

Arqiva submission to National Infrastructure Committee's Call for Evidence on 5G

About Arqiva

Arqiva is a communications infrastructure and media services company operating at the heart of the mobile and broadcast communications industry. Arqiva provides infrastructure for television, radio, mobile and other wireless communication in the UK.

Arqiva operates shared radio site assets throughout the UK, including masts from under 30 to over 300 metres tall. We have worked with the mobile industry over two decades to deliver mobile services to consumers with a significant presence in suburban and rural areas. Our portfolio includes over 8,600 active, and more than 16,500 marketable sites, including radio and television broadcast sites, BT telephone exchange rooftops and use of National Grid pylons.

Arqiva enables the Airwave emergency services network in remote areas through c1,000 of our sites. We are working with DCMS to build new shared sites for villages in 'not-spots' as part of the Mobile Infrastructure Programme (MIP). We also own and operate 50 In-Building Systems to extend the MNOs' coverage and capacity into challenging environments such as Canary Wharf and the ExCel Centre. We are one of the UK's largest public WiFi providers, enabling us to offer unique propositions for venue WiFi and small cell networks, for example at Heathrow airport or in Central London.

Arqiva is building a national Internet of Things ("IoT") network, starting with 10 of the UK's largest cities. Our smart metering service, connecting 10 million homes using long-range radio technology, will be one of the UK's largest machine-to-machine deployments.

Arqiva is a founder member and shareholder of Freeview. We broadcast all eight Freeview multiplexes, are the licensed operator of four of them as well as owning Connect TV - the first company to launch a live IP streaming channel on Freeview. Arqiva is the licensed operator of both national commercial DAB digital radio multiplexes.

Arqiva is a major player in the UK's satellite industry, operating over 80 antennas to geostationary satellites, and providing Telemetry, Tracking and Command support services to some of the leading satellite operators. We are a major provider of permanent satellite services to both Freesat and Sky customers. Arqiva also provides global satellite based services to the broadcast, communications, security, oil & gas and exploration sectors.

Our major customers include EE, H3G/Three, Telefónica/O2, Vodafone, BBC, ITV, Channel 4, Five, Sky, Global Radio, Airwave, Heathrow and Whitbread/Premier Inn.

Arqiva is owned by a consortium of long-term investors and has its headquarters in Hampshire, with major UK offices in London, Buckinghamshire and Yorkshire.

Overview

The much anticipated emergence of new wireless services in the coming years will very likely require creative policy approaches to ensure that those services are allowed to flourish. There is still a lack of clarity as to *precisely* what 5G will be. However it is becoming increasingly clear that the ambition that drives 5G is to deliver outcomes to consumers that will greatly enhance quality of life and experience. This will likely include the delivery of high speed data services to customers – even in otherwise hard to reach areas – as well as new and innovative machine to machine applications.

To enable 5G to deliver on such an ambition, two initial challenges must be met. First, the required spectrum must be identified. Second, the necessary infrastructure must be put in place. These are significant challenges and we are, therefore, grateful for the opportunity to contribute to the National Infrastructure Commission's consultation on 5G. Arqiva is the UK's largest independent provider of mobile network assets. As such we offer a specific insight into the critical role that this sector will play in the provision of infrastructure that will underpin future 5G mobile services.

Independent Infrastructure Providers deliver benefits for all parts of the 5G ecosystem:

- Consumers benefit as they get better coverage and the lower cost of roll out can be passed through to their phone bills;
- Operators benefit from reduced costs and faster roll out of their networks;
- The local community benefits as fewer masts are required so there is less visual impact, and mobile coverage adds to the attractiveness of an area for residents and business; and
- The environment benefits as there are lower energy and construction costs from fewer masts

This submission sets out how 5G infrastructure could be rolled out in a way that minimises costs for operators, thereby enabling services to end users to be provided more cost effectively.

In particular, we focus on two areas in which 5G roll-out could be promoted in a timely and cost effective fashion, namely:

- The role that independent provision of mobile infrastructure can play in minimising costs and disruption in rolling out future 5G networks; and
- How improvements to the planning regime can further facilitate improved roll-out of mobile infrastructure.

Independent mobile infrastructure provision will play a critical role in delivering 5G

While it is not yet clear what 5G will be *precisely*, it is clear that there will clearly be a need for more mobile infrastructure. There will need to be more masts in rural areas to extend the benefits of mobile to all, and there will also need to be additional infrastructure to improve coverage on transport routes such as road, rail and on the underground.

Network operators will rely on access to wireless infrastructure assets to provide future 5G services. While much policy focus is typically given to the requirements of Mobile Network Operators (MNOs), this infrastructure is also crucial to delivering other services such as fixed-wireless broadband, radio and TV broadcast, emergency services and, Internet of Things and machine-to-machine communications.

Increasingly, MNOs have sought to access infrastructure jointly in sharing arrangements. They have done this in the UK by setting up joint ventures (EE and H3G setting up MBNL and Vodafone and Telefónica/O2 setting up CTIL and Beacon) as well as making extensive use of Independent Infrastructure Providers (IIPs), whose business model is based on allowing their assets to be used as widely as possible.

In the UK, the MNOs own and operate the majority of passive mobile assets. However the IIPs constitute a small but significant part of this market. There are difficulties in determining what the precise market share is, but a reasonable Arqiva assessment suggests that in the region of 30-40% of passive assets are provided by IIPs. This contrasts with the United States, where EY has estimated that 84% of market share is accounted for by independent providers.

The contribution that IIPs bring to the mobile ecosystem is, therefore, significant and it will continue to be important as 5G develops. It ensures that greater numbers of consumers enjoy the social and economic benefits of mobile communications. In that respect, we note that many IIP sites are based in rural areas, delivering those benefits to consumers who may otherwise not receive them.

The importance of IIPs is illustrated by H3G's entry into the UK MNO market as the fifth operator in 2003. Due to Arqiva's commercial incentive to share masts, we were a key partner in a fast and cost effective rollout so H3G could rapidly launch its own 3G network.

Wireless infrastructure sharing has grown over the past few years

In a consolidating, competitive and cost-conscious mobile environment, infrastructure sharing has become an increasingly attractive option for a number of reasons, including:

- It facilitates faster roll-out of services as it reduces the potential for delays associated with acquisition, design and build of suitable sites;

- Costs to industry can be significantly reduced if more efficient use is made of existing infrastructure. Moreover, increasing utilisation rates of each tower ensures that the unit costs for network operators can be reduced;
- Co-locating equipment allows for the use of joint backhaul to the core network, further reducing cost to MNOs; and
- Using existing infrastructure can promote greater coverage for more operators sharing masts.

For the additional coverage and capacity required for 5G ensuring that the mobile ecosystem can utilise these benefits will be even more critical.

Additionally, the Electronic Communications Code (Conditions and Restrictions) Regulations 2003 also places an obligation on Code Operators to maximise the use of existing infrastructure. This is, in part, to avoid a proliferation of structures which could cause a negative impact on the environment and/or local communities.

Independent infrastructure provision would be a cost-effective solution to deploying 5G services

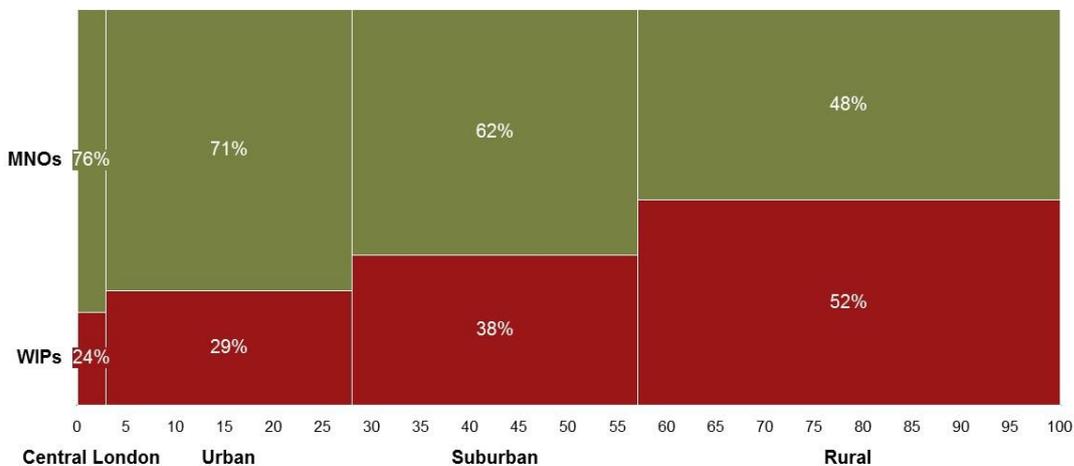

Independent infrastructure providers have a commercial incentive to make their assets available to all wireless network operators – thus facilitating the emergence of 5G services. For example, the average number of sharers on each MNOs' mast compared with that of the IIPs shows that the latter achieve significantly higher utilisation rates through providing access to multiple operators.

As well as competition from within the IIP sector, IIPs face competition from self-providing network passive asset holders such as CTIL and MBNL. This acts as a competitive constraint on their ability to arbitrarily raise prices to MNOs.

As a result of these factors, the otherwise significant fixed costs involved in constructing and maintaining passive infrastructure assets are reduced as more efficient use is made of them. Increasing utilisation rates of infrastructure ensures that the unit costs for MNOs can be lower. This makes it cost effective to improve service coverage, including rolling out 5G to areas where it may be unprofitable for them to invest in additional own assets.

This is illustrated by the diagram below:

Figure 1: Breakdown of sites by player type and location

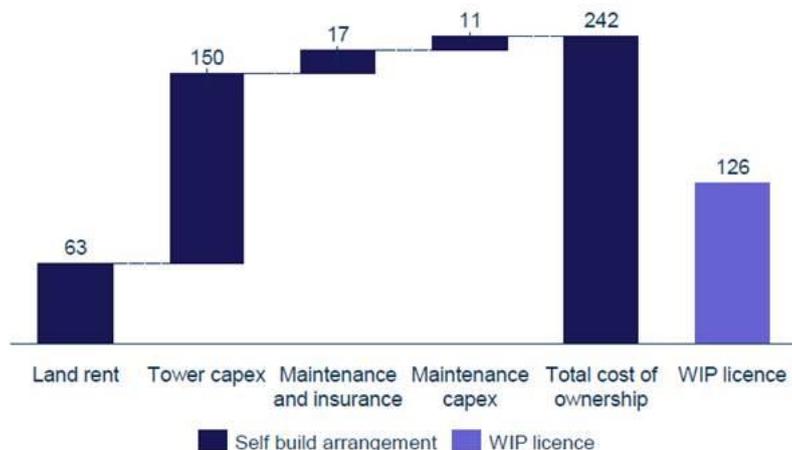

Source: AT Kearney

This diagram shows that despite IIPs accounting for just c.34% of the total UK macro sites, they provide more than half of sites based in rural areas. This is consistent with the benefits we would expect to see from maximising sharing opportunities, particularly where costs of site deployment would otherwise be expected to be high.

The higher rate of co-location achieved by IIPs reduces the need to build more masts, speeds up deployment and reduces MNO lifecycle costs. IIPs are also able to reduce operating costs and lower the cost of capital. This is as a result of the ownership and operation of masts being our core business.

The difference in costs for an IIP operating masts compared to a self-provider was shown by Analysys Mason in the extract below:

Figure 5.6: Total cost of ownership: comparison of self-build tower vs WIP licence model (GBP thousand per site in NPV terms) [Source: Industry submissions]

Source: Financial Impact of Electronic Communications Code Changes, Analysys Mason, May 2016

This report, published in May 2016, was commissioned by the Department for Culture Media and Sport (DCMS) to inform its policy approach to reforming the Electronic Communications Code. That report was accompanied by DCMS implicitly supporting the future development of the independent infrastructure sector:

“we do not want to disrupt market incentives for investment in passive infrastructure by establishing a legal framework to allow compulsory access and thereby subject the market to further regulation”¹

Cost effective infrastructure solutions can help underpin roll out of 5G networks

Significant cost savings could be derived depending on from supply side decisions that are made when rolling out networks. The extent of those savings would largely rely on the precise evolution and make-up of the 5G network that was being rolled out at the time. It would also depend on the mobile technology being adopted to meet the UK’s coverage ambitions. For example, there may be merit in exploring the potential of fixed wireless access solutions for those homes in challenging areas that struggle to receive sufficiently fast speeds indoors.

Finally, we note that the ongoing reform of the Electronic Communications Code and the other policy changes in areas such as planning will improve the prospects for more cost effective mobile broadband provision for all mobile infrastructure providers, thus making a mobile contribution to 5G roll-out an increasingly viable alternative to fixed.

¹ A New Electronic Communications Code, DCMS, May 2016

Changes are required to allow small cell deployment at scale

Small cells already play an important role in the continued deployment of 4G networks and the increasing data capacity that is vital to mobile connectivity. In order to deliver 5G services to mobile users there will be a need to deploy small cells on a scale not previously seen in the UK. Hundreds of thousands of small cells are expected to be rolled out in London alone and over a million will be required across the country.

Small cell deployment in significant numbers will require the use of buildings or other structures, such as lamp posts and other suitable street furniture. As it stands there are challenges to businesses in getting the planning permission that they need in order to roll out small cells. Government has acknowledged this and recently announced a number of changes in the Written Ministerial Statement (HCWS631) (WMS). While the changes are welcome they do not allow industry to roll out 5G in the volumes that are required. For the government to deliver its objective to be a world leader in 5G, at a minimum, the following further changes are required:

- The current limitation only allows the installation of two “small cell antennas” on a building or other structure. This is too restrictive. It does not allow for instances where a third backhaul antenna or other apparatus is required. This could be overcome **by allowing the installation of “small cell systems”, and including “small cell antennas” within its definition** e.g. a “small cell system” means the installation of small cell antennas and any associated apparatus.
- Small cell antennas often face the highway as most suitable buildings are within 20 metres of a highway. The current limitation prevents this and brings about the requirement for full planning permission. The WMS indicates that this limitation will be removed on residential and commercial premises. However this leaves out Council owned properties, such as libraries, schools and depots, which are not commercial premises. In view of this, **the 20 metre highway limitation should be removed entirely.**
- Under current conditions, the prior approval procedures apply to small cell antennas proposed on buildings or other structures (which include lamp posts) within designated areas, e.g. conservation areas. Given the extent of conservation areas, this is a very significant obstacle. **The requirement for prior approval should therefore be removed for small cell systems entirely.**
- It has become increasingly apparent that to allow scalability from 4G to 5G, operators are likely to require cabinets in protected areas. Under current conditions these require prior approval. This problem arose for the cabinets required for fixed line broadband and the Government addressed this by removing the cabinets from this requirement. **The requirement for prior approval for small radio equipment housing in protected areas should also be removed.**

Responses to questions

1. What uses have been envisaged for 5G?

The evolution of 5G will be principally driven by use cases as opposed to technology innovation. There are a number of potential use cases which may emerge. However, we expect that the most significant will be:

- Increased video demand including at higher definitions;
- Connected devices at scale;
- Intelligent transport including autonomous transport;
- e-health; and
- Newer aspirational use cases such as augmented reality and the tactile internet.

We expect Internet of Things (IoT) to develop to the extent that billions of devices will be connected and they will be delivered over 5G and other technologies. This will require lower bandwidth than in most other use cases, However, some of the services will need to be always on and will require super low latency to make extreme real time communications viable. Examples of this are lifeline services centered on healthcare in the home, bringing changes to how and where people are treated.

In our view, there is starting to be that some of services delivered over 5G will require:

1. Densification of the network;
2. High capacity to devices;
3. Very low latency; and
4. Low power consumption.

However, different use case have different requirement so things such as real-time immersive gaming will require the very low latency, and high capacity, but that will sit alongside IoT uses such as the monitoring whether bins are full or empty that will require lower capacity and low power consumption but can live with higher latency.

In terms of broadband delivery, we expect that a combination of technical innovation and public intervention (in particular, the introduction of a universal service obligation) will move the UK towards an environment where all consumers will be able to enjoy 50 Mbit/s+ download speed.

2. Of those use cases identified, which appear most credible from a UK perspective, and over what timeframe?

All of the use cases referred to in our response to question 1 are plausible within the UK. The timing of when they become available will be largely driven by the speed of network deployments. Networks will likely start to rollout at scale from 2019-2020 with all the use cases becoming viable thereafter.

What is becoming clear is that 5G is a global initiative and the UK has to either lead, or adopt, global standards. Equipment manufacturers will not make equipment solely for a UK market at prices that UK consumers will be willing to pay.

3. What is the potential scale of benefits?

While the scale of the benefits is likely to be significant we have not carried out any analysis to quantify that to date.

4. Are there planning or wider legal issues which have the potential to hold back the deployment of 5G networks?

Whatever the system or process, the town planning environment is generally worsened by additional numbers of operators as this creates pressure for more development and pressure on scarce local authority resources. Important stakeholders such as local communities often fail to understand why infrastructure has to be replicated so multiplying its potential impact.

There are therefore good town planning arguments to return to a similar model that existed for 1G, i.e. two wholesale network operators, who provided network time and access to a large number of virtual retailers. This would also be a more direct and efficient way of finding the network synergies that the MNOs are seeking to achieve through network sharing and reflect better their desire to focus on providing services to their wholesale and retail customers rather than the detail of running a network. It also overcomes the difficulties that would be faced by any new entrant who would be confronted with the significant cost of deploying a credible network in order to be able to attract customers.

Such an approach could also help simplify the town planning framework in the UK – in fact there are four different town planning systems in operation in the UK and another three covering the Channel Islands and the Isle of Man. The permitted development rights (PDRs) that apply to Electronic Communications Code Operators are all different. Taking the four UK systems, the PDRs are all based upon the same objective, i.e. to encourage and facilitate the growth and development of modern communications, whilst minimising the potential impact on the natural environment and the built heritage. The systems that grew out of the UK-wide legislation in force before town planning was devolved are now very different. That in itself poses difficulties for Code Operators, but these are made worse in England and Wales where there are issues such as the prior approval process effectively removing the benefits of PDRs.

In England, the amendments to the Code Operator PDRs since their introduction have resulted a number of anomalies. The changes announced in the Written Ministerial Statement on 17 March 2016 (WMS) will lead to further anomalies. For example, a third small backhaul antenna required on a building elevation to support two small cell antennas will still need planning permission, but the same operator will be allowed to install pole mounted antennas on the roof of the same building that can be in excess of 6 metres high at the point of installation. That same operator may have a 15 metre high mast in the adjoining countryside, which even if in a protected area will be given a PDR to extend by 5 metres, another form of development that will have a considerably greater visual impact than a third small antenna on the face of a building.

The prior approval process may have some relevance to the detailed siting and appearance of new masts but, by contrast, its application to mast extensions adds bureaucracy without clear benefits – the mast is already established and its appearance will be dictated by the structure being extended.

This creates challenges with deploying next generation 5G networks, but there are some straightforward policy amendments that could be made to address those challenges.

The key issue is to ensure that the PDRs are properly configured to allow the installation of new apparatus with appropriate, but not excessive controls. When introduced some of the changes in the WMS should help achieve this, although the detail of these changes are yet to be seen. However, the WMS does not go far enough in relation to small cell antennas, we have made representations to DCMS about this already and include that as an annex to the document. While this is important for 4G roll out already it is particularly relevant to the hundreds of thousands of small cells that will be deployed for 5G.

In the longer term the government should consider rewriting the PDRs with the aim of producing a simplified and logical set of PDRs free of prior approval. As it stands the prior approval requirement provide a degree of certainty on timing but are otherwise little different from the requirement for full planning permission.

The Government should also harmonise the PDRs with the overlapping requirements of the Electronic Communications Code (Conditions and Restrictions) Regulations 2003 (Regulations). If brought into harmony the PDRs and Regulations could provide a system of checks and balances that would be more logical and simpler to use (for industry and planning authorities) and one which would better meet the Government's objectives. We would be pleased to work with industry and Government to develop a more effective framework.

5. Are there issues around working across industry sectors which may hold back the deployment of 5G networks?

As noted above, there will need to be dark fibre in order to support ever increasing backhaul demands. This will require enhanced co-operation between industry players and, in the absence of progress, may require a degree of regulatory intervention.

More broadly, we note the concerns raised by Ofcom in its Digital Communications Review on the requirement to improve backhaul provision in the context of BT's role in the market. We support any measures that will lead to such an improvement, given the benefits which would likely accrue to a future 5G roll out.

6. What do the services and uses for 5G suggest about the infrastructure requirement?

The infrastructure requirement will likely involve an evolution of the existing radio access network. These will contain a full Evolved Packet Core on the macro side with requirements for new antennas to support those higher frequencies being proposed for discussion at the World Radiocommunication Conference in 2019. It will also likely require new ground based equipment.

This will require the introduction of more assets. For illustrative purposes, we set out below the likely antenna changes which will be required as the existing radio access network evolves to meet the changing demands which will underpin the growth of 5G services:

Scenario	Antenna Impact	Breach Arqiva Config 6+2	Feeder Impacts	Ground Based Equipment Impact	%-sites Impacted	Deployment Start
700 MHz	Multiband (may require swap)	Yes due to size	Existing	Existing	80%	2019
2.3 GHz	Multiband (may require swap)	Yes due to size	Existing	Existing	60%	2017
2.6 GHz	Multiband (may require swap)	Yes due to size	Existing	Existing	40%	2017
3.4 GHz	New Antennas	Yes	Unknown	Existing	Unknown	2018
2100 MHz reform	Multiband (may require swap)	Yes due to size	Existing	Existing	100%	2018
5 G (30 GHz >)	New	Yes	New	New	100%	2020

7. What level of UK coverage will be optimum and what does this mean for the challenge of delivering higher speeds and lower latency? Are there particular issues faced by urban, suburban and rural areas?

In a 5G world where there will be a need for network that are suitable for services ranging from IoT, to driverless cars to high definition video, coverage needs to be looked at afresh. In the past, coverage obligations have focussed on targets for population or geography but for 5G a new approach is required. Government should particularly look at:

- **Transport routes:** Coverage on roads will be critical for driverless cars while coverage on trains and on the underground is critical for maximising productivity and growth. Coverage obligations for transport routes such as road and rails including the London Underground and tube systems elsewhere in the UK.
- **Rural areas:** There is already a digital divide between those who have services in rural and urban areas. While a USO will help to address this, those who live and work in rural areas should fully benefit from 5G. Therefore the government should consider obligations to deal with coverage in rural areas – this could be linked to the coverage work that is already being done for the Emergency Services Network.
- **Transient populations:** The need for coverage is not just related to areas with high population so the government should consider whether it should target areas with low permanent populations but high transient populations such as business districts or tourist areas where there can be high demand, or safety of life implications.

The existing geographical coverage obligations will be the starting position for future 5G coverage. It is likely that 4G will underpin future networks as 5G networks will be rolled out differently to 4G if it is solely left to commercial incentives. The 90% target UK geographical coverage obligation is technology neutral and is more likely to be achieved by 4G than 5G without specific obligations. Without intervention on 5G, for services such as IoT applications there may be a low capacity, high latency network that rolled out to near universal coverage using low frequency bands. At the same time very high capacity networks will only be rolled out in select urban areas. If the government wishes to deliver the full economic growth and consumer benefits of 5G it will need to consider interventions, in particular through coverage obligations that are more sophisticated than have been used to date.

In addition to this, in urban areas the availability of fibre will be key to the roll out of 5G network. Similarly in rural / suburban the ability to build backhaul networks, whether fibre or wireless, will define the network

8. Are there any 'no regrets' and 'low regrets' infrastructure investments that can be made to support 5G deployment?

We do not offer a view on this question at this time.

9. In what ways could collaboration between infrastructure sectors speed up and improve deployment, and how might it be incentivized?

There is already a significant amount of collaboration between infrastructure sectors. For example Arqiva has an agreement to put mobile infrastructure on electricity pylons and there are similar deals with water towers. Any intervention, or incentives, should not disrupt the arrangements that already exist in the market.

However there are a number of areas where intervention may be beneficial:

- Firstly in making it easier to access BT's ducts to make it easier to roll out the fibre backhaul that is required;
- Secondly to allow access to the railway land, masts and fibre in order to allow improved coverage on trains; and/or
- Thirdly to look at integration of mobile infrastructure when looking at major developments such as new garden cities, new roads or projects like HS2.

10. Are there any relevant international examples in the deployment of telecoms infrastructure that the UK can learn from?

We suggest that most relevant comparisons would be Japan and South Korea. Both countries are leaders in small cell deployment and have deployed at scale. It is important to reflect that the success of these roll-outs was driven, in part, by relaxed planning regimes and ready availability of dark fibre.

11. Who should bear the deployment costs of 5G?

Who pays for 5G deployment depends on which part of the value chain is being looked at, although ultimately it will be the consumer that pays either through the mobile packages that they buy from mobile operators or through taxes and government intervention.

More specifically the majority of the cost of rolling out the infrastructure to support 5G will be paid for by the mobile industry. It is in the commercial interests of the operators to deliver 5G services to customers. However if the government wants to deliver full coverage, that may require targeted intervention(s).

12. What is 5G deployment likely to cost the UK?

We do not offer a view on this question at this time.

13. Are there international examples to draw on?

There are several models of coverage obligations that have been used in spectrum auctions around the world (e.g. in Germany) that may help the UK to deliver the coverage that is needed.

14 Is the existing UK telecommunications model able to facilitate the efficient roll out of 5G infrastructure and technologies?

Delivering 5G will be a significant practical challenge. The expectation is that over a million small cells will be required to roll out 5G and there will also need to build new macro sites and upgrade equipment at existing sites. This will require infrastructure deployment on a scale not seen before in the UK or anywhere else in the world. In order to deliver this there will need to be a significant change in the delivery model for rolling out 5G. This will require changes in a number of areas:

- **Skills:** Developing the skills and the people to roll out the infrastructure at scale;
- **Supply chain:** Ensuring that the equipment and other parts of the supply chain are scaled up and prepared for the delivery challenge; and
- **Planning:** The programme management required to deliver 5G will need to be world class to deliver the network required. Mobile operators will need to ensure that their network, rollout, and other planning is developed in collaboration (with the rest of the industry to ensure that it is realistic. Ensuring that the plan is well communicated and agreed by all parties is prerequisite for success.

Given that the rest of the world will be looking to roll out 5G in a similar timescale this will put further pressure on the model and it will require the UK to start its planning as soon as possible.

15. Is spectrum policy and its management well placed to support future 5G technologies?

With the UK leaving the European Union, it will be even more critical for Ofcom to engage with spectrum policy and developments around the world to ensure that the UK can realise the benefits of harmonisation.

Annex – Changes required allowing small cell deployment at scale

Arqiva has specific experience of Permitted Development Rights (PDRs) in relation to small cells. In particular we have many concessionary agreements with local authorities to manage installations by the Mobile Network Operators (MNOs) on Council owned buildings and street furniture, such as suitable lamp posts, CCTV poles and street signs. The lamp posts are the best and most prolific usable structures, and they extend across entire local authority areas.

For an MNO seeking to deploy a small cell network, access to Council property is therefore a potentially quick and easy means of rapid and comprehensive coverage. This avoids having to reach agreement with large numbers of individual building owners, which would be time consuming and fraught with issues.

The use of lamp posts is also a good environmental solution. Lamp posts are familiar features in townscapes. They have always had an important secondary role in terms of supporting street signage, bins, CCTV apparatus etc. These secondary items, which are usually installed by the Council, are permitted without limitation or condition under their separate PDRs. The introduction of small cell systems is a continuation of the way in which lamp posts are already used as shown in the two examples below.

Another benefit of lamp posts is that they are self-regulating in two respects. First, they are owned by the Highway Authority, which is usually the Council and so the same body as the

Planning Authority. The concessionary agreements from Councils therefore include a range of controls, such as the use of certain structures and matters such as colouration. These remove the need for overlapping town planning controls on siting and appearance.

Second, lamp posts can only support a limited amount of apparatus as they are not generally sturdy structures. Therefore, any relaxations in the PDRs could not result in an excess of apparatus, even in the absence of other controls.

In our response to the Call for Evidence in August 2015, we highlighted some key concerns about the effectiveness of the changes to the PDRs for small cells that were introduced in 2013 and suggested changes necessary to overcome these. Since that time, we have also had a customer cancel a proposed deployment of 100 small cells on lamp posts in a London Borough because the onerous town planning requirements rendered the proposal unviable. This is an ongoing problem.

Insofar as the WMS addresses some of the issues it is welcome. However, in the light of current experience, it is vital that the existing obstacles be removed if small cells are to be deployed in the numbers required. This is explained further below.

The Permitted Development Rights and Changes Required

In setting out what is needed it is relevant that lamp posts are treated in the legislation as a building or other structure and not as a radio mast. We therefore focus on the key constraints with the existing PDRs on buildings or other structures, the effect of the changes announced in the WMS, and the further changes that are required.

Issue 1: The current limitation only allows the installation of two “small cell antennas” on a building or other structure.

- This limit is predicated on the basis that only two antennas will be required, whereas in some cases, for example where a radio link is required for backhaul, this is not sufficient. Breaching this limitation triggers the need for full planning permission.
- Where other apparatus such as small units for radio equipment is required, as shown in the photographs, we have experienced some local authorities interpreting the rights as excluding such apparatus.

Solution: The WMS does not address this issue and it could be overcome by allowing the installation of “small cell systems”, and including “small cell antennas” within its definition e.g. a “small cell system” means the installation of small cell antennas and any associated apparatus.

Issue 2: Small cell antennas often face the highway as most suitable buildings are within 20 metres of a highway. There is a current limitation which prevents that and brings about the requirement for full planning permission.

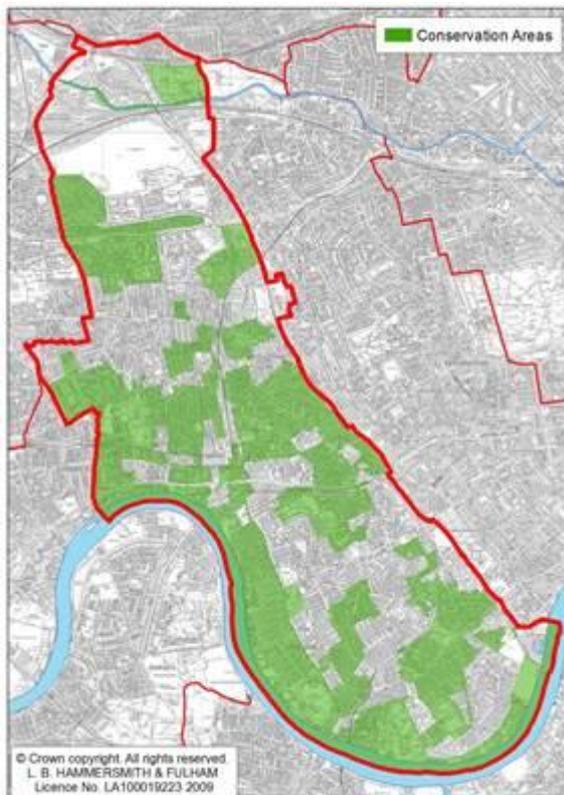

- The WMS indicates that this limitation will be removed on residential and commercial premises but does not remove it from all premises.

- The limitation does not in our view apply to lamp posts, because they do not have elevations, but the legislation should remove the scope for an alternative interpretation that might suggest this limit would apply to lamp posts. It suggests also that Council owned properties, such as libraries, schools and depots, which are not commercial premises might still be subject to this limitation.

Solution: The limitation should be removed entirely.

Issue 3: Under the current PDRs, the prior approval procedures apply to small cell antennas proposed on buildings or other structures (which include lamp posts) within designated areas, e.g. conservation areas.

- To appreciate the significance of this condition, an example of the extent of Conservation Area designations is included below for Hammersmith and Fulham.

- This pattern of extensive designations repeats itself across Central London and many other urban areas.
- In practice there is no difference between an application for full planning permission and one for prior approval – only a degree of certainty on timing. This requirement is therefore a significant burden in terms of timing and cost, as each lamp post has potentially to be the subject of an application, with the need to produce drawings, a location plan, an ICNIRP certificate and other supporting material, including the payment of a statutory fee.

- As indicated above, such an application is also unnecessary for lamp posts where a satisfactory degree of alternative control exists.
- The WMS indicates that the requirement for prior approval will be removed for small cell antennas on residential premises. This relaxation will be extremely limited in its effect. Taking Central London as an example, there are very few residential buildings in the core commercial and tourist areas.

Solution: The requirement for prior approval should be removed for all small cell systems.

Issue 4: The requirement for prior approval for radio equipment housing, within 2.5 cubic metres in protected areas

- Since making our original submissions, it has become apparent that the MNOs have a preference for small equipment cabinets over small units that might be attached to a building or lamp post. This is because the cabinets will offer greater flexibility and scope for upgrading to 5G, which will operate alongside 4G when first introduced.
- As there is a requirement for small equipment cabinets to be subject to prior approval this introduces the same obstacle on rapid and viable deployment. This is the same issue that was identified for the cabinets required for fixed line broadband. Government addressed this by removing them from the prior approval procedure by virtue of Condition A.2 (5)

Solution: The requirement for prior approval for small radio equipment housing in protected areas should be removed.

Building the Future:

The economic and fiscal impacts of making homes energy efficient

Executive Summary

High energy bills are causing considerable financial hardship in the UK, with millions of people living in fuel poverty. One of the biggest causes of the fuel poverty crisis is the poor condition of the UK housing stock, which is one of the least energy efficient in Western Europe.

Improving the energy efficiency of UK homes is an effective way to bring down energy bills, and offers a long term solution to fuel poverty. In addition, it is important to drive carbon emissions reductions, with buildings responsible for almost 37% of all UK carbon emissions.¹

At the same time, the building insulation market contracted by 22% in 2013,² as the installation of cavity wall insulation fell by 46%, the installation of loft insulation fell by more than 87%, and the installation of solid wall insulation fell by 30%, compared with the number of measures installed under the Carbon Emissions Reduction Target (CERT) in 2012.³ The Energy Bill Revolution is calling for a radical new approach to home energy efficiency. They are calling for all low income homes to be given measures, by 2025, to bring them up to Band C on an Energy Performance Certificate (EPC),⁴ and for all other households to be offered 0% interest loans to improve them to an equivalent EPC standard by 2035; delivered as part of a major infrastructure investment programme.

This report has undertaken detailed modelling to assess the economic, fiscal, and environmental impacts of this programme. It concludes that the economic case for making the energy efficiency of the UK housing stock a national infrastructure priority is strong.

In addition to making all low income households highly energy efficient, and reducing the level of fuel poverty, the modelling has established that this energy efficiency programme would deliver:

- **£3.20 returned through increased GDP per £1 invested by government**
- **0.6% relative GDP improvement** by 2030, increasing annual GDP in that year by £13.9bn
- **£1.27 in tax revenues per £1 of government investment**, through increased economic activity, such that the scheme has paid for itself by 2024, and generates net revenue for government thereafter
- **2.27 : 1 cost benefit ratio** (Value for Money), which would classify this as a “High” Value for Money infrastructure programme
- **Increased employment by up to 108,000 net jobs per annum over the period 2020-2030**, mostly in the service and construction sectors. These jobs would be spread across every region and constituency of the UK.

⁴ Energy Performance Certificates (EPCs) are a measure of the level of energy efficiency of a home. The ratings span from A to G. A-rated homes would have relatively low energy bills, whereas G-rated homes would have high energy bills, and be expensive to heat. An EPC band of C represents a reasonably good level of energy efficiency. The average EPC rating in England and Wales is currently D. Increasing the energy efficiency rating (or EPC) delivers a warmer, healthier, and more comfortable home for the resident, whilst reducing the energy bills.

- **£8.61 billion per annum in total energy bill savings** across housing stock, after comfort take (including energy price inflation)
- **Net benefit of £4.95 billion per annum** from the total energy bill savings across the housing stock (after able-to-pay energy efficiency loans have been repaid)
- **23.6MtCO₂ reductions per annum by 2030**, after accounting for direct, indirect, and economy-wide rebound effects. This is roughly equivalent to cutting the CO₂ emissions of the UK transport fleet by one third.
- **Improved health and reduced healthcare expenditure**, due to warmer and more comfortable homes, and improved air quality. For every £1 spent on reducing fuel poverty, a return of 42 pence is expected in National Health Service (NHS) savings.^{5 6}
- **A more resilient economy**, less at risk of shock changes in gas prices, as the economy becomes less reliant on fossil fuels. Investment in energy efficiency in the domestic sector will result in a 26% reduction in imports of natural gas in 2030, worth £2.7bn in that year.

Background

The Government's energy efficiency strategy acknowledges that improving energy efficiency is fundamental to decarbonising the UK economy, combating fuel poverty, maintaining secure energy supplies, reducing domestic energy bills, reducing the need for new electricity generation capacity, and increasing the productivity of businesses. However, successive governments have failed to put in place policies or investment which could realise this opportunity. Within this context, this research seeks to quantify the macro-economic benefits of investing in energy efficiency in the UK building stock, based on the programme objectives of the Energy Bill Revolution campaign. The Energy Bill Revolution is a major alliance campaign to end fuel poverty which is supported by 200 major UK stakeholders.

This study assesses three main areas:

- Quantifying the scale of investment required to upgrade all UK homes to EPC band C by 2035, with all low income homes treated by 2025, and associated energy bill and CO₂ savings from installed energy efficiency measures;
- Modelling tax implications and macro-economic benefits from investment in energy efficiency
- Developing the quantitative and qualitative evidence to support investment in energy efficiency as an infrastructure priority

As such, this analysis represents a comprehensive assessment of the impacts of a substantive programme of investment, considering the (inter-related) impact on macroeconomic indicators and the Value for Money indicators used for infrastructure project assessment in standard cost-benefit analyses.

Domestic energy efficiency retrofit: Investment and bill savings

The domestic energy efficiency retrofit programme presented in this research shows the investment required, and beneficial impacts of improving the energy performance of the whole UK housing stock to EPC band C by 2035. The improvements are financed via grants to low income homes, and 10-year interest free loans to able-to-pay homes. The programme is proposed to be rolled out using a street-by-street delivery model,⁷ starting with areas with a high proportion of low income households, to ensure the effective targeting of low income homes, and to exploit economies of scale.

Discussions with key industry experts and stakeholders have concluded that the level of activity and ramp-up rates presented are realistic, and the industry can scale up to deliver this level of activity. Additional regulatory drivers and financial incentives, such as mandatory energy performance standards, council tax and stamp duty rebates, may need to be considered to drive uptake of energy efficiency retrofits in able-to-pay homes.

The energy bill savings from the energy efficiency programme are shown in Table 0-1.

Table 0-1: Energy bill savings associated with the energy efficiency investment programme

Average energy bill savings for low income homes	£408 per annum £245 per annum after accounting for comfort take ⁸
Average energy bill savings for able-to-pay homes (after energy efficiency loan repayments)	£416 before loan repayment Net benefit of £203 per annum (after able-to-pay energy efficiency loan repaid) ⁹
Total energy bill savings across the housing stock, after comfort take (includes energy price inflation)	£8.61 billion per annum Net benefit of £4.95 billion per annum (after able-to-pay energy efficiency loans repaid)

The investment in the retrofit programme, both by the Government and the private sector, is shown by parliamentary term in Table 0-2.¹⁰ The Government investment consists of grants for low income homes, covering the installation of measures and cost of carrying out the energy assessments. For able-to-pay homes, the Government investment pays for the interest rate subsidy from 8% to 0%, over a 10-year loan term, plus the cost of energy assessments.¹¹

⁷ R Platt, J Aldridge, P Washan, and D Price; *Help to Heat: A solution to the affordability crisis in energy*; IPPR Nov 2013.

⁸ Homes with fuel poor residents often tend to be under-heated due to the high costs associated with heating. This means that modelling of energy demand and energy savings can be over-estimates, as they do not account for the behaviour and energy use patterns of the residents. It can be that, after energy efficiency measures have been installed, the residents increase the warmth of their homes (due to the reduced costs of achieving the warmer temperature), rather than achieving the predicted energy bill savings associated with energy efficiency. This is known as 'comfort take' – and assumed to account for a 40% reduction in the predicted energy bill savings for the purpose of this research.

⁹ This figure represents energy bill savings averaged over a 20-year lifetime for a package of measures. The loan repayment would be twice as large for the first 10 years after retrofit, reducing to £0 thereafter, once the loan has been repaid.

¹⁰ The investment in the retrofit programme is shown by year in Appendix 4 – Programme investments by year.

¹¹ The interest rate subsidy is calculated as the cost to government of guaranteeing the energy efficiency loans (taking the effective loan interest rate from 8% to 5%) plus the cost of direct subsidies (taking the effective interest rate from 5% to 0%) over a 10-year period.

For the first parliamentary term, the total investment required for the low income scheme is £8.1bn, and the Government contribution for the able-to-pay scheme is £4.9bn. As an indication of scale, this compares to over £100bn of committed public investment in infrastructure projects over the next parliamentary term (2015-2020), which includes £24 billion for road building, with £16 billion set aside for new roads. The Government has also committed to the building of High Speed 2 (HS2) which is budgeted at £42.6bn for the construction of the rail link, and an additional £7.5 billion for rolling stock.¹²

Table 0-2: Programme investment made by the Government and by the private sector, for each parliamentary term

Parliamentary Term	Investment in low income scheme (undiscounted) (£bn)	Government contribution to able-to-pay scheme (undiscounted sum of interest payments) (£bn)	Private sector investment in able-to-pay scheme (undiscounted) (£bn)	Government investment in all schemes (undiscounted) (£bn)	Total investment (undiscounted) (£bn)
15/20	£8.1 ¹³	£4.9	£13.1	£13.0	£26.1
20/25	£18.1	£8.4	£22.3	£26.4	£48.7
25/30	£0.0	£9.9	£26.6	£9.9	£36.5
30/35	£0.0	£4.2	£11.2	£4.2	£15.3
Total	£26.1	£27.4	£73.2	£53.5	£126.7

Value for money and tax implications of investing in domestic energy efficiency

The economic scenario analysis was undertaken using Cambridge Econometrics' MDM-E3 model of the UK economy and energy system.

The energy efficiency scenario differs from the baseline in investment expenditure and fuel use, as a result of efficiency measures. Investment in dwellings leads to a positive economic impact on industries supplying the construction sector with energy efficiency products. Changes in expenditure on energy affect consumption outlays and thus revenues of consumer-facing industries and their supply chains. The primary impacts that are modelled in this study are:

- Change in investment including expenditure of measures financed through funding provided for low income homes as well as loans for able-to-pay homes.
- Higher energy efficiency of homes leads to lower energy demand and therefore lower energy bills. The reduction in demand for gas in heating (and for gas used in the power sector which is then consumed by homes for heating) would substantially reduce imports of natural gas.
- Lower energy bills (after accounting for comfort take – which leads to a range of health benefits, as discussed in Section 4.5) lead to higher expenditure on other goods and services. In the case of able-to-pay homes, this is at first largely offset by loan repayments in the first 10 years following treatment.

¹² HM Treasury, *Investing in Britain's future*, June 2013,

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/209279/PU1524_IUK_new_template.pdf

¹³ This excludes £2bn Energy Companies Obligation (ECO) funding, expected to be invested by the utilities for 15/16 and 16/17, to meet ECO targets. Assuming similar level of ECO investment per annum to 2020, the additional investment required in the first parliamentary term is £3.1bn.

The Value for Money assessment is summarised in Table 0-3 (the calculations supporting each item are discussed in Section 4.2).

Table 0-3: Summary of modelling results

Total discounted benefit of energy efficiency investment programme, of which:	£91,186m
<i>Discounted net benefit to consumer spending</i>	£60,651m
<i>Discounted benefit of net government balances</i>	£9,960m
<i>Discounted benefit of net increase in company profits</i>	£15,111m
<i>Discounted benefit of net increase in savings</i>	£337m
<i>Discounted benefit of reduced emissions</i>	£5,127m
Total discounted investment in energy efficiency programme by government	£40,214m
Cost Benefit Ratio (CBR) (total benefit / total investment)	2.27

The Cost Benefit Ratio (Value for Money) indicator of the programme is estimated to be 2.27:1, which classifies the infrastructure programme as “High” Value for Money. The value of health benefits of improved efficiency from the comfort, warmth, and improved air quality in homes, is uncertain to quantify in monetary terms, and has therefore not been included in the formal Cost Benefit Ratio. However, there is evidence that significant health benefits will arise which would add to the central estimate of 2.27.

In terms of GDP, the programme would generate a return of £3.20 per £1 invested in energy efficiency measures by government. For value added, the return is £3.00 per £1 invested. In relative terms, as a result of the energy efficiency investments, GDP will be 0.6% higher in 2030.

The programme results in a net increase in annual employment of up to 108,000 over the period 2020-2030, with most jobs created in the services and the construction sectors.

Investment in energy efficiency in the domestic sector will result in a 26% reduction in imports of natural gas in 2030, worth £2.7bn in that year. As the economy becomes more fossil fuel efficient, the more resilient it becomes to shock changes in gas prices. A 50% gas price spike in 2030, leads to a 0.2% GDP decrease in the baseline scenario, but only a 0.15% decline in the Energy Efficiency scenario. For consumers directly, the gas price spike leads to an increase in energy bills of £220 per home (in 2030) in the baseline. As a result of the efficiency measures, this is reduced by £60 to £160 per home.

Both the direct impact (construction jobs at the installation sites) and many of the indirect impacts (extra employment generated by the spending of additional wages in the economy) stimulate employment and economic activity in close proximity to the sites where the energy efficiency measures are introduced. Given that the modelling demonstrates a net positive impact on output and jobs in the UK, the impacts are therefore fairly evenly distributed across the country (whether looking

at a regional, local, or constituency level): the increase in employment in 2030 ranges between 0.14-0.22% in each of the twelve nations and regions of the UK (against a UK average of 0.19%).

The funding investment and incentivising of take-up of energy efficiency measures by governments is self-financing. The increased economic growth leads to higher tax intake, cumulatively £51.1bn by 2030, or £1.27 per £1 invested throughout the whole period (in discounted terms). In Parliamentary Terms, the Government would be slightly worse off in the period 2015-20, but the investments would yield dividends to governments in the 2020-25 period and considerable payback in the 2025-30 period.

Table 0-4: Government balances (undiscounted)

Parliamentary Term	Government investment in all schemes (undiscounted) (£bn)	Additional government tax revenue (undiscounted) (£bn)	Net impact on government balance sheet (undiscounted) (£bn)
15/20	£13.0	£11.0	£-1.9
20/25	£26.4	£30.4	£4.0
25/30	£9.9	£28.7	£18.8
30/35	£4.2	not modelled	not modelled
Total	£53.5	>£70.2	>£16.7

Table 0-5: Government balances (discounted)

Parliamentary Term	Government investment in all schemes (discounted) (£bn)	Additional government tax revenue (discounted) (£bn)	Net impact on government balance sheet (discounted) (£bn)
15/20	£11.4	£9.7	£-1.8
20/25	£20.1	£23.0	£2.9
25/30	£6.4	£18.4	£12.0
30/35	£2.3	not modelled	not modelled
Total	£40.2	>£51.1	>£10.9

The wider co-benefits

The energy efficiency programme will contribute towards economy-wide emissions reductions of 23.6MtCO₂ per annum by 2030, after accounting for direct, indirect, and economy-wide rebound effects. The Committee on Climate Change has predicted the policy gap in emissions reduction targets from the building (residential and non-residential) sector, required to meet the fourth carbon budget in 2025, to be 17MtCO₂.¹⁴ This gap is based on an analysis of the potential across different sectors in the economy and positive action in the buildings sector has been acknowledged as an essential component of meeting our medium to long term carbon targets. The programme modelled in this research delivers 16MtCO₂ pa by 2025, which is a similar scale to the predicted gap.

