.wlep.co.uk/government-green-light-worcestershire-parkway/> and http://www.worcestershire.gov.uk/info/20254/infrastructure_and_improvement_schemes/995/worcestershire_parkway_regional_interchange) and the redevelopment of Kidderminster Station. Both schemes are being developed in the context of an emerging Rail Investment Strategy for Worcestershire.

However, whilst both initiatives will add considerably to the economic growth potential of the County, full potential will only be realised by the improved connectivity to London and the South East through the reduction in journey times. The game changer intervention here being the investment in the development of the North Cotswold Line as envisioned in the attached document which has the full support of Worcestershire LEP.

Two substantial events have already been held to progress this ambition. On 12th February 2016, Stakeholders, including LEPs, DfT, businesses, MPs and others attended an event Chaired by Lord Faulkner (<https://www.witneyconservatives.com/news/david-cameron-attends-conference-about-north-cotswold-rail-line>) that detailed the Vision (attached) and started to build the Business Case for action. On 29th November 2016, a further event was held at the Houses of Parliament, again Chaired by Lord Faulkner, which agreed to establish a Task Force to take the project forward. Worcestershire LEP and Oxfordshire LEP are currently finalising the Terms of Reference of the Task Force which will engage further with businesses to build a case based on economic growth.

I would commend this initiative to the National Infrastructure Commission and if you have any further queries, please do not hesitate to contact me.

Regards

National Infrastructure Assessment - call for evidence

WWF-UK RESPONSE

10 February 2017

SUMMARY

WWF is a leading global conservation organisation, employing over 5,000 staff in more than 100 countries and with more than five million supporters across the world. We are at the heart of global efforts to address the world's most important environmental challenges. We work with governments, businesses and communities to promote sustainable patterns of development so that both people and nature can thrive. Together, we're safeguarding the natural world, tackling climate change, and promoting prosperous and resilient economies.

It is now widely recognised that a healthy natural world is the foundation of a productive and resilient economy. Yet, from the serious flooding incidents we have seen in recent years (which have been caused at least in part by the way river catchments have been managed), to the health-related impacts of urban air pollution and associated human and economic costs - the evidence shows that we are failing to protect and invest in our natural assets, and that this is already affecting the UK's economy and the well-being of its population. If unabated, these trends will have profound implications for the nation in the future. Accordingly, government, business and wider civil society are increasingly recognising the need to structure economic policy so that it promotes investment in our natural assets and makes the transition onto a sustainable, resource-efficient, low-carbon economic trajectory.

ANSWERS TO QUESTIONS

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

WWF has produced a Greener Budget Report in the last two years, making recommendations about what the Treasury should include through economic policy measures in the Annual Budget that would help to move the UK economy onto a more sustainable growth path. The reports show why that is essential, if we are to remain competitive and prosperous as a nation, in a future resource- and carbon-constrained global economy; one in which climate mitigation policies that will promote the shift to a low carbon economy, and growing resource scarcity including water shortages and increasing competition for land, will change the rules of the game.

Infrastructure development has a crucial role to play in supporting this shift to a low carbon, climate-resilient, and resource-efficient economy. It should:

President: His Royal Highness,
The Prince of Wales KG, KT, GCB, OM
Chair: Sir Andrew Cahn KCMG

Chief Executive: Tanya Steele WWF-UK a charity registered in England and Wales number 1081247 and in Scotland number SC039593, a company limited by guarantee registered in England number 4016725. VAT number 733 761821
100% recycled paper

- Undertake stress testing to assess the impact of future environmental risks to UK infrastructure and the UK economy.
- Be developed in conjunction with the industrial strategy, putting low carbon growth at its heart, for example by setting an objective to become a world leader in the development and integration of low-carbon energy systems with export potential, and which supports the development of a sustainable bioeconomy that can generate considerable growth and jobs.
- Be developed in conjunction with the Emissions Reductions Plan, and include investment in energy efficiency as a key plank of our infrastructure strategy.
- Be developed in conjunction with the 25 Year Environment Plan, which by investing in the UK's natural capital should generate significant improvements in productivity and competitiveness such as through improvements in air quality and health, soil quality, and flood and drought resilience all of which boost productivity.
- Include investment in green infrastructure as a key part of our infrastructure strategy, as green infrastructure can both complement and protect traditional infrastructure and can provide a more cost-effective solution in some cases.

International connectivity is very important for the UK economy, particularly as the Government seeks to negotiate new trading relationships both with and beyond the EU. But the Government must factor the reality of climate change into its international connectivity strategy. Aviation is the most high-carbon form of transport, so its use should be limited as far as possible. For example, video-conferencing can substitute for business travel, saving companies money and increasing productivity, as demonstrated by WWF-UK's One in Five Challenge¹. International rail can also substitute for air freight, as demonstrated in January 2017 by the first UK arrival of a freight train from China². Rail freight is both cheaper and greener than air freight.

Demand for business flights has fallen both in percentage terms and in absolute terms since the turn of the century³, which means that despite all the talk about expanding airport capacity to boost business, much of this new capacity would in fact be used for leisure.

By developing a low-carbon connectivity strategy, which prioritises digital, marine and rail connectivity while reducing reliance on aviation, the UK can remain competitive while meeting its legally binding domestic and international climate change obligations. Failure to meet our climate change objectives will of course result in great damage to the UK economy and to UK connectivity, with ports, airports and international rail terminals all highly vulnerable to climate change impacts such as sea level rise and heightened flood risk.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Green infrastructure can contribute to creating better places to live and work. Green infrastructure such as urban green space can often have important co-benefits, contributing simultaneously to improved health, reduced pollution, flood resilience, recreational and cultural benefits etc. For example, there is a growing literature showing how urban green space can boost mental and physical wellbeing, improve educational attainment, reduce anti-

² Campaign for Better Transport, 2017. First ever freight train from China to the UK arrives <http://www.bettertransport.org.uk/blog/better-transport/first-ever-freight-train-china-uk-arrives>

³ Aviation Environment Federation, 2015. The Great British Runway Myth...why there is no need for a new runway <http://www.aef.org.uk/uploads/Runway-Myth.pdf>

social behaviour, through psychological impacts, increased recreation and improved air quality. The Natural Capital Committee showed that £2.1 billion in healthcare costs could be saved if everyone in the UK had access to good quality green space⁴.

Infrastructure and housing development are closely linked, as new housing generates new infrastructure needs. Where such developments are located will have a big impact on environmental outcomes, which in turn can have a big impact on the people living in that area. A key issue is around flood resilience. Poor management of our land and waterways have contributed to increased flood risk, as more development on flood plains has taken place, and agricultural production practices and adaptations to waterways have exacerbated the problem. The likely impact of climate change on UK weather will be increased precipitation leading to more flooding events, which, as the UK population is already too aware, are very costly. The winter 2015/2016 floods look set to have cost the economy at least £5bn. UK flood defences designed to withstand a 1 in 100 year flood (including those built as recently as 2013) have already failed to protect some local populations and businesses during the storms in late 2015, suggesting a failure to understand the scale and probability of future weather-related threats.

Green infrastructure solutions can address this, and it is vital that the government's forthcoming review of flood defences takes account of the crucial role that improved management of natural capital can play in a cost-effective and future-proofed UK flood strategy.

In accordance with forthcoming revisions to HM Treasury's Green Book on natural capital, information on natural capital impacts and risks should be added to the existing infrastructure pipeline evidence base for all projects in order to help potential investors evaluate investment options⁵.

However, the NIP also needs to recognise that many natural assets are vital 'natural infrastructure' in their own right – providing a range of vital public services of considerable value – and as such should be afforded 'infrastructure' status in the UK's infrastructure planning frameworks. The government has already clearly stated its vision that all public policy should reflect this⁶. Thus natural infrastructure investments should be considered in a consistent way against other infrastructure options, to assess priorities for funding.

The Scottish government is already making progress in this area, having explicitly included investment in natural capital as a key element of its economic strategy – and including priority natural infrastructure projects in its latest National Planning Framework (for example, the Central Scotland Green Network is one of 14 major infrastructure priorities, alongside others such as national broadband).

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

⁶ Defra, 2015. Open Environment speech by Elizabeth Truss. Defra, London, UK.

Water demand

In terms of water demand management, significant water use reductions can be achieved through the installation of water meters. For example, Southern Water's Universal Metering Scheme (just completed) achieved reductions of 15% average use, and up to 30% peak use in critical periods (i.e. when water is scarce). Evidence from the US and Australia suggest further reductions can be achieved through tariffs and reward schemes. In terms of rebound effects, there is some evidence that water savings are maximised just after installation – this makes sense as installation often goes hand in hand with communications and awareness. Indeed awareness-raising is critical for all demand management measures (for example, changes in tariffs only work if people understand the different tariff options). So rebound effects can be countered to some extent by frequent communications. For more information see:

- WWF Itchen Initiative and smarter demand management discussion paper http://assets.wwf.org.uk/downloads/itchen_initiative_report_march_30th.pdf
- Independent Walker Review <https://www.gov.uk/government/publications/the-independent-review-of-charging-for-household-water-and-sewerage-services-walker-review>
- Fairness on Tap http://assets.wwf.org.uk/downloads/fairness_on_tap.pdf
- Waterwise Evidence Base

There are also opportunities for demand management interventions on the wastewater side. For example, using Sustainable Urban Drainage Systems (SUDS) to reduce the amount of rainfall run-off from urban areas that ends up in combined sewers, thereby reducing the volume of wastewater requiring treatment. It's also important to recognise that savings on the water supply side mean savings on the wastewater side (i.e. less water in, less water out). However, we are not aware of any work to quantify this.

Energy demand

There is significant potential for demand management, both in our power system and within our homes.

The deployment of increasing amounts of renewable generation will result in a greater need for demand side management in the **power sector**. The Committee on Climate Change found that Demand Side Response (DSR) in conjunction with greater storage and interconnection would be vital for ensuring security of a system with large amounts of renewable capacity. At the same time smart meters and time of use tariffs stand poised to move consumers towards being “prosumers”, thereby creating more opportunities for demand management in the domestic sector⁷. The greatest opportunities for domestic demand management will occur when heat pumps, electric vehicles, and battery storage systems are deployed on the system in sufficient numbers.

We now turn to **energy** demand management in the domestic sector. Our homes are a significant element of the UK's **energy infrastructure**, accounting for 36% of total UK electricity consumption and 51% of total gas consumption in 2015⁸.

The UK **existing domestic building stock** is old and we are in the bottom third for thermal efficiency when compared with our European neighbours⁹, with considerable potential for improvement through increased fabric efficiency. Failure to address this problem risks increasing the costs of balancing the energy system in future, as in many cases,

⁷ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/467024/rpt-frontier-DECC_DSR_phase_2_report-rev3-PDF-021015.pdf p.9

⁸ DECC (2016) Energy Consumption in the UK

⁹ UK ACE (2015) The cold man of Europe

energy efficiency can meet demand for energy services at a lower cost than supply-side measures¹⁰.

Failure to assess demand-side opportunities when making supply-side decisions risks policy objectives being achieved at greater cost than necessary¹¹. Investing in the fabric efficiency of our buildings will help reduce overall energy demand, in turn helping to reduce the scale of investment required to balance the future energy system.

According to a 2014 study by Verco and Cambridge Econometrics, an ambitious programme of domestic retrofit would lead to carbon reductions of 23.6MtCO₂ per annum by 2030, after accounting for direct, indirect, and economy-wide rebound effects. This is roughly equivalent to cutting the CO₂ emissions of the UK transport fleet by one third.¹²

Transport demand

Limiting transport demand and shifting demand from higher-carbon to lower-carbon modes of connectivity will be essential for meeting the UK's legally binding domestic and international commitments on climate change. Demand management is particularly important for car and plane travel, as these modes of travel are particularly polluting and increases in demand have tended to outstrip increases in vehicle efficiency over recent decades.