¹⁴ Committee on Climate Change, *Meeting Carbon Budgets – 2014 Progress Report to Parliament*, July 2014 (Figure 3) http://www.theccc.org.uk/wp-content/uploads/2014/07/CCC-Progress-Report-2014_web_2.pdf

Improved air quality, and warmer, more comfortable homes will improve health and allow for reduced healthcare expenditure. According to recent evidence, for every £1 spent on reducing fuel poverty, a return of 42 pence can be seen in NHS savings.^{15 16}

The programme would result in a more resilient economy, less at risk of shock changes in gas prices, and less reliant on fossil fuels, as described above.

Investing in energy efficiency – a “high” infrastructure priority

To conclude, the targeted programme of upgrading the energy performance of the housing stock, as proposed by the Energy Bill Revolution, would generate a three-fold return in GDP for every pound invested by government, deliver a high Value for Money infrastructure programme, provide warmer homes with lower healthcare expenditure, provide a long term solution to mitigate fuel poverty, create local jobs, reduce gas imports by a quarter, while creating a resilient economy in the medium to long term, and delivering substantial environmental benefits. These benefits can be realised through a programme that will effectively be a net revenue generator for the Government, by 2024.

¹⁶ Chief Medical Officer, *2009 Annual Report*, 2009. http://www.sthc.co.uk/Documents/CMO_Report_2009.pdf

1. Introduction

The Government's energy efficiency strategy acknowledges that improving energy efficiency is fundamental to decarbonising the UK, maintaining secure energy supplies, reducing domestic energy bills, and increasing the productivity of businesses.¹⁷ The strategy also acknowledges the benefits of energy efficiency in mitigating the health detriments associated with cold homes, purporting energy efficiency as one of the most cost-effective ways of making a sustained reduction in domestic heating costs, and removing homes from fuel poverty.

However, successive governments have failed to put in place policies which can meet the scale of opportunity. The building insulation market contracted by 22% in 2013,¹⁸ as the installation of cavity wall insulation fell by 46%, the installation of loft insulation fell by more than 87%, and the installation of solid wall insulation fell by 30%, compared with the number of measures installed under the Carbon Emissions Reduction Target (CERT) in 2012.¹⁹

The Energy Bill Revolution alliance of 200 national organisations has been advocating for energy efficiency to be made a national infrastructure investment priority with a programme to make every low income home highly energy efficient.

Within this context, this research seeks to quantify the macro-economic costs and benefits of investing in energy efficiency in UK building stock, and to analyse the impact of making energy efficiency an infrastructure priority. The analysis is carried out based on a programme to upgrade all of UK's housing stock to an EPC C standard²⁰ by 2035, through a combination of grants and low interest loans, with all low income homes treated by 2025.

The study assesses three main aspects:

1. Quantifying the scale of investment required to upgrade all UK homes to EPC band C by 2035, and associated energy bill and CO₂ savings from installed energy efficiency measures;
2. Modelling tax implications and macro-economic benefits from investment in energy efficiency
3. Developing the quantitative and qualitative evidence to assess investment in energy efficiency as an infrastructure priority

As such, this analysis represents a comprehensive assessment of the impacts of a substantive programme of investment, considering the (inter-related) impact on macroeconomic indicators and the Value for Money indicators used for infrastructure project assessment in standard cost-benefit analysis. All monetary values in the report are expressed in 2013 real terms, unless otherwise stated.

²⁰ Energy Performance Certificates (EPCs) gives a home an energy efficiency rating from A (most efficient) to G (least efficient)

2. Investing in domestic energy efficiency

2.1 Energy efficiency investment scenario

The energy efficiency investment scenario that underpins the macro-economic modelling was developed in discussions with the Energy Bill Revolution (EBR), and was informed by a consortium of organisations supporting the campaign. The scenario sets out target dates, minimum energy performance standards, and proposed financing routes, for delivering a programme of works in both low income and able-to-pay homes. It was developed taking into account the scale of ambition required to deliver meaningful reductions in domestic bills and meet medium term carbon reduction targets, as well as the capacity of the retrofitting industry to deliver the expected level of activity.

The scenario builds on the proposals outlined in the recent paper by Citizen's Advice *'Raising standards, cutting bills'*,²¹ and the Institute for Public Policy Research (IPPR) report *'Help to Heat'*.²² It consists of a programme to upgrade all UK housing to EPC band C, financed via energy efficiency grants for low income homes, and a 0% interest rate loan for able-to-pay homes, both capped at £10k. The £10k cap is indicative, and has been set on the basis of ensuring most homes treated can get up to EPC band C. In practise, the cap could be varied depending on the type of housing stock in each local authority area. Previous research has analysed the cost of improving fuel poor and low income homes to various EPC standards. EPC C was chosen as a relatively cost-effective standard for the UK housing stock, while delivering meaningful energy bill savings for residents. Improving all low income homes to EPC C standard is also an effective way to tackle fuel poverty as these households are most vulnerable to energy prices rises. It is worth highlighting that the average EPC rating in England and Wales is currently D and the average rating for a fuel poor home is EPC band E.²³

A local authority led, street-by-street approach to delivery is intended to ensure effective targeting and drive consumer demand for energy efficiency by engaging households within certain areas, initially low income areas. Trusted local intermediaries market the scheme, provide information and advice and make sure every household receives a free energy efficiency assessment, similar to the current Green Deal assessment. The area-based nature of the scheme would encourage social awareness on the benefits of energy efficiency, as well as reduce costs due to economies of scale. Local bodies would receive funds from national government to oversee the delivery of area-based programmes and make sure programmes are tailored to meet local circumstances, in a similar way to the Green Deal Communities scheme.

²¹ W Baker, *Raising standards, cutting bills: Healthy homes: a costed proposal to end fuel poverty through higher standards and fairer funding*, Citizens Advice Bureau, June 2014

²² R Platt, J Aldridge, P Washan, D Price, *Help to heat: A solution to the affordability crisis in energy*, Nov 2013

²³ Department of Energy and Climate Change, *Annual Fuel Poverty Statistics Report*, 2014

Key dates and targets are as outlined below.

Proposed UK domestic energy efficiency investment scenario

- All low income homes to be retrofitted to EPC C standard by 2025 through energy efficiency grants capped at £10k²⁴
- All able-to-pay homes to be retrofitted to EPC C standard by 2035 financed through 10 year interest free loans capped at £10k
- 500,000 low income houses retrofitted per year by 2018,²⁵ with 2 million treated to EPC C standard by 2020.
- One million deep retrofits supported per year by 2020 in able-to-pay homes

The programme ramp-up rates (numbers of homes retrofitted each year) is shown in Figure 2-2. Although the proposed programme sounds ambitious, discussions by Energy Bill Revolution with industry experts and stakeholders have indicated that the level of activity and ramp-up rates presented are realistic, and the industry can scale up to deliver this level of activity. Additional regulatory drivers and incentives, such as mandatory energy performance standards, council tax rebates, and stamp duty incentives, may need to be considered to drive uptake of energy efficiency retrofits in able-to-pay homes.

This is not an entirely new approach. There is a precedent in Europe of delivering energy efficiency activity at scale in the domestic sector through a combination of low interest loans and other financial incentives. For instance, in response to the KfW loan and grant programmes for energy efficient new buildings and refurbishments in Germany, the industry was able to ramp up the installation rate of energy efficiency measures from 280,000 homes in 2008 (€6.3bn of loans), to 617,000 homes in 2009 (€8.9bn of loans – of which 65% was allocated for the energy efficiency programme).

2.2 Investment required to upgrade homes to EPC C standard

For the purpose of the macro-economic analysis, the first step was to analyse the investment required to upgrade homes to EPC C standard, and an associated package of energy efficient measures. The energy efficiency measures in the package represent a cost-effective route to achieving the target SAP score,²⁶ based on a marginal abatement cost (MAC) curve; the most cost-effective measures are prioritised to be installed earlier in a package, before the less cost-effective measures are considered. The upfront investment for the measures, and the split between government investment and private sector investment from the home, are summarised below (all expressed as investment per home).

²⁴ This proposed target is the result of analysis undertaken by the Energy Bill Revolution campaign. For previous work, see the Citizens Advice report, *Help to Heat Mark 2: Cutting energy bills now*, 2014. The campaign includes key industry stakeholders, including from major construction sector organisations, and large social housing landlords.

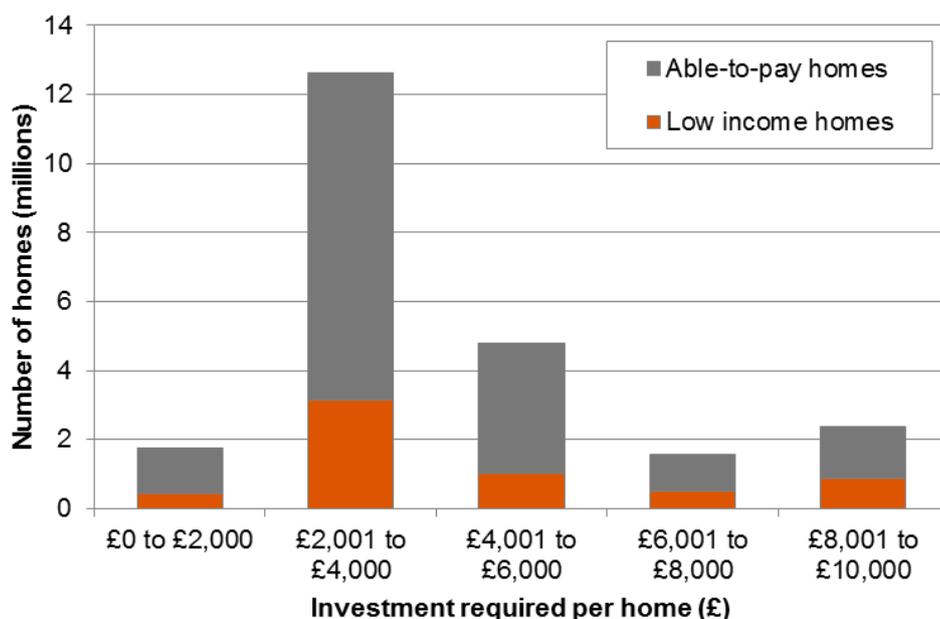

²⁵ UCL Energy Institute, *The KfW experience in the reduction of energy use in and CO₂ emissions from buildings: operation, impacts and lessons for the UK*, 2011

²⁶ The Standard Assessment Procedure (SAP) is the methodology used by the Government to assess and compare the energy and environmental performance of dwellings. Its purpose is to provide accurate and reliable assessments of dwelling energy performances that are needed to underpin energy and environmental policy initiatives.

- Low income homes:
 - Investment required to upgrade homes to EPC C: £4,376 (£4,256 for measures, plus £120 energy assessment fee)
 - Government investment: The full £4,376 is modelled to be subsidised by a government grant
- Able-to-pay homes:
 - Investment required to upgrade homes to EPC C: £4,385 (£4,265 for measures, plus £120 energy assessment fee)
 - Government investment support: £1,595 (£1,475 for interest rate subsidies²⁷ plus £120 energy assessment fee) is modelled to be covered by the Government.
 - Investment by the home / private sector: £4,265, modelled to be covered by the homeowner in instalments over 10-years – i.e. the principal loan value of the retrofit works

Figure 2-1 shows the spread of investment within the housing stock for low income homes.

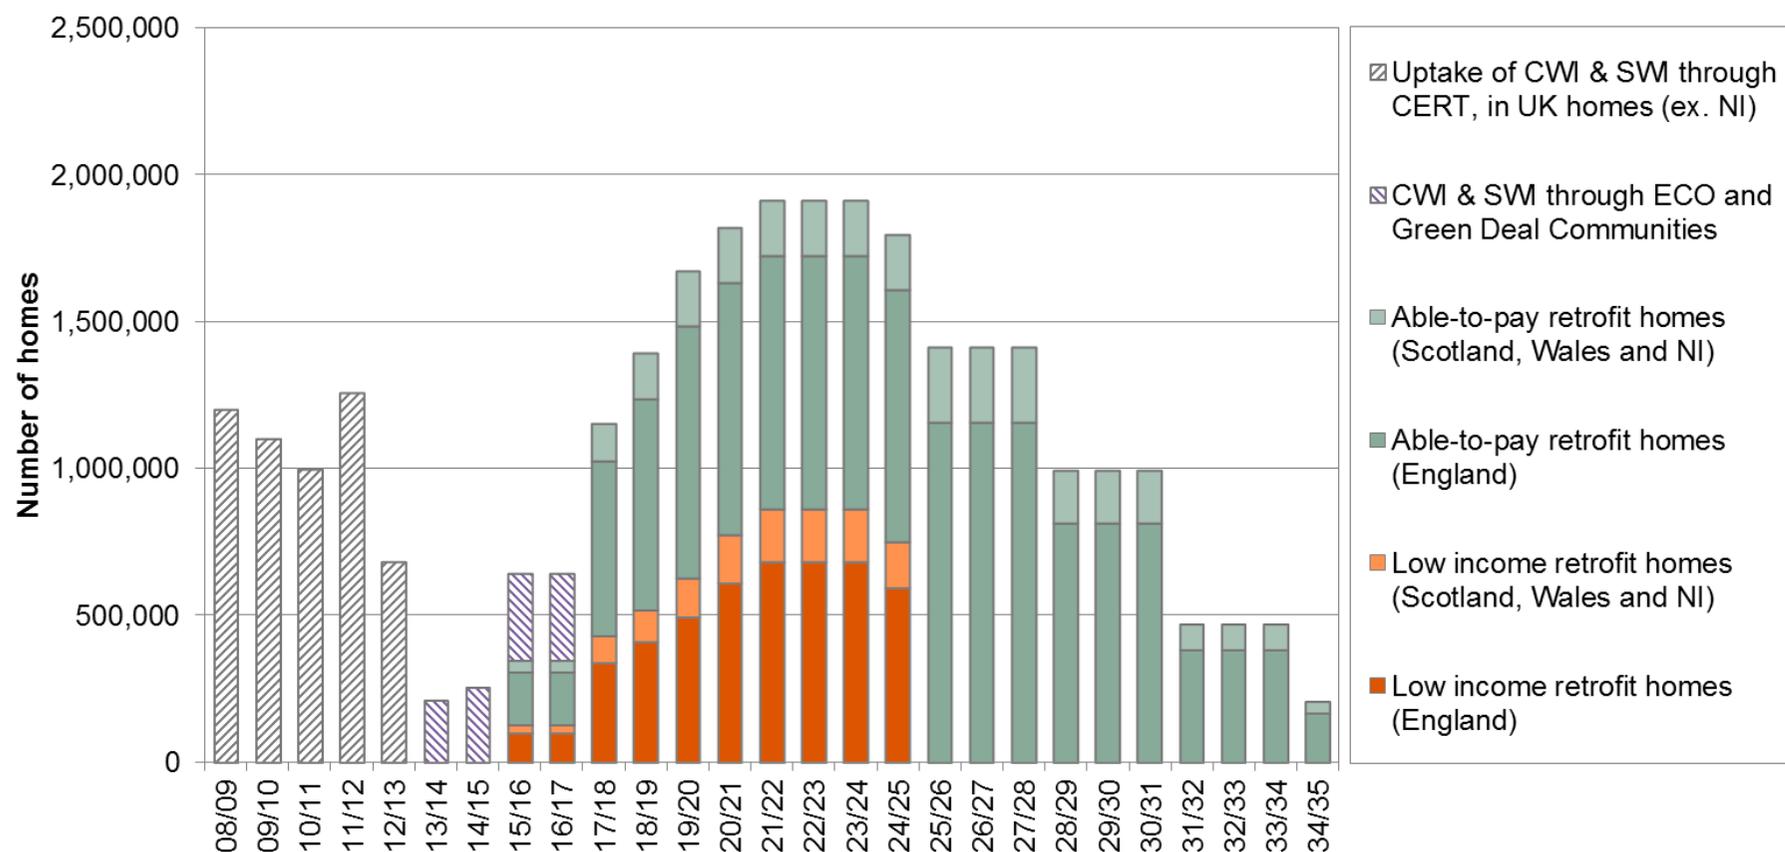

Figure 2-1: Spread of investment within the housing stock

The methodology for calculating the investment requirement is summarised in Section 2.3 and detailed further in Section 6.3. Example packages of measures are shown in Appendix 3 – Technical modelling methodology.

²⁷ For the able-to-pay homes, the current scenario assumes that the Government does not act as the loan provider. Instead, the Government is using a combination of guarantees and direct public subsidies to reduce the interest rate to 0%. This is done by the Government guaranteeing the debt of the Green Deal Finance Company (reducing the interest rate to the consumer from 8% to 5%), and then directly subsidising the remaining loan interest over a 10-year period (i.e. taking the effective interest rate from 5% to 0%). The total government investment is shown as the undiscounted value of both the guarantee and the direct subsidy and assumed to be incurred in the year the measures are installed. In effect, if the direct subsidy is spread out over the 10-year period, the NPV of the Government investment will be smaller.

Figure 2-2: Programme ramp-up rates, in terms of the number of homes retrofitted²⁸

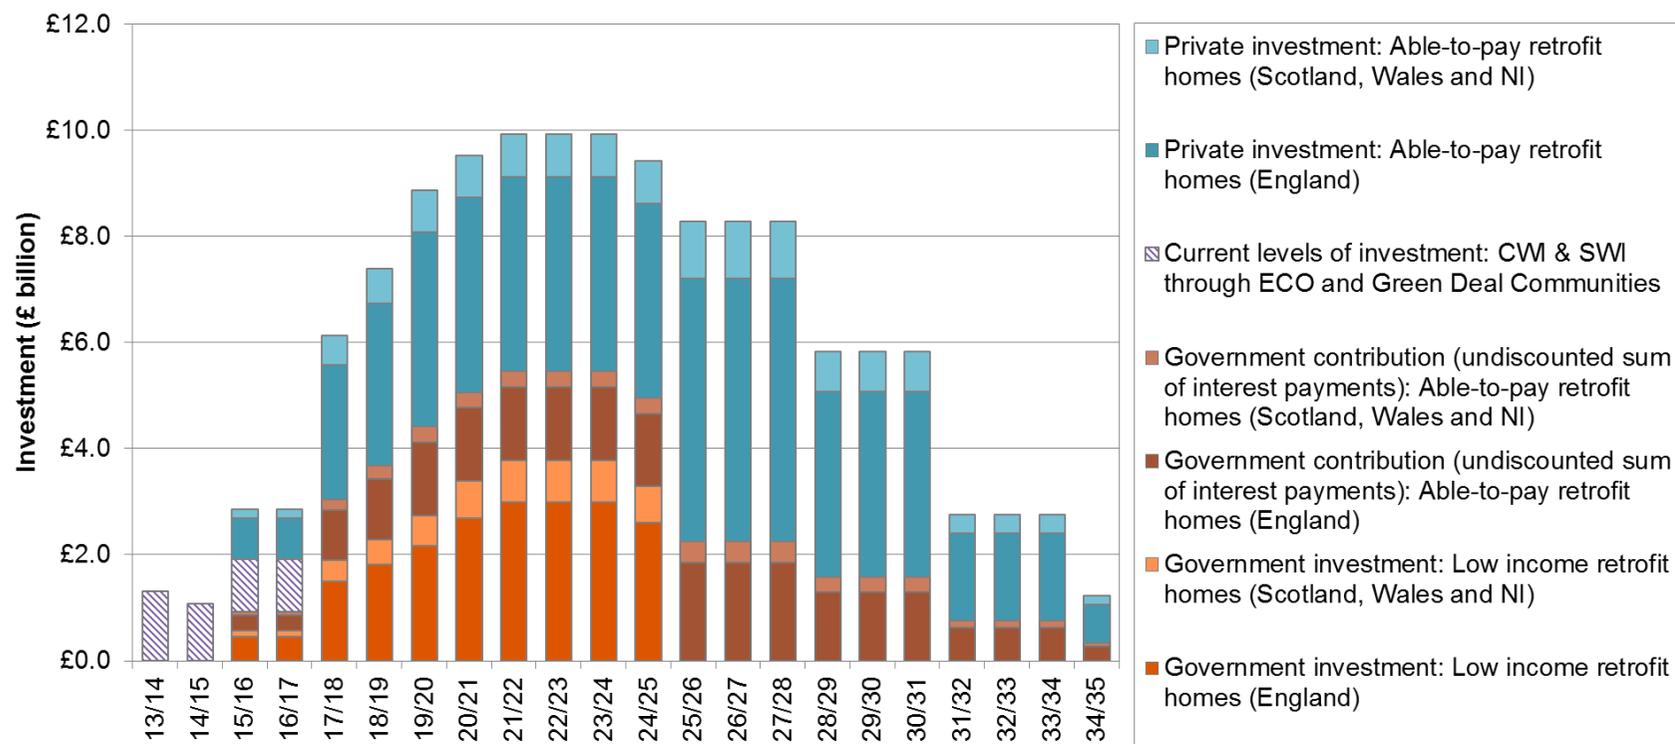

²⁸ The uptake of cavity wall insulation (CWI) and solid wall insulation (SWI) through the Carbon Emissions Reduction Target (CERT) scheme, in UK homes (excluding Northern Ireland (NI)) is taken from two data sources. For the period 2008/09, it is taken from Energy Saving Trust, *CERT Summary Report (Q16) by Local Authority, 2012*, <http://www.energysavingtrust.org.uk/Publications2/Housing-professionals/HEED-PDFs/HEED-publications-for-UK/CERT-reports-Q16/CERT-Summary-Report-Q16-by-Local-Authority> For the period 2012/13 it is taken from DECC, *Statistical release: Experimental statistics, Estimates of Home Insulation Levels in Great Britain: July 2013*, https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/240190/statistical_release_estimates_home_insulation_levels_gb_july_13.pdf

2.2.1 Total investment in upgrading all UK homes

The investment in the retrofit programme each year, by both the Government and the private sector (i.e. investment made by Green Deal Providers or households themselves in energy efficiency improvements), is shown in Figure 2-3 (and shown in table format, in Appendix 4 – Programme investments by year). For the whole UK housing stock, the total government investment in the low income scheme is £26.1bn, and in the able-to-pay scheme is £27.4bn. In the first two years of the programme, the investment made by the Government, and the private sector investment, are each of a similar scale to the current ECO funding.

Figure 2-3: Programme investment by the Government and the private sector²⁹

²⁹ For the able-to-pay homes, the graph shows the £1,595 investment from the Government, in the year that the retrofit works are done. The investment from the private sector in able-to-pay homes is also shown in the year that the retrofit works are done. As a result, the graph shows the up-front investment in retrofit activity, rather than the value of the loan repayments spread over 10 years.

The investment in the retrofit programme, by both the Government and the private sector, is shown by parliamentary term in Table 2-1. For the first parliamentary term, the total investment in the low income scheme is £8.1bn, and the Government contribution to the able-to-pay scheme is £4.9bn.

Table 2-1: Programme investment requirements from government and private sector, by parliamentary term

Parliamentary Term	investment in low income scheme (undiscounted) (£bn)	Government contribution to able-to-pay scheme (undiscounted sum of interest payments) (£bn)	Private sector investment in able-to-pay scheme (undiscounted) (£bn)	Government investment in all schemes (undiscounted) (£bn)	Total investment (undiscounted) (£bn)
15/20	£8.1 ³⁰	£4.9	£13.1	£13.0	£26.1
20/25	£18.1	£8.4	£22.3	£26.4	£48.7
25/30	£0.0	£9.9	£26.6	£9.9	£36.5
30/35	£0.0	£4.2	£11.2	£4.2	£15.3
Total	£26.1	£27.4	£73.2	£53.5	£126.7

2.2.2 Domestic energy bill savings

The energy bill savings generated from the energy efficiency retrofit packages are shown in Table 2-2. As the measures are proposed to be financed using grants for low income homes and interest free loans for the able-to-pay homes, the net energy bill savings are calculated differently for the two groups. Also, the re-bounce effect (also termed as comfort take³¹) is likely to impact the net benefit to fuel poor homes. This phenomenon is explained below:

- For the low income homes, the savings include in-use factors³² and a 'comfort take' factor of 40%³³
- For the able-to-pay homes, the savings include in-use factors and are net of the energy efficiency loan repayments. During the 10 years duration of the loan, some homes may be paying more in loan repayments, than they receive in energy bill savings, as the analysis was done without applying the 'Golden Rule' (savings in each year being greater than the loan repayment for that year). However, after year 10, the homes will receive 100% of the savings.

³⁰ This excludes £2bn Energy Companies Obligation (ECO) funding, expected to be invested by the utilities for years 15/16 and 16/17, to meet ECO targets. Assuming similar level of ECO investment per annum to 2020, the additional investment required in the first parliamentary term is £3.1bn.

³¹ Once energy efficiency measures are installed, the expected energy savings may not be realised as fuel poor homes can now afford to heat their homes adequately. The proportion of energy savings from energy efficiency measures that are not realised due to homes now heating homes for longer or to a higher temperature is referred to as 'comfort take'. There is a range of important health benefits associated with comfort take, as discussed in Section 4.5.

³² In-use factors have the effect of reducing the predicted energy savings from energy efficiency measures, by a specified percentage per measure. The percentage reduction is based on the application of evidence and research and expert recommendation, as adopted by the Department of Energy and Climate Change for the Green Deal and Energy Companies Obligation.

³³ Programmes such as CESP (that focus on low income areas and are likely to impact a higher number of homes in fuel poverty) allow for a 40% comfort take when predicting CO₂ savings. A similar 'comfort take' factor has been used for the purpose of this analysis and applied to all low income homes as a conservative assumption.

The energy bill savings include energy price inflation over time, in line with DECC's central energy forecast scenario.³⁴

Table 2-2: Energy bill savings associated with the energy efficiency investment programme

Average energy bill savings for low income homes	£408 per annum £245 per annum after accounting for comfort take
Average energy bill savings for able-to-pay homes (after energy efficiency loan repayments)	£416 before loan repayment Net benefit of £203 per annum (after able-to-pay energy efficiency loan repaid) ³⁵
Total energy bill savings across the housing stock, after comfort take (includes energy price inflation)	£8.61 billion per annum Net benefit of £4.95 billion per annum (after able-to-pay energy efficiency loans repaid)

2.2.3 CO₂ savings

The CO₂ savings generated from the energy efficiency retrofit packages are shown in Table 2-3. The CO₂ savings take account of grid decarbonisation over time, in line with the Interdepartmental Analysts' Group Guidance for Policy Appraisal.³⁶ The yearly profile of carbon savings is shown in Table 4-2.

The Committee on Climate Change has published analysis of the abatement needed to meet the fourth carbon budget in 2025. The predicted 'policy gap'³⁷ is 10MtCO₂ for residential buildings, and 7MtCO₂ for non-residential buildings, as shown in Figure 2-4. The programme modelled in this research delivers 16MtCO₂ pa by 2025 (as shown in Table 4-2). This is a similar scale to the predicted gap in emissions reduction from the building sector (both domestic and non-domestic).³⁸

The CO₂ savings associated with the energy efficiency programme are shown in Figure 2-3. To put the total CO₂ savings across the housing stock into context, the carbon savings are equivalent to the net annual carbon emissions reductions from 3,840 large (3MW) offshore wind turbines, or 13,380 intermediate (850kW) on-shore wind turbines. Alternatively, the annual CO₂ savings would be equivalent to the annual carbon emissions reductions from removing 10.4m cars (36% of the cars in Great Britain) from the road.³⁹

³⁴ Department of Energy and Climate Change, *Updated energy and emissions projections 2013*, September 2013, https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/239937/uep_2013.pdf

³⁵ This figure represents energy bill savings averaged over a 20-year lifetime for a package of measures. The loan repayment would be twice as large for the first 10 years after retrofit, reducing to £0 thereafter, once the loan has been repaid.

³⁶ Department of Energy and Climate Change, Inter-departmental Analysts' Group (IAG) Guidance for Policy Appraisal, 2011

³⁷ The term 'policy gap' is used by the Committee on Climate Change to express the difference between the emissions projections under current policies, and the emissions projected by the cost-effective path that would meet the fourth carbon budget, i.e. the 'gap' in emissions reductions resulting from insufficient policy framework.

³⁸ Committee on Climate Change, *Meeting Carbon Budgets – 2014 Progress Report to Parliament*, July 2014 (Figure 3) http://www.theccc.org.uk/wp-content/uploads/2014/07/CCC-Progress-Report-2014_web_2.pdf

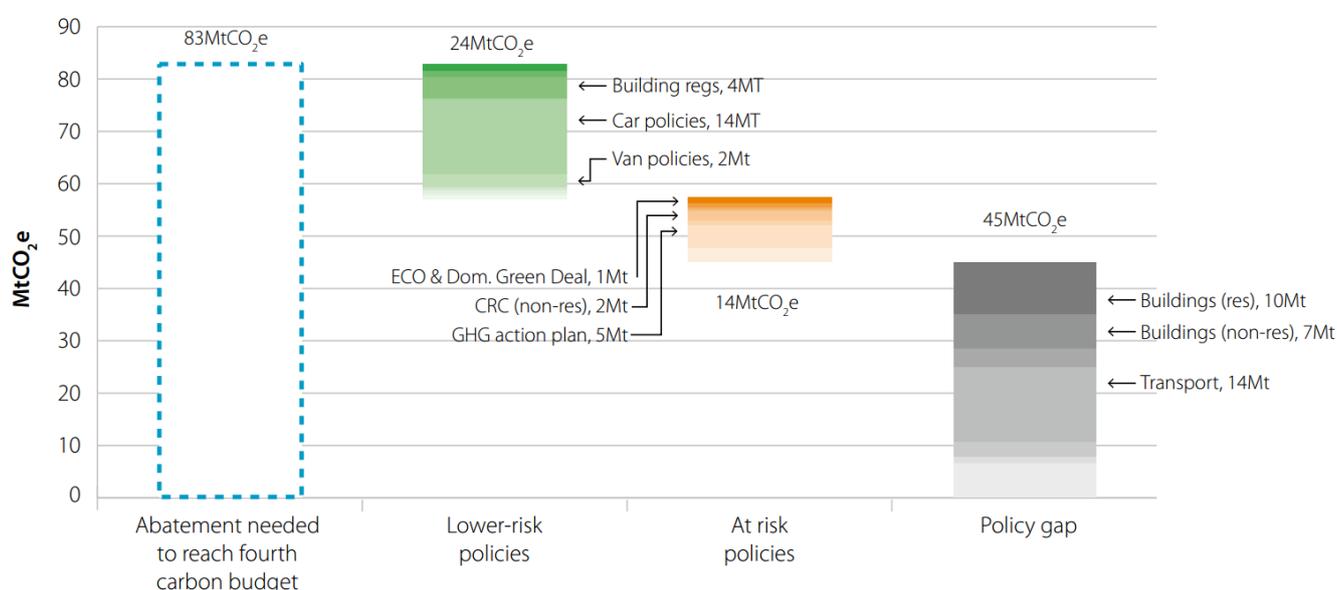

³⁹ Calculation based on average CO₂ emissions per km driven, average annual car mileage, and total number licensed cars on the road, taken from the following sources:

To provide a comparison with the average CO₂ savings for individual homes, as shown in Table 2-3, the carbon emissions from one passenger's one-way flight from London to New York, would be approximately 626 kgCO₂.⁴⁰

Table 2-3: Carbon savings associated with the energy efficiency investment programme

Total (net) CO₂ savings across economy	23.6 million tonnes CO₂ per annum
Average CO₂ savings for low income homes	1,092 kgCO₂ per annum (655 kgCO ₂ per annum including comfort take)
Average CO₂ savings for able-to-pay homes	1,079 kgCO₂ per annum

2.3 Approach to technical modelling and key constraints

The analysis has been carried out using 2012 English Housing Survey (EHS) data to assess the investment required to improve all homes to an EPC C standard. Each home in the EHS dataset is assigned an 'energy archetype', based on its baseline energy consumption and key physical characteristics. Energy efficiency improvement measures are modelled incrementally to determine the most suitable package of measures for each archetype. The energy efficiency measures in the package represent a cost-effective route to achieving the target SAP score, based on a marginal abatement cost (MAC) curve; the most cost-effective measures are prioritised to be installed earlier in a package, before the less cost-effective measures are considered. The modelling methodology is explained in detail in Appendix 3 – Technical modelling methodology.

As the analysis is based on English Housing Survey data, it does not provide a detailed picture of the investment requirement to improve homes in the devolved nations. Investment in improving homes in devolved nations has been extrapolated based on average investment in improvement for homes in England.

The £10,000 cap⁴² on both grants and interest-free loans is intended to avoid a large amount of money potentially being spent on improving a relatively small number of extremely 'hard-to-treat' homes. As a result of this, some homes are not retrofitted to EPC C standard.⁴³ 15% of low income homes, and 16% of able-to-pay homes, do not achieve EPC band C, due to the limit of investment support per home. This is often due to the home having a particularly poor energy efficiency rating before the retrofit, or in need of solid wall insulation; hence requiring a high level of investment to achieve the minimum performance standard. However, despite the cap, these properties would still see a significant improvement in their energy performance.

⁴² The £10k cap is indicative, and has been set on basis of ensuring most homes treated can get up to EPC band C. The cap could be varied in practice, depending on type of housing stock in local areas, and could vary by local authority.

⁴³ Energy efficiency measures are modelled to be added to the package of measures, until either: the home is modelled to have achieved EPC C, or the package of measures reaches its maximum investment value, before going over the £10k cap.

3. Modelling the macroeconomic impact of energy efficiency investment

3.1 Summary of findings

- In terms of GDP (Gross Domestic Product), Cambridge Econometrics modelling estimates a return of £3.20 per £1 invested in energy efficiency measures by government. In relative terms, as a result of the energy efficiency investments, GDP will be 0.6% higher in 2030 (£13.9bn).
- The investment in funding and incentivising take-up of energy efficiency measures by governments is self-financing. The increased economic growth leads to higher tax intake, cumulatively £51.1bn by 2030 or £1.27 per £1 invested throughout the whole period (in discounted terms).
- Cambridge Econometrics estimate a net increase in annual employment of up to 108,000 over the period 2020-2030, with most jobs created in the services and the construction sectors.

3.2 Approach to economic modelling

A scenario analysis was undertaken using the MDM-E3 model of the UK economy and energy system. A baseline scenario was set to compare the alternative investment policy scenario against. The baseline scenario was constructed using the latest data from the Office of National Statistics (ONS) from 2012. For the years over 2013-2018, the latest economic projections for all components of final expenditure, income, employment, wages, and inflation, were obtained from the recent economic growth forecast from the Office of Budgetary Responsibility (OBR)⁴⁴. These OBR growth rates were applied to the latest historical data to obtain a series of consistent projection to 2018. For later years where no official projections were available, Cambridge Econometrics' updated economics forecast was used to extend the projections to 2030. Energy demand projections and end-user domestic prices for gas and electricity were derived from the most-up-to-date central projections from DECC over 2013-2030 (updated in September 2013).⁴⁵

The energy efficiency scenario differs from the baseline in investment expenditure and domestic fuel use as a result of efficiency measures. Investment in dwellings leads to a positive economic impact on industries dependent on the construction sector. Changes in expenditure on energy affect consumption outlays and thus revenues of consumer-facing industries and their supply chains.

Change in overall output also affects government tax intake through several avenues. Impact on consumer expenditure affects consumption tax intake (primarily VAT). Changes in industry revenues are reflected in wages and profits, these in turn affect government revenue through taxation of labour (income tax and national insurance contribution) and profits (corporate tax).

The various measures modelled have different time horizons, which results in different impacts arising from the timing of investments and energy savings:

- Energy efficiency measures affect the construction sector (and supply chain) primarily at the time the measure is implemented

⁴⁴ OBR's latest economic projections released in November 2013 were used

⁴⁵ <https://www.gov.uk/government/publications/updated-energy-and-emissions-projections-2013>

- Resulting benefits to consumers, in the form of lower energy bills and improved health persist over the lifetime of the measures⁴⁶
- Capital repayments by able-to-pay homes are evenly spread over a ten-year period after the investment is made.

In order to assess the macroeconomic impacts on the UK economy, the modelling must explain all the relevant flows of income and expenditure in the economy. The main channels (as explained by MDM-E3) are:

- Change in investment includes expenditure of measures financed through funding provided for low income homes as well as loans for able-to-pay homes
- Higher energy efficiency of homes leads to lower energy demand and therefore lower energy bills. The reduction in demand for gas in heating (and for gas used in the power sector which is then consumed by homes for heating) would substantially reduce imports of natural gas.
- Lower energy bills (after accounting for comfort take) lead to higher expenditure on other goods and services. In the case of able-to-pay homes, this is at first largely offset by loan repayments in the first 10 years following retrofit

In total, there is £127.5bn of investment in energy efficiency measures over a 20-year period. This constitutes £73.2bn from able-to-pay homes (supported by £27.4bn of loan support schemes from the Government) with the rest being direct government funding to low income homes (£26.9bn). This investment thus does not directly affect the spending of low income homes; it does however affect expenditure in able-to-pay homes throughout the period of repayment. By paying for the interest and guarantees, the Government makes the loans 27% cheaper on average for able-to-pay homes.

3.3 Macroeconomic benefits of investing in domestic energy efficiency

The combination of the construction stimulus and lower energy bills outweigh the repayment costs, leading to an increase in GDP of 0.6% in 2030 (13.9bn). The reduced expenditure on gas and electricity is displaced by repayment of the capital investment in the energy efficiency measures and, where net savings arise, spending on other goods and services in the economy.

In the short-to-medium term, there is therefore a positive stimulus in the construction sector (and supply chain) to manufacture and install the various energy efficiency measures (at the expense of the gas and electricity sectors, and supply chains). This yields positive macroeconomic benefits, since gas is heavily imported, whereas the demand generated by the energy efficiency programme yields output and jobs in the construction sector and supply chain (which is predominantly UK based).

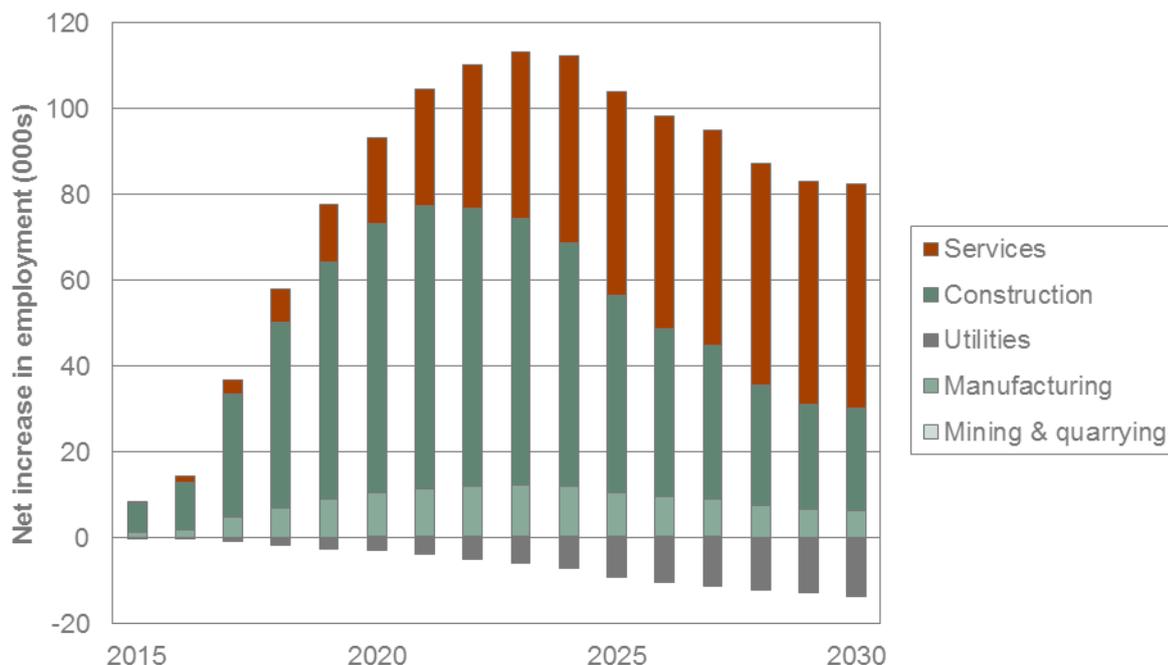

In the longer term, as the energy savings accumulate, there is a considerable net saving to homes (after paying for the efficiency measures) allowing homes to spend much more on other goods and services in the economy. Although a proportion of these goods and services are supplied by imports, a considerable proportion is supplied by UK based businesses. Towards the end of the period modelled the increased sector output and employment is predominantly in the service sectors of the

⁴⁶ The weighted average lifetime of a package of measures comes to 20 years. Some measures have a short lifetime (for example, 10 years for draught proofing), and some measures have a long lifetime (for example, 42 years for cavity wall insulation). Measure lifetimes taken from the Department of Energy and Climate Change guidance document, *Energy Companies Obligation (ECO): Measures Table, 2014*

<https://www.ofgem.gov.uk/ofgem-publications/83100/copyofecomeasurestable-mar2014url.pdf>

economy (see Figure 3-1). Note that the jobs generated in the construction sector mirror the investment profile in Figure 2-3, while the increasing jobs in services reflects the increasing net savings from the energy efficiency measures over time that can be spent on other sectors of the economy. At the peak, employment increases by 108,000 in 2023 and as the investment stimulus is reduced there is a long term net increase in employment of around 70,000 jobs by 2030.

Figure 3-1 Employment impact, by sector

Overall, the positive economic impact leads to an increase in net employment of around 70,000 new jobs by 2030, most of them in services and some in the construction sector and manufacturing supply chains. There are reductions in employment in utilities. In the report *'Jobs, Growth and Warmer Homes'*, Cambridge Econometrics modelling estimated an additional 127,000 jobs would be generated by the energy efficiency programme by 2027. In the report *'Jobs, Growth and Warmer Homes'*, the energy efficiency measures were fully funded by government. In the Energy Efficiency scenario in this report, able-to-pay households fund the energy efficiency measures (where they are able to do so) and are only incentivised (not fully-funded) by government. As a result of the self-financing of measures by able-to-pay households the net gains are smaller because the investment in energy efficiency measures is at the expense of consumer spending on other goods and services. The corollary of able-to-pay households investing directly (with support), is that in this analysis the Government finances are improved and the measures are fully funded (for both governments and homes).

3.4 Government balance sheet

The positive impact on the economy generates enough additional (net) tax revenue to more than pay for the measures. In discounted terms, there is an additional £51.1bn in tax revenues by 2030 (compared to the Government cost of the programme of £40.2bn [2015-34] in discounted cash flow terms), bringing in around £1.27 for every £1 spent, such that the programme would be cost effective for the Government.⁴⁷

As with any infrastructure programme, this programme requires upfront investment with the economy-wide gains from efficiency generating additional tax revenue over the lifetime of the investments. In undiscounted terms, the infrastructure programme would worsen the government balances by around £1.9bn in the next parliamentary term. However, in the subsequent parliamentary term of 2020-25 the additional revenues would outweigh the investment (and investment support) by government and improve the government balances in net terms by around £4bn. Over the 2025-2030 parliamentary term, the net improvement to the government balance sheet (in real terms) would be £18bn (see Table 3-1 and Table 3-2).

Table 3-1: Government balances (undiscounted)

Parliamentary Term	Investment in all schemes (undiscounted) (£bn)	Additional government tax revenue (undiscounted) (£bn)	Net impact on government balance sheet (undiscounted) (£bn)
15/20	£13.0	£11.0	£-1.9
20/25	£26.4	£30.4	£4.0
25/30	£9.9	£28.7	£18.8
30/35	£4.2	not modelled	not modelled
Total	£53.5	>£70.2	>£16.7

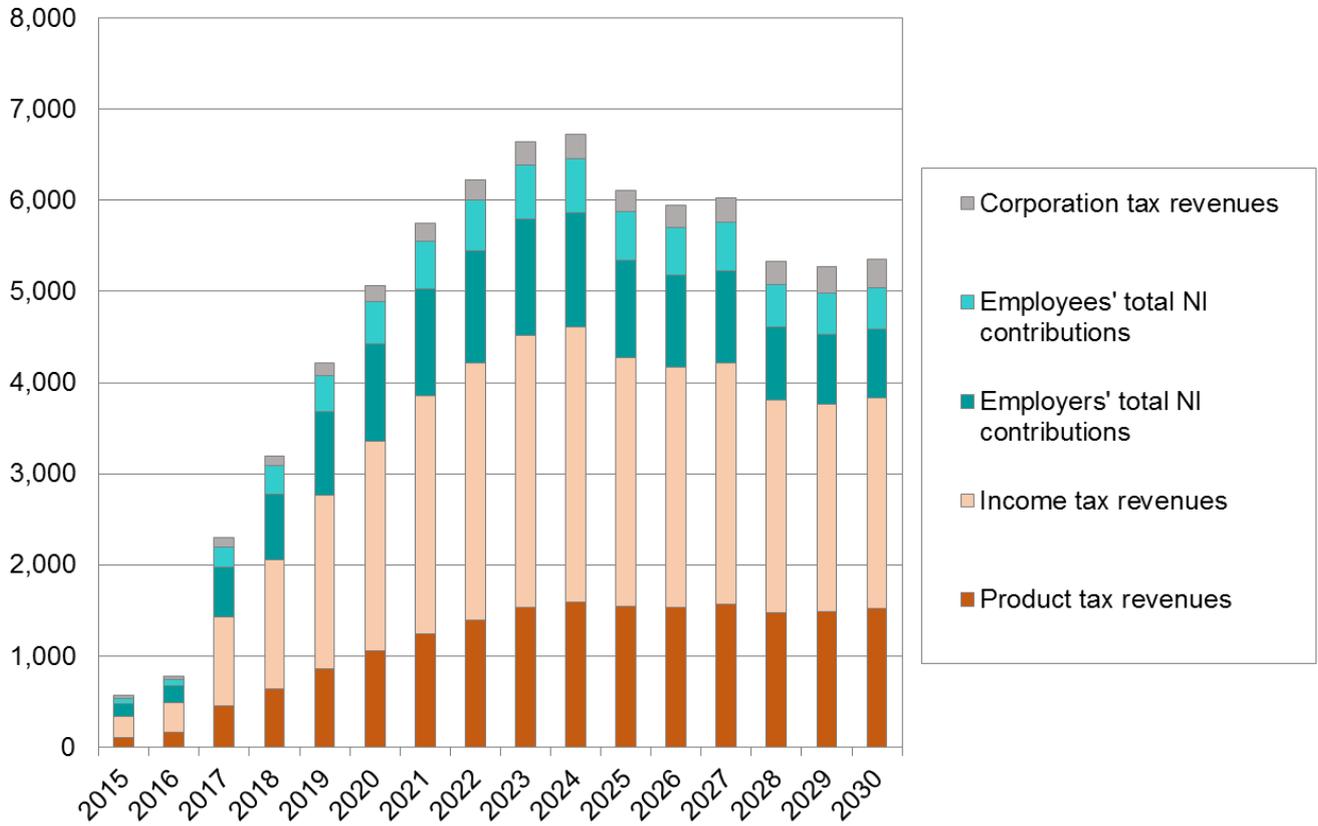

Table 3-2: Government balances (discounted)

Parliamentary Term	Government investment in all schemes (discounted) (£bn)	Additional government tax revenue (discounted) (£bn)	Net impact on government balance sheet (discounted) (£bn)
15/20	£11.4	£9.7	£-1.8
20/25	£20.1	£23.0	£2.9
25/30	£6.4	£18.4	£12.0
30/35	£2.3	not modelled	not modelled
Total	£40.2	>£51.1	>£10.9

⁴⁷ Both the revenue and expenditure numbers are discounted using the social discount rate of 3.5%.

By 2030, around 43% of the additional tax revenue is from income tax, 28% from taxes on products (e.g. VAT) and 23% from social security contributions and 6% from corporation tax (see Figure 3-2).

Figure 3-2: Net change in government tax revenue (£m)

4. Energy Efficiency – An infrastructure priority

4.1 Summary

There is a strong rationale for treating energy efficiency in UK housing stock as an infrastructure priority:

- 1) Cambridge Econometrics modelling estimates the Cost Benefit Ratio (Value for Money) indicator of the programme to be 2.27:1, which classifies the infrastructure programme as “High” Value for Money.
- 2) Improved air quality, warmer and more comfortable homes will improve health and allow for reduced healthcare expenditure, which would add further to the Value for Money indicator.
- 3) An energy efficiency programme will contribute towards economy wide emissions reductions of 23.6MtCO₂ pa by 2030, after accounting for direct, indirect, and economy-wide rebound effects, contributing to meeting the fourth carbon budget.
- 4) Investment in energy efficiency in the domestic sector will result in 26% reduction in imports of natural gas in 2030 worth £2.7bn in that year.
- 5) As the economy becomes less gas intensive, the more resilient it becomes to shock changes in gas prices. A 50% gas price spike in 2030, leads to a 0.2% GDP decrease in the baseline scenario, but only a 0.15% decline in the Energy Efficiency scenario.

4.2 Approach to assessing Value for Money

Infrastructure projects are assessed on a Value for Money indicator called the Cost Benefit Ratio (CBR), which represents the ratio of discounted benefits to discounted investments over the lifetime of a project, using the economic tool of Cost Benefit Analysis (CBA). It is an attempt to compare, in monetary terms, the investment cost by government against the benefits to society (welfare). Often the benefits are not monetary and can include things such as health benefits and reduced greenhouse gas emissions. The purpose of the CBA calculation and the CBR indicator is to provide a metric that allows for comparison across projects.

Macroeconomic modelling, of the sort undertaken here, does not lend itself readily to this concept of Value for Money. The central indicator from the economic modelling, GDP, is an aggregate of all production in the economy and does not therefore distinguish what is being produced. The implication of this is that if society became less healthy and required more healthcare expenditure, this would show up as an increase in GDP but would clearly not be a societal (welfare) benefit.

Consumer spending is a better measure of welfare than GDP but it is not a perfect measure. Real (i.e. adjusted for inflation) consumer spending is a measure of the goods and services that households buy. If it is assumed that households derive utility from what the household buys, then higher spending suggests higher utility and welfare. There are, however, various caveats to this and each of them can be considered in the context of this analysis.

- Firstly, homes may increase their spending to try to compensate for some change in circumstances. In a year when the weather is colder, homes spend more on heating, but they are not better off than during the previous (warmer) year. However, in this analysis, between the baseline and scenario modelled there are no changes in external circumstances.

- Secondly, if the increase in spending is financed out of saving or by higher borrowing, homes are not better off even if spending is higher, but again, this is not the case in the scenario analysis presented here; in fact savings are increased (slightly) and so there is an additional net benefit.
- Thirdly, if the increase in spending has been achieved through a subsidy financed by government borrowing, this can be regarded as homes borrowing from the future (because eventually taxes will have to be raised). This is not applicable in this analysis since governments are able to more than recoup the financing and are better off in net present value terms as a result of the energy efficiency investment. The net benefit to government (after the investment in the measures) should therefore be included as a net benefit since taxes could otherwise be lowered and consumption further increased.
- Finally, if the increase in spending is financed by lower company profits, homes will eventually be affected through, for example, a reduction in the value of wealth held in equities (e.g. through pensions). This is not the case in this analysis as profits (in real terms) increase and so the discounted net change in profits (after corporation tax) should also be included.

The latter three points all relate to the distribution of income, and show the weakness of assuming that shifts in consumer spending can always be treated as a measure of welfare when income and income distribution are changing. Overall, it is argued that the change in consumer spending (with the other balance sheet adjustments), is a suitable measure of welfare, in this context.

The approach to assessing Value for Money does not account for the distribution of benefits across households. However, as low income homes receive grants directly, it is reasonable to assume that the distribution of net benefits accrue disproportionately to low income homes. Moreover, the programme envisages treating all homes that are currently below EPC band C, which is a large proportion of the UK housing stock. Since the net benefits are therefore reasonably well distributed it is reasonable to proxy the increase in consumer spending as a measure of improved societal welfare, which would not *necessarily* be the case if the benefits accrued directly to a small subset of society.

Given the above, our approach to assessing the Value for Money of the energy efficiency programme is to calculate the benefit as the net impact on consumer spending and subtract any net impacts on balance sheets (government, commercial or households). The impact on consumer spending is net of the loan repayments on the energy efficiency measures by households because it would not be valid to include the loan repayment (the purchase of the energy efficiency measures) in the net benefit stream.

4.3 Value for Money

The energy efficiency programme envisaged in Section 2 impacts on consumer spending, and on government, company and household balance sheets, which along with a monetary valuation of the emissions reduction of the programme sum to the net societal (welfare) benefits of the programme. The discounted net benefit stream includes:

- the discounted net change in household consumption between scenarios (net of the investment by able-to-pay households)
- the monetised value of the carbon emissions savings using The Treasury's Green Book guidelines.⁴⁸
- the discounted net change in company profits (after corporation tax)
- the discounted net change in government balances
- the discounted net change in consumer savings

The aggregated net societal benefits are then compared to the direct investment cost to government (see Table 4-1) to determine the Value for Money CBR ratio of the programme. Following the Treasury's Green Book guidance, a social discount rate of 3.5% has been applied.

Table 4-1: Value for Money of the energy efficiency investment programme

Total discounted benefit of energy efficiency investment programme, of which:	£91,186m
<i>Discounted net benefit to consumer spending</i>	£60,651m
<i>Discounted benefit of net government balances</i>	£9,960m
<i>Discounted benefit of net increase in profit</i>	£15,111m
<i>Discounted benefit of net increase in savings</i>	£337m
<i>Discounted benefit of reduced emissions</i>	£5,127m
Total discounted investment in energy efficiency programme by government	£40,214m
Cost Benefit Ratio (CBR) (total benefit / total investment)	2.27

The value of health benefits of improved efficiency from the comfort, warmth, and improved air quality to homes, is uncertain to quantify in monetary terms (estimates from the literature are included in Section 4.4) and has therefore not been included in the formal Cost Benefit Ratio. However, there is evidence that health benefits will arise which would add to the central value of 2.27.

⁴⁸ HM Treasury, *The Green Book: Appraisal and Evaluation in Central Government*, 2011
https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/220541/green_book_complete.pdf

Given the uncertainty in calculating CBRs different qualitative assessments are made to the range of plausible CBR, by government,⁴⁹ such that:

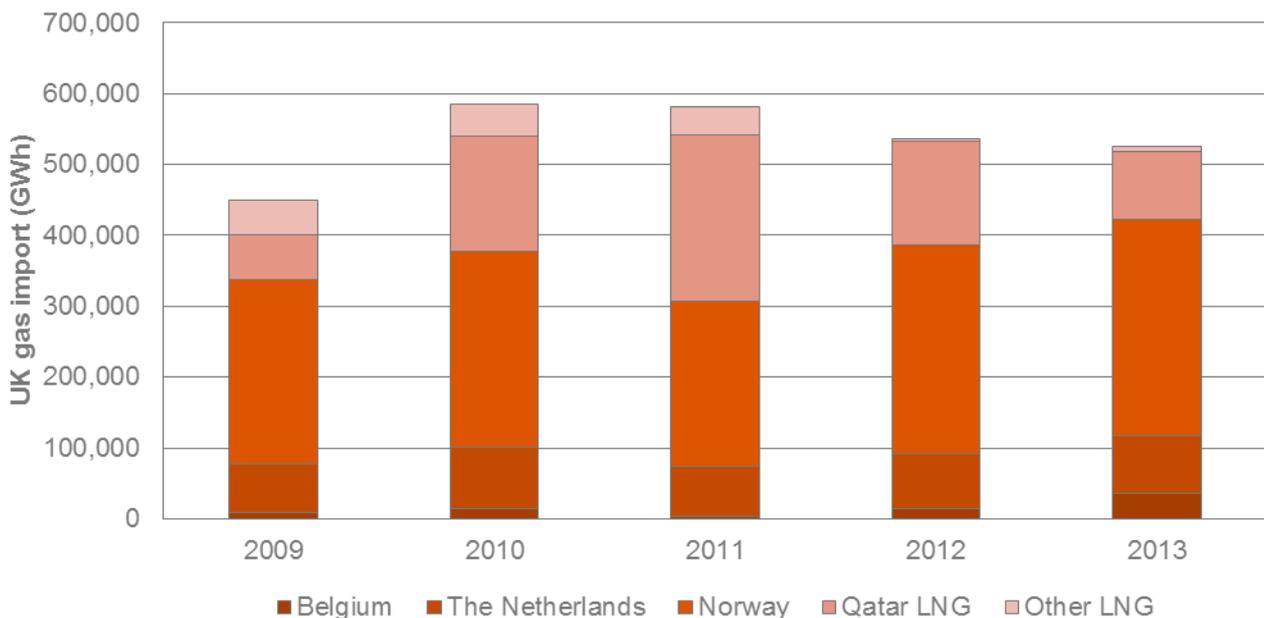

- a CBR between 0 and 1.0 represents 'poor' Value for Money
- a CBR between 1.0 and 1.5 represents 'low' Value for Money
- a CBR between 1.5 and 2.0 represents 'medium' Value for Money
- a CBR between 2.0 and 4.0 represents 'high' Value for Money
- a CBR above 4.0 represents 'very high' Value for Money

In this context, a programme of investing in energy efficiency measures in homes can be considered a 'high' Value for Money infrastructure programme.

4.4 Improved energy independence and economic resilience

The energy efficiency measures lead to a 19% decrease in natural gas consumption by 2030, which leads to a reduction of 26% in imports worth £2.7bn. Currently, most of the UK's imported gas is sourced from Qatar, in the form of liquefied natural gas (LNG), and from various pipelines to Europe (Norway, Belgium and the Netherlands), see Figure 4-1.

Figure 4-1: UK gas imports by source country

The energy system is also more resilient to gas price volatility as a result of the increased efficiency. In each of the scenarios (baseline and energy efficiency), the impact of a gas price spike in 2030 was assessed. In the baseline, a 50% price hike, led to a 0.2% GDP decrease, but only a 0.15% decline in the Energy Efficiency scenario. For consumers directly, the gas price spike leads to an increase in energy bills of £220 per home (in 2030) against the baseline. As a result of the efficiency measures, this is reduced by £60 to £160 per home.

4.5 Avoided cost of environmental externalities

Economy-wide CO₂ emissions are reduced by around 23.6MtCO₂ pa by 2030, after accounting for direct, indirect, and economy-wide rebound effects. For the central estimate of the social cost of carbon (see Table 4-2) this gives a discounted value (over the period 2014-30) of £5.1bn. Most of the emissions reductions come directly from reduced consumption of natural gas in homes, but around one-quarter come from the power sector, as a result of reduced demand for electricity.

Table 4-2: Central estimate of the social cost of carbon

	Annual net emissions reduction (MtCO ₂)	Social cost of carbon (£/tCO ₂ e)	Annual (undiscounted) benefit of reduced CO ₂ emissions (£2013m)	Annual (discounted) benefit of reduced CO ₂ emissions (£2013m)
2013	-	3.49	-	-
2014	-	3.59	-	-
2015	0.2	3.67	0.6	0.5
2016	0.4	3.79	1.6	1.4
2017	1.0	3.92	4.1	3.6
2018	2.0	4.22	8.5	7.2
2019	3.2	4.53	14.5	11.8
2020	6.3	4.87	30.7	24.1
2021	8.2	12.01	98.6	74.9
2022	10.2	19.14	194.7	142.9
2023	12.1	26.28	319.3	226.3
2024	14.1	33.41	470.5	322.3
2025	16.0	40.55	649.8	430.0
2026	17.9	47.69	852.0	544.7
2027	19.7	54.82	1,078.5	666.3
2028	21.1	61.96	1,304.8	778.8
2029	22.3	69.1	1,543.5	890.2
2030	23.6	76.23	1,798.9	1,002.3

4.6 Avoided health costs

The benefits of energy efficient homes go beyond simple carbon emissions and energy security arguments, as energy efficiency can improve the health and well-being of residents, thereby reducing excess winter deaths and lower social care costs and the burden on the NHS.

Children and young people

Children living in cold homes are significantly more likely to suffer from respiratory problems, such as asthma and bronchitis.⁵⁰ Cold homes have an adverse effect on the educational attainment and emotional well-being of young people. Fuel poverty has been linked with mental health complications, as more than 25% of adolescents living in cold homes are at risk of developing multiple mental health problems, compared with 5% of adolescents who have always lived in warm housing.⁵¹

The Disabled and those with health concerns

Many health conditions are aggravated by cold conditions; for example, cardiovascular (such as heart attacks) and respiratory diseases (such as asthma), are caused or worsened by living in cold homes.⁵² This can lengthen recovery periods, and extend the costs of care services. The NHS advises that one of the best ways to keep good health during the winter is to stay warm when at home.⁵³ However, for a person living with disability, there are a range of interlinked issues that make this difficult:⁵⁴

- the typical cost of living for a person with disabilities is 25% higher than average, due to equipment and care
- many are unable to keep active (and hence keep warm) during the winter months
- rates of unemployment are higher, and people are likely to spend more time at home

The elderly and winter deaths

It is estimated that there were 31,100 excess winter deaths in England and Wales over the winter of 2012/13,⁵⁵ and that 30-50% of these were due to cold homes or cold indoor temperatures.⁵⁶ The coldest quarter of housing accounted for 3 times the number of deaths than the warmest quarter of housing.⁵⁷ Whilst the difference between deaths in winter and deaths in summer is common among other European countries, the difference is much greater in the UK than it is for much colder climates, such as Sweden and Norway.

Most of the winter deaths are among the elderly, and are caused by respiratory conditions, strokes, and heart-attacks, due to cold temperatures. In addition to the excess winter deaths, there are many more people who become ill, requiring hospitalisation and social care.

NHS and health costs

Cold homes can be very damaging to the physical and mental health of the occupants, and the association between poor housing and ill health is well established.⁵⁸ The charity supporting elderly people, Age UK, has reported that cold homes are costing the NHS in England £1.36 billion every year, in hospital and primary care, due to the impact on older people's health,⁵⁹ and this excludes the substantial associated costs of social care services. Research commissioned by the Chartered Institute of Environmental Health (CIEH) in 2008, estimated that the treatment of cold-related illnesses and conditions costs the NHS approximately £1bn per year.⁶⁰ It has also been shown that NHS expenditure rises by 2% in the cold months.⁶¹ The NHS budget for 2014-15 is planned to be £108.3bn, meaning that NHS savings potential from an energy efficiency programme is significant.⁶² Investing in energy efficiency measures in low income homes is likely to reduce spending in the NHS on cold-related illnesses. The Chief Medical Officer's Annual Report in 2009 estimated that, for every £1 spent on reducing fuel poverty, a return of 42 pence can be seen in NHS savings.^{63 64}

4.7 Benefits to local economy

Our modelling has demonstrated that investing in energy efficiency measures in homes has a number of distinct effects:

- it bolsters employment and output in the construction sector
- it reduces expenditure on energy
- it increases expenditure on consumer goods and services

This has a net impact of creating jobs and output. Furthermore, a large proportion of the jobs created will be closely linked to the locations where the measures are put into homes, bolstering local economies, and potentially assisting with the Government's stated aim of spatial rebalancing of the economy. The energy efficiency market currently accounts for over 136,000 jobs in the construction and manufacturing industries.⁶⁵ Our modelling estimates an increase of 91,000 additional jobs by 2020 as a result of the programme.

Local jobs

Typically an infrastructure project would generate direct jobs in one specific area or region, due to the fixed location of the project. However, a nationwide retrofit programme would create demand for services across the country, regardless of region. Refurbishing existing homes can be more employment intensive, requiring more labour, and less materials, than the construction of new buildings. The direct construction impact is highly concentrated around the installation location; the skilled tradesmen required to install the energy efficiency measures are distributed across the country,

⁶⁵ Department of Energy and Climate Change, *Energy Efficiency Strategy: 2013*

Update, December 2013 <https://www.gov.uk/government/collections/energy-efficiency-strategy>

so it is likely that a given home will employ a local worker to install measures. However the boosts to the construction supply chain are likely to be more concentrated in certain areas, where large construction material plants are located. Labour can typically be sourced locally (while materials are often imported from elsewhere). Local businesses are well placed to benefit from this programme as most home improvement work is done by local contractors who have existing relationships with residents and who understand the local housing stock. Therefore, the result would be local jobs, local labour and benefits going to small and medium sized enterprises (SMEs); boosting employment and regional economic growth.⁶⁶ There are 142,536 SMEs (1-249 employees) in the construction sector in the UK, employing 876,897 people (an average of 6 employees each).⁶⁷

The Department for Energy and Climate Change stated, as an argument for introducing the Green Deal and Energy Companies Obligation (ECO), that “without further policy intervention, the installation rate of domestic insulation measures are [sic] projected to collapse”.⁶⁸ It could be argued that the underperformance of the Green Deal, and the reduction in ECO targets, that this is still a distinct threat, especially considering the recent announcement of a leading insulation company that 600 jobs are potentially at risk.⁶⁹ The impact on SMEs will take longer to reach the headlines.

The economic benefits of an energy efficiency programme go beyond job creation. The KfW Energy-efficient Construction and Refurbishment programme in Germany in 2010 leveraged €15 of private sector investment in construction and retrofit, and more than €4 went back to the Government in the form of taxes and reduced welfare spending, for every €1 of public funds spent on the programme.⁷⁰

Local economy

The home expenditure impacts will typically be felt in the local area. The reduction in energy usage will lead to a reduction in local jobs in this sector (e.g. engineers maintaining the local energy infrastructure). However, the impact of increasing consumer expenditure on other items is also likely to be felt locally, through increased spending in local shops and locally-based consumer services. Given that the modelling demonstrates a net positive impact on output and jobs in the UK, it is therefore expected that impacts would be fairly evenly distributed across the country (whether looking at a regional, local or constituency level).

Regional modelling results

As the results in Table 4-3 show, this is indeed the case in 2020. At this point in the modelling, the positive boost to the construction sector dominates the macroeconomic impact. Assuming an even distribution of homes requiring energy efficiency measures across the existing housing stock, it can be seen that all regions experience an increase in total employment of between 0.1 and 0.2%. Differences in the absolute increase in employment reflect largely the difference in home density between the regions.

Table 4-3 New jobs in 2020

Region	Additional jobs (000s)	Additional jobs (%)
1 London	10.3	0.19%
2 South East	12.9	0.26%
3 East of England	9.6	0.31%
4 South West	8.4	0.28%
5 West Midlands	8.0	0.28%
6 East Midlands	7.3	0.31%
7 Yorkshire & the Humber	7.3	0.27%
8 North West	9.8	0.27%
9 North East	3.3	0.27%
10 Wales	3.9	0.27%
11 Scotland	7.5	0.26%
12 Northern Ireland	2.6	0.31%
Total	91.0	0.26%

This result also holds in 2030 (see Table 4-4). By 2030 the number of homes receiving treatment is much smaller than at the peak (indeed the grants to low income homes have stopped altogether, and only able-to-pay homes receiving interest free loans are still being treated), and as a result the increase in construction and manufacturing employment (relative to the baseline) is reduced. However, the benefits of homes reducing expenditure on energy, and increasing spending in other areas, result in boosts to some parts of manufacturing and consumer services, and the increase in jobs relative to the baseline remain relatively evenly-spread across the UK.

Table 4-4 New jobs in 2030

Region	Additional jobs (000s)	Additional jobs (%)
1 London	10.8	0.19%
2 South East	10.6	0.20%
3 East of England	7.4	0.22%
4 South West	6.4	0.21%
5 West Midlands	5.8	0.20%
6 East Midlands	4.4	0.18%
7 Yorkshire & the Humber	5.3	0.19%
8 North West	6.7	0.18%
9 North East	2.0	0.16%
10 Wales	2.2	0.14%
11 Scotland	6.4	0.21%
12 Northern Ireland	2.0	0.22%
Total	70.0	0.19%

5. Conclusions

The research has demonstrated the significant economic, fiscal, and environmental benefits of investing in domestic energy efficiency. The programme recommended by the Energy Bill Revolution would generate a three-fold return in GDP for every pound invested by government, deliver high 'Value for Money' as an infrastructure programme, provide warmer homes with lower healthcare expenditure, create local jobs across all UK regions, reduce gas imports by a quarter, while creating a more resilient economy and playing a critical role in ensuring progress towards medium to long term carbon budgets.

These benefits can be realised through a programme that will effectively be cost-neutral in the medium term and a net revenue generator for government in the longer term. The increased economic growth leads to higher tax intake, cumulatively £51.1bn by 2030 or £1.27 per £1 invested over the whole period.

The total energy bill savings across the housing stock equal £8.61 billion per annum (after comfort take and energy price inflation have been considered). The net benefit of the energy bill savings is £4.95 billion per annum (after able-to-pay energy efficiency loans repaid).

This programme should therefore be considered as a capital investment infrastructure priority.

6.2 Appendix 2 – MDM-E3 Model Description

The macroeconomic analysis is based on Cambridge Econometrics' (CE's) model of the UK energy-environment-economy (E3) system, MDM-E3. CE applies MDM-E3 for both scenario analysis and as part of CE's regular energy-economy-emissions forecasting service. It is well-suited for the analysis:

- The model covers the entire UK economy, identifying 87 economic sectors (and 45 explicitly within each of the regions and nations of the UK) and recognising the interdependencies between them (i.e. supply chains); this representation is fully consistent with official UK economic statistics.
- The model has a full representation of the energy system, both in physical flows of energy and monetary terms, with two-way linkages with the economy.
- The model contains behavioural equations to explain final energy demand for more than 20 final energy users.
- The model includes a representation of the UK's power sector by generating technology to explain changes in electricity supply.
- Energy-related emissions are projected as a consequence of energy use.
- The model is a dynamic model, with its behavioural parameters estimated on official UK data. Such a specification allows for non-equilibrium outcomes and path dependency, e.g. the possibility of sustained levels of unemployment in the medium-to-long term, which is a feature of CE's latest economic forecasts

MDM-E3 is used regularly to assess the relationships between economic development and the energy system and, conversely, the impact of energy and carbon reduction policies on the economy.

6.3 Appendix 3 – Technical modelling methodology

The research modelled 2012 English Housing Survey data to assess the investment requirement for improving low income and able-to-pay homes to mid EPC band C standard.

Energy archetypes

Each home in the EHS dataset is modelled as an ‘archetype’, based on energy consumption and key characteristics, as shown in Figure 6-1. Energy efficiency measures are modelled to be included within a package of measures until the post-retrofit SAP score is close to the target score (mid EPC band C). The energy efficiency measures in the package represent a cost-effective route to achieving the target SAP score, based on a marginal abatement cost (MAC) curve.

Figure 6-1: Verco’s ‘energy archetype’ structure

Dwelling size/type	Semi detached/ end terrace	Terrace	Flats (top floor)
		Detached	Flats (mid floor)
Fuel/boiler type	Gas – condensing boilers	Gas – standard boilers	Electric
	Communal heating		
Wall construction	Cavity filled	Solid	Cavity empty
Loft insulation	High	Medium	Low
Glazing type	Double	Single	
EPC Band	A/B	C/D	E/F/G

Energy efficient measures

The measures modelled are broadly those that are eligible under the current Green Deal mechanism. The list of measures is modelled to be applied to the archetype in sequential order. The order is based on: the energy bill savings payback period, investment requirements of measures, and the level of tenant disruption that is involved with installation. The list of measures is given below, and focusses on the key cost-effective measures that are not too invasive or disruptive to install.

- Cavity wall insulation
- Loft insulation
- Draught proofing
- Hot water cylinder insulation
- Combined heating controls, cylinder thermostats and hot water controls
- Double glazing
- Gas-fired condensing boilers
- No secondary heating post refurbishment

- Flue gas heat recovery devices
- Hot water measures – low-flow taps
- Solid wall insulation
- High performance external doors
- Under-floor insulation
- Heating ventilation and air-conditioning controls (including zoning controls) (only for semi- / detached homes)
- Triple glazing
- Waste water heat recovery devices attached to showers

Naturally, not all measures are modelled for all archetypes. The measures are only modelled to be installed if they are applicable to the archetype. For example, cavity wall insulation is only modelled for archetypes that currently have empty cavities, and boiler replacement is only modelled for the archetypes with standard gas boilers, and not in those that already have condensing gas boilers. Heating controls are only modelled to be installed to the least energy efficient homes, i.e. those with EPC bands of E, F, or G. Furthermore, the size of the package is capped based on the total investment. The investment-capping results in very few packages progressing further than the solid wall insulation measure, due to the higher investment requirements of the later measures.

Capping the investment

The SAP improvement targets can, in some cases, result in some high investment measures being included in the package, particularly if the target SAP score is high when compared to the pre-retrofit SAP score of the home. Without a cap on the investment in the retrofit package, 16% of the retrofitted dwellings would receive a package of measures greater than £10,000. Therefore, the capital investment in the package has been limited to a maximum of £10,000. The modelling incorporates this restriction when modelling the package of measures applicable; this decreases the average capital investment for a home, and also decreases the energy performance of that home. This £10,000 grant cap is intended to avoid a large amount of money potentially being spent on improving a relatively small number of extremely ‘hard-to-treat’ homes.

Calculating energy bill savings and carbon savings

The energy bill savings and carbon savings are calculated based on the SAP modelled reduction in energy consumption. Each energy efficient measure, added to the package sequentially, reduces the overall energy consumption of the home. The relevant in-use factors are incorporated for each measure, accounting for underperformance. For the low income homes, the energy savings are further reduced, by 40%, to account for comfort take.⁷¹

The energy consumption is converted into energy bill savings using the *Updated Energy and Emissions Projections* (DECC, September 2013), and converted into carbon savings using the *Interdepartmental Analysts’ Group (IAG) Guidance for Policy Appraisal* (DECC, 2011).

⁷¹ A comfort take factor of 40% was used for the impact assessment of the Community Energy Saving Programme (CESP), for energy efficient installations in low income areas. [Department of Energy and Climate Change, *Impact Assessment of proposals for implementation of the Community Energy Saving Programme (CESP)*, 2009]

Distinguishing ‘low income’ homes and ‘able-to-pay’ homes

In this research, improving the homes of ‘low income’ homes and ‘able-to-pay’ homes, are considered separately. The numbers of ‘low income’ homes for each modelling archetype are derived from the EHS database.

- Low income homes are modelled to receive grants to cover the full investment in the energy efficiency measures, so that packages can be delivered at zero-cost to the homes.
- Able-to-pay homes are modelled to receive 0% interest energy efficiency loans on the retrofit measures. The investment in the measures is financed by the private sector; the homes themselves.

Geographic coverage

This research only modelled English Housing Survey data. It does not provide detailed breakdowns of the investments required to improve homes in the devolved nations. Investment requirements per home, in the devolved nations, may differ from those identified for England due to the differences in the scale of the problem (for example, a high proportion of Welsh housing is off the gas grid) and differences in the nature of the housing stock (for example, a high proportion of Scottish housing is tenements).

Example packages of measures

Examples of low, medium, and high investment energy efficiency retrofit packages are shown in Figure 6-1. The properties are not to be seen as an ‘average flat’ or an ‘average semi-detached house’, but are shown merely as specific examples of package sizes. All three property types are within the low income and able-to-pay groups.

Table 6-1: Example packages of measures

Investment in energy efficiency	Property characteristics pre-retrofit	Retrofit measures	EPC rating change	Year 1 energy bill savings (£)
£691 (low investment)	<ul style="list-style-type: none"> • Top-floor flat • Electrically heated • Cavity wall (filled) • Low level of loft insulation • Double glazing 	<ul style="list-style-type: none"> • Loft insulation (Top up from 50mm) • Draught proofing 	Mid EPC band D to Low EPC band C	£153 (£81 after comfort take)
£4,238 (medium investment)	<ul style="list-style-type: none"> • Semi-detached • Standard gas boiler • Cavity wall (empty) • Low level of loft insulation • Double glazing 	<ul style="list-style-type: none"> • Cavity wall insulation; • Loft insulation (Top up from 50mm) • Draught proofing • Hot water cylinder jacket • Cylinder thermostats & heating controls • Gas-fired condensing boilers • Secondary heating removal 	Mid EPC band D to Mid EPC band C	£507 (£304 after comfort take)
£9,952 (high investment)	<ul style="list-style-type: none"> • Semi-detached • Condensing gas boiler • Solid brick wall (uninsulated) • Medium level of loft insulation • Double glazing 	<ul style="list-style-type: none"> • Loft insulation (Top up from 150mm) • FGHR devices • All hot water measures • External wall insulation 	High EPC band E to Low EPC band C	£202 (£121 after comfort take)

6.4 Appendix 4 – Programme investments by year

Executive Summary

There is a strong case for Government to make home energy efficiency an infrastructure investment priority and to develop an infrastructure programme to deliver it.

- **Energy efficiency investments constitute infrastructure.** Domestic energy efficiency investments can free up energy sector capacity just as effectively as delivering new generation plant, networks or storage would. Energy efficiency investments provide public services, by reducing carbon emissions and improving health and wellbeing. They also provide option value in the face of uncertainty over future energy sector conditions (e.g. uncertainty over future fuel prices)¹. An energy efficiency programme would meet the criteria HM Treasury apply for determining their top 40 infrastructure requirements. It would also fit with the eight characteristics of infrastructure identified in HM Treasury's valuation guidance. In addition, classifying energy efficiency as infrastructure is consistent with the way energy efficiency is considered by a range of international organisations, such as the European Investment Bank and the International Energy Agency (IEA).
- **Energy efficiency investments provide value for money.** Our analysis of Government Impact Assessments shows that they have comparable benefits to other major infrastructure investments. In fact, a programme to make British buildings more energy efficient would generate £8.7 billion of net benefits. This is comparable to benefits delivered by the first phase of HS2, Crossrail, smart meter roll out, or investment in new roads (Figure 1). This finding holds, even without quantifying many of the key social benefits of energy efficiency measures (for example health and wellbeing improvements).
- **An infrastructure programme to deliver energy efficiency measures can overcome key barriers to delivery.** The market failures around energy efficiency provide a strong case for Government intervention. As part of a broad energy efficiency programme there are benefits to delivering a coordinated area-based scheme under a directly funded approach. This could be used to target the consumers who would benefit the most.

¹ The incremental nature of energy efficiencies investments means that strategies can be changed as new information comes to light. This flexibility is not possible with more lumpy capital investments (for example nuclear power plants).

Figure 1. Summary of infrastructure scheme assessments

Source: Frontier Economics, based on sources detailed Box 1 on page 17. The NPV is the present value of the difference between the stream of costs and benefits of each scheme. The BCRs represent the ratio of societal benefits to Government costs (In line with Webtag guidance). The NPV figures do not include wider economic benefits. The base year for the present values varies between 2010 and 2013.

- **There is widespread support for making energy efficiency an infrastructure priority.** Making energy efficiency a public infrastructure priority is supported by leading UK business associations and businesses, including the CBI. It is also supported by core cities. Area-based programmes carried out by core cities are a natural fit with Government's aims to encourage resurgent cities and to support further devolution.

1 Introduction

This Government has identified productivity as one of the major economic challenges of our time. And it has recognised that investment in infrastructure is central to increasing the UK's productivity².

When thinking of infrastructure, it is often the major construction projects that come to mind – road and rail upgrades or investments in large new energy sector assets, like nuclear power stations or gas storage facilities.

But are we missing something by focussing on the big and visible projects? Are there alternative infrastructure investments that could provide greater benefits to the UK?

This report makes the case for classifying domestic energy efficiency as an infrastructure priority.

- Though less visible, domestic energy efficiency investments have many characteristics in common with supply side energy sector investments. In Section 2 we explain why domestic energy efficiency investments constitute infrastructure.
- Energy efficiency is a highly cost-effective way of meeting Government energy and climate change goals. Putting energy efficiency on a common footing with other major investment decisions allows a discussion on investment priorities. Section 3 assesses whether domestic energy efficiency investments provide value for money for the nation, when compared to other infrastructure investments.
- Thinking of energy efficiency as infrastructure will provide insights on how to overcome the market and policy failures that have prevented its widespread delivery. Section 4 describes the implications this has for delivery of energy efficiency.
- Based on this analysis, we conclude in Section 5 that there is a strong case for making domestic energy efficiency investments an infrastructure priority.

² HM Treasury (2015), *Fixing the Foundations*

2 Energy efficiency is infrastructure

Roads, railways, broadband networks, and energy supply investments are well understood to be infrastructure. Their importance to the UK economy is widely recognised³.

Though less visible, domestic energy efficiency investments have many characteristics in common with supply side energy sector investments. But do they constitute infrastructure?

In this section, we review definitions of infrastructure in the literature, and assess how well domestic energy efficiency fits with them.

We conclude that domestic energy efficiency constitutes infrastructure investment.

- **Domestic energy efficiency investments free up energy capacity for other uses, just as investment in new generation or network capacity would. In this way, they increase inputs to the production of goods and services across the economy.**
- **These investments also provide public services, by reducing carbon emissions and improving health and wellbeing.**

This finding is consistent with the way energy efficiency is considered by a range of international organisations, such as the European Investment Bank and the International Energy Agency (IEA). It is also consistent with the inclusion of the smart meter project in the Government's top infrastructure priorities.

2.1 Defining infrastructure

Figure 2 presents the four definitions we found in highly cited literature on infrastructure, alongside recent definitions from the LSE Growth Commission, and HM Treasury.

³ For example, HM Treasury (2015), *Fixing the Foundations*.

Figure 2. Definitions of infrastructure

Source: Frontier Economics

The definitions in Figure 2 cover two aspects of infrastructure: characteristics and functions.

- **Characteristics.** Infrastructure is generally described as capital, or as involving physical structures.
- **Functions.** The two most recent definitions (from HM Treasury and the LSE Growth Commission) describe infrastructure as an input to the production of goods and services and a requirement for the operation of the economy. The older definitions specify the function of infrastructure more narrowly, focusing on the provision of public services.

We have summarised these elements into broad and narrow definitions of infrastructure in Table 1.

Energy efficiency is infrastructure

Table 1. Broad and narrow definitions of infrastructure

	Broad definition	Narrow definition
Characteristics	Capital, physical structures	Large capital investments, with natural monopoly characteristics
Functions	Provides inputs to the production of goods and services	Provides public services

Source: Frontier Economics

We now consider how energy efficiency fits into each element of these definitions, looking first at its characteristics, and then at its functions.

2.2 Characteristics of domestic energy efficiency investments

Table 2 shows a range of common domestic energy efficiency investments, alongside information on their characteristics.

Table 2. Characteristics of common energy efficiency investments

	Cost (incurred upfront)	Lifetime (years)	Energy saving (kWh/year, semi- detached house)	Carbon saving (kg/year, semi- detached house)
Cavity wall insulation	£500 - £1,500	42	4,550	901
Draught proofing	£80-120	10	760	151
External wall insulation	£4,000- £14,000	36	9,373	1856
Heating controls	£350 - £450	12	3,927	797
High performance doors (per door)	£500	30	371	74
Gas-fired condensing boilers	£2,200 - £3,000	12	4,595	910
Internal wall insulation	£4,000- £14,000	36	10,033	1986
Loft insulation	£100 - £350	42	1,741	345
Replacement glazing	£3,300-£6,500	20	2,529	505
Roof insulation (flat roof)	£850 - £1,500	20	2,355	466
Secondary glazing	£1,000 - £1,500	20	1,753	391
Under-floor insulation	£800 - £1,200	42	1,269	252

Source: DECC (2013) *Information for the Supply Chain on Green Deal Measures*

Based on the information in Table 2, we argue that domestic energy efficiency measures fit with the broad definition of infrastructure characteristics, and partially fit with the narrow definition.

- **Broad definition of characteristics: Capital, physical structures.** *Domestic energy efficiency investments constitute physical capital.* Table 2 shows that domestic energy efficiency generally constitutes capital-intensive physical investments into the fabric of buildings. These investments tend to involve sunk costs incurred up front, and a return gained over a long asset lifetime.

Energy efficiency is infrastructure

- **Narrow definition of characteristics: Large capital investments, with natural monopoly characteristics.** *By delivering energy savings, domestic energy efficiency investments increase available energy sector capacity just as investing in large capital natural monopoly assets would.* Though an energy efficiency programme could constitute a major investment⁴, Table 2 shows that individual domestic energy efficiency investments are not large capital investments. Neither do these investments tend to have natural monopoly characteristics. **However, reductions in energy demand (delivered through an energy efficiency programme) can increase available energy sector capacity just as effectively as delivering new large capital investments (such as new generation plant, networks or gas storage)**⁵. Therefore, while domestic energy efficiency investments are not in themselves large monopoly assets, investing in them can have the equivalent impact on the economy as investing directly in large monopoly assets. This equivalence is recognised in supplementary guidance to HM Treasury's Green Book, which explicitly recognises that investment in energy efficiency reduces the need for investment in other energy system infrastructure⁶. The impacts of energy efficiency on energy sector capacity can be highly material: for example, following extensive policy intervention, domestic energy consumption per person has already fallen by 26% since 2000⁷, driven to a large extent by the delivery of energy efficiency measures.

We also note the narrow definition of infrastructure characteristics is more restrictive than that used by Government. For example, the smart meter programme and the Science & Innovation Catapults already form part of HM Treasury's Top 40 infrastructure priority list⁸.

A range of international organisations, such as the European Investment Bank and the IEA also use a less restrictive definition. The EIB has an infrastructure fund targeting energy efficiency and renewables, while the IEA advises infrastructure investment as one of several economic instruments that

⁴ For example, the Committee on Climate Change estimate that 4m investments in cavity wall insulation, 3.3m in solid wall insulation and 3.4m in loft insulation may be required to meet the UK's fourth carbon budget. CCC (2015) *Meeting Carbon Budgets – Progress in reducing the UK's emissions*.

⁵ We note that while these large assets are certainly viewed as infrastructure, not all of them have natural monopoly characteristics.

⁶ The guidance specifies that changes in energy use delivered by energy efficiency investments should be valued by taking the long run variable cost of energy supply. This long run variable cost includes the costs of investment in new capacity (for example, 90% of transmission costs are included). *Green Book supplementary guidance: valuation of energy use and greenhouse gas emissions for appraisal*.

⁷ DECC (2015), *Energy Consumption in the UK*

⁸ HMT (2014), *National Infrastructure Plan 2014*

can be used to improve energy efficiency⁹. In addition, energy efficiency is being targeted by the European Fund for Strategic Investment, a €315 billion fund aimed at financing investment in infrastructure and innovation, and providing financing for SMEs. A French programme offering loans to support energy efficiency retrofits in residential buildings has already been announced under this fund¹⁰.

2.3 Functions of domestic energy efficiency investments

Domestic energy efficiency investments do two things.

- **They reduce energy use.** This reduces bills and frees up energy sector capacity to be used elsewhere in the economy, reducing the need to invest in new energy system capacity. This reduces carbon emissions (Table 2) and decreases the exposure of consumers to volatile fuel prices. In addition, these investments provide option value: because they involve multiple, small incremental investments, the scale and focus of the programme can be adjusted over time, as new information on the state of the world (including on the availability of new technologies) comes to light¹¹.
- **They result in warmer and more comfortable homes.** This increases health and wellbeing¹², and may also increase labour productivity¹³.

There are trade-offs here: if consumers respond to efficiency measures by heating their homes more, the energy and carbon savings associated with these investments are reduced, but greater health and wellbeing benefits are realised¹⁴. There is good evidence that a mix of both functions is delivered¹⁵.

⁹ IEA (2012), *Mobilising investment in energy efficiency*

¹⁰ Pending EFSI regulation. http://europa.eu/rapid/press-release_IP-15-5420_en.htm

¹¹ We discuss option value further in Section 3.

¹² There is both an income and a substitution effect: reduced bills mean more income is available to spend on heating, and heating the home is now relatively cheaper.

¹³ Mitchell, R. J., & Bates, P. (2011). Measuring Health-Related Productivity Loss. *Population Health Management*, 14(2), 93–98.

¹⁴ Analysis of energy efficiency measures tends to take this into account by reducing the energy savings by a ‘comfort factor’. For example, recent analysis by Cambridge Econometrics for E3G uses a comfort factor of 40% for fuel poor homes. Cambridge Econometrics, *The economic and fiscal impacts of making homes energy efficient*

¹⁵ UKERC (2007), *The Rebound Effect: An Assessment of the Evidence for Economy-wide Energy Savings from Improved Energy Efficiency*

Domestic energy efficiency investments fit with both the broad and narrow definition of infrastructure functions.

- **Broad definition of functions: Inputs to the production of goods and services.** By freeing up other energy system capacity, energy efficiency delivers an input to the production of goods and services. The fact that this improvement is made via the demand side, rather than by directly increasing supply side capacity does not affect the economic outcome. In fact, HM Treasury's recent productivity plan is clear that infrastructure can make a contribution to the economy, even when it involves making improvements at a domestic level¹⁶.
- **Narrow definition of functions: Provides public services.** Though homes are generally privately owned, investment in infrastructure measures provides public goods. Freeing up energy sector capacity provides services across the economy. Reducing carbon emissions provides a public service, given that the atmosphere is a public good¹⁷. Reductions in demand also contribute to energy security. In addition, by delivering warmer homes, energy efficiency provides a public service, resulting in fewer winter deaths and reduced cost to the NHS¹⁸. A healthier population is also likely to be a more productive one¹⁹.

2.4 Findings

Based on this analysis, we conclude that domestic energy efficiency is a form of infrastructure (Figure 3).

¹⁶ For example, it describes the contribution that digital infrastructure can make by removing barriers that prevent households from playing their full part in the digital economy. HM Treasury (2015), *Fixing the Foundations*.

¹⁷ While a carbon price is applied to emission from electricity generation, no price is applied on domestic gas use.

Energy efficiency is infrastructure

3 Energy efficiency provides value for money

We have shown that energy efficiency investments constitute infrastructure. However, these investments will require funding, at a time when pressure to manage budgets is very high. It is important, therefore, to ask whether energy efficiency investments deliver value for money.

In this section, we compare the estimates of the net benefits of energy efficiency schemes and with those of other schemes. We report on the standard outputs of the cost-benefit analysis of each project: the net present values (NPV) of benefits to society²⁰ and the benefit-cost ratios (BCRs)²¹.

- **This analysis finds that an energy efficiency programme can have comparable benefits to other major infrastructure investments outside the energy sector.**
- **These findings hold, even though many of the key social benefits of energy efficiency measures (for example in terms of health improvements, or option value) have not been quantified.**

This analysis is based on a review of Government Impact Assessments. We have not undertaken any new modelling work for this project.

3.1 Comparison of Green Book metrics

Figure 4 compares the net benefits and BCRs of an energy efficiency scheme with four other major schemes. This shows that an energy efficiency programme compares well to the alternative investments. An energy efficiency programme could deliver £8.7bn of benefits to the UK, compared to benefits in the range of £6.5bn-£9.9bn for smart meters, HS2 (Phase 1), Crossrail and new roads. These findings hold, even without quantifying many of the key social benefits of energy efficiency measures (for example in terms of health improvements) or the associated option value.

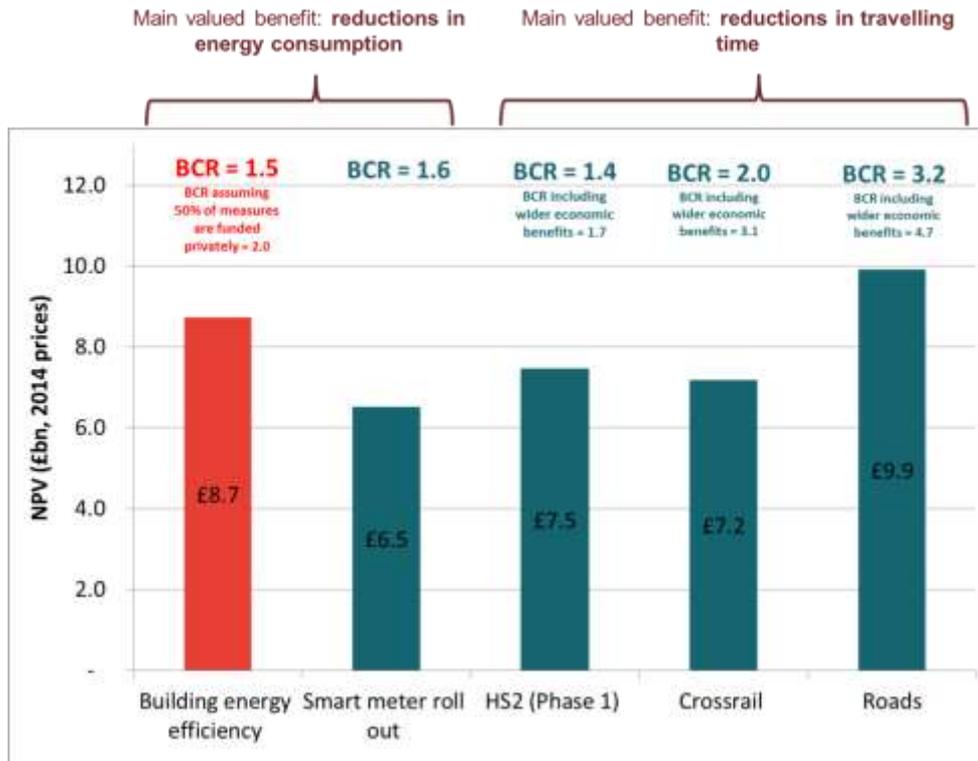

We also note the benefits of energy efficiency schemes are mainly made up of reductions in energy consumption. This is in contrast to the three transport schemes shown in Figure 4, where the core benefits are driven by reductions in travelling time. DfT acknowledges there are uncertainties around the values of time for business travellers in particular (for example, due to ongoing changes in

²⁰ The NPV is the present value of the difference between the stream of costs and benefits of scheme.

²¹ In line with Webtag guidance, the BCRs represent the ratio of societal benefits to Government costs.

working and commuting patterns), and is currently seeking to collect new empirical evidence to review these values²².

Figure 4. Summary of infrastructure scheme assessments

Source: Frontier Economics, based on sources detailed in Box 1, page 17. The NPV is the present value of the difference between the stream of costs and benefits of each scheme. The BCRs represent the ratio of societal benefits to Government costs (in line with Webtag guidance). The NPV figures do not include wider economic benefits. The base year for the present values varies between 2010 and 2013.

Figure 4 draws on a range of published Government impact assessments. We have made some adjustments to the published figures, to ensure the outputs are comparable.

- All figures have been uplifted to 2014 prices.
- Where impact assessments do not include BCRs, we have calculated these. In line with Webtag guidance, the BCRs represent the ratio of societal benefits to Government costs²³.

²² DfT (2014), *Webtag*

²³ DfT (2014), *TAG UNIT A1.1 Cost-Benefit Analysis*, page 7

Further details on the sources of these figures are set out in Box 1.

Box 1: Sources

Energy efficiency programme

This analysis is based on the Department for Energy and Climate Change's (DECC) final impact assessment of the Green Deal and ECO²⁴. This impact assessment analyses the costs and benefits of a major programme of energy efficiency measures in domestic and non-domestic properties to 2022 (the majority of the costs and benefits relate to domestic properties).

This package includes installation of cavity wall insulation (some of which is hard-to-treat) in 2.7m properties. It also includes loft insulation in 1.6m properties and solid wall insulation in 1.0m properties, as well 0.4m installations of draught-proofing, glazing or floor insulation^{25,26}. A small proportion of the costs reported in this impact assessment will be scheme specific costs relating to the Green Deal and ECO.

To calculate the BCR, we have assumed that 100% of the costs relating to the installation of measures are borne by Government. We have also included an estimate of the BCR that assumes 50% would be privately funded by able-to-pay consumers and businesses²⁷.