Car travel can be shifted to public transport (e.g. bus or train) or active travel (e.g. cycling or walking), resulting in substantial air quality and general health improvements as well as reduced carbon emissions. Passenger air travel can be replaced by train or video conferencing, resulting in reduced costs and increased productivity. Road and air freight can be shifted to rail or sea, resulting in reduced costs and an improved safety record.

The Committee on Climate Change (CCC) is clear in its advice to Government that demand management is an essential component of efforts to decarbonise transport, without which technological gains from improved vehicle efficiency and fuel switching to biofuels or electricity will continue to be cancelled out by increasing demand¹³. The CCC is also clear that aviation emissions should be held at 2005 levels in 2050, allowing for some 60% increase in passenger numbers with increased fuel efficiency. The Government must set out a framework for achieving this target.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Competition in the **water services sector** could, like in Scotland, mean that companies put a greater emphasis on customers and compete on service (as opposed to price). While there are some concerns that competition would break up 'natural' geographic monopolies (and perhaps disconnect customers further from the environment where their water is sourced), there are opportunities. For example, we hope that competition would reveal data/information about where water is coming from and the losses at different stages in its delivery. This would help drive demand reduction.

¹³ CCC, 2016. Meeting Carbon Budgets – 2016 Progress Report to Parliament <https://www.theccc.org.uk/publication/meeting-carbon-budgets-2016-progress-report-to-parliament/>

Collaboration between water companies with NGOs is crucial. Wessex Water said that “engaging with the catchment partnership has fundamentally changed our business plan”. The following are needed to help foster collaboration and deliver the Catchment Based Approach (CaBA):

- multi-year seed funding of catchment partnerships in order to leverage private sector investment;
- procurement processes that enable NGOs to deliver. (Many of the big utilities are set up to procure big contracts from multi-national engineering firms for delivery, making it difficult for NGO partnerships as the Rivers Trust charities to go through the procurement process.)

Competition also has a vital role to play in driving down the costs of building new **energy infrastructure**. With regard to low carbon power, competitive auctions have been proven to bring down costs to consumers¹⁴; clearing prices in the 2015 Contracts for Difference (CfD) auction were significantly lower than the administrative strike prices set prior to the auctions. Furthermore, the NAO found that, when compared to initial FiD enabling contracts awarded to selected low carbon projects, competitive auctions clearly delivered better value for money¹⁵.

In order to drive further cost reductions in this area, the Government must set out the timing and amount of future CfD auctions, and should outline the post 2020 Levy Control Framework. Clarity for investors is the key to realising supply chain efficiencies. In Denmark this has resulted in record breaking prices for offshore projects.¹⁶ The Government should also ensure that there is a route to market for the cheapest forms of power generation, onshore wind and solar¹⁷. Allowing these technologies to compete would drive down costs to consumers and ensure that the cost of decarbonisation is not back loaded onto future consumers¹⁸.

Effective competition must be underpinned by access to the market for new technologies. Globally, energy and technology markets are innovating rapidly and the UK’s regulatory framework needs to be suitably responsive to ensure the UK is well placed to capture opportunities. As the NIC identified in their Smart Power report, new and innovative technologies such as storage and demand management currently face a number of barriers to market entry which puts them at a disadvantage compared to more traditional forms of electricity generation. The WWF-UK convened business taskforce on renewables found that since privatisation a complex regulatory framework has built up which distorts the market in favour of incumbent and long established technologies. The taskforce recommended that the Government should remove barriers in the electricity market in order to increase competition and maximise cost reductions.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered? Note: by “funding”, the Commission means who pays for infrastructure services. and how, e.g. user charges, general taxation etc.

Using techniques such as natural capital assessment that capture the value of the multiplicity of benefits provided by green infrastructure is important, as looking only at one type of benefit will result in its undervaluation. And thus finding ways to pool funds across

departments of government that stand to gain from the various different benefits rather than trying to tackle these issues in isolation is also important¹⁹.

For example, as noted above, improving the quantity, quality and use of green space could play an important role in reducing costs relating to mental and physical ill-health. Funding of green space is primarily a Local Authority responsibility, yet much of the benefit is realised by other areas of government, including by the National Health Service, Public Health England and Department of Health, as well as the Department for Work & Pensions (through reduced work absence and benefits dependency) and the Department for Business, Innovation & Skills (through improved workforce productivity). Improved cooperation and joint-funding of natural capital projects across departments, as part of overall UK health care policy, could cut overall costs and improve value for money.

To provide another example: the annual cost of flood damage to properties in England and Wales is projected to rise from £1.2 billion (current average) to as much as £12 billion by the 2080s²⁰. Natural capital flood and coastal risk management (FCRM) solutions can deliver on many government policy objectives, safeguarding businesses, homes and local economies, improving health and storing carbon. Potential beneficiaries include the Treasury, Department for Business, Innovation & Skills, National Health Service, Department of Health, Department for Transport, Department for Work & Pensions, Department for Communities & Local Government, Home Office and Ministry of Defence. Improved collaboration and co-funding would provide greater incentive for flood risks to be considered in departmental planning processes, spread the cost and improve value for money.

Offsetting or compensation payments can play an important role in financing natural capital. Infrastructure development plans should fully embed natural capital concepts, ensuring that all publicly funded infrastructure investments make a positive contribution to protecting and enhancing the UK's natural environment (a government commitment²¹). Thus all infrastructure developments should fully address impacts on natural capital according to the established mitigation hierarchy (avoid, minimise, restore, offset). A mandatory national offsetting scheme should be introduced, to which all infrastructure projects should contribute in order to compensate any unavoidable damage, and ensure a net positive impact on our natural capital. This offsetting scheme should pool finance generated through offsets to finance priority natural capital investments, as identified through the 25 Year Environment Plan with advisory inputs from the Natural Capital Committee.

In addition, we need to see greater coherence in public funding, so different funding sources do not conflict with each other. For example, greater alignment is needed between the objectives and timelines associated with CAP payments, EA flood defence, and water company investment, to ensure we get the best value for the money we are already committed to spending - only central Government can bring them into line to ensure all objectives are met cost effectively. We also need taxes, fines and penalties for pollution and breaches of environmental regulation that reflect environmental damages, with monies raised recirculated into enhancement.

In addition, there is a need to look how to reward farmers better for managing their land in a way that helps contribute towards the construction of more green infrastructure, via more targeted public expenditure, and other arrangements such as Payments for Ecosystem Services. The chance to redesign agricultural policy after the UK exits the European Union provides an opportunity to reshape payments to farmers so that they support the delivery of public goods including green infrastructure that contributes to reducing flood and drought risks and improved water quality.

¹⁹ A Greener Budget Report 2015, Sustaining our Prosperity in a Changing World, WWF-UK

²⁰ HR Wallingford, 2012. The UK Climate Change Risk Assessment 2012: Evidence Report Summary. Defra, UK

²¹ Defra, 2015. The government's response to the Natural Capital Committee's third State of Natural Capital report Defra, London, UK.

Other innovative financing mechanisms could also be considered, such as Environmental Impact Bonds, which involve borrowing upfront to pay for investment in green infrastructure, which will generate public savings in future, thus facilitating repayment of loans. Green Alliance has made innovative proposals for how new markets for land and nature can be generated, through the creation of National Infrastructure Schemes²².

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets? Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

Green infrastructure is an innovative approach, and can sometimes be expected to generate a positive rate of return only in the long term. Sometimes a proportion of the benefits are not monetisable even if they yield important benefits for society. In these situations some form of blended finance or impact investment may be needed, or patient capital or capital that is willing to take greater risks. It is not easy to see where the provision of such finance might come from in the UK. The Green Investment Bank could in principle play this role, but given its imminent privatisation and likely focus on investments with a higher rate of return, it may be less willing to finance these types of projects, and address such market failures. The Natural Capital Financing Facility²³ – established by the European Investment Bank - provides an example of the type of mechanism that could potentially support investment in natural infrastructure. Consideration could be given to the establishment of such a mechanism in the UK.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

In our 2015 A Greener Budget Report, we proposed that the Treasury adopts a natural capital stress testing approach to assessing the risks from future environmental degradation / natural capital depletion to the economy, and different sectors within it. A similar approach could be adopted in relation to impacts on infrastructure, also as a way to analyse the resilience of different potential future infrastructure development trajectories to future environmental risks and trends. We welcome the fact that stress testing relating to future flooding risks has now been conducted through the Flood Resilience Review. But this approach could be broadened out to cover other types of risks, and its impacts on the wider economy also considered, including interdependence across sectors.

Stress testing is used widely in the UK banking sector to evaluate risk exposure and resilience of financial institutions. It has been used by banks for internal risk management since the 1990s, and gained further momentum following the 2008 financial crisis²⁴. In this context, stress testing is used to examine the ‘health’ of a bank in terms of its capacity to maintain its lending and trading activities under different future economic and financial scenarios.

More recently, a number of initiatives have sought to measure carbon risks in the financial sector better (for example, the Bank of England is investigating the potential influence of

²² http://www.green-alliance.org.uk/natural_infrastructure_schemes.php

²³ <http://www.eib.org/products/blending/ncff/index.htm>

²⁴ Bank of England, 2013. A framework for stress testing the UK banking system. A Discussion Paper.

climate change externalities on the stability of the financial system²⁵), and have also adopted a stress testing approach. Thus a similar approach could be adopted to help assess and manage risks associated with changes in natural capital.

A natural capital stress test could identify the exposure of UK Plc and individual economic sectors to potential changes in stocks of natural capital and associated service/benefit provision, and inform decisions about what level of assets should be maintained to mitigate risk (and associated policy / investment requirements). The test could explore the potential economic (and budgetary) implications associated with a range of different scenarios, related for example to changes in specific UK and international natural assets (e.g. watercourses or forest cover) and/or relevant drivers/pressures (e.g. extreme weather events, global warming and population growth). As the process is refined, interactions between scenarios, natural capital assets and/or economic sectors could be explored²⁶.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

A well-designed offsetting scheme could help to make the planning system more efficient and deliver better environmental outcomes. Rather than requiring expensive, site-specific mitigation measures to protect certain species, which often cause unwelcome last minute delays for developers, planning decisions could be taken in line with an overall plan of how best to protect that species within the area. Natural England or another environmental body can be involved in the design of that overall plan. Thus NE would work with the relevant Council early on in its planning process in order to identify the likely adverse impacts from an envisaged development and identify appropriate mitigation measures, which can include offsetting payments made by the developer to support the provision of a better habitat for that species in an alternative location. Woking Borough Council is currently pilot-testing this approach²⁷. WWF believes that properly designed and implemented, biodiversity offsetting can and should achieve net gain for biodiversity, and generate additional finance for investment in natural capital. WWF-UK also believes that it is vital that biodiversity offsetting is implemented within the context of coherent, long-term national strategy for enhancement of natural capital.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

This has been the theme of our other responses in this document. We believe this can best be achieved by:

- Incorporating natural capital assessments (or assessments of the value of nature in terms of its economic and social benefits in other words) into infrastructure development decisions. As emphasised by the NCC, integrating natural capital into the National Infrastructure Plan (NIP) is crucial.²⁸
- Applying the mitigation hierarchy to all infrastructure investments, and undertaking offsetting or compensatory payments where environmental damage is unavoidable to ensure a positive gain for natural capital overall.

²⁵ Michael Sheren, Senior Advisor at the Bank of England, at “Redesigning finance for low-carbon green growth”, House of Lords, 14 October 2015.

²⁶ A Greener Budget, 2016, Choices for a Prosperous Future, WWF-UK

²⁷ <https://www.gov.uk/government/consultations/great-crested-newt-pilot-scheme-in-woking-opportunity-to-comment>

²⁸ Defra, 2015. The government’s response to the Natural Capital Committee’s third State of Natural Capital report. Defra, London, UK.

- Considering opportunities for green infrastructure on an equal footing with traditional infrastructure solutions.
- Undertaking stress testing to assess the resilience of future infrastructure trajectories to future environmental risks.
- Supporting the shift to a low carbon economy, including by supporting energy efficiency measures.

All of these issues are expanded upon elsewhere in our consultation response.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent? Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

Appraisal of infrastructure investments should fully operationalise the recent additions to HM Treasury’s Green Book in line with NCC recommendations²⁹ which include: adopting a clearer framework for assessing how people value changes in natural capital; more coverage of how environmental changes can impact on firms’ profits; assessing impacts of projects on stocks of natural capital, including irreversibility, uncertainty and uninsurable risks.

We would also recommend that natural capital assessments are applied to large scale infrastructure developments, using tools such as InVEST³⁰, a freely available software tool that enables users to map and value ecosystem services, and allows decision makers to assess and quantify trade-offs associated with alternative management choices, and to identify areas where investment in natural capital can enhance human benefits and conservation. This can provide a practical approach to assessing the natural capital impacts of infrastructure development choices in a particular location, and has been applied to assist with infrastructure development decision making. The Natural Capital Project provides a library of relevant information including for example a report on: “[Entry Points for Considering Ecosystem Services within Infrastructure Planning: How to Integrate Conservation with Development in Order to Aid Them Both](#)”³¹, a report on ‘[Natural capital and roads](#)’, and another on: ‘[Key lessons for incorporating natural infrastructure into regional climate adaptation planning](#)’.

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

Adjustments to travel patterns will be needed alongside technological improvements to ensure that transport can make a proportional contribution to achieving the UK’s legally binding domestic and international climate change objectives³². See question 4.

³² CCC, 2016. Meeting Carbon Budgets – 2016 Progress Report to Parliament <https://www.theccc.org.uk/publication/meeting-carbon-budgets-2016-progress-report-to-parliament/>

In terms of new technologies, electric vehicles (EVs) have the potential to be transformative on a number of fronts:

- Electrification reduces both CO₂ and particulate emissions (and zero emissions in use for Battery Electric Vehicles, BEVs), whether or not the energy input is low-carbon/renewable, as electric motors are more efficient than the internal combustion engine (ICE).
- However, it is the combination of EVs with renewable electricity that holds most promise. EVs can help enable greater penetration of renewable electricity by storing electricity when not in use, and potentially discharging electricity back to the grid at times of high demand. This results in a flexibility benefit to the grid and economic benefit to the consumer.
- EVs also represent a major industrial opportunity for the UK. With stable support from Government, the UK can become a world-leading manufacture of EVs for both the domestic and international markets.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Air quality and climate change should be seen as the twin drivers of transport investment in urban areas. Electrification, modal shift to bus, rail and active travel, and potentially the use of sustainable biomethane in freight can all result in significant benefits to both the climate and air quality.

The phase-out of diesel vehicles and their replacement with low-carbon alternatives should therefore be an urgent priority. Diesel cars and vans should be replaced with EVs. Diesel HGVs could be replaced by gas engine vehicles, combined with a sustainable supply of biomethane and appropriate methane slip mitigation measures.

Government should also provide stronger support for increasing efficiency in freight logistics.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Sustainable long distance passenger travel should be supported through investment in the railways and a fairer tax regime for aviation to reverse the current privileged status of aviation.

Sustainable long distance freight would also involve greater and better use of the railways. It will also require substantial investment in the hydrogen economy and/or deploying wireless dynamic charging technology for roads.

16. What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

Both mobility as service and road user charging should be considered as potential policy levers for decarbonising transport, as they can both result in modal shift/demand moderation.

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

The most cost-effective means of decarbonising heat is to reduce heat demand. As noted under question 4, the UK's housing stock is in the bottom third for thermal efficiency compared to the rest of Europe. An immediate and ambitious programme of domestic energy

retrofit, combined with stringent regulations to ensure the efficiency of new build is required to minimise heat demand.

A programme to bring all homes up to an Energy Performance Certificate rating of C by 2035 would help to eliminate fuel poverty and deliver the carbon abatement needed to meet carbon budgets. To achieve this, a total of £100 billion of investment would be required over a 20-year period. This could be achieved by Government providing zero-interest loans to encourage householders to invest, or by regulating minimum energy efficiency standards at the point of sale³³. The latter approach would require minimal public spending, and although would impose a cost on households these would be recouped in the long-run through lower energy bills³⁴. This spending (on domestic labour and goods) compares to the £15 billion spent every year by UK households on increasingly imported gas for heating³⁵.

This energy efficiency programme would meet the criteria HM Treasury apply for determining their top 40 infrastructure requirements. It would also fit with the eight characteristics of infrastructure identified in HM Treasury's valuation guidance. In addition, classifying energy efficiency as infrastructure is consistent with the way energy efficiency is considered by a range of international organisations such as the European Investment Bank (EIB) and the International Energy Agency (IEA)³⁶.

Alongside investment in domestic energy efficiency, existing technologies for decarbonising heat should be rolled out as fast as possible. In particular, heat pumps are a viable solution for homes currently off the gas grid, and district heating should be considered in urban settings. District heat networks provide the added benefit of providing low cost bulk energy storage, which in future could be used to help balance the electricity system (for example by converting excess electricity to heat as is already done in Denmark to balance their high-renewables grid).

Further options for decarbonising heat include the use of hydrogen and biomethane. These need to be developed, tested and analysed before a decision is made on rolling specific technologies out at scale. There are however sustainability issues associated with both these technologies. Hydrogen needs to be assessed in terms of its reliance on carbon capture and storage and continued use of fossil fuels. The use of biomethane in the gas grid needs to be developed as part of a wider bio-economy strategy, considering the various potential uses of biomass and the best way to deploy them across the economy for maximum value. Sustainable biomass is a limited resource, and needs to be targeted at those sectors of the economy where other options for decarbonisation are limited. Robust sustainability standards such as the Roundtable for Sustainable Biomaterials are also essential for ensuring that biomass feedstocks are responsibly sourced, preferably from wastes and residues rather than virgin crops or trees.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

WWF-UK's *Positive Energy* report shows that 60% of electricity demand can be met by renewables in 2030. The Committee on Climate Change recommends that the cost effective pathway to the 2050 emissions reduction target set by the Climate Change Act require a decarbonised power sector 2030³⁷. In order to bring emissions from this sector to below 100g Co₂/kWh the CCC recommends 282 TWh of low carbon generation in 2050 and 55% of

³³ E3G (2015) Taking back control: where next for household energy efficiency policy in the UK?

³⁷ <https://www.theccc.org.uk/wp-content/uploads/2015/10/Power-sector-scenarios-for-the-fifth-carbon-budget.pdf>

generation from renewables. Offshore wind plays a large role and deploys at a rate of at least 2GW per year. Onshore wind and solar have a route to market and flexibility options balance the system. Over the next 25 years the costs of wind and solar will tumble rapidly³⁸.

With rapid price reductions, battery storage will start to play a significant role in the electricity market³⁹. BNEF predicts that the rise of EVs will drive down the cost of lithium-ion batteries, making them increasingly attractive to be deployed alongside residential and commercial solar systems. Storage will enable a lower carbon, lower cost energy system where consumers can take greater control of their electricity usage. At the transmission scale, storage can aid the System Operator in mitigating the variances in supply and demand. Storage will also reduce the overall amount of new generating capacity that is needed and will enable more effective system operation. This enhanced security of supply will allow investment in low carbon generation to be optimised as well as reducing overall energy costs to consumers. At a domestic level, storage will allow consumers to take greater control of their electricity production and usage (becoming so-called “prosumers”), furthering the decentralisation of the electricity grid. Penetration of domestic scale storage links closely to deployment of electric vehicles and take up electric heat. Coupled with the smart meter roll-out, storage will enable a lower carbon, lower cost energy system where consumers can take greater control of their electricity usage.

At the transmission scale, storage will aid the System Operator in mitigating the variances in supply and demand. Storage will also reduce the overall amount of new generating capacity that is needed and will enable more effective system operation. This enhanced security of supply will allow investment in low carbon generation to be optimised as well as reducing overall energy costs to consumers. At a domestic level, storage will allow consumers to take greater control of their electricity production and usage (becoming so-called “prosumers”), furthering the decentralisation of the electricity grid. Penetration of domestic scale storage links closely to deployment of electric vehicles and take up electric heat. Coupled with the smart meter roll-out, the integration of domestic storage and generation presents a considerable opportunity to develop the wider network.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Increased penetration of EVs (battery electric vehicles, BEVs, and plug-in hybrid electric vehicles, PHEVs) is sometimes characterised as a challenge for the electricity system. WWF-UK believes that on the contrary, EVs present significant opportunities for strengthening the electricity system.

Even under an ambitious scenario where EVs account for 75% of all cars in the UK by 2030, a realistic worst case peak demand due to EVs is still below 10GW, which is within the range of National Grid forecasts of load growth⁴⁰. This scenario has all EVs demanding power at the same time. But this is never likely to happen as not all EVs are driven each day and there are different arrival times home.

EVs offer significant benefits beyond reductions in CO₂ emissions (see question 13), especially for households and businesses with solar PV. Households and businesses can choose to charge their EVs using self-supply (e.g. from PV during the day) or use a charge delay device to charge at times of low demand/price and a high share of renewable supply (e.g. in the middle of the night). This can greatly reduce costs as well as emissions, especially compared to conventional fuel – managing the timing of EV charging, to utilise lowest grid

³⁸ <https://about.bnef.com/blog/mccrone-energys-long-term-changed-last-year/>

³⁹ <https://about.bnef.com/blog/coal-and-gas-to-stay-cheap-but-renewables-still-win-race-on-costs/>

⁴⁰ WWF-UK, 2011. Electric avenues: Driving home the case for electric vehicles in the UK. http://assets.wwf.org.uk/downloads/electric_avenues_fullreport.pdf

CO₂ intensity, would increase the carbon savings of EVs from 23% to 41% in comparison to ICEVs by 2030⁴¹.

Furthermore, EV users can also opt to discharge energy from their EVs back to the grid at time of high demand/price. Smart charging tariffs that reward drivers who are prepared to surrender some of their battery capacity would help to encourage the storage potential of EVs.

Finally, in order for EVs to reach their full economic and environmental potential, it will be essential to continue increasing the share of low-carbon, renewable electricity in the UK, and some investment will also be required in local distribution systems and transformers, which are smaller scale and lower specification than national level transmission systems and therefore less able to handle surges in demand.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute? Note: “demand” includes domestic, commercial, power generation and other major sources of demand.

- Universal metering across the country is absolutely essential to addressing the supply-demand deficit. Metering is crucial for implementing sustainable abstraction licences (where every permit includes a “hands-off” flow condition so that abstraction ceases when flows drop to critical levels). Metering is also important for understanding who is using what and when – such information is needed before supply-side options such as transfers from different catchments are pursued. For further information please see:
 - WWF Itchen Initiative and smarter demand management discussion paper http://assets.wwf.org.uk/downloads/itchen_initiative_report_march_30th.pdf
 - Fairness on Tap http://assets.wwf.org.uk/downloads/fairness_on_tap.pdf

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand? Note: this can include, but is not necessarily limited to, governance frameworks across the country.

- Update and maintain existing wastewater and sewage networks to make them fit for a changing climate and an increasing population.
- Require water companies to put in place long-term wastewater management plans (akin to Water Resource Management Plans) that ensure investment in ageing infrastructure to fix leaks and blockages, and an increase in network capacity to prevent sewer spilling and flooding. These would be opened out for stakeholder consultation. (At present for water resources, water companies have a statutory process where they consult on and submit to Secretary of State for sign off Water Resource Management Plans. These look 25 years ahead and ensure that supply is sufficient to meet demand (to a certain level of service), taking into account climate change, environmental sustainability and population growth. There is no parallel process for wastewater, which means that this takes a more ‘break and fix’ approach.)