Other schemes

Figures for smart meter roll out were taken from DECC's final analysis of the programme, reported by the National Audit Office (NAO)²⁸. The HS2 (Phase 1) analysis is based on the HS2 Company's analysis²⁹. Figures for Crossrail are from the Department for Transport's analysis, reported in the NAO³⁰. Figures for roads are taken from DfT's analysis of the Road Investment Strategy, focussing on the benefits of schemes that go beyond existing commitments³¹.

²⁴ DECC (2012), *Final Stage Impact Assessment for the Green Deal and Energy Company Obligation*,

²⁵ DECC (2012), *Final Stage Impact Assessment for the Green Deal and Energy Company Obligation*, , page 164

²⁶ We note that the technical potential for these measures is much higher. For the example, the CCC estimate that the remaining potential to meet carbon budgets is 4.0m for cavity wall insulation, 3.3m for solid wall insulation and 3.4m for loft insulation, CCC (2015), *Meeting Carbon Budgets - Progress in reducing the UK's emissions*. Figure 2.4

²⁷ Whether the measures are privately or publically funded does affect the NPV since this calculated by subtracting total costs (including both private and public costs) from benefits.

²⁸ NAO (2014), *Update on preparations for Smart Metering*,

²⁹ HS2 (2013), *The Economic Case For HS 2*. page 85.

³⁰ NAO (2014), *Crossrail*

³¹ DfT (2015), *Road Investment Strategy: Economic analysis of the investment plan*

3.2 Unquantified benefits of an energy efficiency programme

Not all of the benefits associated with energy efficiency programmes have been quantified in Figure 4.

There are two main categories of direct benefits associated with energy efficiency improvements that are not valued in this assessment: option value and health benefits.

3.2.1 Option value

There is a large degree of uncertainty over future demand and supply conditions in the electricity sector to 2050. For example, global fuel prices can fluctuate significantly, and the future cost of energy generation technologies can be difficult to predict.

In the face of this uncertainty, a standard cost-benefit assessment (such as that carried out for Government Impact Assessments) may underestimate the benefits associated with schemes which can be rolled out incrementally, such as energy efficiency programmes. Because it involves multiple, small incremental investments, an energy efficiency programme has the advantage of flexibility. Unlike large, capital-intense projects (such as the construction of a nuclear plant, for example), the scale and focus of the programme can be adjusted over time, as new information on the state of the world comes to light³².

This option value has not been quantified in the analysis set out in Figure 4. Given the scale of the uncertainty associated with supply and demand in the energy sector, it may be significant.

3.2.2 Health benefits

In their analysis of the energy efficiency programme set out in Figure 4, DECC assume a level of ‘comfort take’³³. That is, they assume that consumers use some of the financial savings they have gained from energy efficiency, to purchase more heating. There are likely to be significant health benefits associated with this as living in cold conditions can be linked to a number of negative physical and mental health impacts. For example, the Hills Fuel Poverty Review found

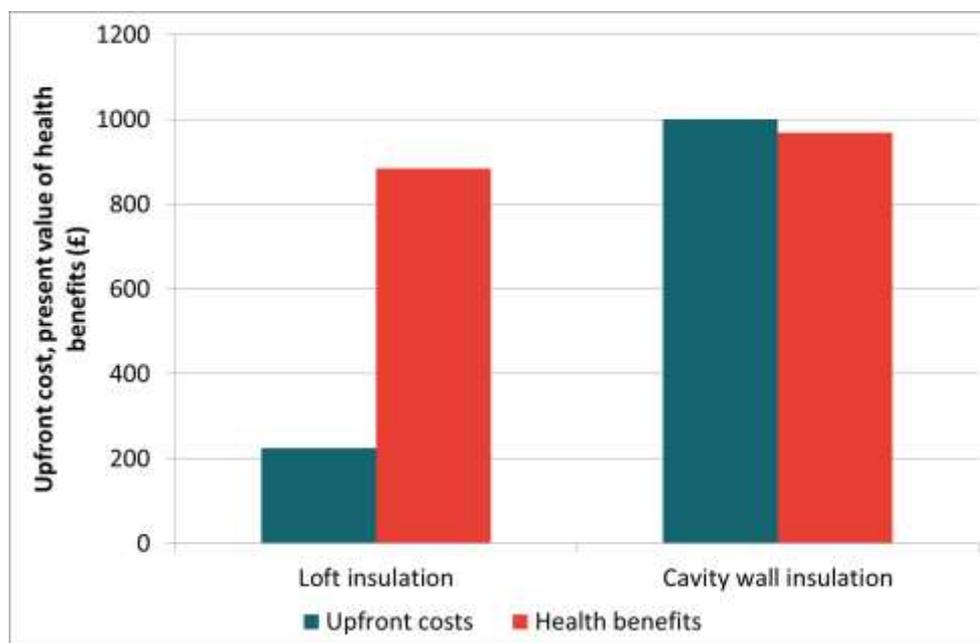

³² We note that it is important for the supply chain that these changes are well-planned and made with adequate notice.

³³ A given percentage level of comfort take means that the energy savings resulting from the installation of efficiency measures will be that percentage lower than they would have been in the absence of the comfort taking.

that low-temperatures in homes can create conditions which increase the likelihood of cardiovascular events, some of which may result in death, exacerbate the risk of respiratory disease and cause physical discomfort, which can contribute to mental health issues³⁴.

DECC has undertaken modelling to value the health benefits associated with some energy efficiency investments³⁵. Figure 5 shows that these can be significant. In fact, for loft insulation, these benefits alone outweigh the costs of installing the measures, even before energy savings are taken into account.

Figure 50. Estimated health benefits of loft and cavity wall insulation, compared to upfront costs

Source: DECC (2013), *Fuel Poverty: a Framework for Future Action – Analytical Annex*; DECC (2013) *Information for the Supply Chain on Green Deal Measures*.

These health benefits have not been valued in the assessment set out above. Again, this is likely to have led to an underestimate of benefits.

³⁴ Hills (2011), *Fuel poverty: The problem and its measurement*.

³⁵ DECC (2013), *Fuel Poverty: a Framework for Future Action – Analytical Annex*

3.3 Comparison according to Government's Top 40 criteria

The strategic benefits of energy efficiency investments may also be important.

Each year, the Government publishes a National Infrastructure Plan. This includes a list of the top 40 priority projects. Published analysis suggests that an energy efficiency programme performs well against the three criteria used in the selection of these projects³⁶.

- **Potential contribution to economic growth.** Macroeconomic modelling by Cambridge Econometrics and Verco for E3G suggests that an energy efficiency programme could have a significant positive impact on growth³⁷.
- **Nationally significant investment that delivers substantial new or replacement infrastructure with enhanced quality, sustainability and capacity.** An energy efficiency programme could be judged to meet this criterion just as well as other schemes which are included in the top 40, for example, the smart meter roll out programme, road investments or the Science & Innovation Catapults.
- **Projects that attract or unlock significant private investment.** An energy efficiency investment scheme has the potential to deliver private investment, where able-to-pay households fund at least some of the cost measures in their homes. Some but not all of the infrastructure schemes in the Top 40 attract private investment. For example, HS2 and most roads are publically funded.

³⁶ HMT (2014), *National Infrastructure Plan 2014*

³⁷ This modelling found that an energy efficiency programme could increase annual GDP in 2030 by around £14bn Cambridge Econometrics and Verco (2014), *Building the Future: The economic and fiscal impacts of making homes energy efficient*

4 Energy efficiency can be delivered as infrastructure

We have shown that energy efficiency investments are a type of infrastructure, and that they provide value for money. We now consider what this means for the delivery of these investments.

This analysis finds that the characteristics of energy efficiency as infrastructure mean that Government intervention is required to deliver the socially optimal³⁸ level of investment for the UK.

It also finds that there are benefits to an approach that is directly funded by Government. It may be easier to deliver a coordinated area-based scheme under this approach and to target the customers who would benefit the most. It is also less regressive to fund an increase in energy efficiency investment through general taxation, rather than through bills.

4.1 Why does Government need to be involved?

HM Treasury has identified eight characteristics of infrastructure that should be taken into account in appraisals of new policy decisions to support infrastructure³⁹. These are set out in Figure 6, along with an explanation of why they apply to energy efficiency decisions, and what this implies for Government intervention.

³⁸ The socially optimal level of investment refers to the level that maximises net social benefits for the UK.

³⁹ HM Treasury (2015), *Valuing infrastructure spend: Supplementary guidance to the Green Book*

Figure 6. Why is Government intervention required?

	Does this apply to energy efficiency?	What does this mean for delivery?
Long-term	Investments have long asset lives	In the absence of Government intervention, there will be underinvestment. Consumers and businesses tend to have a higher discount rate than society as a whole. This means that where costs are incurred upfront, and benefits accrue over long lifetimes, consumers and the private sector will tend to invest less than the optimal amount.
Location specific	Investments are tied to buildings in specific locations	In the absence of Government intervention, there will be underinvestment. The level of sunk costs associated with energy efficiency measures is important. It makes it difficult for businesses to offer credit to customers to install these measures, as to do so is akin to providing an unsecured loan (i.e. businesses cannot reclaim the insulation if the consumer defaults).
Interdependent	There is interdependency between energy efficiency infrastructure and the rest of the energy system	Government intervention can help ensure benefits are maximised. Energy efficiency investments may deliver the greatest system benefits when focussed on particular locations (e.g. where distribution networks are congested) or focussed on reducing energy consumption at a particular time of day (to reduce peak demand). Energy prices for domestic consumers do not currently deliver granular signals on location, and the majority do not deliver timing signals.
Scale effects	Supply chain impacts mean that the scale of energy efficiency programmes is important	Government intervention can help to ensure coordinated delivery. DECC's 2012 Energy Efficiency Strategy identified embryonic markets as one of the four main barriers to the roll out of energy efficiency measures, pointing out that a lack of expertise in a relatively immature market can increase costs and therefore slow roll out. A coordinated approach to roll out (for example, based on local areas) could help markets deliver.
Non marginal impacts	Supports and enables economic output by freeing up energy capacity for other uses	In the absence of Government intervention, there will be underinvestment. Analysis by Cambridge Econometrics suggests that an energy efficiency programme could help stimulate economic growth. Private individuals and business will not take the impact on the overall economy into account when making their decisions, and therefore may invest less than the optimal amount for society.
Shapes preferences	Can change how consumers heat their homes	Government intervention can help secure health benefits. If energy efficiency investments are targeted at the fuel poor, they may result in health benefits, and reductions in costs for the NHS.
Public good aspects	The atmosphere is a public good.	In the absence of Government intervention, there will be underinvestment. Investors in energy efficiency will not take their impact on emissions into account when making their investment decisions. This means that without Government intervention, consumers and the private sector will invest less than the optimal amount.
Market power	Not applicable	

Source: Frontier Economics.

Energy efficiency can be delivered as infrastructure

The analysis in Figure 6 shows that seven of the eight characteristics of infrastructure are relevant in the case of an energy efficiency programme. It also shows that these characteristics have implications for Government intervention.

- **In the absence of Government intervention, there will be under-delivery of energy efficiency investments.** This is the case both because of the infrastructure characteristics highlighted in Figure 6, and because of the well-known behavioural barriers associated with energy efficiency investments (for example those associated with lack of interest, low awareness, risk aversion and lack of trust)⁴⁰.
- A **targeted** approach can help maximise the benefits of an energy efficiency programme by focussing on:
 - the consumers that can gain the most from these investments (e.g. the fuel poor); and
 - interventions that tackle consumption at certain times of day (efficiency improvements that reduce peak demand).
- A **coordinated area-based approach** can also help maximise the benefits of an energy efficiency programme, by focussing on:
 - coordinating area-wide approaches that allow local markets to mature;
 - coordinated targeting of areas where the benefits to the energy system are greater (e.g. areas with network congestion).

An area-based approach can also help overcome behavioural barriers, for example by creating new social norms around efficiency measures.

4.2 What does this mean for direct funding?

At the moment, policy-driven energy efficiency measures are largely financed through ECO and delivered by suppliers. This supplier-led approach can tackle many of the issues identified in Figure 6.

But would a supplier-led approach be the most efficient way of delivering a further increase in energy efficiency investments? There are three reasons why an infrastructure investment programme, directly funded by Government may add value.

⁴⁰ See for example, the discussion in DECC (2012), *The Energy Efficiency Strategy: The Energy Efficiency Opportunity in the UK*

- **A direct Government approach could be more effective in delivering a coordinated, area-based approach.** This type of approach may be difficult to deliver through suppliers, given the number of suppliers that compete in the energy market, their uneven distribution across different localities, and the transaction costs associated with specifying very narrowly who suppliers should target⁴¹.
- **A scheme targeting those customers that will benefit the most in terms of health and wellbeing may be easier to deliver directly through an infrastructure programme, led by cities.** While suppliers can be incentivised to focus on vulnerable customers and the fuel poor, the design of such a scheme can become complex and again can lead to inefficiently high transaction costs. Some of these transaction costs could be avoided by drawing on the knowledge that Government, and in particular Local Government, already has on housing stock and vulnerability of occupants.
- **Bill-payers may be reluctant accept a further increase in the costs of a supplier obligation.** Funding through energy bills (with ECO) is consistent with the polluter pays principle and provides an added incentive for efficiency. However, it will generally be less regressive to fund schemes through general taxation (as is common in Europe)⁴².

⁴¹ We note that internationally, many obligation schemes are delivered through distribution network operators, and these issues do not apply. The UK is the only EU country to use a supplier obligation to tackle fuel poverty.

⁴² CEER (2015), *Status Review of Renewable and Energy Efficiency Support Schemes*

5 Conclusions

There is a strong case for Government to make energy efficiency investments an infrastructure priority, and to introduce a further programme of energy efficiency investments.

- **Energy efficiency investments constitute infrastructure.** Domestic energy efficiency investments can free up energy sector capacity just as effectively as delivering new generation plant, networks or storage would. Energy efficiency investments provide public services, by reducing carbon emissions and improving health and wellbeing. They also provide option value in the face of uncertainty over future energy sector conditions (e.g. fuel prices)⁴³. An energy efficiency programme would meet the criteria HM Treasury apply for determining their top 40 infrastructure requirements. It would also fit with the eight characteristics of infrastructure identified in HM Treasury's valuation guidance. In addition, classifying energy efficiency as infrastructure is consistent with the way energy efficiency is considered by a range of international organisations, such as the European Investment Bank and the International Energy Agency (IEA).
- **Energy efficiency investments provide value for money.** Our analysis of Government Impact Assessments shows that an energy efficiency programme can have comparable benefits to other major infrastructure investments. In fact, a programme to make British buildings more energy efficient would generate £8.7 billion of net benefits. This finding holds, even without quantifying many of the key social benefits of energy efficiency measures (for example health improvements and option value).
- **There is a case for Government intervention, in the form of a publicly funded investment programme and there are benefits to an approach that is directly funded by Government.** It may be easier to deliver a coordinated area-based scheme under this approach and to target the customers who would benefit the most. It is also less regressive to fund an increase in energy efficiency investment through general taxation, rather than through bills.

⁴³ The incremental nature of energy efficiencies investments means that strategies can be changed as new information comes to light. This flexibility is not possible with more lumpy capital investments (for example nuclear power plants).

EXECUTIVE SUMMARY

WSP | Parsons Brinckerhoff were commissioned by Thames Valley Berkshire, Enterprise M3, Solent and Coast to Capital Local Enterprise Partnerships (working closely with the local highway authorities) to undertake an assessment of the economic benefits of strategic transport corridors. As well as enhancing connectivity within the area covered by the four LEPs, the corridors will also provide strategic links to neighbouring LEP areas such as Dorset, points north of Berkshire and the Greater London area.

For clarity, this is not a 'traditional' transport economics as monetised journey time savings and accident reduction benefits have not been calculated. Instead, the focus is on the wider economic impacts of the strategic corridors and specifically, how these can help boost connectivity and productivity in the region.

The geographical area covered by the four LEPs is of significant national economic importance as a large proportion of national wealth is generated here. As an example, the economy in Berkshire and the Thames Valley is one of the highest performing in the country given the very high levels of Gross Value Added (GVA) per head generated. Put simply, this means the area produces a significant share of national wealth - thus it is thus in the national interest for this to continue given how much is contributed to the "national economic cause".

Similarly, the economy of the Solent area is thriving with emphasis on the maritime and related specialist sectors near to Southampton and Portsmouth. For these to continue thriving, enhanced transport connectivity is essential, both between the two cities as well as between the Solent area and other areas of economic importance.

In addition, there is a fast-developing 'hi tech' sector within Surrey that is characterised by very high levels of productivity (GVA per worker). Given this is forecast to increase considerably in the future as these sectors expand, enhanced transport connectivity will be essential. However, without intervention, the very high levels of usage of the county's transport system is causing increasing amounts of delay and congestion and therefore acting as a block to full growth potential.

The 'Gatwick Diamond' agglomeration of industry in Sussex is another major generator of economic wealth. With key transport corridors such as the Brighton Main Line and the M23 / A23 corridor already operating at or near full capacity, corridor enhancements will generate significant economic benefits by enabling the area's growth potential to be realised.

The strategic transport corridors also address the lack of point-to-point connectivity across the region. This is the case for strategic links between Sussex and the Thames Valley where there is presently very poor transport access given the lack of direct links. This is why proposals to significantly enhance the North Downs Line (linking Redhill, Reigate and Guildford with the Thames Valley) are so important. Also, a new corridor between Horsham and the Thames Valley will offer significant economic benefits.

As well as generating economic wealth, the corridors will provide much-needed connectivity between some of the more peripheral areas of the region and centres of high economic growth. In East Sussex, for example, the coastal areas near Eastbourne and Hastings will benefit from much improved connectivity to mid-Sussex, Surrey and the Greater London area.

Improved connectivity is therefore essential for the following **two** key reasons:

- To facilitate continued economic expansion in the region via increased productivity and the national economic benefits this generates; and
- Improved access for workers accessing labour markets and areas of high productivity – this also works ‘both ways’ as firms will have improved access to a larger pool of suitably qualified workers.

The methodology used is based on current DfT guidance whereby agglomeration improvements stem from the enhanced productivity generated by better transport links. This is particularly applicable in the South East where there is a very high level of travel to / from places of employment. The concentrations of residential areas and areas of employment throughout the region mean that long-distance journeys to work are regularly made.

All of the major existing corridors see high levels of journeys being made and therefore if connectivity is improved, productivity will be also enhanced with all the consequent economic benefits this produces.

The wider benefits calculated include the following: **1)** increased agglomeration (through enhanced productivity), **2)** the employment the additional GVA supports and **3)** the various taxation benefits generated from additional employment.

Based on the strategic corridor analysis, the results provide a powerful indicator of the economic benefits that could be generated. The results below show the “Top Ten” corridors and the impacts generated.

SUMMARY RESULTS BY “TOP TEN” CORRIDORS

<u>Corridor</u>	GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATION TAX GAIN
South Coast Relief Road	£5.9 billion	36,000 jobs	£430 million	£282 million
South Sussex Way	£4.4 billion	29,000 jobs	£346 million	£211 million
Mid Sussex to Thames Valley	£3.6 billion	15,700 jobs	£189 million	£174 million
Southampton to Portsmouth	£2 billion	12,300 jobs	£150 million	£95 million
Reading to Waterloo	£1.9 billion	7,500 jobs	£90 million	£90 million
North Downs Line	£1.9 billion	8,000 jobs	£97 million	£89 million
Southern Access to Heathrow	£1.8 billion	8,200 jobs	£100 million	£88 million
A27 Corridor Upgrade	£1.5 billion	9,300 jobs	£111 million	£75 million
Brighton Main Line	£1.5 billion	7,500 jobs	£90 million	£70 million
A3 Corridor Upgrade	£1.1 billion	6,000 jobs	£71 million	£55 million

In overall economic impact terms (ensuring there is no ‘double counting’ of benefits across corridors serving similar geographies), total additional annual GVA would exceed £19.5 billion with over 100,000 additional jobs supported by this additional economic activity. Government would also gain annual additional revenue of £1.2 billion from personal income taxation and just under £1 billion per annum from corporation taxation.

It is important to point out that the above impacts represent the typical impact if this were to happen at the current time. In reality, these impacts will be realised every year from scheme implementation as they represent the difference between the ‘status quo’ (i.e. doing nothing) and the impact with these corridors in place.

There are also **major synergies** between the corridors:

- **Enhancing connectivity along the South Coast:** There are several major conurbations and centres of economic activity along the South Coast. These generate significant levels of economic activity and are forecast to grow in several different ways. Traffic levels and congestion on key corridors has reached a point whereby delays are commonplace. Corridor improvements along the A27, M27 and A31 will therefore enhance overall connectivity on an east-west axis.

In addition, the cities of Southampton and Portsmouth in the Solent area are economic 'powerhouses' in their own right and will benefit significantly from enhanced connectivity between them;

- **Enhancing the links between the South Coast and points further north:** Due to relatively long journey times and the comparative peripherality of the South Coast, several of the corridors put forward will enhance connectivity to London and other major centres of economic activity

The proposed upgrade of the 'A3' (Portsmouth – London) corridor as well as the upgraded Brighton Main Line and upgraded connection between Eastbourne and Surrey will all provide enhanced connectivity

In addition, there will also be considerable synergy between 'north – south' and 'east – west' corridors. Examples include better access to Portsmouth and the Solent area from the A3 corridor and subsequent better connectivity to points east and west (using the upgraded A27 and M27 corridors). Improving the A34 between Southampton and points north will also help to take 'pressure' off some of the other corridors;

- **Enhancing 'north – south' connectivity in the region:** In the Hampshire, Surrey and Mid-Sussex areas, historical corridor development has focussed on the main routes into London. Good north – south connectivity has therefore been difficult to achieve and this has been compounded in recent years by high levels of traffic on the north – south corridors

By proposing new corridors that link Mid-Sussex (Horsham) with the Thames Valley (Bracknell/Reading) as well as upgraded existing corridors (such as the upgraded North Downs Line), connectivity will be enhanced

Better north – south links will enable workers in these major centres to live further away as their commute times will be significantly enhanced. Similarly, improved connectivity between Basingstoke and Reading as well as between Southampton and Newbury will support growth in the region;

- **Enhancing connectivity between the South West / West of the region and London:** Although there are several major transport corridors linking the study area to London, there remain 'pockets' of population and economic activity that are comparatively poorly served. By improving connectivity in these corridors, workers will be able to access a much wider range of employment opportunities.

There is also potential for the corridors to provide strong linkages with neighbouring LEP areas and the wider South East / South West regions.

The analysis has also shown that although the costs of these improvements will be high, the extent of the potential benefits could exceed these by some margin. Although several of these corridors will be major undertakings requiring significant planning, construction works and expenditure, the 'goal' of greatly enhanced economic activity will have major national and not just regional importance. This is why it is vital that these improvements be considered and developed further.

1

INTRODUCTION

1.1 SCOPE OF THE WORK

Enterprise M3, Coast to Capital, Solent and Thames Valley Berkshire Local Enterprise Partnerships, working closely with the local highway authorities, have appointed WSP | Parsons Brinckerhoff to identify, describe and quantify the economic case for improving connectivity in major strategic movement corridors across South East England.

Rather than developing a traditional transport economic case, the objective is to identify outputs that set out the role of transport in raising productivity and supporting economic growth at a transformational level within the South East. As well as recognising the need to strengthen connectivity with London, another key objective is to strengthen existing and promote new corridors that will drive economic growth.

The focus on productivity is important as in the recent HM Treasury publication, "Fixing the Foundations", the Government has set out its 15 point plan to raise productivity, centred on two pillars:

- Encouraging long-term investment in economic capital, including infrastructure, skills and knowledge; and
- Promoting a dynamic economy that encourages innovation and helps resources flow to their most productive use.

The development of a "Modern Transport System with a Secure Future" is identified within the plan as one of the 15 areas of focus.

There are several different types of economic activity that take place and the extent to which transport can influence these is illustrated in Figure 1-1 below. Several of the transport-related impacts shown below are incorporated as part of this study.

Figure 1-1 Economic Activity and the Influence of Transport

1.2 STRATEGIC MOVEMENT CORRIDORS

The development of the movement corridors will be expected to address known and forecast problems and issues and to deliver the following benefits:

- Provision of new homes and business space in appropriate locations;
- Enhanced economic interactions and labour mobility through connectivity improvements;
- Better road and rail access to nationally important ports and airports;
- Improved cross country road and rail routes linking South East economic areas without the need to travel via Central London;
- Reducing congestion and removing bottlenecks on strategic road corridors;
- Improved journey times on the major rail lines into London; and
- Enhancements to the attractiveness of the area for new investment.

1.3 OBJECTIVES OF THE DRAFT REPORT

This report sets out the work undertaken, the methodology used and the findings across the range of issues and topics specified in the study brief.

The remainder of the report contains the following chapters:

- Chapter Two summarises the stakeholder engagement and data collation;
- Chapter Three describes the methodology used;
- Chapter Four identifies the movement corridors;
- Chapter Five contains the initial prioritisation of corridors;
- Chapter Six contains a preliminary identification of potential solutions;
- Chapter Seven contains a summary of potential infrastructure improvements;
- Chapter Eight contains descriptions and diagrams showing how the corridors will link areas of planned housing development; and
- Chapter Nine contains a summary, conclusions and recommendations for further work.

2 STAKEHOLDER ENGAGEMENT AND DATA COLLATION

2.1 INTRODUCTION

A major element of the work has been stakeholder engagement and the collation of relevant data and information. The purpose of this chapter is to summarise the findings from the stakeholder engagement and to provide details of the various items of data obtained.

2.2 STAKEHOLDER ENGAGEMENT

Given the wide geographical area covered by the study and the large number of stakeholders involved and interested in the study, it was important to consult and engage with a variety of organisations at the earliest opportunity.

We set out to do this through the following:

→ Stakeholder Consultation Events:

- Event 1 was held on Tuesday 3rd November 2015 in Horsham and was attended by representatives from local authorities in the study area as well as the organisation representing South East England Councils (SEEC), DfT and public transport operators (such as Stagecoach Rail, operators of South West Trains). The session outlined the objectives of the study and the proposed approach with useful feedback being provided by the attendees
- Event 2 was held on Monday 7th December 2015 in Basingstoke. This was attended by a large number of stakeholders from local authorities and other organisations. WSP | Parsons Brinckerhoff ran through progress to date, including discussion of the economic metrics used and data collated. The preliminary findings for the selected strategic movements were also discussed

→ Individual Meetings with Stakeholders:

- DfT meeting, Thursday 19th November 2015. WSP | Parsons Brinckerhoff met David Bull and economist Jago Penrose at DfT's Great Minster House offices to discuss the objectives of the study and the methodology to be used to calculate economic benefits. The use of current DfT WebTAG guidance as the "building blocks" to the analysis was discussed as well as the way in which other economic impacts not typically associated with transport scheme appraisals
- Surrey County Council meeting (freight issues), Wednesday 25th November 2015. This meeting with Peter Hitchings of SCC's freight team was important as it highlighted the extent of freight and logistics movements in both Surrey and the wider region. Key issues discussed including the extent that freight movements are generated in the area (both road and rail) and the key freight movement corridors
- AECOM meeting, Friday 27th November 2015. AECOM are currently working on the 'Solent Strategic Transport Investment Plan' for Solent LEP and given the synergies between the two studies, a meeting took place where both parties discussed their respective work. AECOM offered to review any Solent-specific corridor proposals and issues emerging from our work
- Stagecoach Rail (South West Trains) meeting, Tuesday 1st December 2015. This meeting with Phil Dominey, Stakeholder Engagement Manager, was extremely useful as Stagecoach are preparing for the upcoming South Western franchise bid and are collating

data across the South East region on forecast housing developments and employment growth. There are clearly synergies between their work and our's. We therefore agreed to remain in regular contact as both workstreams progress.

- Heathrow Hub meeting, Tuesday 2nd February 2016. This meeting with Steve Costello enabled the study team to understand the aspirations of Heathrow Hub (the independent organisation proposing to extend the northern runway at Heathrow Airport). These aspirations include several major transport corridor proposals in the region, including new rail links to the airport that are not dissimilar to some of new rail corridors proposed here
- Highways England meeting, Tuesday 9th February 2016. Meeting with John Henderson to discuss HE's current insight into potential corridor developments in the South East. Again, several of the corridors discussed were not dissimilar to those being proposed here, especially those corridors providing enhanced connectivity between the south coast and points further north as well as better linkage between Sussex and the Thames Valley.

→ **Discussions with Other Organisations:**

- Office of National Statistics (ONS). Given the importance of ONS data covering GVA at a sub-regional level and employment / wage data, WSP | Parsons Brinckerhoff have maintained regular contact with key contacts there (Richard Prothero and Trevor Fenton). Richard has advised on GVA data and other more detailed economic data whilst Trevor has advised on the proportions of GVA data that very broadly represent companies' profits (for corporation tax increase calculations)
- Local Authority Economic Data teams. As well as collating the information described in 2.3, we have obtained useful economic metrics from discussions with various other organisations, including Hampshire County Council's Social and Economic Research Manager (Alan Cole, already well known to WSP | Parsons Brinckerhoff from previous work) and TV Berkshire's Economic Research Analyst (Caroline Perkins).

2.3 DATA COLLECTION AND COLLATION

A major part of the work has been the collation of all relevant data, information and studies. The 'data request' to all stakeholders (including various agencies and local authorities) was issued by each respective member of the LEP Steering Group and covered the following:

→ **Request to Highway Authorities:**

- Transport flow data (by key mode, particularly road and rail)
- Relevant studies and reports covering transport movements and economic development
- Data relating to key freight movements
- Any other information that you consider relevant to this work

→ **Request to Planning Authorities:**

- Relevant Local Plans
- Relevant local economic data where this has been collated (such as local GVA and employment data)
- Any other relevant information covering economic development and trends / projections

Several items were received from local authorities and other agencies, including key data from District Councils in the study area. These are summarised in Table 2-1 below.

Gosport BC	Gosport Borough Local Plan 2011-2029 (adopted October 2015) Transport for South Hampshire and Isle of Wight Evidence Base - Gosport Borough Local Plan (2011-2029), March 2014 Local Plan – Employment Background Paper, June 2014
Gatwick Diamond	Gatwick Diamond BIS Statistics, August 2015 (various economic / demographic metrics for Gatwick Diamond area)
Fareham BC	Fareham Local Plan Part 2: Development Sites and Policies, June 2015 Fareham Local Development Framework, Core Strategy, adopted August 2011 Various employment and transport strategies
East Hampshire DC	East Hampshire District Local Plan Joint Core Strategy Proposed Submission: East Hampshire District Local Plan - Housing and Employment Allocations (incorporating minor modifications), June 2015
Coast to Capital LEP	Strategic Economic Plan (SEP), March 2014 Coast to Capital Housing Policy, September 2013 Various items from local authorities and other organisations (such as Gatwick Diamond – see above)

This data from the District Councils helped inform the housing and future growth analysis reported in Chapter 8. The Local Plan data provided indications of future plans, including new housing and employment site developments in key areas.

To supplement the data received in Table 2-1, we collated additional information from all local authorities in the study area. This meant that we were able to cover the plans of 45 different local authorities.

The figures in Chapter 8 indicate how the corridors will provide essential links and access to new developments throughout the region.

2.4 COLLATION OF ECONOMIC DATA

As well as the data from local authorities and various agencies, we have also collated economic data from sources such as ONS and DfT (the latter via the WebTAG Wider Impacts Dataset). This covers the following:

- **ONS GVA data** (from the most recent dataset available – the 2014 data was made available from ONS on 9th December 2015). The dataset includes:
 - 2014 Workplace GVA by NUTS3 area (see below for further explanation of NUTS3 areas)
 - 2014 Workplace GVA per head (by NUTS3 area) – this represents productivity
 - 2014 Workplace GVA by industry (NUTS3 level)
 - 2012 Workplace-based compensation of employees (NUTS2) – this represents the amount of GVA accounted for by incomes paid to employees and is used, amongst other purposes, as part of the process to calculate corporation tax benefits
- **ONS NOMIS data** (from the latest online dataset available). The dataset includes:
 - Employment data per Local Authority (July 2014 to June 2015 annual data)
 - Earnings data per Local Authority (2015 data)
 - Data on JSA claimants and numbers of businesses per Local Authority
- **DfT Employment / GDP per worker data** (from the current WebTAG “Wider Impacts” dataset). This includes:

- Total employment by Local Authority District (LAD) at five year intervals between 2006 and 2076
- Employment by sector (by LAD) at five year intervals between 2006 and 2076
- GDP per worker by sector (by LAD) for each five year interval as above

Given the importance of this data, further details are provided below.

ONS GVA DATA

The “NUTS3” level is the lowest geography by which ONS produces GVA and productivity data. NUTS stands for Nomenclature of Territorial Units for Statistics and is a standard ‘economic geography’ mapping system used throughout the EU.

To demonstrate this, the NUTS1 level covers the South East region as a whole whilst under this, NUTS2 covers 1) “Berkshire, Buckinghamshire and Oxfordshire”, 2) “Surrey, East and West Sussex”, 3) “Hampshire and Isle of Wight” and 4) “Kent”.

For the analysis we are undertaking, we have compiled data for the following NUTS3 areas in the study geography (highlighted in underscored bold). This also covers the more disaggregated geography incorporated in the December 2014 ONS updates:

→ Berkshire, Buckinghamshire and Oxfordshire:

- **Berkshire**

→ Surrey, East and West Sussex:

- **Brighton and Hove**
- **East Sussex CC**
- **West Surrey**
- **East Surrey**
- **West Sussex (South West)**
- **West Sussex (North West)**

→ Hampshire and the Isle of Wight:

- **Portsmouth**
- **Southampton**
- **North Hampshire**
- **Central Hampshire**
- **South Hampshire**
- **Isle of Wight**

The final NUTS2 area (“Kent”) has not been used as this comprises two sub-regions in the county that are outside our study area (Medway and Kent CC).

We do, however, use GVA data from outside the above NUTS3 areas when looking at corridors that link the study area with ‘outside’ areas. Examples include Wiltshire, Tunbridge Wells, Christchurch and Bournemouth.

As well as the study area defined above, ONS data is also available for the neighbouring LEP areas as defined in the study brief. The ONS datasets are the most comprehensive and up to

date available (note that due to the complexity of collating GVA data, each annual release represents one year in arrears – i.e. the data released in December 2015 was for 2014).

As well as the headline GVA data, productivity metrics are also available from ONS in the form of 'GVA per capita' data. GVA data is also disaggregated by 'worker compensation' (i.e. incomes) and by industrial sector in each area. Both are important datasets and have been used in this analysis. This is explained in more detail in Chapter 3.

ONS have also recently expanded their dataset to cover GVA and productivity for each of the LEPs. As an illustration of just how important the South East (and study area) is in terms of economic activity at a national level, the following two charts from ONS illustrate high performance relative to the UK average.

Figure 2-1 Nominal GVA per Hour Worked - Highest Ranking NUTS3 Sub-regions, 2013

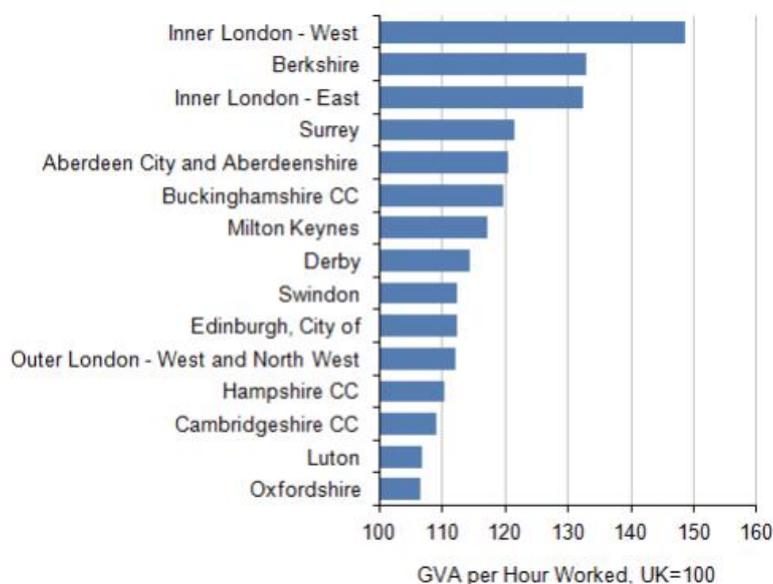

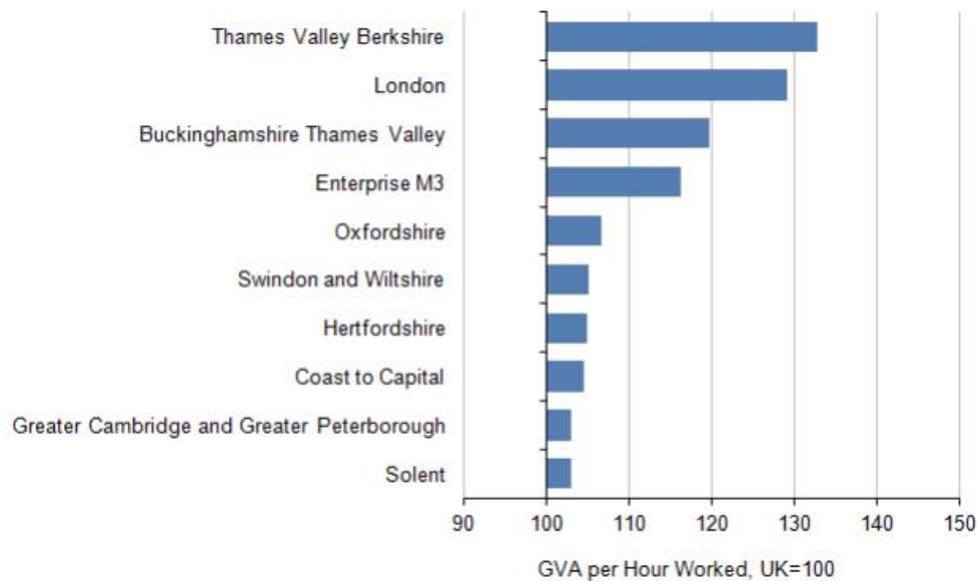

Figure 2-1 clearly shows how three of the areas in study area (Berkshire, Surrey and Hampshire) out-perform the UK average with Berkshire only second to Inner London West. This clearly shows the 'economic importance' of key areas in the South East as more GVA is produced per hour worked compared to many other parts of the country. The South East therefore has the potential to continue contributing substantially to national wealth and the consequent economic benefits this provides to the country as a whole. As a further example of this, Berkshire's GVA per head (based on the most recent ONS data) is almost 85% higher than that in Birmingham.

Figure 2-2 shows similar data, this time for the highest-ranking LEPs, with all four 'study LEPs' ranked in the Top Ten in terms of productivity performance (relative to the national average).

Figure 2-2 Nominal GVA per Hour Worked - Highest Ranking LEPs, 2013

Even before any corridor analysis is undertaken, these are extremely powerful metrics and indicate that with improved transport infrastructure in place, the already strong economic performance (with consequent national benefits) will improve even further.

NOMIS DATA

ONS also publishes NOMIS (“National Online Manpower Information System”) demographic and labour market data. This is up to date data and is important for our work as we use it to disaggregate the available GVA data to more localised areas.

In Berkshire, for example, NOMIS data for employment in each Local Authority District (LAD) can be used alongside workplace earnings data to enable us to apportion Berkshire GVA data to each LAD. Unsurprisingly, the highest proportion of GVA is generated in Reading.

The use of NOMIS is explained in more detail in Chapter 3.

DfT “WIDER IMPACTS” DATA

“Wider Impacts” is the term used by DfT in its WebTAG guidance for transport appraisal. Wider Impacts in this context cover Agglomeration and Labour Market impacts. The former refers to improvements in economic activity in a certain area due to transport improvements whilst the latter labour market changes due to these improvements (i.e. the national benefit of more workers becoming economically active as a result of the transport intervention).

The dataset developed by DfT to calculate these impacts will be used for this study and covers each Local Authority District in the country as well as four key industrial sectors in the economy (Construction, Consumer Services, Manufacturing and Producer Services).

Unlike the ONS data described above (based on out-turn metrics), the DfT WebTAG dataset is provided as a forecast up to 2076.

One key proviso made clear in the dataset is that these forecasts should not be used for any purpose other than estimating Wider Impacts. Their usage for this work is described in Chapter 3.

At the time of writing (February 2016), the DfT's wider economic impacts guidance is being updated to reflect TIEP report recommendations. The update will cover 1) more context-specific appraisals, 2) more transparent reporting and 3) greater consideration of land use change. The elasticities used for Wider Impacts calculation will also be updated with the final guidance update scheduled for November 2016.

Finally, the extent of geographical coverage in the dataset is shown in Table 2-2 below.

Table 2-2 Local Authority Districts in DfT Dataset

COUNTY LEVEL	LOCAL AUTHORITY DISTRICT (LAD)	LEP
West Sussex	Adur	Coast to Capital
	Arun	Coast to Capital
	Chichester	Coast to Capital
	Crawley	Coast to Capital

3 METHODOLOGY

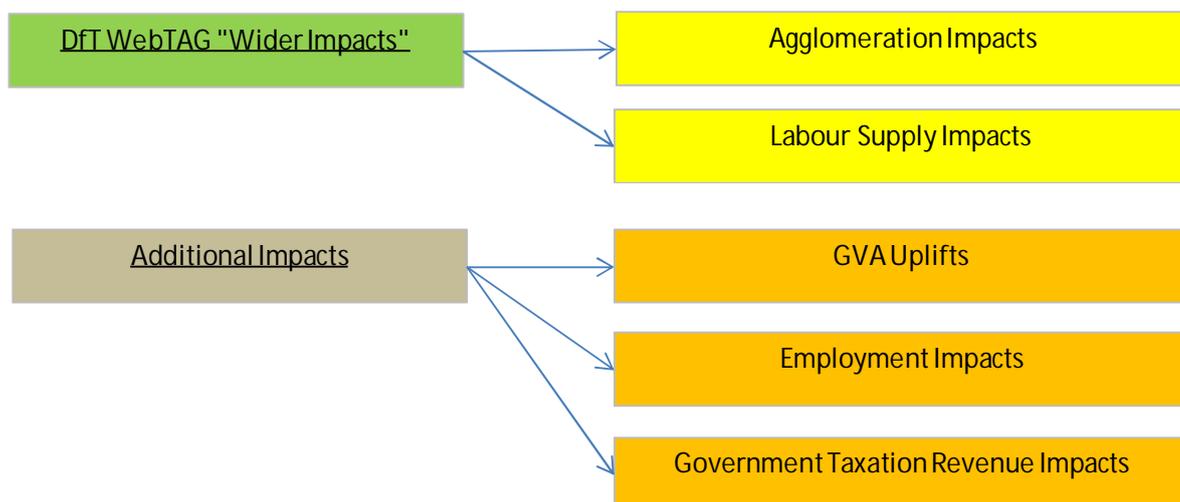

3.1 INTRODUCTION

In this chapter, we set out the methodology used. There are several key features:

1. The “building blocks” of the analysis use recognised guidance based on Treasury Green Book principles (i.e. DfT’s WebTAG approach covering Wider Impacts is itself based on Green Book guidance);
2. Although founded on WebTAG principles, several add-on economic impacts and metrics are derived (such as the impacts improved productivity has on regional GVA, employment and taxation revenues);
3. The impacts are calculated in two ways: 1) firstly, as a “snapshot” of current impacts (i.e. what is the economic impact if the change took place now?) and 2) what is the “longer term” (or forecast) impact over time? – this is explained in more detail below;
4. The approach is used at a high level to identify and prioritise corridors before more detailed analysis takes place for shortlisted corridors (i.e. to include proposed residential developments etc.); and
5. The method is designed to be flexible enough to be able to test several different strategic movement corridors.

To broadly demonstrate which elements of the approach are based on current DfT guidance and which are additional to this current guidance, Figure 3-1 illustrates the various types of impacts and on what basis they are derived.

Figure 3-1 Components of Methodology

We recognised the importance of gaining stakeholder acceptance of the method and in particular, acceptance from DfT given their ongoing work on assessing the wider impacts of transport schemes.

As noted in Section 2.2, we met with DfT on Thursday 19th November at which the following was discussed:

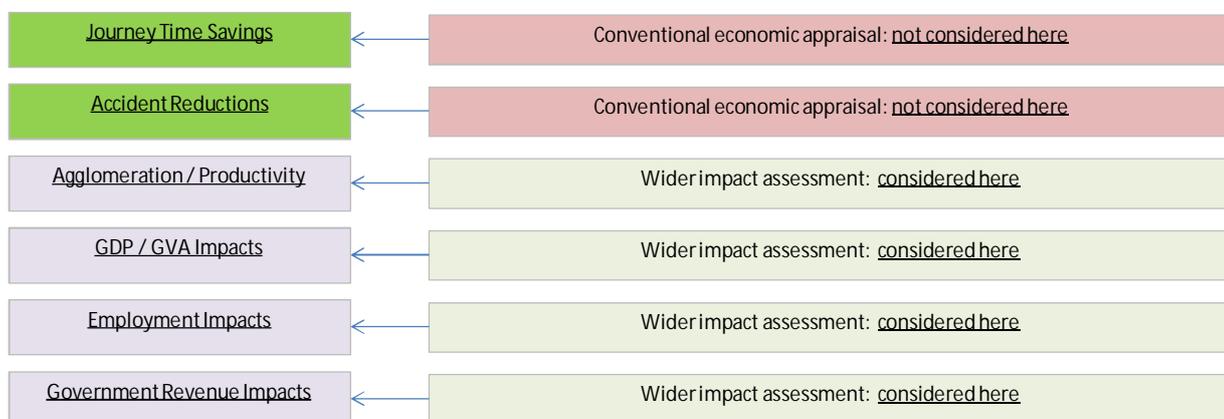

- The intended outcomes of the study;
- The method to be used for this study; and
- Discussion of DfT's own "direction of travel" on assessing the impact of transport on economic development and productivity.

DfT noted the proposed approach, especially the use of current WebTAG guidance and the use of changes in generalised costs of travel to calculate a range of productivity-based economic benefits. We also sought clarification from DfT on a number of data source issues.

Before setting out the approach, it is important to state that transport schemes also generate 'conventional' benefits as well as the wider impacts we are assessing here. Although conventional impacts such as monetised journey time savings and the value of reduced accidents are not quantified here, they nevertheless form part of the justification for transport schemes and when included as part of a full business case, are likely to boost the overall justification for the schemes.

Figure 3-2 sets out the key types of impacts of a transport scheme and those that are quantified as part of this study.

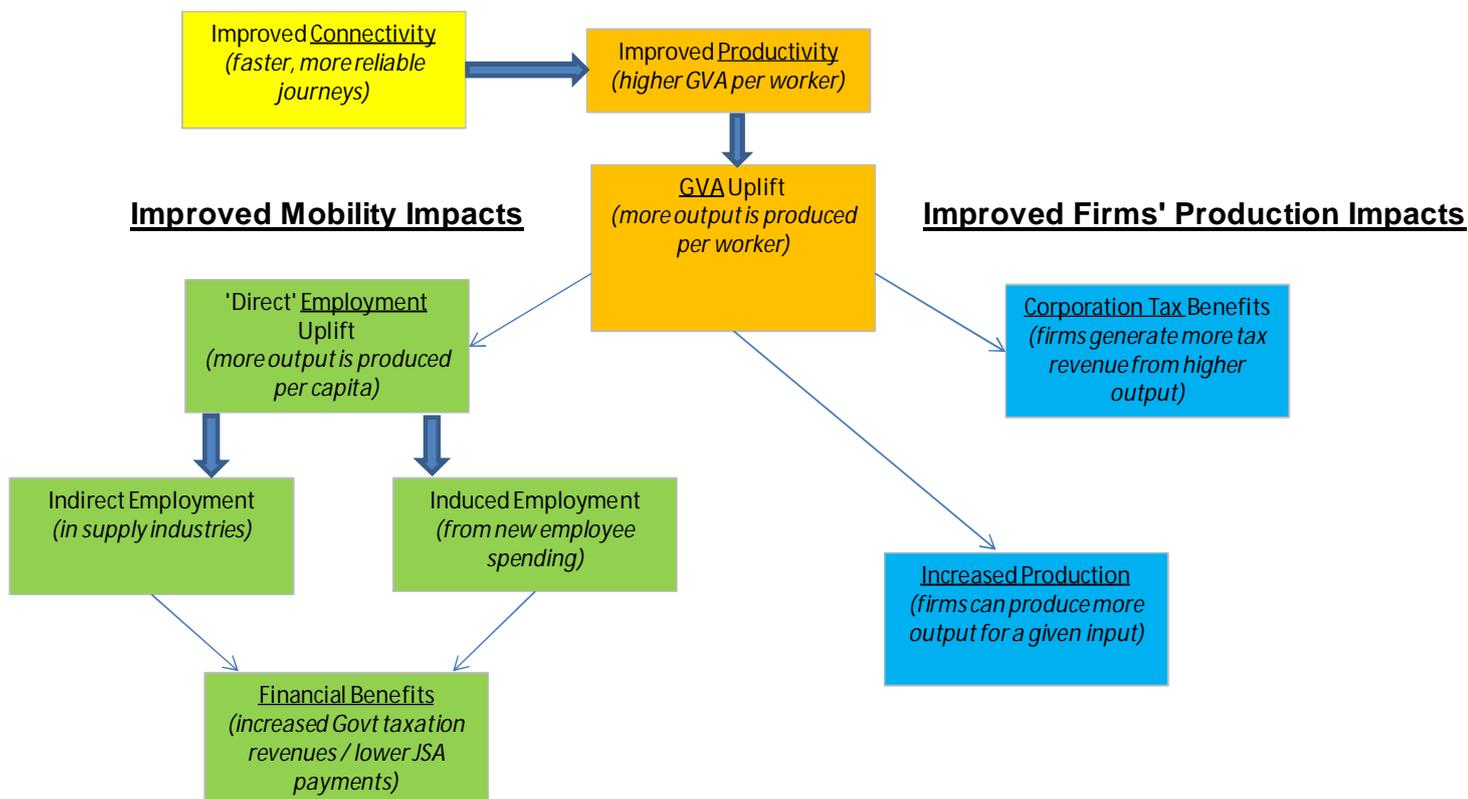

Figure 3-2 Conventional and Wider Economic Impacts of Transport Schemes

3.2 OVERVIEW OF METHOD

To provide an overview of the method, Figure 3-3 shows the key economic impacts that flow from improved connectivity.

Figure 3-3 Overview of Method

The following describes this process:

- In the yellow box, this shows that the principal driver of change (and economic benefits) is the improvement in connectivity in each corridor;
- In the orange boxes, the key effects of improved connectivity are 1) **increased productivity** (due to agglomeration benefits as workers now have better access to higher value jobs and businesses now have better access to a larger pool of suitably skilled workers) and 2) **increased GVA** stemming from higher productivity per worker;
- The green boxes labelled under “Improved Mobility Impacts” refer to the benefits that are primarily due to the improvements in personal mobility (such as better access to / from labour markets) arising from corridor improvements. As well as additional employment supported by increased economic activity, there will be financial benefits to Government in the form of increased income taxation; and
- The blue boxes (under “Improved Firms’ Production Impacts”) indicate the types of impacts associated with improved corporate and business activity. These impacts include 1) increased corporation tax due increased profits from enhanced activity and 2) potential gains from decreases in firms’ production costs (i.e. with reduced transport costs, firms can produce the same level of output at lower costs).

Whereas Figure 3-3 sets out the range of economic impacts stemming from better connectivity, the key steps in the method are as follows:

- The study area (i.e. the area covered by the four LEPs plus the rest of the East Sussex County Council areas as well as the linkages to neighbouring LEPs and London) is mapped with the respective Local Authority Districts (LADs) acting as zones;
- Each potential strategic movement corridor is represented by a link between Origin Point A and Destination Point B (for example, the Brighton Main Line is one such corridor with the A3 road corridor between Guildford and Portsmouth being another);
- Given current DfT “agglomeration” guidance, a productivity impact of improving journey time / journey reliability can be used in each corridor for two purposes:
 - To identify and prioritise corridors relative to each other (i.e. a transformative 15 minute journey time improvement in one corridor may have a very different impact compared to the same improvement in another corridor)
 - To calculate the economic impacts of improvements in each corridor
- Once the productivity impact has been calculated, this can be used to calculate a series of economic benefits, including increased GVA, employment and Government financial benefits; and
- Using graphics and figures, these impacts can be shown on a series of diagrams and maps.

Figure 3-4 shows an example of how this process works in practice. The example chosen is the A3 corridor improvement between M25 Junction 10 (in Elmbridge Borough Council) and Portsmouth.

Figure 3-4 Example of Corridor Improvement Method

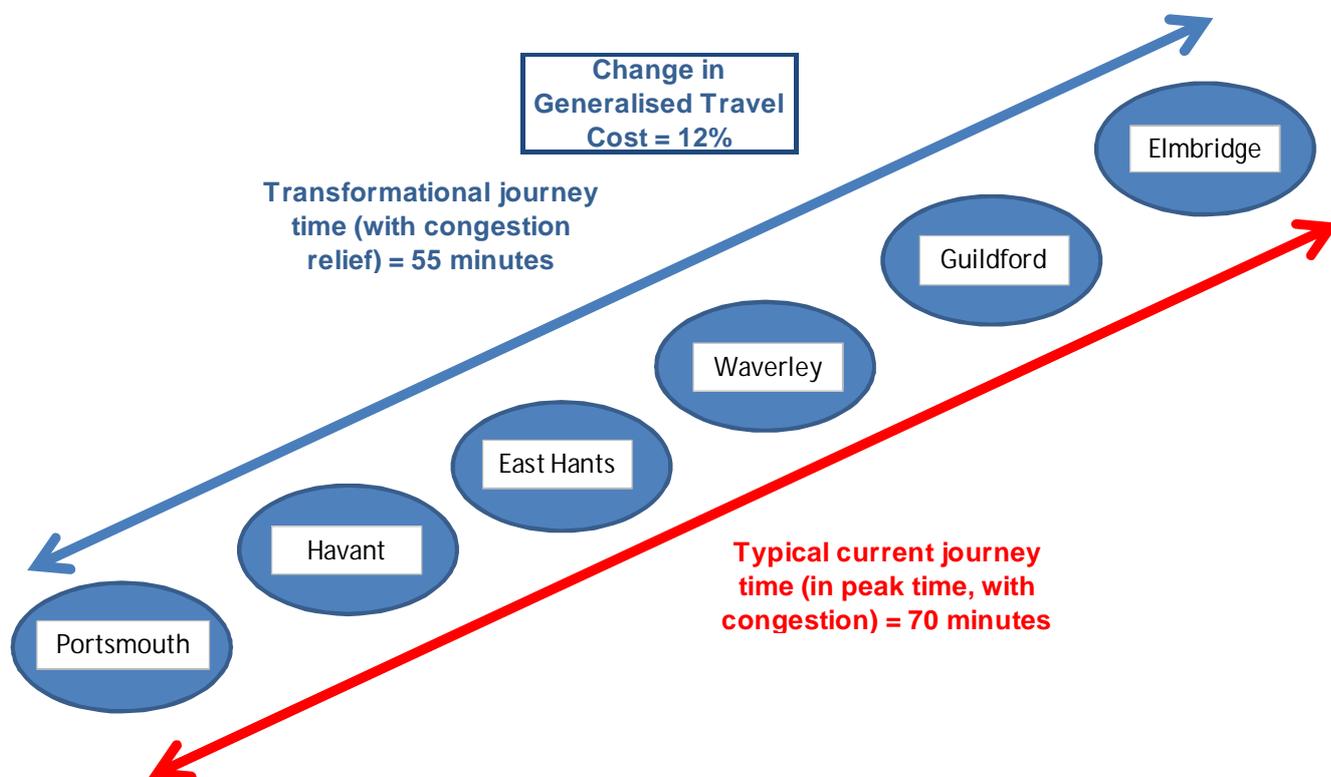

Figure 3-4 shows the Local Authority Districts that the A3 corridor passes through. Assuming a current 'worst case' (congested) journey time of 70 minutes – including, for example, severe delays in the Guildford area – a transformative corridor improvement (suitable widening of the Guildford section etc.) could give a journey time / journey reliability improvement of 15 minutes.

Taking into account given travel values of time and fuel costs, the change in generalised costs (i.e. the monetised value of all key elements of the journey) will be approximately 12% - *in other words, a 12% reduction in generalised costs.*

There are published elasticities by each different sector of the economy (WebTAG categorises these as 1) Construction, 2) Consumer Services, 3) Manufacturing and 4) Producer Services). The elasticities are ratios that are used to calculate the percentage change in productivity based on the percentage change in generalised costs.

The following shows how this process works for each of the four sectors:

- **Construction:** elasticity = -0.057: i.e. a 10% *decrease* in generalised costs gives an 0.6% *increase* in productivity;
- **Consumer Services:** elasticity = -0.047: i.e. a 10% *decrease* in generalised costs gives an 0.5% *increase* in productivity;
- **Manufacturing:** elasticity -0.025: i.e. a 10% *decrease* in generalised costs gives an 0.3% *increase* in productivity;
- **Producer Services:** elasticity -0.157: i.e. a 10% *decrease* in generalised costs gives an 1.6% *increase* in productivity.

To establish whether these 'national' elasticities could be adjusted to reflect more local factors, the Transport Appraisal and Strategic Modelling (TASM) team at DfT were contacted. Their advice was that although agglomeration elasticities are estimated nationally, where a robust case is made for it, it is possible for scheme promoters to utilise more context-specific (for example regional) elasticities. These would be drawn from the literature or estimated from available data. Results from such an approach should be reported as a sensitivity test alongside results using WebTAG elasticities. For this analysis, this could form the basis of more detailed corridor assessment where this is required in future.

It is the changes (reductions) in the generalised cost of travel within each corridor that drives changes in productivity, GVA and the various other economic and financial metrics. Taking the A3 corridor improvement in Figure 3-4, for example, the impacts will be calculated for all LADs in the corridor and not just the 'origin' (e.g. Elmbridge) and 'destination' (e.g. Portsmouth) areas.

For each LAD and for each of the four sectors, the following is calculated:

- The total GVA uplift based on the percentage increase in productivity multiplied by a) GVA per worker, b) total number of workers and c) the proportion of economic activity in that particular sector;
- Direct employment based on the uplift in GVA divided by the amount of GVA required to support each worker in each LAD (the proportion of GVA spent on employee incomes and the proportion of GVA 'spend' retained in each area is also taken into account); and
- Indirect and induced employment is calculated by applying standard employment multipliers to the direct employment totals.

The employment impacts are used to derive **income taxation benefits** to Government as well as the **JSA payment savings** resulting from more workers moving into employment. Both these impacts demonstrate the 'wider' financial gains for Government and use income distribution and JSA data from official statistical sources.

Corporation taxation benefits are calculated by applying the proportion of GVA representing corporate profits and the corporation tax rate to the uplift in GVA.

The economic value of the **increase in production** due to corridor improvements applies to the two sectors most likely to benefit from these impacts; a) the Construction sector and b) the Manufacturing sector. Activities in each of these sectors comprises some form of physical output that can be produced for a lower unit cost when transportation improves within each corridor.

The economic value of these impacts is calculated by applying an elasticity value (-0.052) to the change in generalised cost in each corridor and to the total GVA representing each of the two sectors. The resulting value is a further uplift in GVA.

The above method has several advantages:

- It is based on recognised methods and can be calculated relatively quickly given the information already available;
- It is flexible and can be used to assess different types and lengths of corridors (featuring different modes);
- Once the productivity impacts have been calculated, these can be applied to the latest ONS GVA data to give a regional and national impact; and
- There is sufficient flexibility in the input assumptions for each corridor so that these can be adjusted for sensitivity testing.

It is also important to emphasise that the types of economic benefit described above are based on a “snapshot” of the impacts. In other words, it is possible to calculate the benefits that are likely to occur using current year data for each corridor.

“**Long term**” forecasts have also been produced and these form part of the high level cost-benefit appraisal of each shortlisted proposal. This enables the benefits to be forecast over a given period.

3.3 DATA SOURCES USED

There are several different data sources used. To summarise these and to indicate the geographical disaggregation of the data, Table 3-1 shows each key item and its source.

Table 3-1 Data Sources

DATA CATEGORY	GEOGRAPHY	SOURCE
GVA (includes GVA by industry sector)	NUTS3 level (2013 data released in December 2014)	ONS
GVA (includes GVA by workplace income)	NUTS2 level (2012 data released in December 2014)	ONS
Employment and average earnings data	Local Authority District (LAD) level	ONS NOMIS
Agglomeration elasticities	(By four key sectors in the economy)	DfT WebTAG (Unit A2.1)
Economic output (expenditure) retained in region	General UK data	ONS: detailed household expenditure by gross income quintile group for all households, 2010-2012
Percentage of GVA representative of corporate profit	General UK data	ONS: discussion with Trevor Fenton, Regional Accounts, 27.11.15
UK income distribution by earnings bands	South East data	Govt statistics: https://www.gov.uk/government/statistics/income-and-tax-by-gender-region-and-country-2010-to-2011
UK JSA data	General UK data	Govt statistics: https://www.gov.uk/jobseekers-allowance/what-youll-get

4 IDENTIFICATION OF MOVEMENT CORRIDORS

4.1 INTRODUCTION

We have used a combination of economic data, transport information and general knowledge of the South East region to identify and define strategic movement corridors. The corridors are defined at a high strategic level and comprise both **existing** and **potential** corridors.

This chapter contains a summary of these corridors and the rationale for their selection and further analysis. Once the corridors have been identified, they are prioritised based on the further analyses reported in Chapter 5.

4.2 BASIS FOR SELECTING CORRIDORS

The selection of corridors was based on several factors, including an in-depth appreciation of the key centres of economic activity in the study region and the key transport issues affecting the region. The basis for selecting the corridors is as follows:

- For **existing** corridors, corridors were selected on the basis of known high traffic flows, capacity constraints (especially during busy 'peak' periods) and the extent to which the corridors have a major 'connectivity' purpose. Examples include:
 - **A3 Corridor:** despite the opening of the Hindhead Tunnel in 2011, the A3 continues to experience significant congestion on key sections
 - **Brighton Main Line:** the rail link between Brighton and London provides essential connectivity not only between the South Coast and the capital, but also between major towns on the route
 - **A27 Corridor:** this major road corridor is one of the key transport arteries along the South Coast and experiences significant congestion at key pinchpoints

- For **potential** corridors, a slightly different set of criteria applied as the objective here was to identify corridors where there was unlikely to be major existing flows but nevertheless considerable potential for providing transformative links between major centres. Examples include:
 - **Mid-Sussex to Thames Valley Road Corridor:** linking Horsham with Reading and the Thames Valley, this road would provide a vital new north-south corridor linking mid-Sussex with the economic powerhouse in the Thames Valley
 - **Southern Access to Heathrow:** this new corridor (including use of key sections of existing rail links) would provide crucial southern access to Heathrow Airport from locations such as Guildford, Woking and Staines
 - **"South Sussex Way"** – this is a transformational corridor linking Salisbury (via the A36) with Winchester, Petersfield, Horsham and Tunbridge Wells (to connect with the A21)

The corridors selected do not include some of the principal motorway corridors (such as the M25) as these are currently the subject of other major studies, including Highways England's "M25 South West Quadrant Study" and the various Route Based Strategy (RBS) analyses being undertaken.

The selection of corridors also reflected discussions with stakeholders with the second consultation event on Monday 7th December 2015 providing useful feedback on the initial series of corridors selected.

The corridors also reflected the work already being undertaken in certain LEP areas. We have liaised, for example, with the AECOM team working on Solent's Transport Investment Plan and have therefore selected corridors that reflected their emerging findings.

Examples include improvements in the crucial Southampton to Portsmouth corridor as well as improved links between the Solent area and the other LEP areas (such as the M3 / A34 corridor north of Southampton).

As part of the stakeholder consultation events, the transport mode to be assessed for each corridor was discussed. Taking the 'A3' corridor improvement as an example, the analysis could either focus on the upgrade being based on a single mode (such as road) or could cover both rail and road improvements.

It was agreed that the initial high level economic impact analysis would focus on each corridor initially with further work at the feasibility stage focussing on the most appropriate mode to take forwards.

Rather than view the corridor improvements as low-key, we have assumed that the changes will be 'transformational' in that major journey opportunity, time and reliability enhancements will take place.

Also, the advantage of our method is that we have sufficient flexibility to make quick adjustments to our input assumptions so that the economic impacts can be readily tested.

Finally, the list of corridors is not exhaustive and is primarily intended to demonstrate the economic potential of a series of major transformative corridors across a large area in the South East.

4.3 CORRIDORS EVALUATED

The series of corridors evaluated are summarised in Table 4-1.

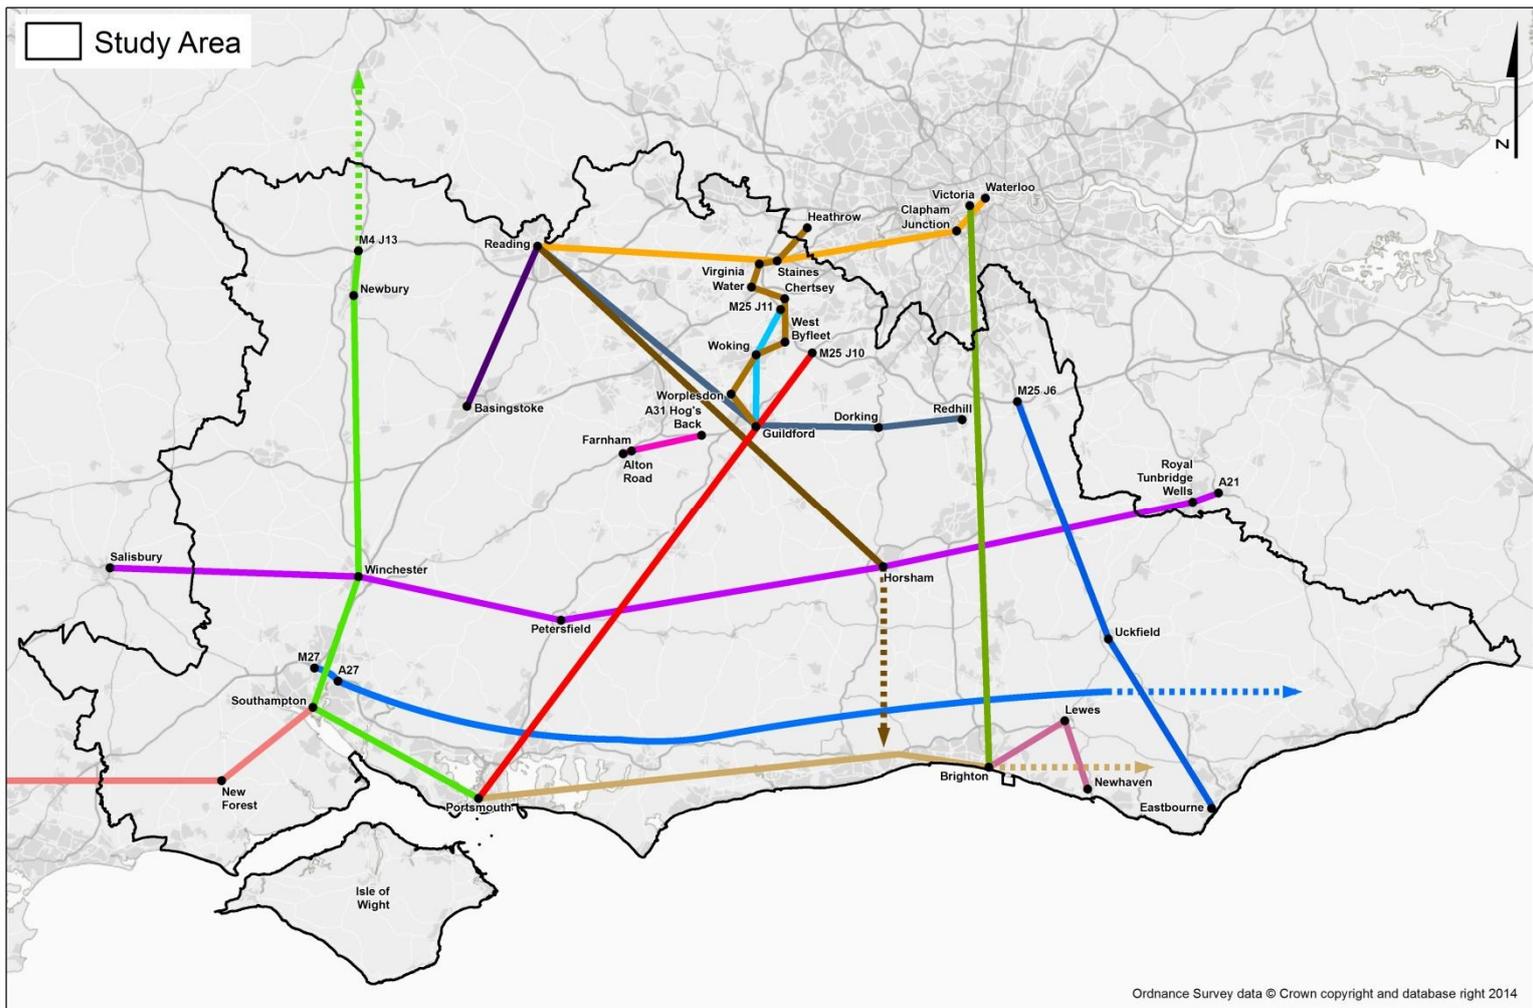

Table 4-1 Corridors Selected for Evaluation

SCHEME	DESCRIPTION / STATUS	RATIONALE
A3 Corridor Improvement	Upgrade of corridor between Surrey and the outskirts of Portsmouth	The corridor between London and Portsmouth – whether by rail or road – is a key transport artery and experiences severe delays at busy periods
A22 Corridor Upgrade	An improvement in the corridor linking Eastbourne on the South Coast with Surrey, the M25 and points further north	The existing A22 road corridor (and parallel rail routes) does not offer good connectivity between this part of East Sussex and points further north (including the M25 and London)
A27 Corridor Improvement	Upgrade of the corridor between Brighton and Portsmouth	There are several 'bottlenecks' on the A27 (e.g. at Arundel and Chichester) – this is a major east-west corridor near the South Coast (note also that the 'Coastway' rail route parallels the A27)
A31 Upgrade	An improvement to the Hog's Back - Farnham - Alton road corridor	The A31 (and its intersection with the A3 near Guildford) is one of the main 'bottlenecks' in this part of Surrey and Hampshire

A33 Road Upgrade (Basingstoke – Reading)	An upgrade of this key road corridor	Traffic data shows how busy this corridor is between two of the key centres of employment in the region
A34 Corridor Upgrade (Southampton to Newbury and M4 J13)	An upgrade of this key road corridor	This is another busy, 'economically important' corridor in the region (traffic data also shows high flows)
A320 Corridor Upgrade	An upgrade of the A320 road corridor linking Guildford with Woking and M25 Junction 11	Based on previous WSP PB work for Surrey CC, Guildford BC and Woking BC, this is one of the key congested corridors in the area
Brighton Main Line Upgrade	Upgrade of the main rail link between Brighton and London	This is one of the main transport corridors in the region (note that the parallel road corridor is the M23 via Gatwick Airport)
Mid-Sussex to Thames Valley New Corridor	A new 'transformative' corridor between mid-Sussex and the Thames Valley	Given the lack of north-south corridors in the region, this transformative corridor will link these two key areas – note that there is also some overlap with the proposed 'North Downs Line' upgrade
Newhaven - Lewes - Brighton Corridor Upgrade	An upgrade of this important corridor between Newhaven and Lewes	The links between these major towns on the South Coast currently involves a time-consuming journey, including the very busy junction between the A26 and A27
North Downs Line Upgrade	Upgrading the current diesel-operated line between Redhill, Reigate, Dorking, Guildford and Reading (this route also provides a direct link between Redhill and Gatwick Airport)	This upgrade would involve enhancing connectivity on this critical corridor – although this has some similarities with the proposed Mid-Sussex to Thames Valley corridor described above, the rail route travels on an east-west axis before heading north between Guildford and Reading
Reading - Waterloo Rail Upgrade	An upgrade of the line between Reading, Bracknell and London Waterloo	Given continued economic growth in the Thames Valley area and relatively slow rail journey times in this corridor, these improvements will allow the key towns in Berkshire to be better connected to various locations on the line into Waterloo
'Southern Access to Heathrow'	A new rail link between Guildford and Heathrow (via Woking, Virginia Water, Staines & Heathrow Airport)	This new corridor will open up new journey opportunities between Guildford, Gatwick - and points south of Heathrow - and the airport
Southampton - New Forest Corridor Upgrade (M27 / A31)	An improvement on the M27 and A31 heading west out of Southampton and the Solent area	This is a busy transport artery connecting Southampton with the New Forest and all points west (such as Poole and Bournemouth)
Southampton to Portsmouth Corridor Upgrade	Both cities in the Solent area are economic 'powerhouses' in their own right and improved connectivity between them will offer significant agglomeration benefits	By improving the existing rail corridor significantly, journey times will be reduced allowing far better connectivity for businesses and workers
"South Sussex Way"	Salisbury (A36) – Winchester – Petersfield –Horsham - Tunbridge Wells to connect with the A21	This is a transformational corridor that will link Wiltshire with Hampshire, Sussex and Kent
"South Coast Relief Road"	This comprises a bypass to the M27 and A27 for traffic not wishing to access Portsmouth, Southampton and Brighton	This transformational corridor will enable drivers to bypass the already congested centres in Portsmouth, Southampton and Brighton

Figure 4-1 shows the geographical location of the corridors across the study area. The figure also shows how the corridors can combine to form a transport movement 'network' across the region and by implication, how important this will be in terms of supporting economic growth (at both the regional and national level).

Figure 4-1 Selected Corridors in the Study Area

5 PRIORITISATION OF CORRIDORS

5.1 INTRODUCTION

The purpose of this chapter is to summarise the findings from the corridor analysis and to use the outcomes of this analysis to prioritise the corridors in terms of the economic benefits they generate.

This process uses the economic methodology described in Chapter 3 and covers the sectoral make-up of the individual economies (in this context, individual economies are those of the Local Authority Districts, LADs, in the study area).

In the final part of the chapter, we address how the movement corridors relate to each other to address issues across the South East and the wider area.

5.2 RESULTS

The results are presented in a series of tables that show the key economic metrics for each corridor.

In overall economic impact terms (ensuring there is no double counting of benefits across corridors serving similar geographies), total additional annual GVA would exceed £19.5 billion with over 100,000 additional jobs supported by this additional economic activity. Government would also gain annual additional revenue of £1.2 billion from personal income taxation and just under £1 billion per annum from corporation taxation.

The values shown in the tables below represent the *additional* benefits generated by the improvements in each corridor. These additional benefits cover the improvements in existing corridors as well as the transformative improvements associated with the new corridors.

The 'headline' impact is the additional GVA generated with the other monetary values shown not necessarily additive to this but nevertheless demonstrating the extent of potential additional revenues accruing to Government.

Before prioritising the corridors, the results for each corridor are presented in the order shown in Table 5-1 onwards. Short descriptions per corridor are also given.

It is also important to emphasise that the results shown overleaf represent those in a single year, i.e. they show what the net impact would be if the change in each corridor took place at the present time. These are powerful impact metrics and they demonstrate the magnitude of the potential benefits of each strategic corridor.

A3 CORRIDOR IMPROVEMENT

Table 5-1 A3 Corridor Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£1.1 billion	6,000 jobs	£71 million	£55 million	£34 million	£19.6 million

The results show the impact of a significant improvement in a long-distance corridor connecting not only two major conurbations (London / Surrey and Portsmouth) but also the intermediate local authority areas affected by the upgrade.

A22 EASTBOURNE - LEWES - UCKFIELD - SURREY CORRIDOR IMPROVEMENT

Table 5-2 A22 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£250 million	1,600 jobs	£19 million	£12 million	£14 million	£5.7 million

This corridor upgrade is based on improving the A22 corridor as far north as the M25 interchange near Godstone in Tandridge. The impacts are therefore concentrated in the boroughs of Eastbourne, Wealden, Mid Sussex and Tandridge. The improvement will also, however, enhance connectivity via the M25 and thus a much wider range of journey opportunities will be opened up.

A27 CORRIDOR UPGRADE

Table 5-3 A27 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£1.5 billion	9,300 jobs	£111 million	£75 million	£32 million	£31.3 million

Upgrading the existing A27 corridor between Brighton and Portsmouth has been a major regional objective for a significant period of time. By improving connectivity through eliminating the bottlenecks at Arundel and Chichester, for example, a large number of economic benefits will accrue. The upgrade also gives much needed connectivity improvements to the fast-growing Solent economic area.

A31 HOG'S BACK - FARNHAM - ALTON CORRIDOR IMPROVEMENT

Table 5-4 A31 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£188 million	1,000 jobs	£12 million	£9 million	£19 million	£9.4 million

Compared to some of the other corridor improvements, this proposed upgrade has one of the lowest levels of impact. At this stage we have considered the benefits as accruing in the LADs of Guildford and East Hampshire given that these are the areas most affected by current congestion levels.

A33 BASINGSTOKE - READING CORRIDOR UPGRADE

Table 5-5 A33 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£728 million	3,400 jobs	£41 million	£35 million	£39 million	£42.8 million

The A33 connects two of the principal centres of economic activity in the South East and by upgrading this corridor, various benefits will accrue. These include GVA uplifts from increased agglomeration and firms' production increases as well as the financial gains to Government shown in Table 5-5.

A34 CORRIDOR UPGRADE (SOUTHAMPTON - NEWBURY / M4 J13)

Table 5-6 A34 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£1 billion	5,900 jobs	£70 million	£50 million	£22 million	£23.9 million

As well as having high traffic flows, the A34 corridor between Southampton, Newbury and Junction 13 of the M4 (and then points further north) has a very important strategic role to play. This strategic role encompasses the connectivity the corridor provides between Southampton (and its major port) and points north, including the Midlands and beyond. Given that this is one of the most important 'north – south' corridors in the region, its upgrade will not only improve north – south connectivity but will also help relieve the pressure on some of the more 'east to west'-facing corridors.

A320 CORRIDOR UPGRADE

Table 5-7 A320 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£545 million	2,500 jobs	£29 million	£26 million	£20 million	£42.3 million

Although one of the shorter corridor upgrades in terms of distance, the A320 remains one of the most important (and most congested) routes in Surrey. As well as congestion coming on / off the A3 and on to the A320, traffic volumes are also very high on this main route to Woking and the M25. As Table 5-7 indicates, even in this comparatively 'localised' area, there will be significant benefits.

BRIGHTON MAIN LINE UPGRADE

Table 5-8 BML Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£1.5 billion	7,500 jobs	£90 million	£70 million	£30 million	£21.9 million

Upgrading the Brighton Main Line (in the key "A23 / M23" corridor) will have significant benefits in Brighton, the Mid Sussex area, Crawley and Croydon. Agglomeration benefits will also accrue from improved access to the 'high value' jobs market in the City of Westminster.

MID-SUSSEX TO THAMES VALLEY NEW CORRIDOR

Table 5-9 Mid-Sussex to Thames Valley Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£3.6 billion	15,700 jobs	£189 million	£174 million	£85 million	£53.8 million

With such a major 'transformational' corridor, there will be significant economic benefits as workers will have much better connectivity with the Thames Valley area whilst workers will also be able to access high value jobs in the Gatwick Diamond area. Companies will also benefit from the transformational corridor as transport access and delivery times will be significantly reduced.

NEWHAVEN - LEWES - BRIGHTON CORRIDOR UPGRADE

Table 5-10 Newhaven –Lewes – Brighton Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£139 million	900 jobs	£11 million	£7 million	£7 million	£8.5 million

The results shown in Table 5-10 indicate the range and scale of the 'localised' economic impacts when the busy route between Newhaven and Brighton (via Lewes) is upgraded.

NORTH DOWNS LINE UPGRADE

Table 5-11 North Downs Line Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£1.9 billion	8,000 jobs	£97 million	£89 million	£27 million	£32.5 million

This rail corridor upgrade will also generate substantial economic benefits as much better connectivity will be provided between Surrey (on an east – west axis linking Redhill, Reigate, Dorking and Guildford) and Reading / the Thames Valley. The route also connects with Gatwick Airport via the section of line south of Redhill. As with the Reading – Waterloo line, current journey times are comparatively slow and the step change provided by this corridor improvement will generate a range of benefits.

READING - WATERLOO RAIL UPGRADE

Table 5-12 Reading to Waterloo Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£1.9 billion	7,500 jobs	£90 million	£90 million	£28 million	£43.5 million

This upgrade of the existing rail corridor between Reading and Waterloo will have several benefits, not least by providing much better connectivity for those travelling between the Thames Valley area and the west London suburbs as well as central London. The comparatively slow journey times on this corridor have been recognised as having a detrimental impact on the economic potential of the area.

SOUTHERN ACCESS TO HEATHROW

Table 5-13 Southern Access to Heathrow Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£1.8 billion	8,200 jobs	£100 million	£88 million	£38 million	£70.5 million

By upgrading existing lines and building new sections of line direct to Heathrow Airport, a large number of new journey opportunities will be opened up. Economic benefits will be generated as much needed access from key locations such as Guildford and Woking direct to Heathrow will be provided.

SOUTHAMPTON - NEW FOREST CORRIDOR UPGRADE (M27 / A31)

Table 5-14 M27 / A31 Corridor Upgrade Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£715 million	4,700 jobs	£56 million	£34 million	£20 million	£21.5 million

The corridor linking Southampton and the Solent area with points west is one of the most important corridors in the region and has been identified in current work being undertaken for Solent LEP. Given that congestion occurs regularly on the capacity constrained sections of the A31, a significant corridor enhancement will unlock significant economic benefits.

SOUTHAMPTON TO PORTSMOUTH CORRIDOR UPGRADE

Table 5-15 Southampton to Portsmouth Corridor Upgrade

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	GVA PER MILE
£2 billion	12,300 jobs	£150 million	£95 million	£65 million	£89.8 million

This corridor upgrade focuses on a major improvement to the existing rail line between the two cities (both being key economic 'powerhouses' in the region). With current rail services characterised by comparatively slow journey times and several stops en route, a major upgrade will not only provide enhanced connectivity but will also relieve the pressure (and traffic congestion) on the nearby road corridors. To meet its economic growth trajectory, the Solent area needs significantly improved transport connectivity and an upgrade of this corridor will help achieve this.

“SOUTH SUSSEX WAY” – NEW CORRIDOR

Table 5-16 “South Sussex Way” Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£4.4 billion	29,000 jobs	£346 million	£211 million	£113 million	£38.2 million

By constructing a transformative corridor in an alignment to the north of the existing M27 and A27 corridors (and therefore bypassing existing points of congestion), significant economic benefits will be generated. This reflects both the transformative effect of the corridor as well as the scale of the impacts realised in all affected local authority areas. These impacts are summarised in Table 5-16.

“SOUTH COAST RELIEF ROAD” – NEW CORRIDOR

Table 5-17 “South Coast Relief Road” Results

GVA	EMPLOYMENT	INCOME TAX GAIN	CORPORATE TAX GAIN	FIRMS' PRODUCTION GAIN	<u>GVA PER MILE</u>
£5.9 billion	36,000 jobs	£430 million	£282 million	£65 million	£86.3 million

This transformative corridor improvement demonstrates the highest level of economic benefits. There are several reasons for this: 1) the corridor covers a long distance and thus there will be benefits experienced across several local authority areas, 2) the transformative nature of the corridor means that compared to the present travel experience, significantly better connectivity will be generated. It is the scale of this differential (and the long distance nature of the corridor) that generates the large benefits shown in Table 5-17.

5.3 PRIORITISATION

Based on the analysis and results reported above, a ‘corridor prioritisation’ exercise has been undertaken. Based on the scale of high level economic benefits that have been estimated, the corridors are ranked as shown in Table 5-18 below.

Table 5-18 Initial Prioritisation of Corridors

SCHEME / RANKING	DESCRIPTION / STATUS	RATIONALE
1) “South Coast Relief Road”	This comprises a bypass to the M27 and A27 for traffic not wishing to access Portsmouth, Southampton and Brighton	This transformational corridor will enable drivers to bypass the already congested centres in Portsmouth, Southampton and Brighton
2) “South Sussex Way”	Salisbury (A36) – Winchester – Petersfield –Horsham - Tunbridge Wells to connect with the A21	This is a transformational corridor that will link Wiltshire with Hampshire, Sussex and Kent
3) Horsham - Reading New Road Corridor	A new ‘transformative’ corridor between mid-Sussex and the Thames Valley	Given the lack of north-south corridors in the region, this transformative corridor will link these two key areas – note that there is also some overlap with the proposed ‘North Downs Line’ upgrade
4) Southampton to Portsmouth Corridor Upgrade	A major upgrading of the existing rail corridor between these two key cities on the south coast	Current rail journey times are ‘uncompetitive’ compared to road (the road links themselves are heavily congested) – this transformative upgrade will thus provide much-needed connectivity enhancements
5) Reading - Waterloo Rail Upgrade	An upgrade of the line between Reading, Bracknell and London Waterloo	Given continued economic growth in the Thames Valley area and relatively slow rail journey times in this corridor, these improvements will allow the key towns in Berkshire to be better connected to various locations on the line into Waterloo
6) North Downs Line Upgrade	Upgrading the current diesel-operated line between Redhill (with onward connection to Gatwick Airport), Reigate, Dorking, Guildford and Reading	This upgrade would involve enhancing connectivity on this critical corridor – although this has some similarities with the proposed Mid-Sussex to Thames Valley corridor described above, the rail route travels on an east-west axis before heading north between Guildford and Reading
7) ‘Southern Access to Heathrow’	A new rail link between Guildford and Heathrow (via Woking, Virginia Water, Staines & Heathrow Airport)	This new corridor will open up new journey opportunities between Guildford, Gatwick - and points south of Heathrow - and the airport
8) A27 Corridor Improvement	Upgrade of the corridor between Brighton and Portsmouth	There are several ‘bottlenecks’ on the A27 (e.g. at Arundel and Chichester) – this is a major east-west corridor near the South Coast (note also that the ‘Coastway’ rail route parallels the A27)
9) Brighton Main Line Upgrade	Upgrade of the main rail link between Brighton and London	This is one of the main transport corridors in the region (note that the parallel road corridor is the M23 via Gatwick Airport)

10) A3 Corridor Improvement	Upgrade of corridor between Surrey and the outskirts of Portsmouth	The corridor between London and Portsmouth – whether by rail or road – is a key transport artery and experiences severe delays at busy periods
11) A34 Corridor Upgrade (Southampton to Newbury and M4 J13)	An upgrade of this key road corridor linking the strategically important area around Southampton (including the major port) and points north	This is another busy, 'economically important' corridor in the region. The 'north – south' route linking Southampton with Berkshire and all points north (including Oxford and the Midlands) has a major national and regional strategic role. Traffic flows are also very high in the existing corridor and thus an upgrade will be very timely
12) A33 Road Upgrade (Basingstoke – Reading)	An upgrade of this key road corridor	Traffic data shows how busy this corridor is between two of the key centres of employment in the region
13) Southampton - New Forest Corridor Upgrade (M27 / A31)	An improvement on the M27 and A31 heading west out of Southampton and the Solent area	This is a busy transport artery connecting Southampton with the New Forest and all points west (such as Poole and Bournemouth)
14) A320 Corridor Upgrade	An upgrade of the A320 road corridor linking Guildford with Woking and M25 Junction 11	Based on previous WSP PB work for Surrey CC, Guildford BC and Woking BC, this is one of the key congested corridors in the area
15) A22 Corridor Upgrade	An improvement in the corridor linking Eastbourne on the South Coast with Surrey, the M25 and points further north	The existing A22 road corridor (and parallel rail routes) does not offer good connectivity between this part of East Sussex and points further north (including the M25 and London)
16) A31 Upgrade	An improvement to the Hog's Back - Farnham - Alton road corridor	The A31 (and its intersection with the A3 near Guildford) is one of the main 'bottlenecks' in this part of Surrey and Hampshire
17) Newhaven - Lewes - Brighton Corridor Upgrade	An upgrade of this important corridor between Newhaven and Lewes	The links between these major towns on the South Coast currently involves a time-consuming journey, including the very busy junction between the A26 and A27

5.4 HOW THE CORRIDORS RELATE TO EACH OTHER

Although the impacts of the corridors have been assessed individually, there are clearly major synergies between the corridors. Similarly, when regarded as 'clusters' of corridors, they will have a significant local and regional impact.

The various relationships between the corridors are described below:

- **Enhancing connectivity along the South Coast:** There are several major conurbations and centres of economic activity along the South Coast. From Eastbourne and Brighton in the east to Portsmouth and Southampton in the west, these areas generate significant levels of economic activity and are forecast to grow in several different ways – not least in terms of new housing developments and continued growth in employment.

Traffic levels and congestion on key corridors has reached a point whereby delays are commonplace. Corridor improvements along the A27, M27 and A31 will therefore enhance overall connectivity on an east-west axis whilst the transformational concepts of an 'A27' relief road bypassing the major centres of population (and congestion) will also enhance economic activity in this area.

In addition, the cities of Southampton and Portsmouth in the Solent area are economic 'powerhouses' in their own right and will benefit significantly from enhanced connectivity between them. The improved connectivity between the two cities will then link in with the other improved corridors to offer a major regional enhancement.

- **Enhancing the links between the South Coast and points further north:** Due to relatively long journey times and the comparative peripherality of the South Coast, several of the corridors put forward will enhance connectivity to London and other major centres of economic activity away from the coast.

The proposed upgrade of the 'A3' (Portsmouth – London) corridor as well as the upgraded Brighton Main Line and upgraded connection between Eastbourne and Surrey will all provide enhanced connectivity.

In addition, there will also be considerable synergy between these 'north – south' corridors and those proposed on an 'east – west' axis. This will significantly enhance journey opportunities for those travelling into the area from the north and who then want to travel east or west on the South Coast to their final destinations.

Examples include better access to Portsmouth and the Solent area from the A3 corridor and subsequent better connectivity to points east and west (using the upgraded A27 and M27 corridors). Improving the A34 between Southampton and points north will also help to take 'pressure' off some of the other corridors such as the M23 and A3 corridors;

- **Enhancing 'north – south' connectivity in the region:** In the Hampshire, Surrey and Mid-Sussex areas, historical transport corridor development has focussed on the main arterial routes into Greater and Central London. This applies to the main rail and road corridors (such as the main lines between Southampton and London and Portsmouth and London). Good north – south connectivity has therefore been difficult to achieve and this has been compounded in recent years by high levels of traffic on those north – south corridors that do exist

By proposing new corridors that link Mid-Sussex (Horsham) with the Thames Valley (Bracknell/Reading) as well as upgraded existing corridors (such as the upgraded North Downs Line), connectivity will be enhanced

This is essential for a variety of economic and growth reasons, not least the enhanced connectivity between major centres such as those in Berkshire and the 'Gatwick Diamond' area. Better north – south links will enable workers in these major centres to live further away as their commute will be significantly enhanced. 'Knock-on' benefits will include positive impacts on housing development

Similarly, improved connectivity between Basingstoke and Reading as well as between Southampton and Newbury (and points further north as noted previously) will support growth in the region;

- **Enhancing connectivity between the South West / West of the region and London:**
Although there are several major transport corridors linking the study area to London, there remain 'pockets' of population and economic activity that are comparatively poorly served. Examples include the Reading to London Waterloo route where journey times are much longer than those on other main line routes into London whilst major centres of economic activity (such as those near Bracknell) face long journey times into London

By improving connectivity in these corridors, workers will be able to access a much wider array of employment opportunities in London, Reading and elsewhere. These improvements will be captured in the agglomeration analysis reported previously with productivity being enhanced and a range of economic benefits stemming from this.

The movement corridors therefore enhance connectivity across a range of complementary geographies with several of the east – west corridors having major synergies with the north – south corridors.

There is also potential for the corridors to provide strong linkages with neighbouring LEP areas and the wider South East / South West regions. For the main ports in Portsmouth and Southampton, good connectivity for freight traffic will be essential, especially given the forecast increase in containerised flows and the need to have good linkages between the ports and the Midlands / the North.

6 IDENTIFICATION OF POTENTIAL SOLUTIONS

6.1 INTRODUCTION

In this chapter, a range of options is set out for each of the short-listed corridors. This covers the following:

- Identification of a range of options for addressing known problems in each corridor; and
- An assessment of 'deliverability' of each corridor.

For presentational purposes, the deliverability of a "Top Fifteen" of corridors has been assessed with the key issues covered including engineering, planning and other technical constraints. In reality, all the corridors selected will have different levels of 'deliverability' with the smaller schemes tending to be more deliverable in terms of the lesser amounts of physical works required.

This means that the deliverability "gradings" given in this chapter are independent of the extent of the likely economic benefits that will be generated. An analysis of high level costs and benefits is the subject of analysis in Chapter 7.

6.2 ANALYSIS OF POTENTIAL SOLUTIONS

To make this part of the work as clear and transparent as possible, the findings are reported in tabular format.

In Table 6-1, the range of options and deliverability issues is summarised for each corridor with the colour coding on the right-hand side indicating how the 'grading' of deliverability (i.e. **green** = achievable, **amber** = deliverable but with caveats / key issues and **red** = problematic).