⁴¹ WWF-UK, 2011. Electric avenues: Driving home the case for electric vehicles in the UK. http://assets.wwf.org.uk/downloads/electric_avenues_fullreport.pdf

- Take action to stop raw sewage overflowing into rivers from pumping stations, treatment works and other assets which can exacerbate flooding, as well as polluting rivers and damaging wildlife.
- Minimise urban creep, require permeable paving surfaces and significantly extend sustainable drainage systems (SuDS) to reduce surface water flooding, and also to provide biodiversity, recreation and water quality benefits.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

(1) Investment in the Catchment Based Approach (CaBA)

Discussions with companies and catchments at part of our WaterLIFE projects have made it clear that government multi-year investment in catchment partnerships is absolutely vital to achieve CaBA. This initial investment can help leverage private sector and other investment in natural capital.

(2) Ensuring baseline regulation. Smarter, properly targeted, adequately enforced regulation is a vital back bone to the 25 Year Environment Plan. This regulatory backbone should comprise three core things:

- i. The 25YP should include binding targets that defend and extend those set out in the WFD and other key European legislation. The scope and ambition of the WFD makes it one of the most important pieces of environmental legislation ever passed. The Environment Agency estimate that getting to good status where all benefits outweigh costs (which equates to about 75% water bodies) would generate £8BN net value to UK economy. These rewards have not been reaped because of poor implementation of the WFD. Therefore the government must reiterate its intentions and commitment to the WFD in the 25YP, and ensure that the WFD's binding targets are a key part of 25YP. This will ensure that planning now (e.g. Water Company PR19 and what replaces CAP) is sufficiently geared up to meet the WFD 2027 deadline and recoup that £8BN value.
- ii. Investment in natural capital should be underpinned by a fair and level playing field – with clear catchment rules to control pollution and abstraction that everyone complies with regardless of their sector. Such rules are a key part of 25YP. Abstraction reform is a key opportunity to put in place controls on abstraction, but it's also clear that controls on diffuse pollution are urgently needed. Following a Judicial Review initiated by WWF in 2015, Defra and the EA now need to consider using Water Protection Zones and other regulatory tools such as General Binding Rules to control pollution. Market based approaches also offer opportunities in the right circumstances, but must work hand-in-hand with regulation.
- iii. The 25YP should set out that, post Brexit, legal mechanisms to hold the government to account for delivery of the 25YP are crucial. The EC currently has oversight and reporting of EU environmental law: it acts as a watch dog and this has led directly to many of the UK's environmental improvements. It's crucial that there are equivalent mechanisms post-Brexit to ensure institutional oversight, clear consequences for failing to deliver and opportunity for public and NGOs to hold the government to account.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk? Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

When it comes to flooding, we must shift from trying to defend against defined flood events in particular locations to taking effective, economically viable and environmentally sustainable action that enhances our resilience to flood risk across whole river catchments.

No single solution will act as a silver bullet for flooding; we need a package of targeted measures that are proportionate to the risks and that deliver maximum benefit for limited taxpayers' money.

WWF's work with the Chinese Ministry of Water Resources (<https://www.adb.org/sites/default/files/publication/30246/flood-risk-management.pdf>), during which we reviewed the history of flood management internationally, highlights the fact that the most effective approaches aren't just based on engineering. So we need complement engineering approaches with social and environmental considerations in order to address the drivers of floods (linked to climate and land use) and the vulnerability of communities (which link to access to information, insurance, warning systems, emergency plans, etc). This calls for a portfolio approach to flood risk management, which balances process measures (early warning systems, planning etc), communications, flexible “grey” infrastructure and maintenance/restoration of critical “green” infrastructure (or natural flood management (NFM) approaches).

Evidence from research and practical experience suggest that NFM approaches can contribute significantly to flood risk reduction and that they can also provide “bonus features” alongside flood risk reduction – such as improved water quality and enhanced biodiversity – which means that they are economically attractive.

For example, WWF Scotland's River Devon trial project showed that, measures such as blocking obsolete field drains and restoring upland woodland could reduce peak river flows downstream by 11%. Larger schemes in the Netherlands, US and China have shown even more impressive results, in terms of floodwater storage and risk mitigation, from ensuring that areas of floodplain and wetlands are maintained or restored:

- The goal of the Dutch “Room for the River Programme” is to give the river more room to be able to manage higher water levels. At more than 30 locations, measures have been taken that give space for the river to flood safely. This will allow the branches of the Rhine to cope with a discharge capacity of 16,000 cubic metres of water per second without flooding. As well as increasing safety, the measures will also improve the overall environmental quality of the river region.
- In the US, the Yolo Bypass is a 240km² floodplain with levees that protects Sacramento from flooding. The Bypass takes up to 80% of the Sacramento River's floodwaters during major events. In addition, the floodplain is used for agriculture and large areas of floodplain wetlands provide critical habitat for wildlife, including many wetland species which are declining elsewhere. (<https://www.adb.org/sites/default/files/publication/30246/flood-risk-management.pdf>)
- Wetland management projects on the Yangtze river in China have restored lakes and wetlands in a way that store flood water, improve water quality and help restore bird and fish populations. One restoration project in Hubei province involved opening sluice gates to reconnect three lakes to the river during peak flows. This effectively restored 448km² of wetland and providing 285m³ of floodwater storage. (<https://www.adb.org/sites/default/files/publication/30246/flood-risk-management.pdf>)

Recommendations for the UK government:

1. Invest in natural capital (which recognises the intrinsic value of biodiversity) by ensuring national funding for targeted large-scale river restoration and creation of wetlands to increase storage in lowland wetlands.
2. Invest in, commit to and extend catchment management approaches – recognising catchment partnerships' essential role and expertise to tackle flooding.
3. Use some of the substantial taxpayer funding for farm subsidies to reduce upland run-off and soil erosion. Where voluntary measures are failing improve the enforcement of existing regulations to change farming practices.

N.B. The portfolio approach to risk management is also important to drought risk management. Addressing water resources shortages isn't just about supply-side solutions such as water transfers or increasing reservoir storage. A balance of demand measures, process measures and flexible grey infrastructure and maintenance/restoration of critical green infrastructure is needed.

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

WWF-UK is calling on the Government to develop a bioeconomy strategy with natural capital and resource efficiency at its heart, to support the UK's broader circular economy and climate change objectives⁴². This strategy should ensure that biomass is responsibly sourced and deployed efficiently and effectively across the economy. One of the key planks of such a strategy would be operationalising the cascading use principle, which means ensuring that biomass resources are used and reused first and foremost for food or materials, with energy only recovered once the biomass is on the brink of biodegrading and has no further material use.

Current bioenergy policies and incentives do not support cascading use. For example, the Renewable Transport Fuel Obligation (RTFO) incentivises the use of crops for biofuel while the Contracts for Difference (CfD) scheme supports the burning of wood for power generation. This is particularly illogical when both these sectors have multiple other, more sustainable options for replacing fossil fuels. We are encouraged by the lack of additional CfD funding for biomass and recent proposals to cap the use of crop-based biofuels.

The bioeconomy strategy should realign Government policy to favour food and material use of biomass, and its reuse and recycling, to keep carbon locked up in solid biomass for as long as possible. This will help to meet landfill and recycling objectives. Bioenergy from residual biomass should be targeted at sectors that require specific fuel characteristics, such as industry and aviation, and potentially shipping and freight.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be? Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

Promoting the circular economy would help us to compete in a future carbon- and resource-constrained global economy. It would also generate jobs and growth. But currently incentives for the development of a circular economy are weak. Industry figures are increasingly calling on the government to do more to promote the shift towards circularity,

⁴² WWF-UK, 2017. Bioeconomy: risk or opportunity for nature and climate? <http://blogs.wwf.org.uk/blog/climate-energy/bioeconomy-risk-opportunity-tackling-climate-change/>

particularly by improving policy incentives, access to affordable capital and government procurement rules, and by publishing a clear plan of action based on a strategic, whole-economy approach⁴³. Many of the UK's competitors in Europe, Asia and the Americas have already made such commitments and are reaping the rewards⁴⁴.

A wide range of policies and economic instruments could be considered to promote a more circular economy, and promote growth of the bioeconomy, including⁴⁵:

- increasing the lower rate of landfill tax and a tax on incineration,
- introducing a primary resource tax and targeted product taxes,
- differential VAT rates,
- pay-as-you-throw policies,
- 'feebate' schemes,
- increasing access to finance for resource efficiency measures (particularly for SMEs),
- including targeted use of public funds to improve the investment profile of projects / reduce risk, and
- strengthening and broadening public procurement policies to favour bio-based products, with a preference for reused and recycled products, certified to FSC or RSB standards.

Resource resilient UK – A report from the Circular Economy Task Force. Green Alliance, London, UK.

Introduction

We welcome the opportunity to respond to the National Infrastructure Commission's (NIC) call for evidence on the National Infrastructure Assessment (NIA). We make three main recommendations:

1. Integration of natural infrastructure within other infrastructure planning – natural infrastructure are diffuse systems, so can be affected by small changes to new and existing assets. We highlight the importance of building resilience into the system and ensuring that impacts on the environment are minimised. We also urge the NIC to integrate natural infrastructure where possible into the design of strategic infrastructure projects from the outset and opportunities for retrofitting natural infrastructure into existing assets. These are small but significant ways of bolstering our resilience to the challenges of climate change and population growth.
2. In addition to integrating natural infrastructure there is also a strong case for large-scale natural infrastructure investment: habitat creation and restoration to deliver our infrastructure needs. For example managed realignment projects to protect against flooding, creation of farm ponds to reduce water demand from agriculture and large scale urban green and blue space development to reduce pressure on our sewerage systems. Such options also deliver other benefits including health and well being, reduced urban heat island effect, improved water quality and enhanced biodiversity which more traditional infrastructure lacks.
3. We recommend that the NIC undertakes, or recommends a process for achieving, a natural infrastructure asset register, based on an analysis of the scale, condition and maintenance investment needs of natural infrastructure that delivers ecosystem services. This opportunity mapping can help to understand the quality of the asset base, the scale of investment needs and to maximise multiple benefits and natural infrastructure delivery.

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Investment in natural infrastructure can be extremely cost effective compared with other forms of infrastructure. Damage to these assets can be costly: soil degradation in England and Wales costs farmers and wider society an estimated £1.2 billion per year in lost productivity, flood damage, reduced water quality and other costs. By contrast, investment in natural infrastructure can be extremely cost effective. The Natural Capital Committee concluded that there was a strong economic case for “Wetland creation on around 100,000 hectares... benefits cost ratios of 3:1 would be typical, with to 9:1 possible in some cases”. According to the Environment Agency, achieving “good” status for all water bodies could bring £21bn of benefits at a cost of £16bn.

The benefits that accrue from well-planned natural infrastructure investment may be cross-sectoral and inter-generational and cross-societal. For example, there is great potential for large-scale managed realignment projects (c. 100,000 hectares) around the UK's coastline, which could defend communities, businesses and critical infrastructure from flooding and the impacts of climate change, while providing amenity value and important habitat. WWT's Steart Marshes project cost £20.7 million, while the Environment agency's assessment of the natural capital of the site in 2015/2016 was between £15 and £28 million. It supports local agriculture and aquaculture, as well as providing habitat, amenity and flood defence.

The Government should undertake a mapping exercise to identify the most cost-effective opportunities for natural infrastructure investment across a range of habitat types.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Quality of life can be improved by incorporation of green and blue spaces in places of work and in communities. As well as providing direct health benefits, such as cleaner air, natural urban infrastructure can contribute to mental and physical health and wellbeing.

Greenspace has been associated with lower levels of stress (Thompson et al., [2012](#)) and reduced depression and anxiety (Beyer et al., [2014](#)), while interacting with nature can improve cognition for children (Taylor and Kuo, [2009](#)) and individuals with depression (Berman et al., [2012](#)) People who move to greener urban areas benefit from sustained improvements in their mental health (Alcock et al., [2014](#)). There is also specific evidence that higher levels of visibility of blue space is associated with lower psychological distress (Nutsford et al [2016](#)).

This is also a social and demographic issue. The Natural England Monitor of Engagement with the Natural Environment found the percentage of children taking visits at least weekly was noticeably higher amongst those not in the Black, Asian and Minority Ethnic (non-BAME) population (74%) compared to those in the BAME population (56%). The percentage who never visited (in the 12 months prior to survey) was higher among the BAME population (17% compared to 11% amongst the non-BAME). The percentage of children taking visits at least weekly was also higher amongst members of the most affluent, compared to the least affluent group (77% compared to 65%). The percentage who never visited was higher among the least affluent population compared to those in more affluent groups (14% compared to 9%).

Investment in green infrastructure is a cost-effective approach to tackling chronic health problems. For every £1 invested in Green Gym infrastructure, £2.55 has been saved in the treatment of inactivity related illness (based on life cost averted savings). If every household in England were provided with good access to quality green space it could save an estimated £2.1 billion in health care costs, according to [Natural England](#).

Urban green infrastructure can also be vital for wildlife, helping to connect up pockets of habitat, in accordance with the Lawton Principles.

All infrastructure projects should aim to maximise the provision of green and blue space, taking into account these wider benefits. For example research indicates that there is a strong positive perception and preference for water in urban environments (Volker & Kistemann [2012](#)). This should include redevelopments and commercial developments in urban areas, as proximity to housing is most likely to maximise the social value of greenspace.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Demand management is currently underutilised within the water sector. Much more could be done to reduce demand than currently. Innovation in demand management is low, encouraging innovation could make great improvements.

Residential demand management

Water companies could drive much greater demand management through the development of a wide package of measures through the next Price Review (PR) process. This needs buy in from and to be facilitated by Government and Ofwat to encourage such measures before resorting to large supply side options before it will be considered by water companies. Such measures should include education measures for the general public to better understand issues around water scarcity and use. Packages of measures should include a combination of smart metering, social tariffs and environmental tariffs. Initially we would welcome a number of in depth pilots. These need to be set up and monitored for a number of years not just 6 months. This will help inform further PR processes and address issues such as uncertainty. Universal metering and particularly a wider role out of smart meters additionally assist in better understanding the actual scale of leakage within water company assets. The sustainable economic level of leakage (SELL) is not helpful in driving leakage reduction as water companies are able to simply do the minimum required rather than driving distinction.

Current average per capita consumption is 139 litres per person per day. Three water companies average 130 litres per person per day whereas two companies average consumption at 161 litres per person per day. Consumption in metered households currently get down to average 123 litres but range from 106 litres to 158 litres and there is a huge differential between metered and non-metered households; the latter average at 153 litres (180 litres maximum unmetered company average, 133 litres minimum)¹. This highlights how much gain can be made simply from metering, but also the huge variation between water companies.

The need to meter should not solely be made with respect to water scarce areas as it is currently. Our water demand should be considered from a countrywide perspective driving demand down across the country. These statistics show the huge gains in demand which could be made if all feasible households were metered, together with social tariffs, a programme of public education and efficient

¹ DiscoverWater <http://www.discoverwater.co.uk/amount-we-use> (accessed: 27th January 2017)

plumbing retrofits. It could easily be conceived that demand could be driven down by 30 litres per person per day – roughly equating to 2,100 million litres of water saved every day.

There are many examples of water efficiency measures that have driven efficiencies in the region of 14–30% reduction in water use². Many of these approaches are not yet being delivered in England and those that are could be more ambitious. So substantial savings could still be made.

- Estonia drove water consumption down from nearly 200 litres per inhabitant per day to under 100 in 15 years through increasing the value of water.
- Houston delivered a number of successful pilots which included an education programme, plumbing retrofits, audits, leak detection and repair, an increasing-block rate structure, and conservation planning. As a result in 2002 they predicted a 7.3% reduction in water demand by 2006 and savings of more than \$260 million.
- In Tampa, Florida their landscape evaluation program resulted in a 25% drop in water use. Measures included high efficiency plumbing retrofits, an increasing-block rate structure, irrigation restrictions, landscaping measures, and public education.
- Cary in North Carolina have a water conservation program which consists of public education, landscape and irrigation codes, toilet flapper rebates, residential audits, conservation rate structure, new homes points program, landscape water budget, and a water reclamation facility. These aim to reduce retail water production by an estimated 4.6mgd by the end of 2028, a saving of approximately 16% in retail water production. These savings reduced operating costs and have already allowed Cary to delay two water plant expansions.

Few UK examples consider community scale demand management – e.g. large scale multi-dwelling water re-use in new development. Such projects need wider than water company buy in and would need to be considered at the outset of a large development and include public engagement. Such projects do not currently feature in water companies’ business plans and consideration should be given as to how to incentivise innovative demand management.

Water efficiency and energy efficiency are linked – a large proportion of our energy use goes towards heating water. Therefore water efficient and energy efficient new build requirements would go a long way to reducing demand in both water and energy. For example a lot of water is wasted when running the tap/shower to get the hot water through. Conversely energy would be saved if less water was being heated.

However, it is not just water companies who are responsible for reducing water demand. Industry and the general public need to better understand that water is a finite resource that needs to be managed sustainably. It is important for all stakeholders to take responsibility for demand reduction. There are efficiencies to be made within various industries and the retail sector. Regarding the former, there is currently little incentive to do so as water is cheap and their abstraction licenses

² US Environmental Protection Agency (2002) Cases in Water Conservation: How Efficiency Programs Help Water Utilities Save Water and Avoid Costs

allow them, in most situations, the amount they need. Regarding the latter there is concern that the new competition market may in fact reduce efficiency in this sector rather than drive it as it is likely to drive prices even lower.

Agriculture

Given the dominant role of irrigated agriculture in global water use, management practices that increase the productivity of irrigation water use can greatly increase the availability of water for other human and environmental uses (Tiwari and Dinar, 2002). Of all sectoral water demands, the irrigation sector will be affected most strongly by climate change, as well as by changes in the effectiveness of irrigation methods³. It is the areas in the UK which are at greatest water scarcity which have the greatest agricultural demand for water. To date little has been done to incentivise demand change in agricultural water use, but there is potential for substantial savings to be made. Uptake of advances in technology is a step in the right direction, but ultimately we should be asking whether we should be growing the most water intensive crops in the most water scarce areas of the UK. Structuring incentives in a new food and farming system to move away from the most water intensive processes and towards water efficiency measures would be a substantial improvement over the current Common Agricultural Policy.

We recommend

- Energy and water efficient new builds to drive down energy and water demand and pressure on our energy, water supply and waste water infrastructure
- An ambitious package of measures including metering and public education to drive down water demand; price signals and incentives to drive down water demand in agriculture and other industry and encourage innovation in technology

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Maintenance and repair of natural infrastructure is too rarely considered as an alternative to building new infrastructure. For example, instead of building new flood walls, investment in degraded natural assets should be considered as a cost-effective alternative, especially taking into account wider benefits.

A proper assessment of alternatives is hampered by a lack of knowledge of the state of repair of current natural assets and the investment needed for maintenance and improvement. Such an assessment could form part of an objective analysis of the amount of funds required to achieve the Government's ambition to be the first to leave the environment in better condition; it could help to

³ Intergovernmental Panel on Climate Change (2007) Fourth Assessment Report: Climate Change https://www.ipcc.ch/publications_and_data/ar4/wg2/en/ch3s3-5-1.html

justify and quantify the scale of investment in a new agricultural subsidy scheme focused on payments for public benefits.

Until consideration of restoration of natural assets is considered, it will not be possible to choose the most cost-effective solutions for a range of infrastructure needs.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Competition and collaboration can both play an important role in the provision of environmental infrastructure services, such as pollination or flood risk relief.

For example, introducing an element of commissioning and competition in a post-Common Agricultural Policy (CAP) system for farm support could help to discover least-cost options for investment in environmental infrastructure. This would need to be supported by (1) targets and responsibilities for land-owners and businesses to improve natural capital and natural infrastructure to drive demand and (2) a clear system of mapping ecological opportunities, commissioning of interventions and monitoring of delivery. Examples of the way this could work include Dieter Helm's proposals for Catchment Systems Operators and WWT's proposals for [Catchment Commissioners](#). This approach could help towards delivering more sustainable land and water management and better integration of water supply, waste water and flood management.

Collaboration is also important where natural infrastructure assets are "landscape scale" and diffuse. These can be inhibited by a failure to cooperate by a singly land-owner. Current cooperative options under CAP demonstrate the multiplication effect of positive benefits where interventions are adopted over several farms. Collaboration can also help realise other funding pots and partnerships previously out of scope.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Provision of environmental infrastructure services could be improved by updating the Treasury Green Book to reflect the latest in natural capital thinking. A new system of farm support could combine public subsidy and private markets, based on the principles of polluter pays and provider is paid.

Funding for green space and sustainable drainage systems is often difficult, especially with respect to retrofitting and current cuts within local authorities. Incentives to reduce surface water runoff would help to promote retrofitting of SuDS and a more flexible approach to collaborative funding could help deliver greater multiple benefits for example flood funding and WFD funding.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Natural infrastructure investments are hampered by a range of market failures. There are not enough disincentives to avoid environmental damage and environmental improvements are not properly rewarded.

At small scale, this leads to poor everyday decision-making. For example, sustainable drainage systems are not planned properly because the costs fall upfront on a developer, whereas the benefits accrue gradually to communities and wildlife. Similarly, farmers are not incentivised to invest in sustainable practices because of the short-term and area-based focus of agricultural markets and support systems.

At large scale, the major upfront costs of projects like managed realignment are usually only funded through collaboration between Agencies and NGOs, instead of attracting more reliable forms of funding like flood grant-in-aid.

New markets and new ways of internalising environmental costs/benefits could overcome this barrier. Setting Government objectives for habitat creation, creating markets and rewards for sustainability in a new farm subsidy system could help to provide the certainty of long-term revenues needed to create financing options.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Efforts to speed up the planning process must be balanced against quality (including environmental resilience) and overall efficiency. In some cases, the Government's efforts to streamline the planning process has led to less resilient developments and associated infrastructure; in other cases, reducing regulation can be counterproductive and, in fact, slow down efficient development.

For example, the Government's reluctance to update urban flood resilience policy has led to increased flood risk and delays in planning.

Well-designed sustainable drainage systems (SuDS) can be built affordably and without delay in nearly all kinds of development as well as retrofitted in established developments. This can reduce flood risk, safeguarding homes and other infrastructure, at the same time as providing amenity, habitat and water quality improvements.

Current national and local policy does not provide clear governance arrangements around SuDS whilst promoting SuDS in large developments. Without clear direction and responsibility for delivering, adopting and maintaining SuDS leads to long discussions between developers and planning authorities around SuDS options.

A number of local plans have included statements to the effect that SuDS cannot be used as part of green/open space requirements, this means that developers have to use additional space to create SuDS and green/open space which reduces viability options. It is believed that this approach is taken because of a perceived concern around public safety and SuDS systems. It would be useful to issue guidance around how and where green infrastructure sits within the planning system and to clarify

such issues. A recent Welsh Government report⁴ highlights that viability training for local planning officers is a good way forward. We would advocate this to include a better understanding of how green infrastructure options may or may not affect viability.

In addition Highways Authorities can have a contradictory approach to developers and local authorities proposed SuDS schemes leading to further delay. Highways Authorities have no legal driver to adopt SuDS and have an automatic right for run-off to be released direct into water courses, regardless of quality. This conflicts with all the work being done to improve water quality under the Water Framework Directive by water companies, local authorities and others. If water run-off from highways was required to pass through SuDS in new development this could help improve water quality and reduce issues around design of SuDS and drainage in a new development. This would facilitate development and agreement over drainage systems, removing the often current perverse situation of dual systems for residential runoff and road runoff.