Table 6-1 Identification of Potential Solutions

CORRIDOR	DELIVERABILITY ISSUES				DELIVERABILITY GRADING
DESCRIPTION	OPTIONS	ENGINEERING	PLANNING	OTHER	
“South Coast Relief Road”	A new transformative corridor situated on an alignment to the north of the existing M27 / A27 corridor (i.e. the new corridor would bypass all the major towns on the route)	This has been evaluated on the basis of a new road corridor being built (although rail could also be considered) – <u>this is a major engineering undertaking</u> passing through key areas	The corridor will pass through some areas of high environmental sensitivity, not least in the South Downs National Park (SDNP) area. This will therefore require careful planning consideration	The scale of this undertaking should be not underestimated, although the economic analysis has shown the extent of potential benefits in this key east-west corridor	
“South Sussex Way”	As with the ‘South Coast Relief Road’, this transformative corridor will require significant infrastructure works across a considerable distance	<u>This will be a major engineering undertaking</u> requiring a long term programme of construction works throughout the proposed corridor. The considered has been considered as a road project although a rail corridor will also offer the same level of improved connectivity	As with any infrastructure of this scope and size, extensive planning will be required over a long term period. Environmental considerations and concerns will also need to be dealt with through accepted procedures	This is clearly a significant infrastructure project that will require careful evaluation and planning. Given the importance of continued good connectivity into the major towns and cities on the coast, suitable connecting links should also be provided with these	
Mid Sussex to Thames Valley New Corridor	A transformational corridor (considered as a road corridor at this stage). Would pass through an area of very high environmental sensitivity before accessing the Thames Valley area	This corridor will require significant works and significant investment (whether as a road or rail link). Given that there are very few such ‘north – south’ corridors in this part of the study area, the works will involve the forging of a new alignment	By taking a ‘direct’ route between Horsham and Reading, the corridor passes through the Surrey Hills Area of Outstanding Natural Beauty (near Dorking etc.). This will require significant mitigation (such as tunnelling) as possible re-routing away from the ‘optimal’ corridor	Although of clear economic benefit, this proposed corridor does pass through some highly ‘sensitive’ areas and there may be scope to compromise and realise at least a high proportion of these benefits through the upgrade of similar corridors such as the North Downs Line (see below)	
Southampton to Portsmouth Corridor Upgrade	A major upgrade of the existing rail corridor between the two cities – to facilitate much faster journey times through faster journey times and fewer station calls	Will require significant works to a level similar to that scoped for the full Brighton Main Line (BML) upgrade – to enhance capacity, this could feature some form of ‘passing loops’ so that faster services could overtake ‘stopping’ services on the corridor	As with all major rail upgrades, significant time and expenditure would be needed for the planning and feasibility stages. A demonstration of very clear economic benefits could accelerate this process by placing the scheme higher in the DfT’s “list of priorities”	Although the scale and scope of a major upgrade of this rail corridor is significant (and needs to take account of the stations that are on the line), the corridor and infrastructure does already exist and this will make implementation easier compared to some of the other corridors	
North Downs Line Upgrade	A major upgrade of the existing diesel-only corridor linking Gatwick Airport, Redhill, Reigate, Dorking and Guildford with Reading (this has already been extensively evaluated by Surrey CC and their consultants,	From an engineering perspective, this is feasible given that no major new corridor construction is required – the technical aspects of what is proposed are covered in the extensive feasibility work undertaken by Arup.	Major rail upgrades require an extensive and time-consuming planning horizon that will mean this upgrade is likely to take several years before fruition	Given the current climate of rail funding constraints (both in this Control Period, CP5 and the next, CP6), there may be concerns about obtaining the level of funds necessary for this upgrade. The demonstration of all benefits will therefore be essential	

CORRIDOR	DELIVERABILITY ISSUES				DELIVERABILITY GRADING
DESCRIPTION	OPTIONS	ENGINEERING	PLANNING	OTHER	
	Arup)				
Reading - Waterloo Rail Upgrade	To improve journey times on this key rail artery between Reading, Bracknell and London Waterloo. Suitable capacity enhancements will also open up the possibility of selected trains making fewer stops	A number of engineering solutions could enable journey times to improve on this corridor although as with several rail enhancements in the South East, the very high capacity utilisation towards the London end of the route may make this difficult (and very expensive)	As noted for other rail corridor improvements, these types of enhancements require significant planning and evaluation before Government approval (and funding) is given	Although this does not involve the construction of new corridor infrastructure, the characteristics of the current service (i.e. several station stops and relatively slow journey times) are not easily enhanced without major works, disruption to existing services and expenditure	
'Southern Access to Heathrow'	This will comprise a new rail corridor between Guildford, Woking and Heathrow Airport (using several sections of existing lines on different routes)	Although a significant undertaking, the use of several sections of existing lines will assist the feasibility and deliverability of the overall programme. Where new sections of line are required, however, extensive works will be needed	As with the North Downs upgrade, this corridor will require a significant amount of planning across a number of different stakeholders. Adherence to all current rail planning guidelines and procedures must also be followed	The proposed corridor passes through several densely populated areas and will therefore require a significant consultation programme before the proposals are accepted – previous initiatives such as the 'Airtrack' proposal did not proceed for a number of reasons, including issues surrounding the number of level crossings on the route	
A27 Corridor Upgrade	Targeted <u>road</u> improvements at key locations, including the long proposed bypass at Arundel and capacity enhancements near Chichester (as well as other capacity enhancements currently being evaluated by Highways England)	The works proposed on the A27 corridor have been evaluated in detail in recent years, with the proposed works at Arundel, for example, being developed over several years. In general terms, the engineering aspects of this corridor upgrade are feasible	The A27 corridor passes through some relatively dense / well populated areas – there are also areas of environmental sensitivity with the Arundel Bypass, for example, being frequently opposed on environmental grounds in the past	Highways England has been developing plans for the A27 corridor over several years – work is currently ongoing. As one of the main east-west arteries in the region, its upgrade will be feasible and will generate significant benefits	
Brighton Main Line Upgrade (A23 / M23 Corridor)	An upgrade of this key economic artery linking the South Coast with London (as well as several 'intermediate' centres of economic activity such as the Gatwick Diamond area)	The Brighton Main Line is currently the subject of a major upgrade study by DfT (Coast to Capital are heavily involved with this). The line is currently operating at the limits of its capacity and any enhancement will require major infrastructure works	Planning for the BML upgrade will require lengthy procedures to be followed, including Network Rail's full range of project feasibility analysis. There will also be several stakeholders who need to be consulted, including the local authorities and train operating companies	By requesting that the current BML study be undertaken, the Government (and the Treasury) have shown clear intent that the line's upgrade will play a key part in generating economic growth in the region. The upgrade can also be linked to the plans to develop a secondary link between Brighton and London ("BML2")	
A3 Corridor Upgrade	Targeted <u>road</u> improvements at key locations, including capacity enhancements in the vicinity of the M25	These works will require significant enhancement works, especially in the Guildford area where the 'narrowness' of the existing corridor will necessitate	Given that a significant proportion of the works will be in a relatively dense, urban area, extensive planning consent will be required	In the Guildford area, the A3 improvements will need to be accompanied by works on 'feeder' and connecting roads as current problems are not	

CORRIDOR	DELIVERABILITY ISSUES				DELIVERABILITY GRADING
DESCRIPTION	OPTIONS	ENGINEERING	PLANNING	OTHER	
	interchange and in the Guildford area	major works		just constrained to the main corridor	
A34 Southampton – Newbury / M4 J13 Upgrade	Major road corridor improvement on this section of the A34 – to include appropriate widening and junction works where required	Selected works have already commenced on sections of the A34 and this will continue this process, albeit throughout the whole section of the road. Key ‘pinch points’ and ‘bottlenecks’ will be addressed and suitable widening works / dualling will provide additional capacity	As well as passing through / near urban areas, the A34 also passes through areas of extensive countryside in both Hampshire and Berkshire – any planning of the upgrade works will therefore need to take account of these factors and the sensitivities associated with them	The entire A34 corridor linking the Solent area with Berkshire, Oxford and points north has long been identified as a critical transport link in the region (covering both freight and light vehicle movements). Although the works required for such a major upgrade will be expensive and time consuming in terms of planning, the regional (and national) benefits are likely to be significant	
Basingstoke to Reading Corridor Upgrade	Currently focussed on the A33 road corridor between these two centres of economic activity, the corridor is also served by a rail link (operated by both GWR and Arriva Cross Country)	The engineering works will focus on the enhancement of the existing corridor with any capacity constraints dealt with accordingly (such as carriageway widening and other works that will enhance journey times)	Planning of the works in this corridor can follow on from the consultation and preparation already undertaken for the “Basingstoke A33 corridor improvements” programme (being supported / promoted by Hants CC as well as EM3)	With the “Basingstoke A33 corridor improvements” scheme already comprising £9.5m of improvements along the A33 in Basingstoke (major works at the Crockford and Binfields Roundabouts, along with a minor potential scheme at Taylor’s Farm roundabout), this upgrade could follow on from these planned works	
M27 / A31 Corridor Upgrade	To upgrade this east - west road corridor to eliminate major bottlenecks and ‘pinch points’	To implement widening / dualling works where necessary and to address locations where capacity is constrained (such as some of the major junctions, including that at Ringwood). The works would build on the proposals already developed by Highways England for this corridor	Several schemes in this crucial corridor (such as the Ringwood improvements) have already reached the planning / feasibility stage and the upgrading works could build on this to offer a complete strategic corridor upgrade (subject to environmental and related considerations)	As well as generating economic benefits to the region, an upgraded A31 corridor will also reduce the high level of accidents currently observed on certain sections of the road	
A320 Upgrade	Given the very high levels of traffic observed on this key road corridor linking Guildford with Woking and the M25, works will cover junction improvements as well as capacity enhancements where these improve travel times and journey reliability (through	The A320 corridor passes through densely populated, urban areas – this means that major upgrading works will be disruptive, time-consuming and expensive (although the subsequent benefits to local and regional traffic will be substantial)	Given the characteristics and location of the A320 corridor, the works will need to be carefully planned with consideration given to the disruptiveness of the works and the potential environmental impacts	Improvements to the A320 in this relatively short but strategically important corridor have been seen as necessary for several years (given the level of congestion and delays that occur). Improving this corridor will also help relieve knock-on delays on the A3 corridor near Guildford and will thus have significant regional benefit	

CORRIDOR		DELIVERABILITY ISSUES			DELIVERABILITY GRADING
DESCRIPTION	OPTIONS	ENGINEERING	PLANNING	OTHER	
	reduced congestion levels)				
A22 Corridor Upgrade	The A22 corridor between Eastbourne on the South Coast and the M25 intersection at Godstone in Surrey is a strategically important route – its upgrade (through capacity enhancements to improve journey times) will significantly enhance connectivity to / from East Sussex	The A22 would require significant works to enhance capacity through suitable widening and dualling (as well as a programme to address key junctions that cause delays and lengthen journey times)	This will be a major upgrade over a relatively long distance and will thus require extensive planning and feasibility analysis. Passing through both urban and rural areas, any environmental issues will also need to be addressed and mitigated	Certain parts of the South Coast experience peripherality from the 'high growth' areas in Surrey and the Greater London area. This corridor upgrade is therefore of major regional importance. It will also provide better connectivity between the South Coast and the 'mid Sussex' towns	
A31 Upgrade	The A31 Hog's Back section of road and its intersection with the A3 near Guildford experiences considerable congestion and delays (and is also dangerous given the nature of the gradients and merging movements). An upgrade of this section of the A31 will thus make traffic movements considerably better	The A31 Hog's Back improvement would require significant works, especially in terms of the topography of the area and the complex nature of the current intersection with the A3. However, this proposed upgrade is relatively short and is situated in an existing corridor – this will make the improvements easier to implement	A major planning and feasibility exercise will be necessary, including appropriate environmental impact assessments	The A31 Hog's Back section of road and its intersection with the A3 has long been seen as a major bottleneck in the area and its improvement will generate significant benefits	
Newhaven - Lewes - Brighton Corridor Upgrade	This upgrade will provided much-needed better connectivity between Newhaven, Lewes and Brighton in East Sussex	The current junction between the A26 and A27 is a major 'bottleneck' in the area and its removal through suitable upgrade works will be a major undertaking	A major planning and feasibility exercise will be necessary, including appropriate environmental impact assessments given the characteristics of the local area	Given the need to improve connectivity to the important regional economic centre in Brighton, this will be an important upgrade.	

6.3 MODAL OPTIONS AND ACCESS TO THE CORRIDORS

Table 6.1 shows that where new corridors have been identified as having a large positive economic impact, the deliverability of any modal solution will be challenging e.g. South Sussex Way and Mid Sussex to Thames Valley Corridor. The reasons for the new corridors having large calculated benefits are fundamental to understand when developing any proposed solution.

The existing transport infrastructure (any mode) that gives the current level of access and connectivity between the centres of population in the new corridors is either direct or convenient and the hypothetical transport infrastructure solutions assume that there would be significant improvements in journey times and direct access to and from the new corridor from residential areas and employment areas. This means that in the development of any modal options, the accessibility on to and off the corridor will be a key consideration.

The corridors identified are either a single mode or appear as a default choice for the given corridor. However, the access to and from the improved corridor will similarly need to be a key consideration when generating physical schemes to ensure that the improvements generate the desired outcomes.

In the course of writing this report, Highways England produced a complimentary report '*Orbital Connectivity - Orbital Strategic Public Transport in the West and South Beyond the M25*'. This report highlighted the current difference in modal share depending on the twin variables of inter-urban journey times and the provision of public transport services within an urban area. The report is appended as an Annex to this report.

7 PRIORITISATION OF POTENTIAL INFRASTRUCTURE IMPROVEMENTS

7.1 INTRODUCTION

Based on the analysis of potential solutions identified in Chapter 6, this chapter contains a further prioritisation assessment whereby the overall financial and economic feasibility of the infrastructure investments is evaluated at a high level.

The term 'infrastructure investments' reflects the following:

- An 'investment' to cover the outline capital (and operating) costs that need to be incurred to realise the economic benefits over a specified period of time;
- The high level economic benefits likely to accrue over the appraisal timescale – in this case, up to both 30 and 60 years (similar to other appraisal timescales); and
- The particular characteristics of the corridor upgrade (its rationale and timetable for construction etc.).

To develop this high level economic and financial analysis, we have taken the 'snap shot' economic analysis reported in Chapter 5 and have extended this so that a 30 to 60 year forecasting period is covered. The estimated high level cost of each corridor also forms part of the analysis and is one of the key input assumptions. All costs and benefit values are subject to standard discounting methods. This is as follows:

- A discount rate of 3.5% per annum is applied for the first 30 years of the appraisal period; and
- A discount rate of 3% is applied for the remaining 30 years in the period.

For the purposes of this high level analysis, the calculations assume that the corridor upgrades take place in the near future with the stream of benefits following on after scheme opening. The metrics shown in Table 7-2 therefore reflect this assumption although in reality, the corridors are long term propositions and several years will elapse before construction / upgrade work can take place. The right-hand column in Table 7-2 therefore provides commentary on the realistic timeframes anticipated for each corridor.

The high level analysis is not a 'conventional transport economics' appraisal as we are not quantifying traditional benefits such as monetised journey time savings (to users of the corridors) nor are we calculating the economic benefit of reduced accidents due to transport improvements.

The monetised benefits included here are those described in Chapter 3 (such as GVA increases and various financial returns to Government). In a fully compliant DfT appraisal, it would be necessary to also include more 'traditional' transport economics impact as well as these wider impacts. This issue has also been addressed in Section 3.1.

These initial results do, however, show the extent to which high level scheme costs compare with forecast economic benefits.

We have evaluated both a 30 year appraisal time horizon as well as the longer 60 year period to give a broader range of feasibility indicators.

7.2 HIGH LEVEL COST DATA

For this high level cost benefit assessment, a series of cost estimates have been drawn from existing data sources. These cover both road and rail with differentiation between 'upgrade' and 'new corridor' schemes (and costs).

This is summarised in Table 7-1 below.

Table 7-1 High Level Cost Data

DATA SOURCE	DESCRIPTION	COST PER KILOMETRE (£ MILLION)
New Road: Arundel Bypass	This comprises a major new section of dual carriageway constructed away from the existing A27 alignment. The cost shown here is based on Bypass Option B (and an average of the 'low' and 'high' estimates)	£37.5 million
Upgraded Road: A303 / A358	This comprises upgrades of sections of the A358 and A303 (Ilchester – Sparkford) roads. The cost here is thus an average of the two	£17 million
New Rail Corridor: Brighton Main Line (BML)	This per km cost is based on the full upgrade cost (£15 billion) of the BML programme as recently evaluated on behalf of DfT	£174.2 million
Reopened / Upgraded Rail Corridor: Uckfield - Lewes	This is based on the estimated cost per km of reopening the Uckfield to Lewes line (this is a complete upgrade cost and includes a new tunnel). The estimate is also based on an average of a 'low' and 'high' estimates	£53.5 million

These costs have also been augmented with additional data where this is available. For example, the North Downs Line upgrade cost estimate includes an 'operating cost' element covering the cost of additional train services and rolling stock.

In addition, some scheme cost estimates are a composite of the data shown in Table 7-1. To demonstrate this, the proposed new rail corridor between Guildford and Heathrow Airport incorporates elements of both upgraded existing lines as well as sections of new corridor.

Two economic output metrics are used to indicate feasibility: 1) a Net Present Value (NPV) and 2) what is termed a 'high level economic benefit to cost ratio'.

7.3 ANALYSIS AND RESULTS

Table 7-2 below contains a summary of the infrastructure investments analysis. As well as the rationale for each corridor project, summary costs and benefits are indicated (in discounted form).

An indicative timetable for delivery is also shown in Table 7-2.

Table 7-2 Potential Infrastructure Investments

CORRIDOR TITLE	RATIONALE	ECONOMIC METRICS		IMPLEMENTATION
		COSTS	BENEFITS	LIKELY TIMESCALES
“South Coast Relief Road”	A transformative, new corridor linking Southampton with Brighton (and providing a alternative corridor to the current M27 / A27)	A high capital cost of circa £4.1 billion (with annual operating expenditure of £3 million) could be supported by the very high economic impacts forecast. In high level economic benefit to cost ratio terms, these could be as high as: 1) 30 years: 24.7 2) 60 years: 38.0	The benefits are the highest of all the corridors evaluated and total £95 billion over 30 years and £145 billion over 60 years (both total are based on discounted amounts)	This is a long term corridor concept and could take up to 20 to 30 years before fruition (reflecting planning and feasibility time horizons)
“South Sussex Way”	Another transformational, new corridor – this will cover a considerable distance and will link Salisbury in Wiltshire with Hampshire, Sussex and Kent	A high capital cost of circa £6.4 billion (with annual operating expenditure of £3 million) could be supported by the very high economic impacts forecast. In high level economic benefit to cost ratio terms, although not as high as the ‘South Coast Relief Road’, these could be as high as: 1) 30 years: 12.1 2) 60 years: 18.6	Forecast (discounted) benefits are also high: 1) 30 years: £71 billion 2) 60 years: £110 billion	This is another long term, transformational corridor concept. Its total distance is likely to mean that it would need to be planned and built in phases / stages (20 to 30 years for full scheme implementation). Its construction will, however, relieve pressure on the M27 / A27 upgrade proposals
Mid-Sussex to Thames Valley Corridor	To provide a much-needed north-south corridor linking the Thames Valley with mid-Sussex	A capital cost of circa £3.1 billion (with annual operating expenditure of £1 million) would be supported by the forecast benefits to achieve the following high level economic benefit to cost ratios: 1) 30 years: 19.8 2) 60 years: 30.6	Total forecast (discounted) wider economic benefits are as follows: 1) 30 years: £56.8 billion 2) 60 years: £87.9 billion	Although likely to generate substantial economic benefits, the environmental and engineering issues surrounding construction of this corridor mean it is a long term proposition (taking up to 15 to 20 years to deliver)

CORRIDOR	ECONOMIC METRICS			IMPLEMENTATION
TITLE	RATIONALE	COSTS	BENEFITS	LIKELY TIMESCALES
Southampton to Portsmouth Rail Corridor Upgrade	To radically improve connectivity between these two key cities in the Solent area by means of a major rail corridor upgrade	A capital cost of circa £5.2 billion (with annual operating expenditure of £0.5 million) would be supported by the forecast benefits to achieve the following high level economic benefit to cost ratios: 3) 30 years: 6.6 4) 60 years: 10.3	Total forecast (discounted) wider economic benefits are as follows: 3) 30 years: £31.8 billion 4) 60 years: £49.3 billion	As this corridor and rail infrastructure already exists, timescales to complete this upgrade could be comparatively short (could be implemented in the next 15 to 20 years)
Reading to Waterloo Upgrade	Given relatively slow journey times between key towns in Berkshire and London (on the Reading to Waterloo route), this upgrade envisages significant capacity enhancements on the route so that faster journey times are possible	Even with a very high capital cost estimate of £8.4 billion (with annual operating expenditure of £2 million), the following high level economic benefit to cost ratios would be achieved given the extent of potential wider benefits in this key corridor: 1) 30 years: 3.8 2) 60 years: 5.9	Total forecast (discounted) wider economic benefits are: 1) 30 years: £29.2 billion 2) 60 years: £45.2 billion	Significant rail infrastructure enhancement would be required, particularly to accommodate faster / more frequent train services towards the eastern end of the route (i.e. closer to Waterloo) – for this reason, it is likely to take 15 to 20 years to build
North Downs Line	To greatly improve rail connectivity on this economically important artery linking the 'North Downs' area (and Guildford) with the Thames Valley	Depending on the scale of upgrade envisaged, a high capital cost (£4.3 billion) investment would still generate significant returns on investment as shown by these high level economic benefit to cost ratios: 1) 30 years: 7.3 2) 60 years: 11.3	Total forecast (discounted) wider economic benefits are: 1) 30 years: £29.1 billion 2) 60 years: 45.1 billion	Given the long timescales typically required for major rail upgrades (to cover planning and feasibility as well as construction), this could take 10 to 15 years to build
'Southern Access to Heathrow'	To build on former proposals to build a new rail link into Heathrow Airport (via a spur off the existing Reading – Waterloo route). The proposed corridor would link as far south as Guildford and would use existing sections of line where necessary	Based on capital costs of £3.9 billion and £1 million p.a. operating costs, the resulting high level economic benefit to cost ratios based on the wider benefits generated would be: 1) 30 years: 8.1 2) 60 years: 12.5	Total forecast wider economic benefits are very similar to those of the proposed North Downs Line upgrade: 1) 30 years: £28.8 billion 2) 60 years: £44.6 billion	This is another major infrastructure scheme where extensive planning and further feasibility analyses are required before any funding / implementation decisions are made – as with the North Downs upgrade, this could take 10 to 15 years to build

CORRIDOR TITLE	RATIONALE	ECONOMIC METRICS		IMPLEMENTATION
		COSTS	BENEFITS	LIKELY TIMESCALES
A27 Corridor Upgrade	To bring to fruition long-standing plans to upgrade the A27 corridor between Brighton and Portsmouth (and to address key 'bottlenecks' in the corridor)	If the total upgrade cost was £1.4 billion, for example (with operating expenditure of £1 million per annum), the following high level economic benefit to cost ratios would be achieved 1) 30 years: 19.8 2) 60 years: 30.4	Based on this preliminary evaluation, total (discounted) wider economic benefits are: 1) 30 years: £25.0 billion 2) 60 years: £38.7 billion	Depending on the current work being undertaken by Highways England on the overall feasibility of the A27 corridor upgrade, it is possible that works could commence in the next 5 to 10 years. The Government stated in December 2014 that the corridor would receive investment as part of its Strategic Road Network (SRN) and this may mean that implementation could happen sooner compared to other corridors
Brighton Main Line Upgrade	The transport link between Brighton and London is of strategic importance to the region – although this proposal has focussed on the main Brighton to London rail link, the corridor is also served by the A23 / M23	Based on the "full scale" upgrade cost of £15 billion (with assumed £3 million annual operating expenditure), the following high level economic benefit to cost ratios would be achieved – these ratios could potentially be higher if some of the more 'intermediate' upgrade proposals were used as the basis for the corridor upgrade: 1) 30 years: 1.1 2) 60 years: 2.6	Based on this preliminary evaluation, total (discounted) wider economic benefits are: 1) 30 years: £23.4 billion 2) 60 years: £36.3 billion	The BML upgrade is currently being assessed by DfT and depending on the results of this study, further work could be undertaken on this major upgrade. Timescales for implementation are likely to remain in the 'long term' category given the nature and scale of the works (next 10 to 15 years)
A3 Corridor Upgrade	To improve connectivity in the A3 corridor (Surrey – Portsmouth / Solent area) by addressing key sections where there are capacity constraints (such as the section near Guildford as well as adjoining feeder roads)	Based on a high level estimate of capital expenditure for total corridor improvement (£1.4 billion), the following high level economic benefit to cost ratios could be achieved: 1) 30 years: 14.5 2) 60 years: 22.3	Based on this preliminary evaluation, total (discounted) wider economic benefits are: 1) 30 years: £18.4 billion 2) 60 years: £28.4 billion	Following on from the Hindhead Tunnel opening in 2011, further proposals for the A3 corridor include major widening works in the Guildford area as well as improvements near the Hog's Back junction. The scale of these (and the necessary planning requirements) will mean that it could be 10 to 15 years before scheme implementation

CORRIDOR		ECONOMIC METRICS		IMPLEMENTATION
TITLE	RATIONALE	COSTS	BENEFITS	LIKELY TIMESCALES
Southampton to Newbury A34 Corridor Upgrade	To improve this key strategic route linking Southampton with Berkshire, Oxford and points north	With an upgrade cost between Southampton and J13 of the M4 of approximately £1 billion, the following high level economic benefit to cost ratios would be achieved: 1) 30 years: 17.4 2) 60 years: 26.7	Based on this preliminary evaluation, total (discounted) wider economic benefits are: 3) 30 years: £16.5 billion 4) 60 years: £25.6 billion	This is a major corridor upgrade that could take 15 to 20 years to fully implement. Nevertheless, incremental improvements over time could help achieve the overall goal of a complete corridor upgrade (with the high economic benefits this will generate)
Basingstoke to Reading Corridor	To improve connectivity between Basingstoke and Reading by upgrading the A33 corridor	Based on a high level capital cost estimate of £460 million, the following high level economic benefit to cost ratios could be achieved: 1) 30 years: 26.3 2) 60 years: 40.1	The evaluation of the A33 upgrade indicates the following wider economic benefits: 1) 30 years: £11.5 billion 2) 60 years: £17.8 billion	Work on upgrading the A33 north of Basingstoke has already been evaluated and subject to consultation. The additional works proposed for this corridor upgrade could therefore be scheduled within the next 5 to 10 years
M27 – A31 Corridor Upgrade	To upgrade sections of the M27 – A31 corridor between Southampton and Dorset (Poole / Bournemouth) – to facilitate improved journey times and connectivity	Based on a capital cost estimate of just under £1 billion, the following high level economic benefit to cost ratios could be achieved: 1) 30 years: 13.6 2) 60 years: 20.9	Significant wider economic benefits would be generated: 1) 30 years: £11.9 billion 2) 60 years: £17.5 billion	Some works on this busy, important corridor are already being evaluated / planned and this proposed corridor upgrade can be developed from this (and could be completed in the next 5 to 10 years)
A320 Corridor Upgrade	To provide significant capacity enhancements on this comparatively short but very highly used section of road	Given a capital cost estimate of approximately £335 million, the following high level economic benefit to cost ratios reflect the high level of agglomeration increase-based (and other) economic benefits that could potentially be achieved: 1) 30 years: 27.3 2) 60 years: 41.9	Significant wider economic benefits would be generated: 1) 30 years: £8.5 billion 2) 60 years: £13.3 billion	This corridor upgrade is over a relatively short distance compared to other corridors and could therefore be implemented in a shorter timescale (10 to 15 years). The upgrade could be linked with improvements to the A3 near Guildford

CORRIDOR TITLE	RATIONALE	ECONOMIC METRICS		IMPLEMENTATION
		COSTS	BENEFITS	LIKELY TIMESCALES
A22 Corridor Upgrade	This corridor upgrade will enable Eastbourne and the East Sussex coast area to have significantly enhanced connectivity with Surrey, Greater London and other areas of economic importance in the region	Based on capital costs of £1.2 billion, the following high level economic benefit to cost ratios could potentially be achieved: 1) 30 years: 3.6 2) 60 years: 5.6	The following wider economic benefits could be generated: 1) 30 years: £4.0 billion 2) 60 years: £6.2 billion	This is major corridor upgrade and given its length, could be upgraded in stages (over the next 15 to 20 years), with the key capacity 'bottlenecks' addressed first before other strategic widening and dualling works takes place. This is very much a long term corridor proposal
A31 Upgrade	This upgrade is required given that this section of the A31 and its intersection with the A3 is the source of much congestion and delays (as well as being a major accident risk)	Based on capital costs of £550 million, the following high level economic benefit to cost ratios could potentially be achieved: 1) 30 years: 5.7 2) 60 years: 8.8	The following wider economic benefits could be generated: 1) 30 years: £2.9 billion 2) 60 years: £4.6 billion	Compared to some of the other strategic corridors, this upgrade covers a comparatively short distance and could be implemented within relatively short timescales (10 to 15 years)
Newhaven - Lewes - Brighton Corridor Upgrade	This upgrade will facilitate much better connectivity between Newhaven and Brighton as well as providing better links to Lewes (both Newhaven and Lewes will also gain better access to jobs in Brighton)	Based on capital costs of £440 million, the following high level economic benefit to cost ratios could potentially be achieved: 1) 30 years: 5.4 2) 60 years: 8.3	The following wider economic benefits could be generated: 1) 30 years: £2.2 billion 2) 60 years: £3.5 billion	As with the A31 upgrade, this is a comparatively short-distance corridor (although major works will still be required, especially in terms of addressing the existing 'bottleneck' at the busy A26 / A27 junction). This could take 10 to 15 years.

8

HOUSING, GROWTH AND FUTURE DEVELOPMENT

8.1 INTRODUCTION

The analysis described up to this point has addressed the economic impact of developing strategic transport corridors in terms of key economic metrics such as additional GVA and employment opportunities.

In addition, and to reflect that the corridors will be developed in the future, several background factors need to be taken into account. These include:

- **Housing developments:** the study area is one of the fastest-growing in the UK with forecast growth in population putting increasing levels of pressure on the need to develop new housing;
- **Growth in key sectors:** as well as background economic growth, several “high tech” and “high value” sectors across the study area will continue to expand. Taking the information technology sector as an example, growth in this sector will not only generate higher levels of GVA but will also generate higher productivity levels as each worker will produce more GVA; and;
- **Other developments:** in addition to housing developments, other major developments are also planned across the region and these will be impacted by / have an impact on the strategic corridors proposed.

The purpose of this chapter is to describe the types of developments taking place, the urgent need for these developments in the study area (particularly housing that is affordable to workers in the region) and ultimately, how the strategic corridors will have a crucial role to play in terms of 1) helping facilitate the developments in the first place and 2) how the developments themselves will support the impacts generated by the corridors.

8.2 KEY DEVELOPMENTS IN EACH LEP AREA

Each LEP area has clear, distinct objectives with respect to economic and housing development. By summarising the key objectives and aims of each LEP area, the types of developments proposed are made clear.

THAMES VALLEY BERKSHIRE

Berkshire and the Thames Valley has continued to display strong employment growth in recent years and this growth is likely to continue into the future given the concentration of employment in the key ‘high value’ sectors that continue to perform well. These include telecoms, IT, professional services and the utilities sectors. There are clusters of professional services activity within Bracknell Forest and Reading with workers very much reliant on good transport access (both rail and road) to access these high value jobs.

The impact of the different employment clusters on travel patterns in the TVB LEP area is demonstrated by the three broad ‘travel to work areas’ (TTWAs) defined below:

- **“Reading TTWA”:** this comprises all of Reading and Wokingham boroughs as well as the majority of Bracknell Forest (and includes parts of South Oxfordshire, West Berkshire, Windsor and Maidenhead and Hart);

- **“Slough and Heathrow TTWA”**: as well as including all of Slough borough and parts of Windsor and Maidenhead, most of this area is situated towards the east of the LEP and covers Runnymede, Spelthorne, South Buckinghamshire and the London Boroughs of Hillingdon and Kingston upon Thames; and
- **“Newbury TTWA”**: this area covers most of West Berkshire and parts of Wiltshire, Basingstoke and Deane and Test Valley.

These travel to work areas have a major influence on the housing market given that the location and development of housing in Berkshire reflects both household migration and travel to work patterns from surrounding local authority areas.

Given that growth in working age population is forecast to decrease across the majority of Berkshire authorities whilst growth rates increase across a number of nearby authorities, these anticipated trends are also likely to have an impact on travel to work patterns to, from and within Berkshire. The likely outcome that travel flows into Berkshire will increase over time as a result of these developments places even greater emphasis on the need to improve key movement corridors.

To accommodate future population growth in the LEP area and to ensure there is sufficient housing (at affordable levels) for the workers needed in the future, there are extensive plans for housing development across the various local authorities in the area.

As stated in the LEP’s Strategic Economic Plan (SEP), it is crucial that housing availability and affordability do not constrain the future growth of Berkshire’s economy. The SEP also makes it clear that plans for housing growth *must* take account of wider infrastructure constraints. As evidence of this, the LEP’s Infrastructure Programme states that it is imperative to invest in transport to unlock some major housing developments.

Similarly, to ensure that economic potential is not constrained by labour supply issues, congestion problems must be addressed and planned housing - some of which is dependent on upfront infrastructure investment – must be delivered as quickly as possible.

Through the Thames Valley Berkshire Local Growth Deal, the LEP is supporting seven transport schemes in 2015/16 (out of 22 in the whole Growth Deal). The purpose of these investments is to unlock housing development sites (for example, there are over 16,500 houses linked to these schemes) and to increase the overall capacity of the network to deliver the level of reliable journeys the economy requires.

Although these are relatively small, ‘localised’ schemes compared to strategic movement corridors, they nevertheless provide clear evidence of the importance of transport infrastructure as a means of unlocking development and more importantly, the fact that these schemes are being strongly promoted indicates the urgency with which infrastructure is required.

SOLENT

The Solent LEP area is an internationally-recognised economic hub incorporating the Isle of Wight, the major cities of Portsmouth and Southampton, the M27 corridor and the Solent waterway. The area has particular strengths in key economic sectors and also has world-class universities, a strong base of high quality Further Education colleges and excellent transport links.

The continued economic success of the area is very much dependent on the communications inter-dependencies between the cities and the wider Solent area with the Solent economy’s significance extending considerably beyond the LEP area (and thus making an important contribution to the national economy).

Continued and improved transport access to the major hubs centred around Southampton and Portsmouth is critical given the economic importance of these hubs as well as the centres of economic activity within the LEP area.

In its evidence base to support the Solent Strategic Economic Plan (SEP), the LEP's "Connecting Growth" initiative sets out how strategic (and local) transport links impact on the Solent economy both now and in the future. One of the key outcomes from the analysis is that new housing and employment floor space will support growth whilst transport infrastructure will perform a critical role unlocking these sites (and thus encouraging and accelerating inward investment).

There are already several examples of where strategic growth opportunities have been identified and some of these are shown below:

- In the Fareham and Gosport peninsula, there is a requirement for a package of transport investments that unlock opportunities for strategic housing and employment growth at the Solent Enterprise Zone at Daedalus and at the 6,000 home Welborne development (the transport schemes include an upgrade to Junction 10 of the M27, associated junction improvements on the local road network and new highway access to the Solent Enterprise Zone);
- To accelerate the delivery of the strategic housing site at North Whiteley (located near to Junction 9 of the M27), there is a requirement for a new highway to be constructed joining the existing Whiteley Way with the highway network to the north. This will unlock the 3,500 new homes proposed; and
- As well as road connectivity improvements, the rail corridor between Portsmouth and Southampton has a significant role to play enhancing movements across the sub-region whilst also providing better connections to Southampton Airport and points east.

Improvements to this rail corridor will 1) relieve pressure on the already busy M27, 2) improve labour and business interaction between the two cities (and the areas in between) and 3) provide improved rail access to the airport from the east. As rail journey times in this corridor are comparatively long, movements are still concentrated on the M27 corridor and this increases delays and congestion.

A more detailed list of sites where 'unlocking' is essential for development is provided below:

- **Welborne:** a planned 6,000 home development situated to the north of Fareham (112,000 square metres of employment floor space is also proposed). Unlocking the site will require infrastructure developments, specifically new and improved strategic transport infrastructure at Junction 10 on the M27 - this is essential to initiate the development;
- **North Whiteley:** as described above, this strategic growth area will provide 3,500 new homes and associated infrastructure. Support is required for a major new transport link serving both the proposed growth area and the existing community (which at present has only one main highway access on to the M27);
- **Marchwood military port:** the Sea Mounting Facility at Marchwood has been taken on by Solent Gateways Limited, who will be operating the site. There are opportunities for growth at this site through port-related activity other than the sea mounting facility that will continue to operate here;
- **Solent Enterprise Zone:** the first phase of development is already underway and further phases are being planned. Although road improvements are underway to enhance accessibility between the M27 and the Enterprise Zone, "transformational" schemes are also needed to provide an alternative route to the Gosport Peninsula (i.e. the current route from the M27 via the A32 is extremely congested at certain times of the day); and

- Other sites, including the **Ford Site**, **Eastleigh Riverside** and **Southampton Airport** (the redeveloped site will provide a prestigious and attractive new gateway to Southampton), **Gosport Waterfront** (a priority site in the Solent Strategic Economic Plan) and **Itchen Riverside** (a regeneration project in Southampton covering an area of 105 hectares on both sides of the River Itchen - a draft Master Plan is currently being prepared).

Although this list is not exhaustive, it does provide an indication of the types of development sites that are needed to accommodate the area's growth plans and the transport / infrastructure interventions necessary to unlock them.

At a more strategic level, the demands placed on the main transport networks, combined with the impact of planned housing and employment growth, will severely constrain the Solent economy if not addressed.

This is why strategic movement corridors will play a key role in an integrated transport network that enables forecast growth at the three International Gateways (the ports of Southampton and Portsmouth and Southampton International Airport) as well as at key housing and employment sites.

ENTERPRISE M3

Although the economy of the Enterprise M3 area is very powerful in its own right (e.g. Enterprise M3 is ranked second out of 39 LEPs in terms of the local business base), there is a relatively restricted employment market and when this is combined with a growing demand for higher level and Science, Technology, Engineering and Mathematics (STEM) skills, along with an ageing population, high levels of out-commuting and low graduate retention, there is a strong risk that future economic growth will be impeded.

This will have both regional and national impacts given the strength of the economy in the area and how much it contributes in terms of GVA and productivity.

The labour market restrictions are being exacerbated by a shortage of housing and in particular, housing that is affordable to workers. This means that 1) the Enterprise M3 area cannot offer suitably priced housing to those workers who are needed to support economic growth and 2) the area is unable to compete effectively with the employment opportunities available in London.

It is for these reasons that the LEP and stakeholders in the region are supporting sustainable economic development solutions and the creation of more balanced communities. A series of focused sustainable transport measures are also being pursued to reduce the very high levels of congestion experienced in the LEP area.

To help facilitate economic growth and to realise the potential of the area, housing provision must be accelerated. The LEP's strategic ambition is to therefore support and accelerate (via infrastructure provision) the delivery of housing by up to 25% above the baseline achieved between 2003 and 2013 (typical annual baseline delivery was approximately 920 units per annum). This means that with Government support, up to 11,500 new homes will be delivered over the next 10 years. This acceleration of delivery would be achieved without an increase in the Local Plan targets set by individual local authorities. There are two factors in achieving this goal:

- The infrastructure funding contained in the LEP's Local Growth Deal submission; and
- Support for strategic transport interventions.

To help achieve these targets, a number of strategic development sites are in Enterprise M3's **Growth Towns** and **Step-up Towns** whilst a series of targeted interventions – including transport interventions - will play a key part in realising their potential.

One key message from the LEP's Strategic Economic Plan is that to facilitate the necessary housing growth, it is vital that Government not only invests in the infrastructure schemes set out within the Growth Packages and more widely, but also that it commits to working to help accelerate those strategic schemes being delivered by Highways England and Network Rail.

Specific projects include Junction 9 of the M3 and the A3 corridor improvements near Guildford.

The two largest sites in the Enterprise M3 area – Whitehill and Bordon (4,000 homes) and Wellesey in Aldershot (3,850 homes) were both due to start on site in 2014/15 and present a considerable opportunity for the area. Further examples of the Growth Towns and Step-up Towns (and their respective infrastructure schemes) are shown below:

→ **Growth Towns:**

- Basingstoke: includes packages of highways projects to improve capacity and support housing development such as the 'Basingstoke North' and 'South West Corridors to Growth' schemes
- Farnborough: includes a package of highway projects to address congestion in Farnborough such as the capacity improvements on the A325, A327 and A3011
- Guildford: includes a sustainable transport package for Guildford and a package of highways projects including improvements to the Guildford gyratory and a Sustainable Transport Package
- Woking: includes an investment package to tackle major congestion issues (such as Victoria Arch capacity improvements), a sustainable transport package and A320 / A322 road improvements to help progress plans to accelerate housing delivery, including the regeneration of Woking Town Centre

→ **Step-up Towns:**

- Aldershot: includes a sustainable transport package
- Andover: includes a sustainable transport package
- Camberley: includes highway improvement schemes to ease congestion on the A30 / A331 corridor and the approach to the M3 approach plus sustainable transport packages for Frimley and Camberley
- Staines: includes the Wider Staines-upon-Thames sustainable transport package - aimed at improving access to Heathrow and employment sites
- Whitehill and Bordon: includes an Inner Relief Road (to accelerate development and regeneration of the green town and development of housing and large scale commercial and retail development) plus a sustainable transport package

COAST TO CAPITAL

In its Strategic Economic Plan (SEP), Coast to Capital LEP states that essential infrastructure - particularly transport infrastructure - is reaching capacity and is no longer robust enough to support future growth. In addition, the housing market needs unblocking if there is to be sufficient capacity for economic growth.

In other words, there cannot be sustainable economic growth without housing growth since shortages of housing (at affordable prices) makes it difficult for employers to attract and retain the workers needed to grow their businesses.

As part of the Coast to Capital Transport Programme, three types of transport schemes have been identified. The aim of these is to unlock stalled economic growth across the LEP area:

- **Connectivity and capacity schemes** to unlock new land by providing new and/or enhanced transport connections;
- **Sustainable transport packages** which regenerate areas by tackling congestion and improving journey quality and reliability; and
- **Resilience schemes** to help keep the network operating at all times of the day and week.

The LEP has also identified 20 schemes which would directly unlock new housing, jobs and/or employment floor space. These schemes provide the transport capacity or connectivity needed for one or more new developments to be viable. In many cases, these schemes would tackle problems that cause severance and delays.

There are thus several schemes already put forward to enhance connectivity and unlock new development. In several cases, schemes have been implemented and to the west of Horsham in West Sussex, for example, new junction and road links connect the A24 with new housing developments.

Coast to Capital's Strategic Economic Plan also sets out how the LEP will invest in infrastructure (including transport) to bring forward existing housing permissions that are currently blocked and to also enable an increase in new permissions. Based on the LEP's strategic ambitions for new housing, these initiatives will bring forward an *additional* 7,331 homes.

To demonstrate the magnitude of housing need in the Coast to Capital area – and thus the urgent requirement for improved transport infrastructure to unlock these sites - interim findings from ONS and the Department of Communities and Local Government (DCLG) suggest that the LEP area will need to accommodate an additional 95,000 households between 2011 and 2021 to meet future demand. This is because an additional 190,000 residents are expected in the area.

The local authorities in the area have identified potential sites with a capacity to deliver 62,800 new homes over the first 10 years of the Local Plan period and 98,851 new homes up to 2031. Over an assumed 20 year period, this equates to approximately 5,400 new homes per annum, Given that a much smaller build rate was achieved over the previous ten years (4,350 new dwellings per annum), there is a clear role for new infrastructure to play in increasing this.

8.3 HOW THE STRATEGIC CORRIDORS WILL SUPPORT GROWTH

From the above, it is evident that there is **a)** an urgent requirement for new housing in the region to support growth and **b)** a need to increase the rate of house building so that this growth potential can be realised.

Provision of strategic transport corridors will help unlock much needed housing development as the enhanced connectivity between local authority areas will be one of the main enabling factors. This will be particularly applicable as the housing programme looks to gather pace and will reflect the polycentric nature of the study geography.

There will be a dynamic relationship between the corridors and the new developments as several of the proposed housing sites (such as Whitehill and Bordon) are of a significant size and scale - not only are the corridors therefore essential to help improve connectivity to these new sites in the first place, they are also necessary to accommodate to the increased movements generated by the developments.

To indicate how the strategic corridors interact with housing development plans in each local authority area, the figures below show the basic alignment of each corridor together with what level of housing development is required / proposed.

9 SUMMARY, CONCLUSIONS AND RECOMMENDATIONS FOR FURTHER WORK

9.1 SUMMARY OF WORK

We have developed a quantitative approach that uses recognised DfT “Wider Impacts” guidance as the main building block to establishing how strategic corridor improvements can generate a range of benefits. These impacts include those not typically captured in conventional transport scheme appraisals.

The approach has been developed so that different corridor concepts can be tested quickly and across different geographies (and distances) in the study area. Based on improvements in connectivity, a series of economic benefits have been calculated covering increases in GVA at a ‘local’ level (based on improvements in productivity), increases in employment (supported by the increased GVA) and increases in taxation-based revenue streams to Government.

The work has focussed on the impact of a change to current travel characteristics in each corridor. These impacts are then extrapolated forward over a 60-year appraisal period so that the high level cost-benefit assessment can be undertaken.

For the high level cost benefit assessment, a series of cost estimates were taken from existing data sources. These cover both road and rail schemes with differentiation between ‘upgrade’ and ‘new corridor’ schemes (and costs).

The initial findings have shown that large-scale ‘transformational’ corridors could generate a high level of wider economic impacts, especially when the corridor serves several Local Authority Districts (LADs). These benefits do, however, need to be traded off against the feasibility of the corridor, both in terms of cost (likely to be very high for major schemes) and deliverability. The latter reflects the various engineering and environmental characteristics of each scheme.

OTHER CONSIDERATIONS

9.2 ACCOMMODATING HOUSING GROWTH

Data from the local authorities, including Local Plan data on housing requirements across the region, were also collated. Where major housing developments are proposed (such as at Whitehill and Bordon near the A3 corridor), these have been placed in the context of the strategic corridors put forward. As shown in the series of figures in Chapter 8, there are major housing requirements at strategic points within each corridor.

Although the interaction between transport infrastructure, housing and economic growth is a complex one (with transport infrastructure often being a prerequisite for new housing development), there is no doubt that the South East region requires a level of housing provision significantly above what has been delivered historically.

The new corridors can therefore help unlock these developments and thus boost the rate of supply of new housing.

9.3 REFINING OPTIONS AND DEFINING SCHEMES

Having demonstrated the potential economic impacts of the new corridor proposals, further work will be required to investigate each option in more detail. This will include more detailed costing of the proposals as well as more in-depth analyses of land use impacts and the impacts on housing / employment sites.

The modal choice for improvement schemes needs careful consideration and will be highly dependent on the existing configuration of the transport network in each town or city along a corridor. This will necessitate a different local solution to ensure that any corridor improvement adds full value to each location.

9.4 STRATEGIC PLANNING – PAN PUBLIC SECTOR APPROACH

This report has highlighted the potentially large economic benefit from investing in transformational transport infrastructure schemes in the study area. By its nature, the work assumes that 1) the different transport infrastructure providers responsible for the proposed improvements would be the 'deliverers' of the schemes and that 2) the other important subsidiary issues that need to be addressed would be in place or planned by other infrastructure providers or planning authorities.

Each corridor identified in this study will therefore need a 'Joint Investment Plan' involving both national and local authorities. This joint planning approach will help identify the overall corridor improvement and the local changes necessary to accommodate and maximise its benefits. In undertaking such joint working, all options for solutions should be considered using the principal of 'fundability' (i.e. that investment capital is a single pot from the public and private sector) and that the most cost effective deliverable solutions are prioritised.

The joint working between national and local authorities will also encompass all issues that affect socio-economic well-being, including interdependencies and trade-offs between local authority areas.

The need for a pan-public sector approach to strategic planning would ideally also directly influence spatial planning policy in whatever arrangement (and in whose jurisdiction it manifests itself in the future). Some current transport demand, particularly on the highway network, is a result of uncoordinated planning and transport policy both between the local planning authorities and the planning authorities' transport infrastructure providers.

A particular example is encouraging development and higher densities of residential development around existing or proposed public transport services and interchanges to maximise their use and create additional public transport services for neighbouring areas. This policy has reduced existing demand on the highway network and has freed up capacity for other uses in several examples in the UK and globally.

Joint spatial/land use planning across geography similar to this study area could also help refine the strategic infrastructure requirements and allow local authorities to trade housing and employment allocations so that new development can be located in the most economically advantageous areas and maximise the benefits of any transport infrastructure investment.

9.5 URBAN CONNECTIVITY AND PUBLIC TRANSPORT PROVISION

The four LEPs and transport authorities that commissioned this study consulted with interested parties and stakeholders before appointing WSP | Parsons Brinckerhoff. As a result of this consultation, Highways England commissioned a complementary study that considered the existing differences in modal share depending on the twin variables of inter-urban journey times and the provision of public transport services within an urban area. This is the *Orbital Strategic Public Transport in the West and South West beyond the M25* study referred to earlier.

The findings of the report should also be taken into consideration when considering the issues discussed in 9.3 and 9.4. The report was commissioned by Highways England to highlight that the investment and improvement in the Strategic Road Network (SRN) will not in isolation provide the enhancement in capacity and improvements in access necessary to realise the economic potential of the study area, and that consideration to all modal solutions and access to and from the strategic corridors was of equal importance.

A key finding was that where existing inter-urban journey times were better for rail compared to road, user numbers were markedly higher on rail than in similar areas. In addition, a high density of public transport provision within an urban area also increased the percentage of users using rail for inter-urban journeys. The reason for this is assumed to be that more people access rail stations by public transport making the end to end journey on public transport easier and more attractive (hence the higher modal share).

To bring this into the context of the issues discussed in 9.3 and 9.4, urban areas need to be of a minimum size and population density to generate sufficient demand to have a dense public transport network that is financially sustainable for operators. This is to ensure long term planning policies enable the concentration of housing growth in existing urban areas, as opposed to distributing growth to smaller towns and villages where public transport provision cannot cater for the majority of new demand created.

In consultation with Highways England, the concept of parkway stations, park and ride and park share facilities is also an area they wish to be explored as part of any corridor improvement schemes. Such facilities constructed upstream of existing congestion “hot spots” could provide some degree of relief by allowing people to meet at convenient rendezvous locations and share onward journeys. Other options include 1) transferring to public transport for access to town and city centres and 2) when situated next to a rail line, provide a parkway interchange for people making longer distance rail journeys, particularly into London. It is appreciated that there needs to be spare peak time rail capacity to allow the concept to work in terms of parkway stations and that the infrastructure necessary could be costly.

The report is appended as an Annex to this report

9.6 RECOMMENDED FUTURE WORK – MODAL SHIFT

The existing highway and rail network in the study area serves to allow movements within the economic geography and through it. Although this is true of most areas in the UK, the presence of London, the Channel Ports and Heathrow and Gatwick airports makes the situation more extreme compared to other areas. Therefore it will also be important to consider investment in options and solutions further afield that could free up capacity on the existing network.

An example would be for the LEPs and local authorities to influence the recently commissioned M25 SW Quadrant Study to look at traffic using the network to access Heathrow and Gatwick airport that has to travel through the study area and to investigate options for modal substitution that result in demand reduction. The previously mentioned Heathrow Southern Rail access could also be evaluated in terms of creating direct access from the Great Western Main Line and the Basingstoke to Woking Line.

The North Downs Line improvement would encourage some modal shift for accessing Gatwick Airport but could also be enhanced by the creation of direct interchange at Farnborough between the North Downs Line and the Basingstoke to Waterloo Main Line. The interchange will also help connectivity between Basingstoke and Guildford.

9.7 RECOMMENDATIONS – STRATEGIC TRANSPORT MODELLING

This study has deliberately not considered the monetised journey time savings and accident reductions of standard transport economic benefits and has focused on the wider benefits. This means that the value of the corridor improvements in terms of a Benefit Cost Ratio (HIGH LEVEL ECONOMIC BENEFIT TO COST RATIO) will be higher than has been estimated in this study. In addition, any new corridor or improved corridor will attract strategic traffic passing through the area and this economic impact has been not been calculated. Transfer of strategic traffic could also reduce the available capacity for movement in the area.

These three issues could be broadly calculated by a Strategic Transport Model which is a recommended next step in prioritising the corridors for scheme development and investment across the study area. Highways England's Regional Transport Models may be suitable for this purpose when they are available later this year.

EXECUTIVE SUMMARY

Alongside the various studies being carried out as part of the Government's Severn tidal power feasibility study, the assessment of the possible constraints in terms of supply chain is also an important consideration in any decision on whether the Government could support any option.

The implementation of a tidal scheme in the Severn estuary, especially a large one (or a combination of smaller schemes), would require not only a great amount of materials and equipment but also large scale innovative construction design and installation processes (numerous caissons, long embankments, sluices, locks etc). Although most of the technologies and construction design are proven and mature, the magnitude of the largest schemes would require a multi-national joint venture.

In order to make sure the regional, national and international market will be able to meet the project's likely level of demand, a supply chain survey has been undertaken. This survey is based on the responses to a specific questionnaire sent to Trade Associations, Manufacturers, Contractors, Ports and other bodies, and also on existing reports.

The survey is mainly focused on the following topics which have been considered as the most sensitive in terms of supply chain and which could stall the project and/or increase the costs and lead-time:

- Vessels for dredging, caisson installation, embankment construction...
- Aggregates for concrete, ballast and embankment fill (sand and gravel, crushed rock and armour stone)
- Concrete for caissons and other civil works (cement, rebar...)
- Caisson construction yards
- Turbines and generators
- Availability of skilled labour

As for the other construction materials and mechanical or electrical equipment (e.g. sluice-gates, cranes, transformers, cables, switch gear...), even for the larger schemes, the magnitude of the demand is not considered as a major concern on the international market. Provided the procurement process is adequately managed, securing these materials and equipments should not be a particular problem either on the UK market or on the international one.

However, at this stage of the study some questions remain due to the lack of detailed information and data. In particular, the report does not provide relevant information on the impact on road and rail transport during the construction phase. This impact depends heavily on the location of the construction and manufacturing sites (caisson, precast facility etc), and of the quarries and ports where materials and equipment will be landed. Sea and rail transport are likely to be preferred so as to meet sustainability objectives.

Vessels

As vessels will play a major role in the preparation works (dredging) and in the installation or construction of the various structures, their availability on the international market is a key factor.

The current demand for marine equipment remains critical, due to a steady demand from the oil and gas industry and an increasing demand for offshore wind deployment, in particular in Europe. Nevertheless, a Severn scheme would require mainly dredgers, tugs and crane-barges for the installation of caissons and equipments and these types of vessels are unlikely to compete with the demand for vessels for offshore wind deployment (e.g. Jack-Up barges...).

Most of the vessels required for a Severn scheme are available on the UK and European market but orders would have to be placed well in advance (from 1 to 2 years) to ensure availability at the required time and to secure the appropriate or specific vessels. Due to the harsh conditions in the Estuary (currents, waves...) or to the specific requirements (e.g. deep dredging), some existing vessels would have to be adapted or modified.

The Dutch Eastern Scheldt storm surge barrier, commissioned in 1986, is a good example of innovative construction technologies which lead to the development of various purpose-built vessels. The building of a Severn tidal scheme would also rely on innovation and new dedicated vessels could be envisaged so as to be independent from the current market.

Aggregates

Aggregates (sand and gravel or crushed rock) are by far the largest quantities of construction material required for the Severn schemes, in particular for the Cardiff-Weston barrage but also for the lagoons (embankment).

As the demand for aggregates for construction fill (embankment) and ballast is very high, the use of suitable dredged materials from foundation and navigation channels works could significantly relieve the pressure on the market. Mainly dredged sand and gravel could be considered as a substitution of ballast and construction fill for the barrage schemes (for the Cardiff-Weston barrage, these dredged materials could replace all the sand and gravel required). On the other hand, for the lagoon schemes, the volume of suitable dredged materials is too low (or even non-existent for the Bridgwater Bay lagoon) and it is unlikely that the remaining aggregates for construction fill and ballast could be sourced from the UK market. In order to meet this demand, several possibilities could be envisaged: significant increase in the current extraction capacity or additional imports from overseas quarries. New licenses for dredging could also be considered, in particular in the Bristol Channel.

The demand for armour stone (which cannot be sourced in large quantities in the UK) is far beyond the current imports from Northern Europe, apart from the Beachley barrage. For the other schemes, only a significant increase in the delivery rate of existing rock quarries (e.g. Glensanda) and in overseas imports (e.g. Norway) could meet this demand.

Secondary and recycled aggregates could also make an important contribution to the supply of construction aggregates, in particular for ballast. China clay and slate waste could be used for a STP project, as the main quarries are respectively located in Devon and Cornwall or in North Wales.

Concrete

Aggregates for concrete could all be sourced from the national market, and for the smaller barrages (Shoots and Beachley) as well as for the Welsh Grounds lagoon, the regional markets could provide most of these materials.

The other concrete components (cement, rebar...) can be easily sourced from the UK market and for steel from the national and international market. Various concrete batch plants would have to be installed on each construction site, in particular for the caissons construction, but this is standard practice for any large construction project.

Caisson construction yards

The location of the caisson construction yards is critical and should take into account various parameters such as: environmental impacts, consent process, caisson transport cost, site characteristics (e.g. water depth, transport network for material and equipment delivery) and carbon footprint. At this stage, it is difficult to confirm that the potential identified sites (existing ports or shipyards and coastal sites) are suitable.

For the smaller schemes, potential sites could be envisaged along the Bristol Channel, but for the Cardiff-Weston barrage several sites would be required either around the UK coast or elsewhere in Europe (e.g. Netherlands or Northern Spain).

Turbines and generators

Only three European turbine manufacturers have the expertise and capacity to deliver specific tidal range turbines (bulb turbine or Straflo turbine) as well as their generators. The major Chinese turbine manufacturers also might be able to deliver a % of bulb turbines, provided they work under the supervision of one of the European turbine leaders.

The ongoing experience of a consortium of these 3 manufactures for the Brazilian Madeira hydro project (delivery of 72 bulb turbines) would provide interesting feedback and would confirm soon that procuring about 100 turbines is feasible for the smaller schemes.

As for the Cardiff-Weston barrage, delivering such a large number of turbines (more than 200) is considered as very challenging by the manufacturers using only existing facilities. A consortium between them is not the only key to success. So as to increase the delivery rate and the manufacturing capacity, a development and procurement strategy is likely to be set up by these manufacturers and investment in a new plant or in an assembly facility could be envisaged.

Skilled labour

The report also addresses labour and skills issues and provides additional information from existing surveys. According to the various respondents, it is confirmed that shortage of workforce in marine and civil engineering, mechanical and electrical installation, as well as in site supervision, are likely to occur. The various energy projects scheduled/proposed in the UK in the period to 2030 (nuclear plants, wind farms...) would all be competing for similarly skilled people.

The current economic downturn brings about many skill transfers within the industry and construction sectors and a significant shortage of labour and skill might be expected when the economy recovers. However, locating the caisson construction yards in various sites in the UK (or in Europe) would minimise labour shortages and international joint-ventures set up on purpose for the construction may well mitigate the remaining labour problems.

I - INTRODUCTION

STP Feasibility study

The feasibility study of tidal range power development in the Severn Estuary is being managed by a cross-government group led by the Severn Tidal Power (STP) team from the Department of Energy & Climate Change (DECC). The Terms of Reference of this study are as follows:

- assess in broad terms the costs, benefits and impact of a project to generate power from the tidal range of the Severn Estuary, including environmental, social, regional, economic, and energy market impacts;
- identify a single preferred tidal range project (which may be a single technology/location or a combination of these) from the number of options that have been proposed
- consider what measures the Government could put in place to bring forward a project that fulfils regulatory requirements, and the steps that are necessary to achieve this
- decide, in the context of the Government's energy and climate change goals and the alternative options for achieving these, and after public consultation, whether the Government could support a tidal power project in the Severn Estuary and on what terms

Public Consultation

In Phase 1 of the study, 10 potential development options (the long-list) have been considered (including barrages, lagoons, a tidal reef and tidal fence) and the Government carried out the first public consultation (January-April 2009), on the following:

- a recommended shortlist of 5 schemes for more detailed analysis this year
- the scope of the Strategic Environmental Assessment (SEA) that is being carried out within the feasibility study
- the issues the feasibility study is considering and how these are being approached

Over 730 responses were received from this 1st Public Consultation and most of them agreed with the scope of the SEA work proposed. Some detailed changes have been suggested and made to the SEA objectives, including to the Resources and Waste topic which is closely linked to the supply chain issues:

- to promote sustainable use of resources particularly with respect to aggregate
- to reduce waste generation and disposal, increase re-use and recycling and achieve the sustainable management of waste

Additional points most frequently raised in consultation responses will be also assessed by the feasibility study:

- the impact of any scheme would have on the local infrastructure and on local communities, including on roads and services, navigation, the Severn Bore, and construction effects
- compliance with the environmental and other legislation that applies to the Estuary and related areas
- where and how raw materials and skills needed to build a scheme would be sourced
- the overall CO₂ balance of a scheme including emissions associated with construction, and knock-effects on infrastructure and services
- the impact on the environment, including the geomorphology of the Estuary and how sedimentation might affect scheme feasibility

Supply Chain Study

The implementation of a tidal scheme in the Severn estuary, especially a large one, would create considerable demand across the entire supply chain. The project would generate supply chain issues, including securing:

- sufficient basic materials (steel, concrete, aggregates...)
- suitable marine and land equipment
- caisson fabrication capacity and yards
- timely supply of mechanical equipment, in particular turbines
- timely supply of electrical equipment, in particular generators, transformers...
- suitable logistics and installation plant

- skilled and experienced contractors and sub-contractors
- access to skilled and experienced labour forces, scientific advisors and project supervisors

Moreover, the location of the construction sites (including caisson yards), quarries and manufacturing plants may also impact the existing regional and even national transport network (road & rail).

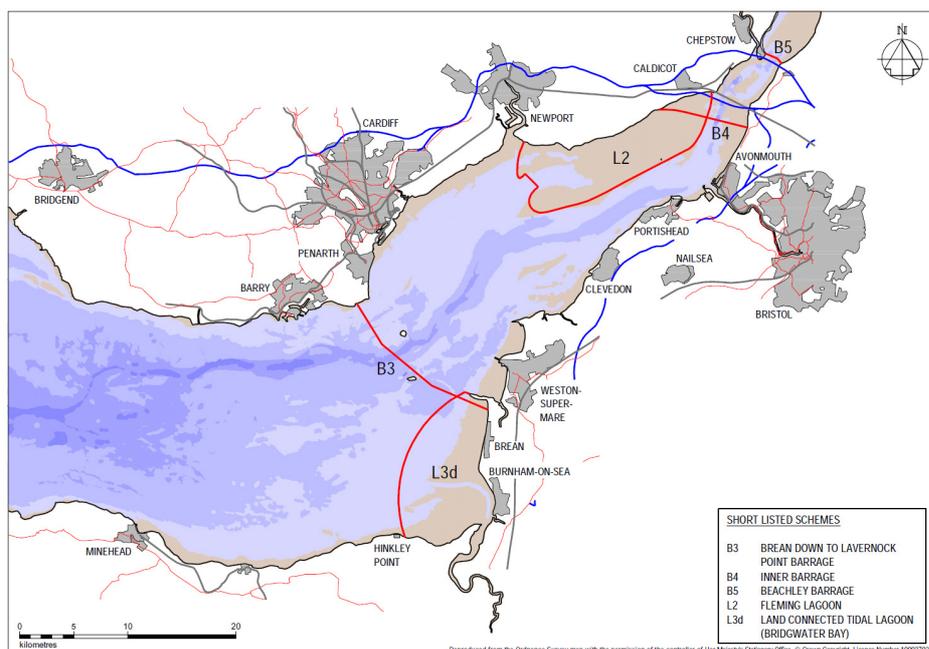

The availability of materials could impact upon overall project costs through both direct cost increases and time overruns. A lack of materials would stall the project and could also add a premium onto material prices. This is especially true for the larger schemes due to the vast quantities of materials required.

Difficulties in procuring marine plant equipment and turbines could also occur due to resource competition from other projects in European countries (and elsewhere) which all have to meet similar renewable energy targets. Competition for plant could increase costs through the creation of a price premium as well as delay project completion.

We propose to test the market's capability to meet the potential demand for a range of Severn tidal power schemes - this would also give manufacturers and suppliers advance notice of possible future demand, thus allowing them time to gear up their production capacity (provided a scheme is decided and planning permission obtained). This is why the STP Team decided to launch an overall study on supply chain issues in addition to the work being done by the Parsons Brinckerhoff-led consortium under the SEA contract.

The conclusions of this report should help inform the choice of the preferred scheme so as to mitigate the risks of delay and cost increases. The report is mainly focused on the 5 proposed short-listed schemes (base case); the interim results of the ongoing optimisation study of the schemes have been taken into account in this survey, particularly the embankment design (tonnage of materials) and number of turbines:

- **Cardiff-Weston Barrage:** A barrage crossing the Severn estuary from Brean Down, near Weston super Mare, to Lavernock Point, near Cardiff. It could generate 8.6GW –nearly 5% of UK electricity and twice the capacity of the UK's largest fossil fuel plant.
- **Shoots Barrage:** Further upstream to the Cardiff-Weston scheme. It could generate 1.05GW, equivalent to around the size of a large fossil fuel plant.
- **Beachley Barrage:** The smallest barrage on the proposed shortlist, just above the Wye River. It could generate 625MW, equivalent to around the size of medium fossil fuel plant.
- **Bridgwater Bay Lagoon:** Lagoons are new concepts which impound a section of the estuary without damming it. This scheme is sited on the English shore between east of Hinkley Point and Weston super Mare. It could generate 1.36GW (base case)
- **Welsh Grounds Lagoon:** An impoundment on the Welsh shore of the estuary between Newport and the Severn road crossings. It too could generate 1.36GW (base case)

Map of the 5 short-listed schemes

According to the size of the schemes and also to their design, the report tackles the supply chain issues for the 2 categories of schemes (a lagoon has a longer length of impoundment construction than a barrage relative to the impounded area):

- Barrage: Cardiff-Weston, Shoots and Beachley
- Lagoon: Bridgwater Bay and Welsh Grounds

During the preliminary optimisation analysis of the feasibility study, the design of each scheme has been improved (alignment, number and size of turbines...). For lagoons, cost and resource estimates have been based on conventional rockfill embankment construction. Although other forms of construction, e.g. the Fleming Group's tied wall proposal and geosynthetic reinforced embankments, have been considered, conventional rockfill has the greatest certainty of technical feasibility and represents a worst case form of construction in terms of material and labour resources. A better estimate of the quantities of construction materials has been made available for all shortlisted schemes and this report is based on this updated assessment.

The report is focused mainly on the following critical supply chain topics:

- Vessels
- Main civil works
 - concrete (cement + aggregates + rebar)
 - materials for embankments (aggregates & armour stone)
- Main mechanical equipment
 - turbines
 - other steelworks: gates, cranes and sluices
- Main electrical equipment
 - generators, transformers, switchgear...
- Labour and skills

In order to identify the major constraints in terms of supply chain and resources, a questionnaire was prepared for the above list of topics (see Appendix 1). The questionnaire also tackles labour and skills issues and specific questions are asked, including comments on the DTZ survey undertaken in Phase 1 of the STP feasibility study, so as to update some data.

This questionnaire was split into 2 parts:

- a short presentation of each scheme, including an estimation of the quantities of materials required for the construction as well as the main characteristics of the various equipment to be manufactured (base case).
- a list of questions for each topic

This questionnaire was sent in June 2009 to various Manufacturers, Contractors, Trade Associations, Ports and other bodies (see list – Appendix 2); about 100 questionnaires were emailed.

About 25% of recipients sent a detailed and comprehensive response in relation to their core activity. It is interesting to note that very few responses came from Electrical and Mechanical (excluding Turbines) bodies, mainly because the delivery of such equipment is not considered as a concern. Regarding Labour & Skills issues, very few responses were sent due to the difficulty at this level of study to estimate the real skill needs and to assess skill shortages. Phone calls, meetings and additional emails with the respondents provided further information.

Additional information was also found from various documents (books, brochures, websites...) and published reports and surveys (see Appendix 3 "Sources of Information").

For each question, a summary of the most relevant responses is set out in the report as well as some recommendations or proposals suggested by some respondents.

The level of supply chain constraints is assessed and summarised for each short-listed scheme according to the following scale within the regional, national and international markets:

- ☺ : no particular concern – available according to scheduled timescale
- ☹ : medium concern – high demand but enough resources or suppliers/manufacturers
- ⊗ : major concern – very high demand and/or lack of resources or suppliers/manufacturers – high risk of delay (lead time)
- ☹^{sc} : critical concern – no resource or shortage of supplier/manufacture – serious risk of delay (lead time)

☺ : no particular concern – available according to scheduled timescale
 ☹ : medium concern – high demand but enough resources or suppliers/manufacturers
 ☹☹ : major concern – very high demand and/or lack of resources or suppliers/manufacturers – high risk of delay (lead time)
 ☹☹☹ : critical concern – no resource or shortage of suppliers/manufacturers – serious risk of delay (lead time)

Severn Tidal Power - Supply Chain Issues Shoots Barrage Scheme - Summary

Major Components	Main Constraints	Alternative Solutions	Availability in the Market												Overall Supply Chain Level			
			Regional				National				International				☺	☹	☹☹	☹☹☹
			☺	☹	☹☹	☹☹☹	☺	☹	☹☹	☹☹☹	☺	☹	☹☹	☹☹☹				
Vessels

Aggregates supply takes into account available dredged materials

II - VESSELS

Introduction

For the construction of each scheme, various vessels should be required for the following tasks:

- dredgers for foundation preparation, caissons installation (in particular for turbine caissons so as to provide sufficient submergence for the turbines), navigation channels (also caisson towing channels from construction yards): trailer suction hopper dredgers, large cutter suction dredgers, grab dredgers (clamshell), dragline, ladder or continuous flight bucket dredgers...
- jack-up construction crane barges (e.g. for rock dredging pre-treatment by drilling and blasting),
- towboats, tugs (e.g. for caissons towing),
- vessels for caissons ballast filling,
- floating cranes or cranes barges for light equipment installation, bulkheads removal...(fully rotating crane)
- heavy load crane barges or heavy lift crane vessels (e.g. heavy derrick barge, sheer-legs cranes) for turbines, transformers, gates installation,
- bottom-dump or side-dump barges/split hopper barges for embankment construction and placement of underwater fills
- rock transport (pontoons, barges...) for embankments and armouring construction,
- supply, services, safety and crew boats

Due to the specificity of these tidal schemes located in a harsh sea environment (high tidal velocity at spring tides, waves...), all the marine vessels will play an essential role in the project development. The construction method, seabed preparation and transportation of materials and equipments will rely on the availability of these vessels and also on their performance and ability to achieve specific tasks.

Since sea embankments and breakwaters are being constructed in ever more severe environments, their designs are becoming increasingly sophisticated as a result of advanced understanding of hydrodynamics of wave interaction with the structure and the sloping bottom. Experience has been accumulated worldwide and translated into these improved and complex designs. For the constructor, this means the positioning and placement are very demanding. Large crane barges with high stability and greater reach are required; mooring systems are used with increased holding capacity for taut-line moorings.

Availability of these types of vessels in the national and international market

According to the Marine Contractors responses, it is difficult to give precise figures at this stage if the exact requirements of the vessels are not yet defined. The duration of the project, the scope of work and the requirements of warranty surveyors would be vital for the definition of the requirements, also of importance are e.g. sailing distances, water depth, lifting heights and weights, crew requirements (with regards to nationality or Health and Safety requirements).

The availability of large and specialised marine equipment (trailer suction hopper dredgers, large cutter suction dredgers, heavy load crane barges...) is under pressure in the international market. Only small equipments such as small dredgers, tugs, barges, pontoons, cranes can be easily sourced within the national market.

Vessels of the types and sizes required for a Severn Tidal Power scheme operate on an international scale. Very few of the above listed vessels are available inside the UK national market at present but most of major European Dredging and Marine contractors (mainly from Belgium and the Netherlands) have a representation in UK (e.g. Boskalis, BAM, Van Oord, DEME...) and all are capable of undertaking these works and would have the appropriate equipments given sufficient lead in times. A worldwide mobilisation could be also possible, in particular from the Middle and Far East market where new suppliers have been created. Consortia or Joint Ventures could be envisaged between European Dredging and Marine Contractors.

For large projects, contracts are generally placed well in advance (from 0.5 year up to 2 years) so as to ensure availability at the required time and to secure the appropriate or specific vessels. Key to success is proper advance sourcing, contracting and planning hand in hand with the suppliers. Marine Contractors are unable to predict for future periods further away than 2-3 years and spot markets such as "Salvage projects" which are unpredictable but may have some duration, may also disrupt their forecast. Moreover, ongoing international long term contracts might pose a

problem in terms of availability: some vessels can operate several years in the same country for different projects in order to make cost-effective their transportation and deployment.

Here are some examples of advance booking requirements:

- Vessels requiring from 18 to 24 months advanced booking:
 - Jack-ups are limited in availability (very small fleets) and generally booked well in advance (> 1.5 to 2 years)
 - Sheer-legs cranes with high capacity (e.g. >1000T) are limited and should be booked > 1.5 year in advance
 - Dredgers, in particular for deep water, are also limited in availability (very few suitable vessels) and generally booked well in advance (> 1.5 year)
- Vessels requiring at least 6 months advanced booking:
 - Tugs are a commodity, availability is generally not a problem.
 - Lifting barges (flattop with crawler crane)
 - Barges, workboats ...etc.

Nowadays, there is limited availability of dredging equipment within the world (particularly grab dredger; the only UK based seagoing commercial grab dredger is operated by UK Dredging, in Cardiff) due to large developments in the Middle East and Africa currently employing much of the available plant (marina and ports projects); India and China are also future large dredging markets but the existing fleets and planned vessel construction in the Far East would meet this new demand but not add to the European resource. Nevertheless, the current collapse in the worldwide property market could slow development in the Gulf (e.g. Dubai projects) and in parts of South East Asia, which might release dredgers for use in the Bristol Channel if the economic recession remains long-term.

Moreover, those dredging vessels capable of working in the Severn Estuary environment, and with the ability to address the deep dredged depth, are critical. Some existing dredgers could be modified so as to meet these technical requirements: e.g. cutter suction dredgers may need to be re-fitted for the Cardiff-Weston barrage to reach the maximum depths required.

**Case study - The large rock cutter section dredger “D’Artagnan”
Example of a large dredger**

A large rock cutter suction dredger (“D’Artagnan”) has been commissioned, built (2003-2005) and is in operation by the French subsidiary (Société de Dragage International - SDI) of the Belgium Marine Contractor DEME (Dredging, Environmental & Marine Contractor). This dredger is one of the largest in the world and it can dredge to a depth of 35m, and is equipped with two inboard dredge pumps and one submerged dredge pump on the cutter ladder. The dredged material can be pumped ashore through a 1,000mm discharge pipe (at a distance of up to 10km). The ship is equipped with a modern barge loading system which can load barges moored alongside the dredger. It includes among other things a buffer system which enables dredging for a longer period under unfavourable weather conditions. The dredger is equipped with two propellers (3,700kW each) that can generate a speed of nearly 12.5 knots.

Nevertheless, the specification requirements of a STP project in respect of rock dredging and cutter deployment should be studied so as to make sure this vessel is appropriate.

The rock barges and rock transportation ships which are very specific vessels would generally be chartered on the international market, or be provided by the rock suppliers. As the sources of large size rocks are not in the UK but mainly in northern Europe (Norway...), these barges and vessels are in great demand, mainly for port construction or refurbishment (breakwater dykes...). The long distance rock transportation vessels might have to be supplemented by additional vessels, chartered in, modified or built from new. Rock barges are routinely repaired and re-fitted most seasons, and this work can be done around UK shores.

Jack-up vessels are certainly the most critical due to the small number of existing vessels in Europe and the steady demand for offshore wind farm installation. But installation processes (in particular for caissons) are unlikely to rely on Jack-up vessels, maybe with the exception of final placement.

The caissons will be floated into position, and will mainly require tugs. Tugs are relatively easy to source, and are not routinely used for wind farms.

Work barges, inshore craft and safety vessels are available in the UK, but may be in increasingly short supply as the offshore wind market ramps up.

Need for specific built or retro-fitted vessels

It is normal practice on a large project for construction equipment, including vessels, to be modified or adapted to suit the particular requirements of the project, e.g. the harsh marine conditions of the Severn estuary. Yards in UK such as A&P Tyne and North European shipyards have capability to undertake such works. Modifications or re-fits vary widely, but could typically take from six months to a year to procure, and execute.

As with the Dutch Delta Scheme (e.g. Eastern Scheldt storm surge barrier), it is also possible that purpose-built vessels will be required for sea bed preparation and for caisson placing. These new vessels are likely to be built in the following places, China, South Korea or Latvia or Poland. New vessels typically take from two to three years to procure. It was common place to buy Build Slots in recent years but this is now not the case because the vessel construction market is now weakening after seeing several years of extremely high activity.

Compatibility of the harsh site conditions with vessels

The unique environment of the Severn Estuary with high current velocities at spring tides, the extreme tidal range and the sediment load are bound to present several significant challenges to the designers and constructors for station keeping, manoeuvring and operations (e.g. high bollard pull vessels engaged to tow caissons do not normally have to cope with such conditions). Accurate positioning and placement of caissons is likely to be a challenge (mooring and winching robust systems). The particularly high volume of suspended material within the estuary would be a significant challenge in relation to a number of issues and would be a considerable factor influencing how the caissons are placed. The installation methods outlined by STPG in their 1989 report addressed these issues in some detail and showed how existing technology and vessel types could be used (modified / fitted out for the purpose).

Most existing jack-ups can only move at wave heights of 1.5 m and below. In the Bristol Channel these conditions are much shorter in duration than most other near shore locations around the UK. The wind speeds encountered would also limit operating hours and also the number and lengths of time when movement of the barges is possible. It is possible to design Jack-Ups to move in wave heights up to 2.5 metres, and this is increasingly the standard for offshore wind farm vessels.

The bigger challenge would however be the preparation of the surfaces onto which the caissons will have to be landed. These will have to be accurately levelled, to tight tolerances, and these graded surfaces will be very vulnerable until such time as the caissons have been sunk onto them during neap tides. It is very possible that this levelling work will have to be performed more than once on many caissons, because it will often be the case that a week to ten days may pass when it is not possible to sink a caisson due to bad weather condition. During the time between weather windows, the tidal currents are likely to move large amounts of sand and silt along the seabed into any excavations.

Therefore innovative solutions for the foundation preparation could be envisaged like those used for the Eastern Scheldt storm surge barrier in the 1980s (see below case study; prefabricated mattress consisting of reinforced geotextile fabrics and graded stone layers laid out by a specific vessel - Cardium).

The offshore wind and offshore oil and gas industries have already developed construction capabilities in harsh marine environments which could be helpful for the Severn estuary.

Although the conditions will reflect the equipment choice, it will be more of a factor on the installation methods and constraints rather than on the equipment itself.

Ports

Further study of the available vessels, their dimensions and requirements, will determine the ability of the existing ports to accommodate them. Port operators will seek to continue all existing cargo movements and will thus seek to accommodate new opportunities on other berths (this will also depend on the international trade situation). Most of the Severn estuary ports are able to provide facilities for a wide range of vessels of varying sizes (Port Talbot, Bristol,

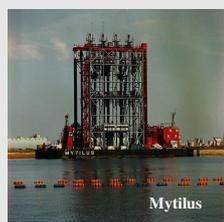

Cardiff...). A number of alongside facilities exist at these ports but depending on requirements, some bespoke facilities may need to be developed to meet the project requirements. Upgrade and improvement might be required at any of the Severn estuary ports to accommodate large and numerous vessels (e.g. dredgers) or to deal with heavy loads (e.g. turbines) as it is unlikely that the existing infrastructure and cargo facilities will be adequate for them. Development land at these ports is also available to support the vessels requirements.

Case study - The Eastern Scheldt storm surge barrier (Oosterschelde – Delta Works) Example of construction innovation

The Eastern Scheldt storm surge barrier (completed in 1986), was the most ambitious part of the Delta project. The original plan was to build a 9km dam in the mouth of the Eastern Scheldt (20 to 40m depth; 3m tidal range). Preparatory works started in 1967 with the construction of 3 islands: Roggenplaat, Neeltje Jans and Noordland. In 1973, 5km of dam had been built but, under pressure from scientists, the fishing industry and environmental associations, parliament decided to launch further studies so as to protect this unique natural habitat. In 1975, the government decided that a storm surge barrier with sliding gates should replace the initial dam. This scheme would protect against flooding while conserving the ecosystem: the barrier would remain open when conditions were normal (3/4 of the original tidal movement is therefore maintained) and would be closed when sea water levels were high. The technology needed to construct this huge barrier had yet to be invented and the experience gained building the other Delta dams was not suitable. The idea was to place 65 prefabricated concrete piers in a very firm stone foundation and to insert 62 large steel sluice-gates between them. The final project consisted in constructing 3 barriers implemented in the 3 remaining channels: the Hammen, the Schaar van Roggenplaat and the Roompot (total length: 3km). Parliament approved this plan in 1979.

The Eastern Scheldt storm surge barrier was such an exceptional project that a new approach had to be taken to every part of its construction. A consortium of Dutch contractors was formed (Dosbouw) and cutting-edge methods and materials were used. Most of the prefabricated and construction works (piers, foundation mattress, storage of armour stone...) were carried out in the Neeltje Jans and a temporary bridge was built to connect the island to shore.

First, at the construction site, large diameter dolphin and anchor piles (steel cylinder piles) were driven to serve as moorings for the extensive floating construction operations to come. The loose sands in the top 10-20m of the foundation under the barrier were then compacted by vibratory means. A special floating rig, the **Mytilus**, jetted and vibrated 4 large diameter vibrating needles (2.1m diameter – 18m length) down to a depth up to 50m below sea level. The entire compression process took place under water and continued 24h per day. The ship consists of five pontoons: a main pontoon of 18.9m long and four auxiliary pontoons with a total length of 32.9m. On the ship were lifting cranes 55m high. The lifting winches which were fixed to them had a pulling power of 120t. The construction cost of the Mytilus was €15.9m in 1986 (about £29m in 2009).

As bed protection, improvement and depth compaction were not enough to ensure that the piers could be placed safely, a foundation had to be constructed to prevent scouring. Polypropylene mattresses filled with graded layers of gravels were used (36cm thick, 42m wide and 200m long). They were made at a factory specially built for their production in the Neeltje Jans island. The mattresses were winched up on a huge floating reel and then placed on the specially-designed vessel, the **Cardium** which laid them at a rate of 10m per hour during slack water period. This vessel was also able to dredge the upper seams of the seabed before laying the protection mattress. An additional gravel ballast mattress was finally laid over the sands to prevent erosion so as to protect the mattresses against wear, which could be developed through the opening and closure of the gates. The construction cost of the Cardium was €49.9m in 1986 (about £96m in 2009); the actual cost was eighty percent higher than expected.

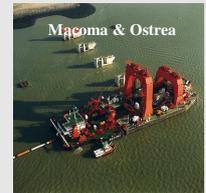

The 65 concrete piers were constructed inside 3 large construction docks 15m deep which were excavated, diked off and dewatered using 320 underwater pumps. The piers are colossal structures made of prestressed concrete: 30 to 40m high and their dry weight was up to 18,000t. A purpose-built factory produced 450,000m³ of concrete over 4 years. The piers were hollow and were filled with sand when they were in position. As all the piers had to be completed in only 4 years, they were produced in staggered batches with work beginning on a new pier every 2 weeks. At the peak of the activity 30 piers were being constructed simultaneously.

When all the piers in a construction dock were completed, the dock was flooded and the encircling dike was opened so that they could be towed to one of the channels in the mouth of the Eastern Scheldt. A giant catamaran crane barge, the **Ostrea** vessel was designed and built to lift the piers in the construction dock, transport them to the channels and then place them with great precision on the foundation mattress (margin error of a few cm). The Ostrea was the flagship of the Delta fleet. With its

length of eighty-seven metres, the typical U-shape and a capability of 8,000 horsepower, it was a most impressive ship. With the open side of the 'U', the ship manoeuvred around the pier. The ship could steer easily, thanks to its four screw propellers. On both sides there were two giant goliath cranes 50m high. The piers were fixed to these cranes. As the cranes could not lift more than 12,000t whereas the piers weighed 18,000 tonnes, the piers were only half-lifted and transported to their final location. It took 1 year to place all the 65 piers. The construction cost of the Ostrea was €34m in 1986 (about €65m in 2009).

The **Macoma** vessel was specially built to moor the Ostrea while it was placing the piers and to clean the site immediately beforehand. The piers were positioned with a pin-point accuracy at slack water using very sophisticated measuring equipments. It took a year to place them all. This pontoon was situated exactly in front of the place where a pier would be placed. When the Ostrea had taken a pier, it moored against the Macoma. To offer the Ostrea some stability, the pontoon had a coupling mechanism with a power of 600 tonnes. The Macoma also had a second function: an enormous vacuum cleaner was used to ensure there was no sand between the pier and the bottom. This was an extremely difficult

task, because the tidal movements moved large amounts of sand each day. The construction cost of the Macoma was €20.4m in 1986 (about €38m in 2009).

For even greater stability and protection from the powerful tidal currents, the piers were embedded in sills made up of armourstone (up to 10t each). A specific vessel, the Trias was designed specially to lay the top layer so as to avoid any damage to the piers. This vessel was equipped with a long, extendable arm that could place the heaviest stones accurately. 5m tonnes of stones were needed and since they were not available in the Netherlands, they were shipped over a 4 year period from Germany, Finland, Sweden and Belgium. The construction cost of the Trias was €11.3m in 1986 (about €20m in 2009).

At the final stage, the service ducts, pier capping units, sluice-gates, sill beam and upper beam had to be put in place. The hollow service ducts, which would later be covered by a road, were laid on top of the piers. The ducts contain the operating and control equipment for the gates. The steel gates (from 6 to 12m high) were suspended between piers. The biggest sluice-gate weighs 480t. A specific barge-crane, the Taklift 4 was used for the installation of the gates.

Many other specific vessels were used for this project: Portulus, control vessel with underwater vehicle for controlling proper mattress installation, 2 self positioning stone dumpers (2,000t load), Johan V geotechnical reconnaissance pontoon, Jan Heijmans vessel which helped the Cardium place the mattress, the Sepia and Donax I vessels which worked with the Macoma during the placement of gravel ballast on the mattresses...

The total construction cost of the scheme was €2.7bn in 1986 (about €5bn in 2009) and the cost of all the purpose-built vessels accounted for about 6% of budget. The maximum workforce was 1,600 people for the construction.

The barrier had a revolutionary design. Many techniques had not been used before and if they had, it was not during such a large-scale project as this one. There were no ships suitable for the construction of the storm surge barrier. For the building of the dam, several vessels were designed, which were individual tours de force. The ships were all "state-of-the-art". Most of the ships were provided with a system which could automatically and very precisely determine the location of the ship. The bearing techniques for orientation were quite new. In addition, new techniques were used to identify the surface and the structure of the sea bottom. Equipment such as gyroscopes and accelerometers would have been indispensable. To process the data flows provided by the equipment, large computers were necessary.

The main purpose-built vessels like the Cardium, Ostrea and Macoma, have never been used on other projects because of their specific design. Nevertheless, this Delta project has proved that challenging works can be overcome thanks to innovative construction solutions and also to specific tools and dedicated vessels.

Competition from other offshore construction projects

The increasing focus on offshore wind, wave, tidal stream and European Super Grids is likely to increase the pressure on the existing vessel resource. However, firm commitment to these programmes will make sure that new investment is brought in to alleviate the current scarcity of supply. As offshore wind turbines are increasing in size (to 5 or 6 MW and even 8 MW, in particular floating wind turbines which are currently being developed in Norway), new cost effective and fast installation methods are likely to be developed in the short term. So as to take advantage of the short weather windows and to optimise the duration of the mast and nacelle installation, Marine Contractors envisage now to build specific vessels able to lift and transport a pre-assembled wind turbine (mast + nacelle + blades) and to fix it to the foundation structure or to anchor it. Therefore, very few of the existing installation vessels would be adequate for installing turbines or foundations in the years after 2020 (or maybe earlier). This may actually release some of the existing vessels back onto the market, as they become redundant, through lack of sufficient lifting capacity at the hub heights that will be required for 6 MW and above turbines. Nevertheless, these vessels might also then move to the Far

East to service countries like India and the Philippines that are looking to install large scale wind farms off their coasts using smaller wind turbines; but this scenario is not confirmed. Therefore, the availability of heavy lift barges or transportation vessels for a STP scheme could be better than expected.

Competition from concurrent large construction projects may increase costs as demand for the resources of plant, labour and materials surpasses supply. Early involvement of the contractor(s) and suppliers would contribute to the project's success by engaging those parties in the development process and providing, at the relevant stage, certainty by securing resources.

It is relevant to note that if the London Gateway Project is resumed (initially scheduled in 2009-2013 but postponed), the demand for Marine equipment might be slightly put under strain (30 million m³ dredging, 1,300 m quay construction...).

Conclusion

Availability of dredging and marine equipment changes to satisfy global demand and the major vessels likely to be required for the STP scheme would need to be assessed in more detail now so as to provide an input to the overall scheme selection process. The particular environment of the Severn Estuary is likely to influence the type of vessels and their fittings. Forward planning and early engagement with suppliers would address the vessel availability, modifications to suit the demands of the environment and the timeframes.

The demand for specialised marine equipment is likely to remain steady (in particular due to planned offshore wind energy projects but also due to forthcoming wave and tidal developments), the long lead-in times of a STP project should provide an opportunity to address potential equipment capacity gaps. Anticipated changes are more likely to occur in the geographical location of the equipment rather than due to change of workload.

Also, the construction method must be optimised or even innovated so as not to be too dependent on the international vessels market (e.g. many moles or similar rock walls in the past have been serviced by rail mounted Goliath cranes installed on the crest of the structure; it is possible that a similar approach could be used on the barrages or lagoons to supplement crane vessels).

The Eastern Scheldt case study has proved that innovation can bring efficient responses to technical challenges and purpose-built vessels can also be envisaged for specific tasks.

III - MAIN CIVIL WORKS

Introduction

During the preliminary optimisation analysis of the feasibility study, the design of embankments and breakwaters for navigation locks were modified and based on conventional embankment fill and rubble mound. All the figures have been updated and the results come from the best variant of each short-listed scheme. The volume and tonnage of materials, in particular for the embankments, has been re-assessed according to the most suitable alignment, taking into account the sea-bed quality (volume of dredged materials required) and the water depth. Further studies on alternative solutions for embankment design (e.g. Fleming wall proposal for the Welsh Grounds lagoon) are being undertaken as potential alternative forms but conventional embankment fill and rubble mound is the worst case scenario in terms of labour and material resources and provides greater technical certainty.

The summary of the main construction materials required for each scheme is set out as follows:

Barrage schemes - Embankment and breakwater (lock) construction

	Barrages					
	Cardiff-Weston		Shoots		Beachley	
Embankments						
Overall crest length (km)	3.8		5.46		0.57	
Foundation preparation	million m ³	million ton	million m ³	million ton	million m ³	million ton
Sand bed (on dredged surface)	0.479	0.814	0.271	0.461	0.043	0.073
Embankment Structure	million m ³	million ton	million m ³	million ton	million m ³	million ton
Control structure rockfill (0.1 - 1t; 70% crushed rock - 30% armour stone)	1.598	3.516	0.401	0.882	0.103	0.227
Containment mounds (tonne quarry-run rock; crushed rock)	1.385	3.047	1.806	3.973	0.144	0.317

Sources: Parsons Brinckerhoff & DECC

In order to compare the demand for construction aggregates with the regional and national output capacity statistics (breakdown: sand & gravel – crushed rock – armour stone), each category of materials required has been classified according to this breakdown. It has been assessed that control structure rockfill and derrick stone are made of 70%

crushed rock and 30% armour stone; filter type 1 (0.6 – 35mm) are supposed to be gravels in the survey but they could also be small crushed rocks.

As for landing areas for the navigation lock (estimate: 3 million m³), dredged materials from foundation preparation are likely to be suitable.

A – Aggregates and armour stone

Introduction

In this report, the word “aggregates” refers to the following materials for civil works:

- aggregates for concrete (sand & gravel; crushed rock)
- materials used as fill for embankments (sand core, crushed rock), caissons (sand ballast) and sand bed on dredged surface

Armour stone (and rock armour) are large stones (> 1t) used for embankment and breakwater slope protection.

The supply of aggregates for construction (concrete aggregates, ballast, embankment fill, armour stone...) is one of the major issues for each STP scheme due to the very large volume of materials required.

There are two main streams of aggregates supply: “primary” aggregates (sand, gravel and crushed rock), extracted from the ground (quarry or gravel pit) or dredged from the seabed (marine aggregates), and “recycled and secondary” aggregates.

Primary aggregates are produced from naturally occurring mineral deposits, extracted specifically. Most construction aggregates come from hard, strong rock formations by crushing to produce crushed rock aggregate or from naturally occurring particulate deposits such as sand and gravel (either land-won or marine dredged). The most important sources of crushed rock in Britain are limestone (including dolomite), igneous rock and sandstone.

Recycled aggregates generally arise as a result of reusing materials, such as concrete and brick, from demolished buildings, roads and hard-standings. **Secondary aggregates** are the by-products of other processes, either minerals-related, such as waste material from slate and china clay extraction, or from electricity generation and manufacturing, such as ash from coal-fired power stations and slag from iron and steelmaking.

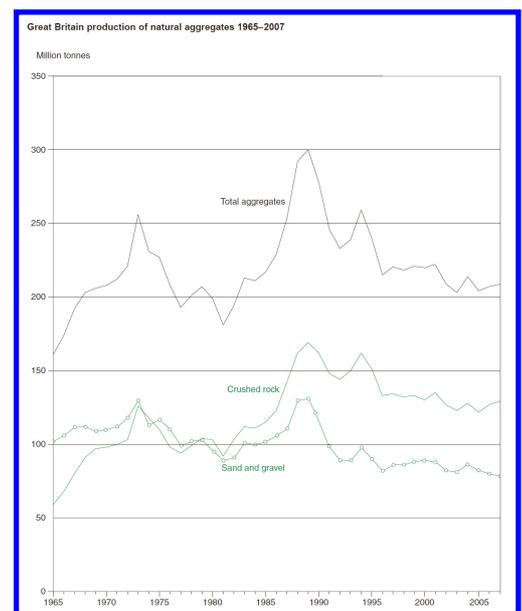

Data for 2005 has been used throughout this report because this is the year for which most complete information is available. Updated data from 2007 or even 2008 (when available) are also mentioned.