We recommend

- The removal of developers automatic right to connect and Highways Authorities right to discharge into a water course

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

- Include ecological expertise at the design stage and design for multiple benefits, including maintenance planning
WWT in partnership with RSPB have published guidance on designing SuDS for multiple benefits which can be downloaded [here](#).
It is not enough to assume biodiversity benefits from green infrastructure. It is not only the type of system used but how that system is designed and managed. A simple sedum green roof offers far less biodiversity benefit compared with those with more diverse vegetation. Green roofs can be designed and developed to incorporate microhabitats customized for particular species and/or more closely mimic natural habitats, with varied microtopography (including hollows and "clifflets"), scattered rocks, rubble, dead wood, and roofs can even be designed and planted up as wetlands.
- Understand the importance of protecting existing habitats and species
Remnant natural habitat is usually more diverse than newly created habitat. There are two important factors to this: understanding where important areas for biodiversity are which shouldn't have infrastructure built on them and retaining pre-development habitat within a development site where possible.
- Requirements around compensatory habitat: establish a principle of net gain.
Where a project is viable but damages are identified, compensatory measures should be additional to the actions that are normal practice under Habitats Regulations and other

⁴ Welsh Government (2017) Longitudinal Viability Study of the Planning Process
<http://gov.wales/docs/desh/publications/170116longitudinal-viability-study-of-the-planning-process-en.pdf>

relevant legal protection. The role played by the site concerned in relation to the biogeographical distribution should be replaced adequately in order to establish a coherent network of habitats.

Moreover, compensation should be established early and upfront, with fail-safes built in. A site should not be irreversibly affected by a project before the compensation is actually in place. In instances where such habitat takes a long time to mature, extra compensation for interim losses should be assured. A precautionary multiplication factor should be applied to plans for compensation for environmental costs in order to guard against risk of failure in new habitat creation.

- Integrate natural infrastructure into design of more traditional infrastructure; retrofit natural infrastructure into maintenance and renovation projects; consider whether a natural infrastructure approach could meet the objective as opposed to hard infrastructure or using a combination of both.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

We recommend four particulars should be made when considering cost benefit analysis of infrastructure projects.

- 1) Natural Capital - The Natural Capital Committee in their third report recommended that the National Infrastructure Plan should incorporate natural capital into each of the main infrastructure sectors, following the mitigation hierarchy for managing impacts (avoid, minimise, restore, offset). An investment programme for natural capital should also explicitly feature in the National Infrastructure Plan. Within a natural capital approach it is important that social and environmental costs and benefits, including non-monetised, are accounted for within decision making. Natural infrastructure can offer a great value for money approach if accounted for properly.
- 2) Taking account of the long term – The Government has recently reiterated its commitment to leaving the environment in a better condition than it received it. In order to ensure this is true for future generations, the discount rate applied to cost benefit analysis must be quite low - considerably closer to zero than the Treasury’s Green Book value, for instance. A low discount rate does not simply highlight environmental impacts it increases the relative importance of the future, compared to the present. Many large scale infrastructure projects are very long-lasting with expected economic lifetimes spanning many decades, such as airports or nuclear power plants. Many physical infrastructure projects also have long-lasting environmental effects, beyond the lifetime of the project. In undertaking a cost-benefit analysis for infrastructure spending, a low-discount rate should be applied when judging the merits of

additional spending to reduce environmental impacts and increase natural capital and ecosystem services. This includes natural infrastructure projects, where societal benefits are often accrued over the long-term.

- 3) Alternative options - Cost-benefit analysis is often constrained by the range of alternatives it considers. When a highway is congested, building a bigger highway often seems like the appropriate option. The losses caused by congestion could well be great enough that the construction of the new, wider highway would win in cost-benefit terms. But such an analysis only answers the question, “If there were no choices except the status quo or the new road, which would be better?” Other options such as improved railroad and bus service, or urban planning measures to reduce transportation demand, might be even more attractive – if they were included. By limiting the analysis to the status quo vs. one preferred alternative, the framing of the question can often determine the answer. Reframing the question – for example, asking “What is the least-cost strategy for reducing congestion on a highway by a given amount?” – may yield a different solution⁵. In particular, natural infrastructure options should be considered as alternatives wherever possible.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

We welcome the NIC looking into the option of a zero carbon power sector and encourage this ambition. In order to achieve a zero carbon power sector we need to see the following:

- Greater efficiency in residential and industrial use e.g. carbon smart/zero carbon new homes which will help reduce the pressure on the power industry.
- Research and innovation into energy storage (to iron out the intermittent nature of renewables such as solar and wind), carbon capture and storage (as an important but previously unutilised piece of the tool box) and commercialisation of new technologies such as wave energy.
- Diversity of options and a well-connected grid – a zero carbon power sector must adopt a wide range of energy measures to provide the energy needed. There is no one energy source answer. We are fully supportive of renewable energy power, but each strategic option needs to be considered on a case by case basis to determine whether their impact on the environment is environmentally cost effective.
- Political will – the EU report Roadmap 2050 concludes that achieving a minimum 80% CO₂e reductions in 2050 based on zero carbon power generation in Europe is technically feasible and makes compelling economic sense.

Evidence indicates that campaigns to tackle water demand could be used to reduce the daily peak demand patterns which reduces the pressure on network pumping energy costs during peak use

⁵ Ackerman, F. (2008) Critique of Cost-Benefit Analysis, and Alternative Approaches to Decision-Making, Friends of the Earth.

times. Water companies can use demand-side strategies to also achieve efficiencies in the distribution of urban water (e.g. reduced energy for pumping in pressurised water system, pipe augmentation deferrals, peak energy demands)⁶.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: “demand” includes domestic, commercial, power generation and other major sources of demand.

Within the UK water is not valued appropriately. Non-essential and commercial uses are often treated in the same way as the provision of essential, domestic supplies—in other words, water continues to be treated as a low-value and unlimited resource.

We need all sectors to work together to end the assumption that water should be an unlimited resource. Water scarcity is not just the responsibility of water companies. For example agriculture uses 70% of the UK’s water; any system needs to include agricultural changes as well as retail efficiencies and reducing household demand. However, we can do a lot better than currently to reduce household demand, but in order to be successful we need a system of smart metering and smart tariffs to protect the vulnerable (see answer to Q4).

Regarding supply options, there are environmental risks to be considered on a case by case basis and which need to be taken into account during decision making to minimise environmental risk and damage. Before large supply options are given a go-ahead it should be clear how demand options and leakage reductions are being optimised before considering supply options. Ensuring demand efficiencies are made will be vital to our resilience to more varied precipitation from climate change and to help deal with the challenges of an increasing population. One way would be to ensure all new houses are built to an energy and water efficient standard. As these houses would require metering, house buyers should experience reductions in water bills. High users who would find increased bills difficult to pay could be supported using social tariffs.

We will need a package of options in order to be most resilient but also need to ensure that cumulative supply options do not cause environmental degradation as well as considering the merits and risks of each individual option.

There is currently no join up between water resources, waste water management and flood management. A more holistic approach at a catchment scale is needed as suggested in Q24. By slowing the flow throughout a catchment, the environment will have a greater resilience to drying out in times of low precipitation, which ultimately will slow down our lead in to drought scenarios. Creating and restoring wetlands and ponds in the countryside (many of which have been filled in or drained) could

⁶ Beala, C.D., Gurung, T.R., Stewart, R.A. (2016) Demand-side management for supply-side efficiency: Modeling tailored strategies for reducing peak residential water demand, *Sustainable Production and Consumption*, 6: 1-11

reduce pressure on our water supply. Theoretically, to supply the entire current usage for irrigation water would require 13,000 ponds of 1ha area and 1m mean depth. This is approximately the same as the total number of 1ha water bodies that currently exists⁷.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Long term waste water plans

We currently have no long term waste water plans as we do with water resources. This would mean that waste water companies would have to develop supply and demand options over a 20 year period. Without a greater understanding of our asset base we can have no notion of scale of investment needs and no plan for capital or maintenance investment. We support the real time monitoring of combined sewer overflows. This will give us a better understanding of the scale of overflows and through a waste water plan be able to identify an approach to prioritising need. These plans should include a programme of work to identify where to best retrofit and deliver SuDS.

Manage water more holistically

A more holistic approach between water supply, waste water and flood management is needed. 2013 national policy statement for waste water states that demand management measures could achieve a reduction in sewer and treatment capacity required for England of greater than 1 billion litres per day⁸.

Water efficient homes

Currently developers have an automatic right to connect new development to the sewerage system, even if that system is at capacity. **At a very minimum sewerage companies should be statutory consultees in designing new developments and the automatic right to connect should be removed.** This will allow sewerage companies to have much more control over sewerage capacity. Additionally by reducing water demand as mentioned above can reduce pressure on the sewerage system. As such water efficient new homes, commercial development and infrastructure could help ensure our sewerage system is able to cope with increasing population. Small changes to existing infrastructure and considering the role of natural infrastructure within new infrastructure design can help address diffuse pollution problems and reduce pressures on the system.

A network of sustainable drainage systems

In addition to reducing demand, reducing surface water run off could substantially reduce pressure on the sewerage system. SuDS should be designed into new developments from the outset. Together

⁷ Biggs, J. (2007) Small-scale solutions for big water problems, Pond Conservation

<http://freshwaterhabitats.org.uk/wp-content/uploads/2013/09/Defra-small-scale-solutions090108.pdf>

⁸ DEFRA (2012) National Policy Statement for Waste Water: A framework document for planning decisions on nationally significant waste water infrastructure

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/69505/pb13709-waste-water-nps.pdf

with a suitable retrofit programme SuDS will provide a buffer to future challenges. For example Thames Tunnel will manage current capacity but Thames Water acknowledge the need for a system of SuDS so that increasing population and urbanisation can be managed in London.

SuDS need a strategic rather than simply opportunistic approach looking at where they could be best applied. Achieving this will require a better understanding of where effective, high quality SuDS are already in place—there is currently no systematic assessment of where SuDS provision could be improved. An opportunity mapping exercise should be undertaken in our major urban areas (at the very least). This will increase understanding of where SuDS would be best placed from a geology perspective and a surface water flood risk perspective, but also regarding where they might be best integrated into current green space and also for joining up or creating stepping stones between green space. Ultimately a network of SuDS could be developed which will holistically provide surface water drainage with added benefits much better than ad hoc retrofitting. How such a network of SuDS works within a wider catchment approach should also be investigated.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

We fully endorse a catchment-based approach to water management, integrating management of supply, waste water and flood risk. There are a number of alternative models for achieving strategic natural and built infrastructure investment and water management at the catchment scale. One way would be to have a catchment commissioner. Catchment commissioners could be appointed landscape scale responsibility to deliver national targets in locally appropriate ways. They should identify multi benefit long term investments; ensure that environmental plans are integrated at development stage; enable long term funding for projects and create new commercial opportunities for investment in nature.

By using a whole catchment approach we are able to understand inter-relationships better and undertake large scale habitat creation and restoration in order to tackle water supply, waste water and flood risk management together. Being able to develop large scale measures to tackle multiple benefits can offer great value for money if an ecosystem services approach is taken alongside a traditional cost benefit approach.

Such an approach needs to identify measures across the whole landscape from the uplands through the urban environment, lowlands and coast. The measures should include a combination of more traditional hard infrastructure with associated natural infrastructure as well as small and large scale natural infrastructure, from leaky dams to the creation of floodplain meadows and a network of urban blue and green spaces and sustainable drainage. All stakeholders need to be engaged and the bigger picture needs to be managed by the catchment commissioner as individual projects are delivered.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Natural flood management (NFM) schemes tend to be low-cost and can provide multiple benefits.

However, they cannot always be modelled with the same certainty as engineered solutions, their benefits may be long-term and diffuse, and they may require broader cooperation; these challenges can be overcome by building in incentives and strategic mapping for long-term delivery.

Some Natural Flood Management measures can be modelled and funded successfully – particularly those providing flood storage. However, the ways in which cost-benefit analysis for flood risk management capital and maintenance works are determined tends to favour large-scale, hard engineered schemes.

Measures with “diffuse” benefits (including many land management measures addressing infiltration and overland flows) are hard to justify under the current approach, even though they may deliver more benefits at lower cost in the long-term. NFM requires an integrated approach that seeks to restore natural processes to achieve multiple environmental benefits. A more flexible, integrated approach which can take account of the wide range of societal benefits is likely to lead to better and ultimately more cost-effective solutions to managing flood risk. At present, opportunities to incorporate NFM approaches alongside more traditional flood defences are limited by this narrow cost-benefit approach.

Natural Flood Management increases rainwater infiltration, slows flows and stores floodwaters. NFM can contribute to flood prevention in conjunction with traditional, engineered defences. Many NFM measures include an engineered component – there is a spectrum of interventions.

- **Improving infiltration:** habitat creation; arable reversion to grassland; soil structure improvement; reduced grazing; contour-ploughing; crop selection; blocking field-drains; channel buffer strips.
- **Slowing flows:** hedgerow planting; bank construction; upland grip-blocking; floodplain storage; woody debris dams; engineered ‘leaky’ dams; inter-tidal habitat creation; restoration of channel sinuosity.
- **Storing floodwaters:** two-stage channels; re-connection of river channels with their floodplains; engineered washlands; retention ponds and bunds.

Catchments characteristics vary widely. The challenge is to identify where NFM can reduce risks and the extent of land management change required. The Cumbrian Floods Partnership pilots will test co-ordination of environmental and flood management planning, new funding models, and integrated local planning. The Greater Manchester pioneer will also hopefully help to incorporate urban natural flood management measures into wider catchment management.

There is sufficient evidence to justify many types of measures:

- The Pickering NFM scheme slowed river peak flow by 15–20%, saving Pickering's museum and several homes, according to Environment Agency analysis. Around half of the reduction in flood water in Pickering was due to the upstream land management measures, and half through the effect of the flood storage area.

- The Southlake Moor scheme in Somerset used agri-environment and flood funding to restore a 200-hectare wetland SSSI and create formal flood storage of 1.2 million cubic metres.
- Upper catchment flood storage on Lustrum Beck to reduce risk to 150 properties in Stockton on Tees.
- Defra's Multi-Objective Flood Demonstration Projects (National Trust's [Holnicote Estate](#); [Making Space for Water](#); [Slowing the Flow](#)) all showed that NFM intervention reduces the impact of smaller floods (1:5, 1:25 year) and helps property that would not otherwise be cost-effective to protect.

New academic research shows that NFM interventions can desynchronize flood peaks at the catchment scale, and demonstrates that some NFM measures need to be applied over much longer timescales. Small communities are a challenge, where economic benefits may not justify the costs of hard defences. However, NFM can provide additional benefits (for example, recreation and tourism) which if properly accounted for can make NFM a cost-effective solution.

More significant impacts could be achieved if NFM was scaled-up and applied more widely. The recent Natural Flood Management Handbook published by the Scottish Environmental Protection Agency sets out an approach for producing a catchment plan. However, planning tools for deploying appropriate measures remain relatively immature. **Planning for NFM benefits needs to be integrated with local-level environmental planning for biodiversity and water quality.**

Opportunity mapping: Forestry Commission published the first national opportunity map in 2012 and offered enhanced rates of grant for woodland planting in priority areas for the last two years of the England Woodland Grant Scheme. This resulted in the planting of 1857 ha of new woodland targeted to reduce flood risk. **This kind of opportunity mapping should be undertaken for a range of different habitat types, including wetlands.**

Dear Sir / Madam

National Infrastructure Commission - National Infrastructure Assessment Call for Evidence

Thank you for the opportunity to respond to the National Infrastructure Commission's call for evidence supporting the National Infrastructure Assessment.

As the monopoly water and waste water company for the Yorkshire region we are committed to delivering outcomes that meet the needs of our current and future customers, and protect the environment. We're committed to playing our part in responding to the challenges of climate change and population growth through adaptation and mitigation, which will contribute to the commission's objectives.

Our response addresses the questions raised regarding water and waste water and flood risk management. We have also provided our views on some of the cross-sector questions raised in the call for evidence.

We would welcome an opportunity in the future to discuss in more detail any aspects related to the areas covered in the assessment.

Should you have any queries regarding any elements of our response, please contact me at email address: [email address redacted]

Yours faithfully,

[Signature redacted]

[Job title redacted]

Enc.

Yorkshire Water Response to the National Infrastructure Assessment (NIA) Call for Evidence

Yorkshire Water has provided the following feedback in regards to the call for evidence published by the National Infrastructure Commission on 27th October 2016.

About Yorkshire Water

Yorkshire Water is a privately owned monopoly water and sewerage company delivering around 1.26 billion litres of drinking water a day to 5 million domestic customers and 130,000 businesses across the Yorkshire region. We also collect about 1 billion litres of waste water and safely return it to the environment.

We operate 695 water and waste water treatment works and look after 83,300km of water and sewerage pipework. In 2011 following new government legislation, we adopted 22,000km of private sewers.

We expect to be serving around 5.9 million customers by 2040, that's an extra half a million households in our region (the equivalent population growth of a city the size of Leeds). This will place increased demands on our water supply systems, the sewer network and waste water treatment works.

We welcome the opportunity to respond to the National Infrastructure Commission call for evidence to support the NIA, and would be happy to discuss any points raised in more detail in due course.

Please find our responses to the cross-sector questions: 1, 3, 4, 5, 6, 7, 9, 10, and 11 and questions 22 through to 26 which address water, waste water and flood risk management.

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

We have a number of water and waste water infrastructure projects in our plans and others in consideration as part of the development of our Water Resource Management Plan (WRMP).

There are many issues that add to the complexities of the drainage landscape, of which the effective control and management of storm water is one. Continued investment is required across our region to reduce the volume of storm water entering our sewers remove surface water and so enhance the capacity of our sewer network which will support future population and business growth (see response to question 23).

In addition water catchment and river restoration investments will help ensure continued flow of ecosystem services from the natural environment, including raw water quality and flood attenuation, supporting long term sustainable growth.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Infrastructure should be designed to protect and enhance the five capitals (natural, social, economic, human, and manufactured) in order to maximise flows of ecosystem services, as described in the protocol published by the Natural Capital Coalition ¹.

Housing growth is a priority nationally and locally within our region to support economic growth and improve quality of life. Indeed an additional 800,000 people are forecast to be living in the Yorkshire region by 2040.

The above five capitals and infrastructure needs (for other utilities as well as water/waste water) are essential factors in the planning process. It is vital that these are considered, especially in the context of future accelerated house building programmes.

¹ <http://naturalcapitalcoalition.org/protocol/>

5. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

There are a number of areas where demand management may assist with improving resilience of service, which we address in question 22.

In regards to water demand management the Adaptation Sub Committee ² suggests that across the England we could achieve a household per capita consumption (PCC) value of 92 litres/hour/day by 2050, assuming delivery of all the demand-side feasible options around household consumption and leakage and preferred options from companies WRMPs.

6. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

As a water and sewerage company (WaSC) serving a large population over a wide area we continually have to balance the need for maintenance and repair of assets and network infrastructure with construction of new assets. Key factors when considering investment in new assets is whether we are effectively locking in to a high energy high carbon infrastructure, or are providing new solutions that take a more holistic view, and consider demand management and whole catchment management.

In regard to existing network infrastructure, UKWIR ³ undertook a common research study to assemble evidence to determine whether an increase in rates of renewal and/or rehabilitation of water and waste water network infrastructure might be needed to ensure long term stability.

Their analysis indicated that under most scenarios considered, rates on expenditure on renewal and rehabilitation of water mains and sewer networks will need to increase if long term deterioration in levels of service is to be avoided. The range of increased activity and expenditure will be dependent on a company’s relative network assets age and type.

Our regulatory framework with the introduction of totex helps companies develop the most appropriate solutions and removes the potential for capex bias within the industry.

² CCRA2: Updated projections of water availability for the UK Final Report (Aug 2015)

³ UKWIR - Long Term investment in Infrastructure (RG05B) Working Paper 5: Analysis (Oct 2016)

7. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Greater partnership working with local and national organisations such as local authorities, city region groups, and the Environment Agency is the ambition in order to develop the optimised solutions required for economic growth and to protect the environment. We recognise that collaboration often takes longer to deliver solutions, being dependent on commonality in agendas and available capacity and funding, therefore carries more uncertainty.

We have established a flood partnership steering group to identify opportunities to work together on flood risk. We engage with the Sheffield City Region and Leeds City Region groups and stakeholders across Hull to advance plans for future blue / green infrastructure development.

In regards to the role of competition in the supply of infrastructure, the future regulatory approach for water and waste water services in England and Wales (Water 2020)⁴ includes the promotion of more competition in the financing and provision of new infrastructure.

Ofwat's new regulatory approach aims to incentivise water companies to use direct procurement for customers (DPC) for high-value infrastructure projects, which may otherwise be provided by the water company.

8. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by "funding", the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

Across utilities the debates on the balance between costs being recovered from current and future customers are ongoing. The water sector continues to operate a 5 year regulatory price control cycle and a framework where customers' preferences for services and their willingness to pay are evaluated. This in effect becomes the mandate for companies to deliver on their commitments.

There may be more cases in future where large schemes need to be considered outside usual funding and customer charging arrangements so that the long term challenges of climate change and large population growth can be addressed.

Through working in partnerships to deliver solutions at a holistic 'whole' system level, we can enable potential efficiencies from working together, unlock alternative engineering solutions and may enable consideration of alternative funding streams.

⁴ Ofwat Water 2020: our regulatory approach for water and wastewater services in England and Wales – overview (May 2016)

Consideration of how we can collaborate and innovate in funding across companies, local authorities, developers, regulators and government is essential in order to use all the tools needed to foster sustainable economic growth and improve people's quality of life.

Wider use of natural capital assessments in decision making could also draw in more beneficiaries of soft and hard infrastructure solutions and promote a role for payment of ecosystems services in the future.

We note the government's recent proposals to inject funds to deliver the infrastructure required to enable some accelerated new housing development programmes to progress.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

To achieve resilient drainage infrastructure will require increased integration and the way in which we operate our business today will need to change. The current approach is to work in cooperation with Local Resilience Forums on business continuity planning, including the use of shared exercises to understand our collective resilience.

We have a key reliance on energy and information and communications infrastructure providers to deliver our services to customers. We work closely with them to understand risks based on common standards for resilience (for example all critical assets protected to 1 in 200 year floods).

Despite our local partnerships being successful to date there would be benefits in a more centralised risk management regime, including a role for a central body accountable for resilience planning. For example on flood prevention and protection to encourage wider use of catchment scale approaches and best practice and linking of local and national plans.

This presents a significant opportunity to advance how we, as a water and sewerage company (WaSC), can play a more active role and move the industry towards delivering its overall goal of providing ever more flexible, adaptive, resilient and sustainable, water and drainage systems for our customers.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Water companies already engage through the planning process to:

- understand how their infrastructure is likely to be impacted from development that is planned to take place across the area they cover;
- highlight to planning authorities infrastructure constraints and phasing requirements and;
- plan for necessary infrastructure.

Ensuring the most appropriate drainage infrastructure is planned and delivered for growth is not always prevalent. Issues commonly arising include:

- a) Lack of information from developers on drainage proposals, resulting in reliance on drainage planning conditions;
- b) Lack of consultation with WaSCs on major planning applications;
- c) Limited ability for WaSCs to promote strategic and holistic solutions to drainage infrastructure through planning policy and development management
- d) Limited opportunity for WaSCs to encourage integrated water management strategies through planning policy and development management at a sub-regional and local level
- e) A lack of open long term plans for waste water infrastructure capacity and investment that can be used to influence spatial planning and identify opportunities for investment in other assets/solutions.

Water UK are currently undertaking a project on 21st Century Drainage⁵ seeking to identify the major risks for drainage in the future, and to provide options for policy makers. National policy should promote 21st century drainage infrastructure as a key element of infrastructure planning policy.

Strategic policy should support cross council boundary consideration and co-operation of drainage issues through the local plan process and engagement with the development of other strategic flood plans (e.g. Local Flood Risk Management Strategies, Flood Risk Management Plans and River Basin Management Plans).

Local level policy should support the appraisal and development of integrated water management strategies to support local plan policies and site allocations.

Consideration should be given to WaSCs becoming statutory consultees in the planning process for major development applications. Planning conditions should support foul

⁵ Water UK - 21st Century Drainage Programme (<http://www.water.org.uk/policy/improving-resilience/21st-century-drainage>)

drainage and SuDS conditions where applicable and encourage the effective monitoring and enforcement by relevant bodies.

Removing the automatic right of connection of surface water to the sewer system will enable us to prepare more intelligently to meet current and future needs by effectively managing storm water and creating future network capacity to support population and economic growth. Schedule 3 (sustainable drainage) of the Flood and Water Management Act 2010 (FWMA) should be implemented consistently. This requires that drainage systems are approved by the unitary authority before construction commences. We explain more on this under question 23.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

We would welcome a wider use across sectors of the natural capital assessment framework to identify infrastructure options with highest benefits.

Policy and planning should be utilised to encourage blue / green infrastructure partnerships. Asset owners should think about not only the assets that they operate but also how to utilise adjacent assets owned and operated by others and to think about working collaboratively to identify and deliver more cost effective and environmentally sustainable solutions.

For example in order to tackle capacity constraints within a sewage network, implement blue / green infrastructure and active controls to create headroom by either removing or delaying flows rather than installing additional capacity through network reinforcement or storage. Such opportunities can reduce surface water transport and treatment costs, defer or negate investment in infrastructure upgrades, and reduce pumping costs and carbon output.

A key component of the periodic review regime is the National Environment Programme (NEP). The NEP includes requirements for water companies to undertake improvement schemes, or where more evidence is required, to investigate a particular problem. Each water company's NEP is different, as there will be different issues in every region. However there are some common areas, such as improving the quality of water that is discharged from sewage treatment works, ensuring that raw water abstractions do not impact adversely on habitats, and improving the quality of bathing waters.

We continue to uphold environmental protection standards, e.g. the Water Framework Directive (WFD), and the Urban Waste Water Treatment Directive (UWWTD).

Water and wastewater (drainage and sewerage):

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Supply-demand challenge

There is a growing risk of significant drought impacts across many regions of the UK from the effects of climate change in combination with the pressures of population growth and environmental drivers. The Adaptation Sub-Committee (ASC) of the Committee on Climate Change commissioned an assessment of projected water availability⁶ for the UK, which submits supply-demand balance deficits could be widespread by 2050 under a high population growth and high climate change scenario, and not only confined to the South East of England.

The implementation of supply side and demand side adaptations and interventions could substantially alleviate such deficits in the future. Key to alleviation is that household and business consumption reductions are implemented and sustained and measures within water company plans deliver the forecast yields.

There is a growing demand for water services – from domestic, agriculture and industry. This impacts on security of supply and leads to infrastructure stress. However, there is also a growing awareness and understanding that water is as important for cities as energy, digital communications infrastructure, or climate, and there are risks and opportunities related to water that will affect economic growth and prosperity.

Urbanisation will continue to change our built environment. 82% of the UK's population now live in urban environments, with growth predicted to continue. Water available is not being managed optimally. To better understand future needs and maintain the balance of supply/demand we need to expand our knowledge on water management.

There is a general perception there's no shortage of water. The public seem unaware of the problem of water scarcity – this is perhaps compounded by the fact we get high levels of rainfall. There is a public mind-set issue when it comes to using reclaimed water and this may be a barrier to uptake of recycling. Over the coming years we, as a society, are going to have to get used to re-use, and a better understanding of the value of recycling is vital to secure future supplies.

Integrated water management (IWM) is an effective way to make this transition.

⁶ CCRA2: Updated projections of water availability for the UK Final Report (Aug 2015)

Demand management

Behavioural change is required for household and business customers in order to drive a demand management response to water resource resilience. We are engaging with customers to help increase awareness and ultimately change behaviours. We are mindful of the potential difficulty of encouraging customers to reduce demand in areas that are presently not water stressed.

It is already clear that there is no single solution that will deliver a supply-demand balance. The range of solutions should include:

- the adoption of building standards for new builds (Wales has made progress)
- surface water drainage solutions
- dual systems with a potable and non-potable supply
- increasing the metered population

These all require significant collaboration and willingness from developers and local authorities and would take time to deliver measurable effects on overall demand. We recognise the potential tension between additional water supply requirements on developers and other cost pressures such as the need to provide appropriate percentages of affordable housing. We note that Water UK, Defra, and Ofwat are currently going through a process of considering potential changes in how developers are being charged, which may also influence this area.

Supply side management

Given the variability in future supply-demand deficits, intra- and inter-regional large scale water transfer connections and water trading may offer good value (raw and potable water). Such solutions would be bespoke to each water company and its neighbour's situation. There are significant technical, financial and environmental challenges which require further work to determine the benefits to be realised and the appropriate planning process.

We continue to focus on improving leakage positions year on year. Both the regulatory regime and our customer priorities encourage us to perform well in this area. We also recognise we have ageing network assets and the rates of expenditure on the renewal and rehabilitation of water mains and sewers will need to increase in the long term if deterioration in levels of service is to be avoided.

We are currently investigating innovative approaches to demand management and considering how applicable they may be to the Yorkshire region. The work to understand potential approaches is drawing on research and best practice from other parts of the UK and internationally.

In these areas the National Infrastructure Commission could be a powerful advocate for innovation.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

We acknowledge the challenges of maintaining and improving the condition and capacity of our sewers to meet the future demands of climate change, more frequent extreme weather events and population growth across our region.

Ageing sewer infrastructure lacks flexibility in regard to these demands. This restricts our ability to improve network resilience to future demands. It also hampers our ability to facilitate optimal risk and investment management decisions.

We work in partnership with city region groups within Yorkshire to encourage their strategic approaches to blue / green infrastructure. City region groups cover both urban and rural areas within their territories and we focus on the use of green infrastructure (GI) around streetscapes and new highways, including the use of storm water attenuation and sustainable drainage systems (SuDS).

There are however a number of policy and institutional barriers to implementing SuDS more widely. A recent survey on SuDS by the Chartered Institution of Water and Environmental Management (CIWEM)⁷ found that 70% of respondents think current planning policy does not sufficiently encourage SuDS and only 8% think the current standards are driving high quality SuDS. The report also highlights that there is no requirement for local authorities to report on SuDS uptake.

The government is undertaking a review of the automatic right of connection for surface water to sewers as part of its review of the Housing and Planning Bill. Although history may suggest the position will not greatly improve, progress has been made in devolved administrations.

In response to the European Water Framework Directive, Scotland introduced the Water Environment and Water Services (Scotland) Act 2003 for which it is a legal requirement for all developments of two or more properties to have SuDS.

Northern Ireland extended the powers of NI Water to adopt sustainable drainage systems and to require construction of SuDS through the Water and Sewerage Services Act (2016). The Act supports this by introducing restrictions on the right to connect new surface water sewers to the public network.

⁷ CIWEM - A Place for SuDS? (<http://www.ciwem.org/wp-content/uploads/2017/02/A-Place-for-SuDS.pdf>)

For England we need to remove the automatic right to connect for surface water to the sewer system, and consistently implement Schedule 3 (sustainable drainage) of the FWMA.

It is of particular importance to resolve these matters in the near term, as the need for high volumes of new housing across the UK is paramount. This housing pressure includes calls to increase housing density. Increased density drivers should be balanced with cost effective surface water infrastructure including GI.

The challenges for drainage infrastructure can be assessed in terms of hydraulic capacity and non-hydraulic impacts. Lack of hydraulic capacity or headroom will ultimately constrain development and economic growth. Sewer misuse adversely affects customer service, the environment, operational expenditure and regulatory performance.

GI can work better, cost less, be more reliable and provide more benefits than conventional infrastructure. There are many potential benefits of using GI including air quality, amenity, carbon reduction / sequestration, cool runoff temperature, creates green space and wildlife habitat, increased infiltration to groundwater and aquifer recharge, insulates buildings, rainwater harvesting, reduce runoff.

We should encourage creativity with water and foster right culture for GI, and importantly develop the right skills in the workforce. We continue to work with the sector through the 21st Century Drainage programme led by Water UK. This programme is the ideal vehicle from which to drive long-term thinking.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

Water companies have a significant role in addressing sustainability, improving water security and conservation. In order to maximise this we require a stable regulatory and market environment with a long-term focus. Integrated water management (IWM) is central to effective management of water, waste water and flood risks. Through development of an integrated model companies can manage their networks, abstraction and discharges in a dynamic controlled way balancing flows into treatment and controlling the energy costs associated with this activity. Related benefits could include river quality and environmental improvements, reductions in flooding incidents, energy and carbon footprint; and increased security of supply.

There are opportunities for a shift in how we can manage water in urban areas. The three streams of urban water cycle - potable water, wastewater and storm water are intricately linked. Greater integration of clean and waste water processes can be achieved, providing the adaptive capacity to more readily deal with the challenges we will face.

IWM does require engaged and active partnerships working together and there may be value in having a single body or organisation managing from the centre. Improving the

management of storm water will be an increasing imperative in the face of climate change and development. Legislation should be strengthened to encourage the provision of SuDS and water companies have a part to play in this alongside local authorities and developers.

Green infrastructure and upstream catchment management provides opportunities to recharge water tables and aquifers and benefits the environment.

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

The Adaptation Sub Committee⁸ have assessed future projections of flood risk for the UK and submit that we can expect a 150% increase in the expected cost of damages from flooding by the 2080s.

The report concludes that "additional investment in maintaining and enhancing flood defences and much wider uptake of property-level protection measures and SuDS would be needed to fully offset the increase in risk expected under a 2°C climate projection. Under a 4°C projection, not even this enhanced level of adaptation would be sufficient to completely offset the increase in risk."

Maintaining current levels of protection requires additional funding over and above that already allocated to the Environment Agency. We believe government should publish a long term strategy for flood risk management so that organisations can see how their activity can support the approach.

Again we reference enforcement of the planning system and implementation of Schedule 3 of the FWMA will support future resilience, as building continues on flood plains around the UK.

It is important to maximise the overall value of infrastructure design. Preferred options for infrastructure provision are based on financial accounting but effective inclusion of broader environmental and social impacts should now be incorporated. Clarity on drivers, benefits and beneficiaries would lead to better integrated solutions and may attract or unlock alternative sources of funding.

We require clarity about the schemes that will replace CAP and the agri-environment schemes so that we understand the policy landscape we are working in and determine appropriate investments to maintain or enhance current levels of flood resilience.

⁸ Climate Change Risk Assessment 2017: Projections of future flood risk in the UK (Oct 2014)

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

We are working with partners in our region on developing natural flood management (NFM) solutions, for example management of peatland and green infrastructure.

The evidence suggests that NFM can play a part in flood risk management alongside other measures (hard/soft engineering, removing surface water, not building in flood plains, property level protection, etc). NFM techniques can typically reduce the peak flood flow by around 10% and are best suited to managing more frequent, smaller scale flooding as well as having additional benefits such as biodiversity and amenity value.

Introduction in the building regulations of requirements to incorporate flood resilient materials and products would help improve the position, but would not address current housing stock that may come within a flood risk area in the future.

The effective control and management of storm water creates capacity in the waste water networks through hard and soft engineering solutions and active controls, which help alleviate the frequency and scale of flood events in urban areas.

End