A-1 Primary aggregates

Primary aggregates production in the UK - Background

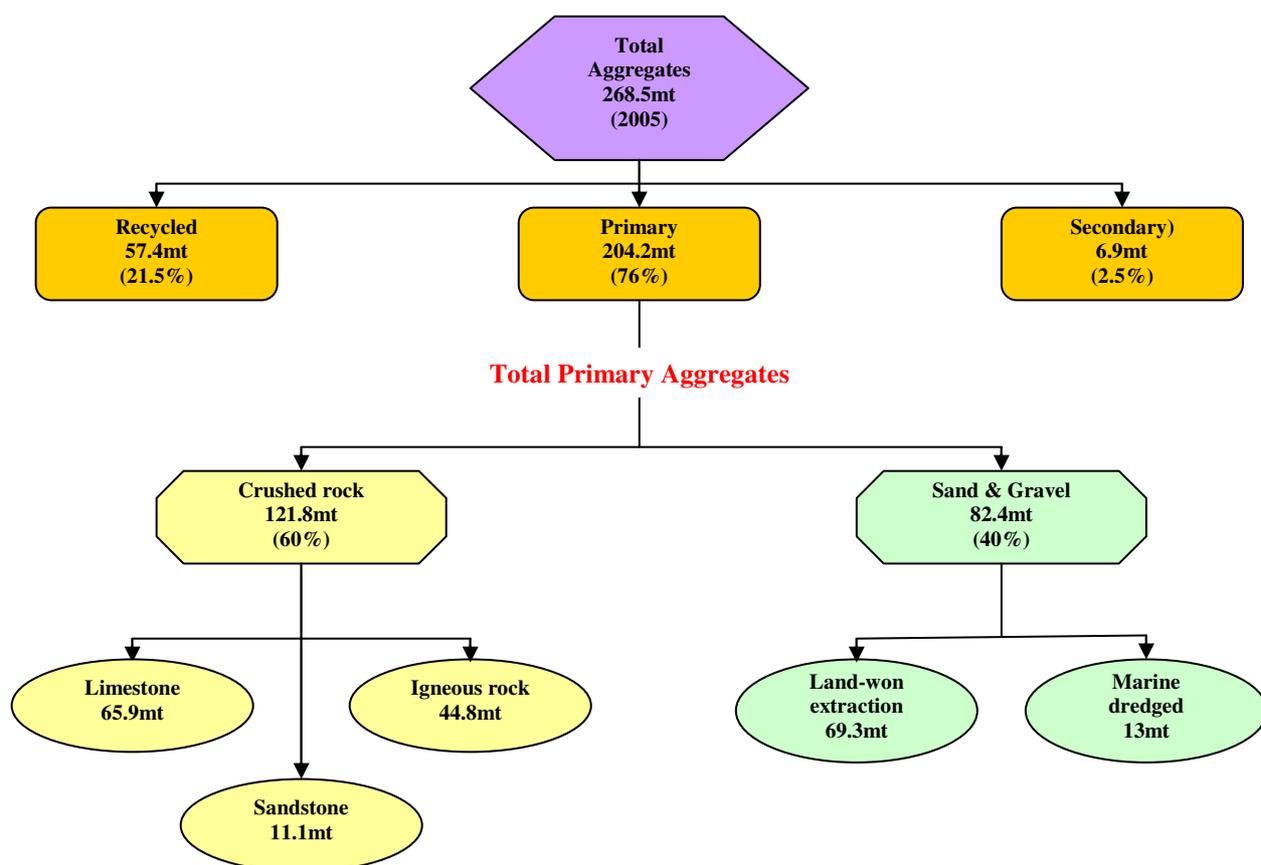

Sales of primary aggregates peaked at 300mt in 1989 but have since declined considerably. In 2007 about 208mt of primary aggregates were extracted for sale in Great Britain, comprising 62% of crushed rock, 31% of land-won sand and gravel and 7% of marine dredged sand and gravel. In 2005 the data were as follows: 204mt of primary aggregates, including 60% of crushed rock and 40% of sand and gravel (including marine dredged); see “GB - aggregates supply chain” figure below.

In England and Wales, the principal source of crushed rock is limestone, accounting for about 67% of supply, whereas in Scotland igneous rock is the dominant source of crushed rock (93%). No marine dredged sand and gravel is landed in Scotland, whilst in England and Wales marine sources accounted for 17% and 40% of total sales of sand and gravel, respectively. Northern Ireland produces sand and gravel only from land-won and also crushed rock (average output of 20mt; 27.1mt in 2007).

UK: sales of primary aggregates by Region and Country – 2005

Sources: Annual Minerals Raised Inquiry 2005, ONS for GB. Department of Enterprise, Trade and Investment for Northern Ireland

The latest available data in 2007 are set out in the following chart:

Great Britain – Production of primary aggregates (sand and gravel – crushed rock) by Region – 2007
 Source: British Geological Survey – UK Mineral Yearbook 2008

The relatively stable sales of recent years ended abruptly towards the end of 2008 with the global economic decline causing a significant fall in the demand for aggregates. The Mineral Products Association estimate that sales of crushed rock aggregates fell by 12% in 2008 as a whole, while sand and gravel sales fell by 15% compared to 2007. The outlook for 2009 is not good with demand predicted to be at its lowest level since 1997. The economic crisis and the downturn in aggregate sales have had a significant impact on many operators with sharp falls in profit, plant closures and job losses being announced by most companies.

As the development of a Severn Tidal Scheme (if decided in 2010) could not start before 2015 (or even later), this gives us hope of a construction market recovery and an improvement of the aggregates production in the UK.

Primary aggregates consumption in the UK

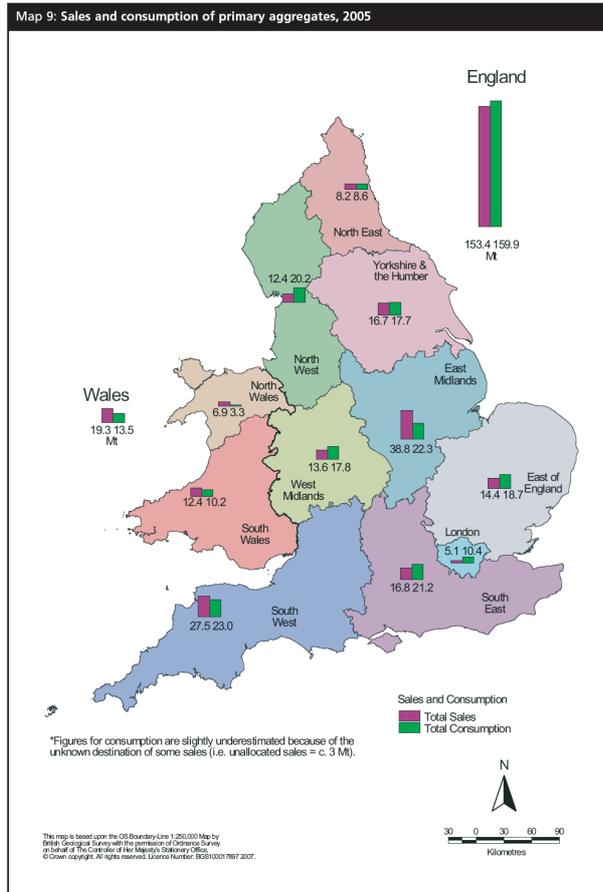

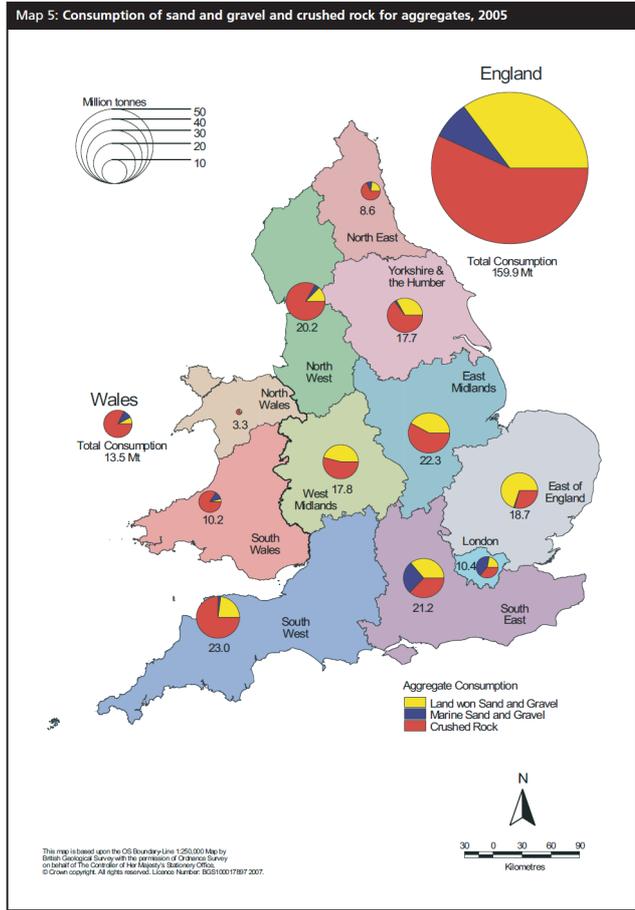

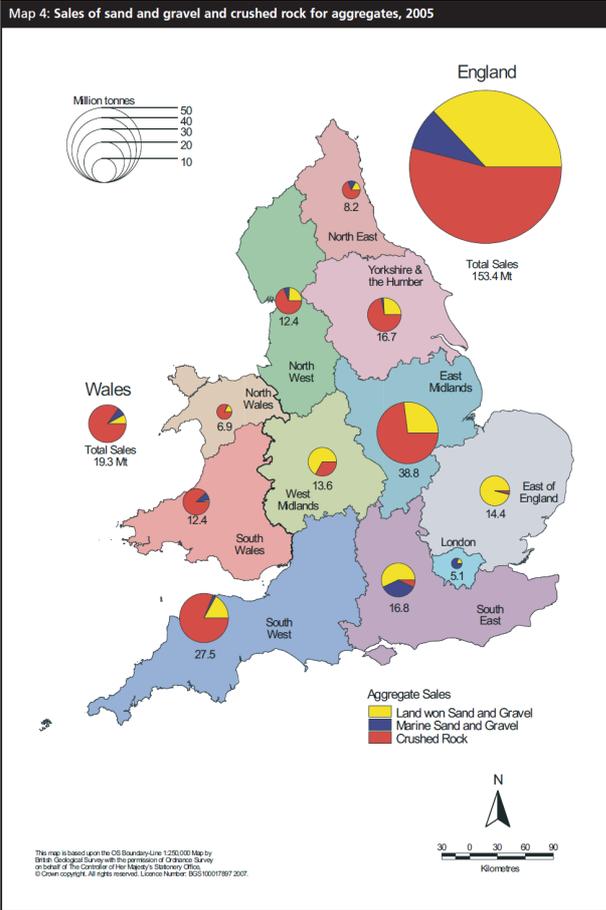

The UK has large resources of material suitable for use as aggregates. Historically, the UK has been self sufficient in the supply of primary aggregates and imports have not been necessary (excluding armourstone). The average total consumption of primary aggregates in the UK is about 220mt per year (production plus imports less exports; about 208mt in Great Britain). The total consumption of primary aggregates in Great Britain is set out in the following table:

Year	Crushed rock (mt)				Sand and gravel (mt)			Total Aggregates (mt)
	Limestone	Igneous rock	Sandstone	Total	Sand	Gravel	Total	
2005	66	46	11	123	43	39	82	205
2006	70	46	11	127	42	38	80	207
2007	67	51	12	130	42	36	79	208

Consumption of primary aggregates in Great Britain – 2005 - 2007
 Sources: British Geological Survey and ONS

In 2005, 205mt of primary aggregates were consumed in Great Britain, including 160mt in England and 13.5mt in Wales.

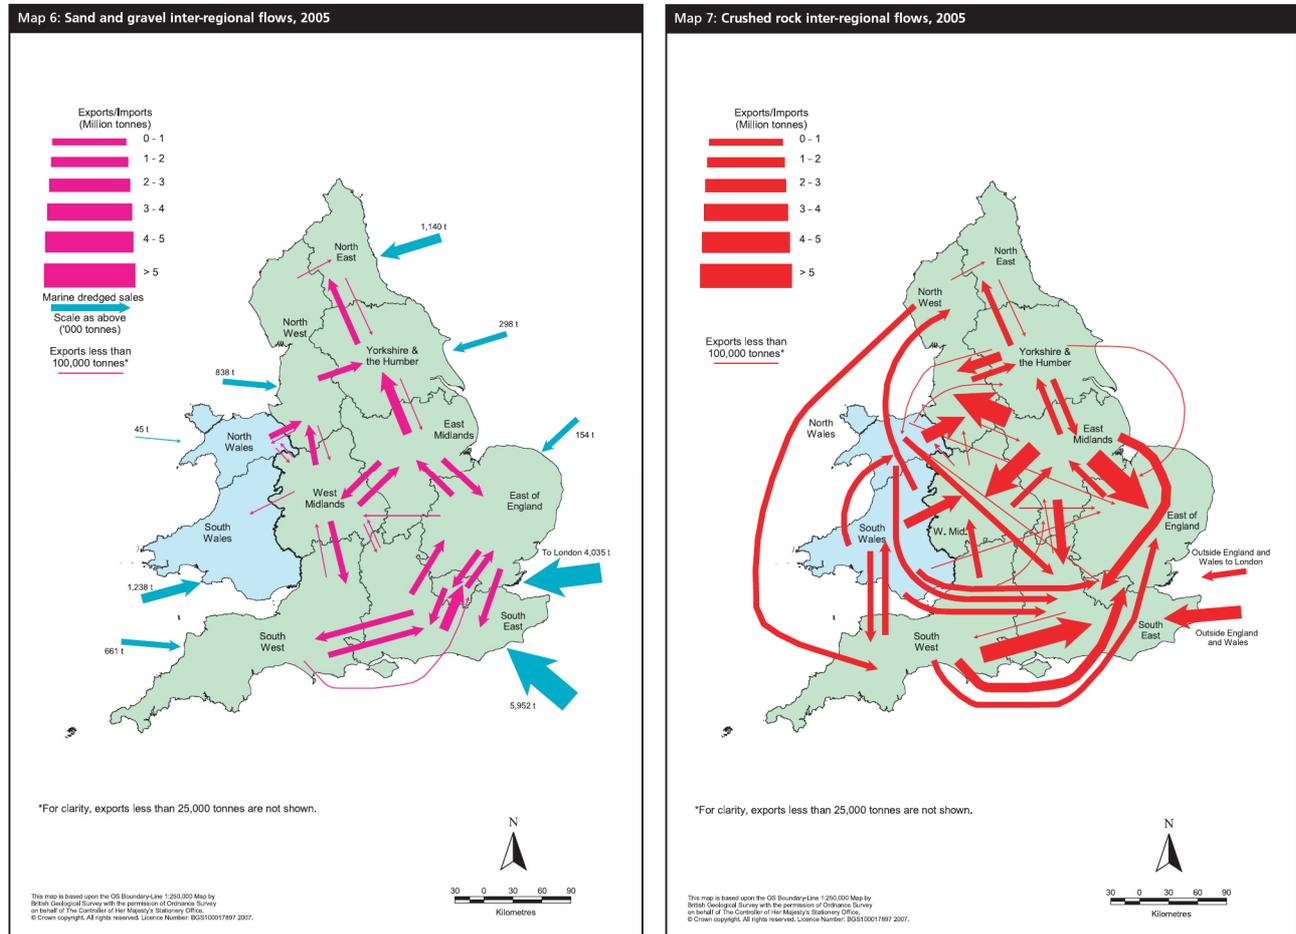

The following maps summarizes the sales and consumption of primary aggregates in England and Wales:

Sales and consumption of primary aggregates - 2005
 Source: Collation of the results of the 2005 Aggregate Mineral Survey for England and Wales
 British Geological Survey - May 2007

Inter-regional flows of primary aggregates

However, the distribution of these primary aggregates resources is uneven. In particular, there is an almost total absence of hard rock suitable for crushed rock aggregates in Southern and Eastern England, where demand is high. Consequently, there is substantial and increasing movement of aggregates within the UK and especially to these areas by rail and road. To a more limited extent, there is also shipment from Scotland and, on a lesser scale, from Wales and Northern Ireland.

Primary aggregates inter-regional flows - 2005

Source: Collation of the results of the 2005 Aggregate Mineral Survey for England and Wales
British Geological Survey - May 2007

There are over 1,600 aggregates quarries in the UK, roughly split 40:60 between sand and gravel sites and crushed rock (1,300 quarries in Great Britain and a fleet of 28 marine aggregate dredgers). Wales and South West England together have 124 quarries and 22 wharves for marine dredged aggregates. There are also a large number of aggregates producers, which range from single quarry owners to multi-national companies operating many sites throughout the country. Five multi-national companies (Tarmac Group, Hanson Aggregates, Aggregates Industry, CEMEX and Lafarge Aggregates) currently account for more than 70% of total aggregates production in the UK.

The principal modes of transport employed for the distribution of aggregates sales from quarries and wharves are as follows: 90% road, 9% rail and 1% shipment by water. Crushed rock is very often transported by sea from coastal quarries in the UK (Scotland – Glensanda, Wales and Northern Ireland) to destinations principally in England (average of 3mt/year; 90% of the crushed rock is from outside England). For crushed rock the proportion of rail deliveries increased to about 15%.

End-use of aggregates

Generally, primary aggregates are used for the following purposes:

- Concrete aggregates
- Asphalt and roadstone
- Construction and fill (e.g. embankment, dyke...)
- Rail ballast

- Mortar...

The breakdown of primary aggregates production (including marine aggregates) by end-use in Great Britain, Wales and in the South West is set out in the following table (based on 2007 data):

Region/Country	Production of primary aggregates by end-use (mt & %) - 2007			
	Concrete aggregates	Construction uses & fill	Other uses (roadstone, railway ballast...)	Total (mt)
South West	9.5 (32.5%)	9.3 (31.9%)	10.4 (35.6%)	29.2
Wales	4.6 (22.1%)	8.5 (40.9%)	7.7 (37%)	20.8
England	63.3 (42.2%)	40.6 (27.1%)	46.1 (30.7%)	150
Scotland	10.4 (28.1%)	12.4 (33.4%)	14.3 (38.5%)	37.1
Great Britain	78.3 (37.6%)	61.5 (29.6%)	68.3 (32.8%)	208.1

Production of primary aggregates (sand, gravel & crushed rock) by end-use (2007)

Source: UK Mineral Yearbook 2008 - British Geological Survey

The specific breakdown of sand and gravel production (land-won and marine dredged) by end-use in Great Britain, Wales and in the South West is set out in the following table (based on 2007 data):

Region/Country	Production of sand & gravel by end-use (mt and %) - 2007					
	Sand		Gravel		Sand & Gravel for construction fill	Total sand & gravel (mt)
	Building Sand (mortar...)	Concreting Sand	Other uses (binder...)	Concreting Gravel		
South West	1.1 (16.2%)	2.9 (42.6%)	0.1 (1.5%)	1.2 (17.6%)	1.5 (22%)	6.8
Wales	0.7 (30.4%)	0.9 (39.1%)	0.1 (4.3%)	0.4 (17.4%)	0.2 (8.7%)	2.3
England	10 (14.9%)	25.9 (38.6%)	0.2 (0.3%)	21.2 (31.6%)	9.8 (14.6%)	67.1
Scotland	1.6 (17.8%)	3.4 (37.8%)	0.1 (1.1%)	1.9 (21.1%)	2 (22.2%)	9
Great Britain	12.3 (15.7%)	30.2 (38.5%)	0.4 (0.5%)	23.5 (30%)	12 (15.3%)	78.5*

Production of sand and gravel by end-use (2007)

*78.5mt: land-won 64.7mt; marine 13.8mt

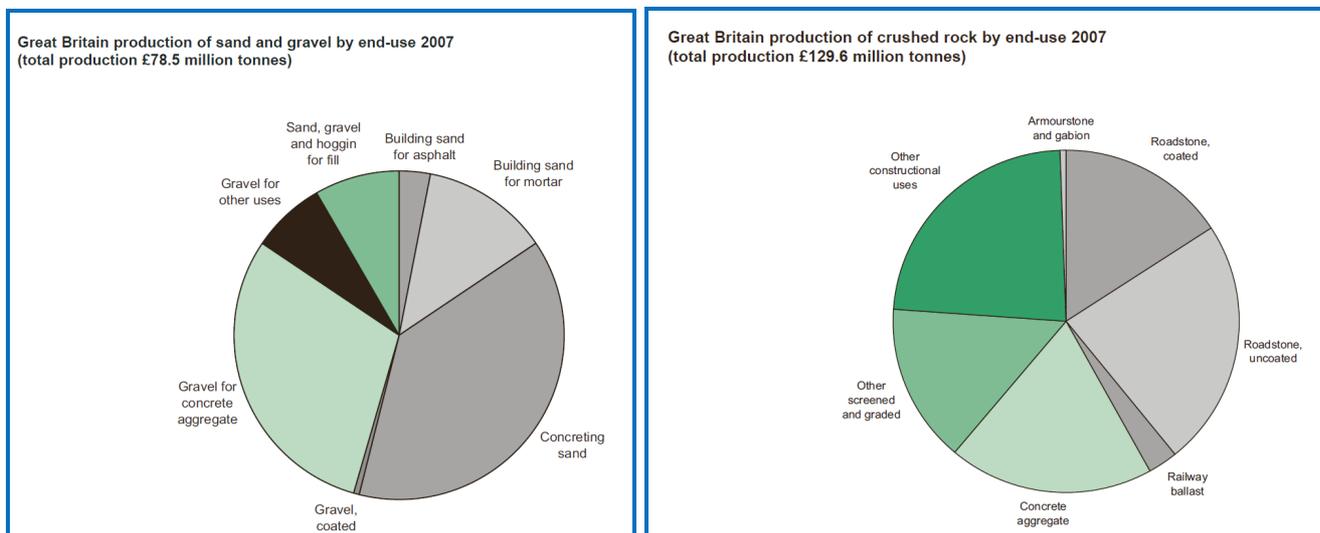

Finally, the specific breakdown of crushed rock production by end-use in Great Britain, Wales and in the South West is set out in the following table (based on 2007 data):

Region/Country	Production of crushed rock by end-use (mt and %) - 2007					Total crushed stone (mt)
	Roadstone	Railway ballast	Construction uses & fill	Concrete aggregate	Armourstone & gabion	
South West	8.8 (39.3%)	...	7.8 (34.8%)	5.4 (24.1%)	0.06 (0.3%)	22.4
Wales	6.4 (34.6%)	0.3 (1.6%)	8.3 (44.9%)	3.3 (17.8%)	0.07 (0.4%)	18.5
England	33.1 (39.9%)	2.3 (2.8%)	30.8 (37.1%)	16.2 (19.5%)	0.45 (0.5%)	82.9
Scotland	11 (39.1%)	1.3 (4.6%)	10.4 (37%)	5.1 (18.1%)	0.26 (0.9%)	28.1
Great Britain	50.5 (39%)	3.9 (3%)	49.5 (38.2%)	24.6 (19%)	0.78 (0.6%)	129.6

Production of crushed rock by end-use (2007)

Source: UK Mineral Yearbook 2008 - British Geological Survey

These tonnages and breakdowns of end-use will be used to assess the impact of the aggregates demand (aggregates for concrete, ballast and aggregates for embankment fill) for the shortlisted STP schemes on the regional and national market, assuming the breakdown in % remains the same. As an increase in the production capacity is likely to occur due to a better economic situation (higher demand expected), these 2007 figures will be increased by a few % so as to get a more relevant and realistic assessment.

Breakdown of sand-gravel and crushed rock production in Great Britain - 2007
 Source: UK Mineral Yearbook 2008 - British Geological Survey

Exports of aggregates

The UK is, in fact, a net exporter of aggregates. This is primarily due to export of sand and gravel dredged on the UK Continental Shelf but landed at foreign ports, principally in the Netherlands, Belgium and France (amounting to about 6mt/year). There are also exports of crushed rock from Glensanda, Britain's only coastal superquarry located on Loch Linnhe in western Scotland (Morvern Peninsular). The average exports of primary aggregates from the UK are 12mt/year (8mt of sand and gravel, including 6mt of marine dredged; 4mt of crushed rock).

(a) Including production from marine dredging.

(b) Great Britain only.

(c) For a number of years, a significant amount of armourstone imports are believed to be wrongly classified as 'granite, crude'. In 2007, this figure was 326 446 tonnes, and this has reduced from 1 331 520 tonnes in 2005, suggesting this issue is being addressed.

(d) Principally marine-dredged sand and gravel.

Source: HM Revenue and Customs.

However, the Crown Estate Commissioners give the following figures for marine-dredged sand and gravel landed at foreign ports (tonnes): 2003: 6 095 640; 2004: 6 191 867; 2005: 6 471 453; 2006: 6 714 659; 2007: 6 649 041.

UK – Imports and exports of primary aggregates (2003 – 2007)

Source: UK Mineral Yearbook 2008 - British Geological Survey

Imports of aggregates

The average imports of primary aggregates to the UK are 3mt/year (0.9mt of sand and gravel, 0.6mt of crushed rock and 1.5mt of armour stone).

Norway is by far the leading rock supplier for the UK and around 1.8mt of aggregates was imported from Norway in 2005: 0.2mt of sand and gravel, 0.3mt of armour stone and the remainder was crushed rock aggregates for railway ballast, concreting aggregates, asphalt aggregates and material for road sub base. Norway exports an average of 10 - 12mt of crushed rock aggregates (including armour stone) to Europe from 20 coastal hard rock quarries and exports also 0.2mt of gravel from 3 sand and gravel producers. There are currently 8 main quarries in Norway (Larvik, Jelsa, Tau, Askoy, Dirdal...) exporting crushed rock and armour stone to the UK and they have in excess of 2,000mt of reserves (igneous and metamorphic rocks).

Norwegian hard rock quarries have annual outputs in the range 1 to 2.5mt/year, with the largest quarry Jelsa (operated by Norsk Stein A/S) having annual production of about 3.5 to 5mt/year (350mt reserves). Norway has deep-water anchorage, low tidal range and a well developed infrastructure to allow for harbour facilities for medium to large bulk carriers.

The other overseas aggregates providers for the UK are Ireland (0.4mt in 2003), Denmark (0.3mt in 2003) and France (0.5mt in 2003).

The major constraint on the ability of overseas sources to export more rock aggregates to England or Wales is not the ability to supply but more the capacity of the receiving wharves to unload and distribute the aggregates (the cost of bulk aggregates is very sensitive to transport logistics). With the cost of a new large bulk carrier barge (97,000t) being around £50 million and smaller 30,000t ship £15 million, the industry requires a guaranteed long term market to justify such investments. Ships with a capacity in excess of 15,000t are required to be economical to import crushed rock aggregates or rock armour. There are not many wharves that have deep enough water to take these vessels. Moreover, a viable minimum of suitable land area to stockpile rocks is around 1.5 hectares so as to hold around 125,000t of single size crushed rock aggregate or 70,000t of mixed grades. In England, stockpile areas at wharves vary in size from 0.4 to 12 hectares.

There are currently 30 wharves where crushed rock aggregate is landed in England. The average amount of crushed rock imported through each of the medium to large crushed rock wharves in England ranges from 50,000 to 600,000t per year. Currently 62% of all crushed rock aggregates landed at wharves is distributed by road. The largest wharf unloading crushed rock aggregates is the Isle of Grain (North Kent) which is able to handle over 2mt/year; the majority of aggregates imported from the Glensanda quarry are landed at this wharf.

With current infrastructure and number of wharves and concerns over maintaining aggregates quality, the maximum additional amount of crushed rock aggregates that could be landed in England is estimated at an additional 2 to 3mt/year. If more rock aggregate is to be imported, then there will be a need for existing wharf capacity to increase. Several locations have been identified as additional wharves with potential to land crushed rock aggregates: 6 in the North West, one in the Bristol Channel (Barnstaple, Devon) and the bulk of the remainder in the South East. Issues to be considered in locating future wharf sites include:

- Access to adequate deep water
- Enough space to stockpile aggregates
- Access to suitable roads and rail with capacity to transport aggregates
- Neighbourhood issues

Another constraint to be considered will be the weather windows when this rock can sail from the main West and North European quarries, and more especially, be landed. Generally for rock supply to the UK East coast, vessels wait for a suitable weather window, before making a rapid crossing to the landing site. Special measures are taken to very rapidly unload the barges in as short a time as possible, to refloat them before the next weather system comes in. These short sea crossings will not be possible for the Severn estuary which is located too far, and it is likely that the rock will need re-handling from deep sea to shallow draft vessels.

It may prove necessary to modify some existing vessels in order to adapt them for rock handling. Rock is a very demanding cargo, and hulls and holds need considerable amounts of sacrificial steel plating to protect the structure of the vessel from damage from rock impact on loading and unloading.

Armour stone

The armour stone market is very variable, with possibly large tonnages imported in one year at one port and almost none in another. It is difficult to produce the large blocks of rock required from UK quarries because the rock is often fractured and, in most cases, it is not possible to load directly into ships or onto barges. Therefore, very little of the rock armouring used around the UK comes from Britain. The Scottish quarry Glensanda has a huge reserve of granite rock and large capacity of sea transport (and good rail connection to other mainland quarries); therefore, it could also be envisaged to extract more rock armouring from this site. Glensanda is Europe's largest granite quarry.

Due to the requirement for a dense and highly durable rock for this particular application, it is highly likely that the rock for these embankments or breakwaters would come from Norway or Northern Europe (Sweden...) and Western Europe (France, Spain; coastal quarries), where much of the existing rock armouring is currently sourced. Rock will be

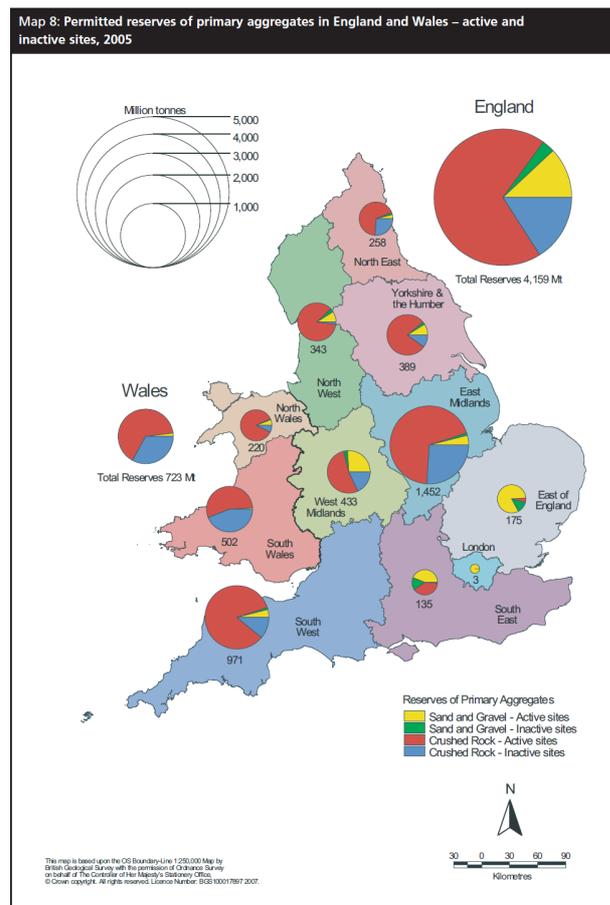

required in different sizes: the most critical will be the large armour rock. The development and blasting plans for the quarry have to ensure that an adequate quantity of each size can be obtained. These plans must include temporary roads so that the hauling to the sorting and stockpiling areas can be carried out efficiently. But most quarries are not prepared to drill and blast specifically for armour stone as it disrupts normal production.

Reserves of aggregates in the UK

Total permitted reserves for aggregate use in active and inactive sites in England and Wales (including sites that have not yet been opened at the end of 2005) were 4,882mt (4,159mt for England and 723mt for Wales).

In England, crushed rock accounted for 85% (3,556mt); sand and gravel the remaining 15% (603mt) whereas in Wales, crushed rock accounted for 97% (704mt); sand and gravel the remaining 3% (18mt). In Scotland, the reserves estimates were 1,491mt in 2005: crushed rock accounted for 92% (1,368mt) ; sand and gravel the remaining 8% (123mt).

Many of the UK quarries producing the highest quantities of aggregates have some, albeit limited, capacity to increase their supplies in the short term with the need for only minimal investment. This potentially could be in the order of 10 to 12mt/year. However, increasing the rate of extraction would also increase the depletion rates of the permitted reserves for these quarries. This is likely to result in an increase in applications for planning permission to release extra reserves in order that the individual companies could ensure long term viability.

British Geological Survey - May 2007

Aggregates production in England and Policy

In England there is a well established mineral planning system which includes the principle that the construction industry should receive the aggregates required, consistent with the principles of sustainable development (Department for Communities and Local Government – DCLG – Mineral Policy Statement 1: Planning and Minerals - 2006). A National and Regional Guidelines for Aggregates Provision in England is regularly published and revised and these guidelines indicate how provision for the supply of aggregates should be made to meet anticipated future need. The DCLG is committed to keeping these guidelines under review. The last National and Regional Guidelines for Aggregates Provision in England (2005-2020) recommend generally lower levels of provision than the previous set issued in 2003 due to an overall fall in national demand for aggregates and an increase in use of alternatives to primary aggregates, notably construction and demolition waste.

Nine Regional Aggregates Working Parties provide technical advice (e.g. assessment of the resources and demands) to the DCLG and to the Government Offices and Regional Assemblies.

The aggregates supply chain in England is shown in the above figure:

England: Aggregates supply chain (2005)

Sources: Mineral Extraction in GB 2005, Collation of the results of the 2005 Aggregates Minerals Survey for England and Wales and Survey of arising and use of alternatives to primary aggregates in England 2005

Total imports into England in 2005 were 9.5mt (4% of its primary aggregates needs), of which 95% was crushed rock. The primary source for these imports is Wales (6.2mt: 5.6mt crushed rock and 0.5mt sand). Other sources include Norway (1.6mt), Scotland (1.5mt, mainly from the Glensanda quarry), Northern Ireland (1mt) and France (0.2mt).

Aggregates production in Wales and Policy

In Wales a new mineral planning system is under development which will seek to reconcile the demands for aggregates with sustainability issues. Mineral Planning Policy Wales (2000) sets out the land-use planning policy guidance of the Welsh Assembly Government in relation to minerals, extraction and development in Wales (it includes all minerals, except marine aggregates). Minerals Technical Advice Note 1 (MTAN1): Aggregates (2004) sets out detailed advice on the mechanisms for delivering policy for land-based aggregates extraction by Mineral Planning Authorities and the aggregate industry. The Welsh Assembly Interim Marine Aggregates Dredging Policy (2004) seeks to ensure sustainable, objective and transparent decision-making to meet society's needs for aggregates dredged from the Bristol Channel, Severn Estuary and River Severn. Primary aggregates production in Wales is about 19mt/year (2005) and is dominated by crushed rock. Policy contained within MTAN1 suggests the following recommendations:

- Aggregates should be worked in as close a proximity as possible to the market
- Rail and water modes are favoured over road transport
- The total level of production in Wales should not exceed 27mt/year before 2010

Primary aggregates production in Wales is dominated by crushed rock which represents about 86%. Crushed rock is made up of limestone and dolomite (73%), sandstone only in South Wales (15%) and igneous rock (12%). Land based sand and gravel extraction is far more developed in North Wales than in South Wales where marine dredging provides most of this material thanks to large deposits in the Severn Estuary and Bristol Channel.

There are also large quantities of mineral waste (slate, colliery spoil...) which can be used. Around 6mt of recycled aggregates are available and about 30% of them can be re-used for construction aggregates.

Aggregates production in Scotland and Policy

In Scotland, the National Planning Framework sets out the strategy for long term spatial development. Scottish Planning Policy (SPP) 4 – Planning for Minerals (Scottish Executive 2006) sets out planning policies that are intended to ensure that a steady supply of material is maintained to meet the demand and the economy in an acceptable and sustainable manner. Production levels are around 30-35mt/year; in 2005 the production output was 29.5mt (crushed rock: 22mt; sand and gravel: 7.5mt) and 5.5mt were exported, mainly from the large Glensanda coastal quarry (including 1.5mt to England). The overall contribution from recycled and secondary aggregates is around 18%.

Glensanda quarry, formerly owned by Foster Yeoman Ltd is now part of Aggregates Industries Ltd. Output from the Glensanda quarry is around 6 to 7mt/year (granite aggregate), of which 1.5mt is exported to England and the bulk of the remainder (about 70%) to other countries in Europe through ports in the Netherlands, Belgium, France, Denmark and Sweden and in depots in Germany and Poland. The quarry has permission to produce a maximum of 15mt/year (800mt reserves). This quarry serves the market both in the UK and beyond, with crushed rock aggregate being transported via the world's largest self loading transport ships (two 97,000t carrying capacity ships and one 37,000t ship owned by Yeoman Glensanda). Aggregate from Glensanda is used primarily for rail ballast and concreting aggregates (80%), with the remaining 20% being used for road sub base. Aggregates for the South East England market are discharged at a major terminal on the Isle of Grain in Kent (capable of handling over 2mt/year); material is then transhipped onto barges for transfer to Gibbs Wharf on the Thames in Essex, as well as other ports in southern and eastern England. Rock can also be landed directly at Robins Wharf on the Thames at Northfleet; other terminals include Liverpool, Greenock, Southampton and Great Yarmouth.

Other locations in Scotland have been identified as suitable for large quarries exporting aggregates. However, such developments raise substantial environmental concerns and the attempt to develop a major coastal quarry on Harris in the 1990s was unsuccessful.

A-2 Marine aggregates

The Crown Estate owns most of the mineral rights to the seabed and issues commercial licences to explore and extract sand and gravel in English and Welsh waters. The Crown Estate owns the territorial seabed (out to 12 nautical miles) and the rights to explore and utilise the non-energy mineral resources of the continental shelf (out to 200 nautical miles). An extraction licence is only issued if permission to dredge is given by the Marine and Fisheries Agency in England (shortly to become the new Marine Management Organisation - MMO - following the introduction of the Marine Bill) or the Welsh Assembly Government according to a Dredging Permission process. Any new licences to dredge would typically be subject to tendering and in places there are permitting constraints mainly arising from environmental concerns and conservation designations. Although licences are commonly acquired through tender rounds, it is also possible for a developer of a major project to apply for their own specific licence to The Crown Estate, particularly if existing licences are not capable of supplying required volumes and/or qualities. The developer would then obtain permission to dredge the sea bed, possibly linked with the Infrastructure Planning Commission (IPC) decision. Alternatively under “normal” circumstances it is estimated that it would take 3-4 years to get a permission to dredge under the new MMO-administered scheme.

licensed areas

The existing policy structure in the Welsh portion of the Bristol Channel is determined by the Interim Marine Aggregate Dredging Policy, published by the Welsh Assembly Government in 2004. This sets a cap on the marine extraction tonnage that is permitted in Welsh waters, and also sets a policy requirement for extraction to progressively move further offshore. There is no equivalent in English waters and the marine aggregates supply depends mainly on the market demand and is not constrained by ratio.

There are currently 80 Crown Estate licensed areas in the UK (50% on the East Coast) producing approximately 23mt of marine aggregates per year (21.54mt in 2008; 23mt in 2007 and 24,16mt in 2006). In 2008, 13.1mt was landed in England and Wales and of this total, 1.486mt landed in the Bristol Channel.

The potential supply of marine aggregates is not as constrained as this might suggested. In the Bristol Channel and Severn Estuary, the permissions are not resource-limited. Whilst permissions are typically issued for a maximum extraction from an area which is based on pro-rata across the term, it will often be possible to vary an existing permission to allow a more rapid extraction rate. There is also the possibility that additional tonnage may be approved with an updated environmental statement. Nevertheless, there are areas of environmental sensitivity, particularly in the upstream part of the Severn Estuary which may restrict dredging activities but these are likely to be mitigated.

Marine aggregates (sea-dredged sand and gravel) have made an important contribution to aggregates supply in the UK. In addition to landings at wharves for construction use (55 wharves throughout England and 13 in Wales), marine aggregates are also landed at numerous coastal locations for beach nourishment and contract fill or exported to Europe. In 2006, the amount of marine aggregates dredged along the UK coast was about 24.16mt/year and the main end-use was as follows:

- About 13.4mt (55%) for aggregates construction (concrete...) for the English and Welsh market
- About 6.7mt (28%) for exports to Europe
- About 4.2mt (17%) for beach nourishment and contract fill in the UK

There are substantial reserves of sand (no significant reserves of gravel) mainly in the Severn Estuary and the Bristol Channel suitable for construction aggregates and civil engineering purposes. The locations of sand reserves are well understood and concentrated in two areas:

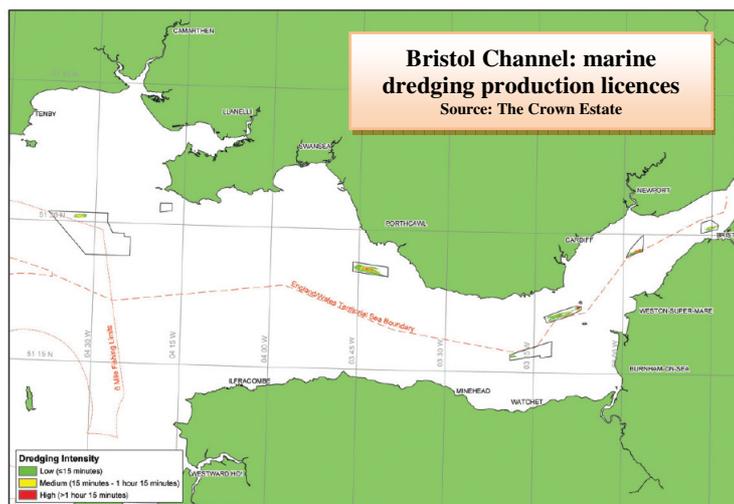

- Upstream in the Severn Estuary (westward to the Holms) and
- Significant resources farther offshore, lying in the central Bristol Channel, south of Carmarthen Bay

According to the Crown Estate, the national primary marine aggregates reserve (50:50 Sand/Gravel) is 120mt and the national primary marine sand reserve (less 20% gravel) is 83mt. These estimates (2008 survey) represent reserves available on consented production licence areas. The area of the seabed licensed for marine aggregates dredging in 2007 totalled 1,344km² (0.12% of the UK seabed) and only 137.6km² (11.7%) has been already dredged. The declared reserves significantly under-report the volumes of sand lying in the Bristol Channel as only permitted reserves are

presented. With additional permitting, enough marine aggregate resources are likely to be available to comfortably satisfy any of the development options.

Nevertheless, marine aggregates reserves are not directly comparable with terrestrial figures as these reserves are constrained by the relatively short term of environmental permissions, rather than the availability of the resource. In this region, the potential resource of marine aggregates (particularly sand) is substantial.

Around 21% of the sand and gravel used in England and Wales is now supplied by the marine aggregates industry. In the Bristol Channel, 11 production licences, operated by British Dredging Ltd, Hanson Aggregates Marine Ltd, Llanelli Sand Dredging Ltd and United marine Dredging Ltd extract about 1.5mt/year (1.77mt in 2007) from a permitted licensed tonnage of 2.62mt. In 2007, 1.05mt were landed at Welsh wharves and 0.72mt at English wharves. South Wales is uniquely dependent on marine dredged sand which accounts for more than 90% of its supply.

In the UK, the dredging fleet is operating today at capacity (28 purpose built dredgers with a total hopper capacity of 112,000t). Investment is required to maintain the dredging fleet in the near future. The age profile of this fleet shows that 81% are more than 15 years old and 26% of vessels are older than the generally accepted working life of 25 years. The cost of building a new vessel is in a range £25 to 40 million. Typically a 5,000t capacity vessel is able to dredge up to 1.2 million tonnes of aggregate a year, more than the largest sand and gravel quarries on land.

After landing at the wharf, transport by road is the main distribution method (93% of total landings) and this distribution is limited to, on average, 50km. Therefore, whilst the marine aggregates industry does have the ability to increase their proportion of aggregates supply, it is currently broadly limited to the geographical areas it already supplies. For a project of the magnitude of a STP scheme, as the demand for marine aggregates is high, changes in the transportation and/or landing points (wharves) would be required so as to ease the delivery of these materials to the construction sites. The Bristol Channel wharves are often in smaller ports (e.g. Newport), although aggregates are also delivered into Avonmouth.

As with many dredging projects, extraction rates may be accelerated by the relocation of vessels to the point of demand. On short turnarounds, associated with shorter transit times a single 5000t dredger would be able to produce significantly >2 million tonnes per annum of dry discharged sand or significantly more using wet discharge.

A-3 Secondary and recycled aggregates

Introduction

Secondary and recycled aggregates make an important contribution to the supply of aggregates and help reduce the rate at which primary aggregates resources are depleted. Maximising their use is a key objective of Government policy and supply from these sources has increased significantly in the last decade (e.g. 26% of total aggregates supply in England in 2005).

National and Regional policies seek to promote the use of secondary and recycled aggregates and are compatible with recycled aggregate demand. These materials are available in the UK, and transportation by sea from Cornwall to the Severn should be within economic reach. The amount of potentially available secondary and recycled aggregates being used is, however, felt to be reaching its maximum; additional material that could be supplied in the future is estimated to be around 7mt/year, based on 2005 sales rates (56mt in England: 48.9mt of recycled aggregates and 6.9mt of secondary aggregates; 67mt in the UK). The current market share of around 26% in England is expected to grow to 30% by 2011.

The % of secondary or recycled aggregate used for concrete construction is likely to remain low because the exposure conditions, environment and quality of concrete required for marine structures with a design life of 120 years plus may preclude the use of these materials. On the other hand, ballast for caissons could rely significantly on these materials.

China clay waste

China clay resources in Britain are confined to the granites of South West of England (Devon and Cornwall). There is, however, a significant volume of waste materials arising from china clay extraction available in the South West with the potential to be used in such projects.

China clay sales were 1.35mt in 2008 compared with 1.67mt in 2007 (peak output of 3.28mt in 1988). Today production is confined to the St Austell Granite (85% of sales), the south-western margin of the Dartmoor granite, and on the adjacent but separate Crownhill Down Granite. The UK is a major exporter of china clay and in 2008 1.19mt (88%) of sales were destined for export, including 0.75mt to Europe.

The extraction and processing of china clay involves the production of very large quantities of waste (22mt of waste material is generated for the extraction of 2.5mt of china clay) and about 90% is suitable for the recovery of secondary aggregates (sand and coarse aggregates), the remaining being a micaceous residue which is disposed of. China clay waste is exempt from the Aggregates Levy and sales for aggregates use have increased from 2.1mt in 2001 to 2.6mt in 2005. It is also estimated that 450-600mt of china clay waste are currently stockpiled in spoil pits, and the quantity is increasing year on year as more is tipped (about 15-20mt/year); an estimated 45-100mt is potentially useable.

Without any further investment, china clay waste could contribute at least 2-2.5mt/year to replace primary aggregates in a wide range of applications. Sales of china clay waste are mainly in the South West but small quantities are also shipped to London and the South East. Most of the china clay is transported by road and a marginal sea transportation (due to the rising cost of sea freight and fuel and the lack of available vessels) is done from ports facilities like the Port of Fowey (rail connected + deepwater, which has the capacity to load vessels with up to 6,000 tonnes of secondary aggregates) or Pomphlett docks (Plymouth). A higher contribution of china clay aggregates in a STP scheme would require investment so as to optimise the transportation (rail and sea).

PFA and GGBFS

PFA (Pulverised Fuel Ash from coal fired power stations) and GGBFS (Ground Granulated Blast Furnace Slag) are both likely to be considered as cement replacement. Availability to meet the construction programme would need to be investigated for the larger schemes and might not be adequate from UK sources. UK sources of slag for use as a cement replacement material were being fully utilised before the current recession. In recent years about 20% of the UK cement market has been met from slag and PFA sources (about 3mt/year). Nevertheless, there may be a shortage of PFA when a STP scheme construction is launched.

There are still significant stockpiles of fly-ash at UK coal-fired power stations and, aside from transport costs, there are unlikely to be any constraints in their supply in the medium term. GGBS is no longer produced in high quantities in the UK and importation from Europe is required now. If the supply is not sufficient, then sources outside the UK would be investigated (Many of the major suppliers are international companies and therefore able to secure these supplies from abroad) and alternative concrete mixes might be used for some of the concrete to provide the required durability in sea water. There are also possible new products which should be available in substantial quantities by the time construction of an STP scheme is likely to start.

Slate waste

In South West England, only four active slate quarries remain in Cornwall. From the average 2mt/year of slate waste arising from these quarries, approximately 0.2mt per year are available for use as aggregates but mainly for low grade applications (bulk fill, pipe bedding...) because they are considered as weak materials. This is why these materials are

generally used within short distance (20 miles) from the quarries; the exemption from the Aggregate Levy would now enable these materials to be transported further.

In North Wales, slate waste has a better quality and can be used in higher value application, such as sub-base, concrete... Nowadays only two quarries, Penrhyn and Oakeley, remain in operation. Permitted reserves of slate in North Wales were estimated at 42.5mt in 2005.

The process of slate quarrying generates vast amounts of waste rock. There are estimated to be 700-900mt of slate waste in North Wales (Gwynedd), and over half is constrained by a range of environmental designations or by distance from any possible bulk transport options. However, the remaining 270-370mt in the Bethesda and Blaenau Ffestiniog districts are suitable for use as aggregates. Current extraction is increasing this amount by 6mt a year. Slate waste could, theoretically, supply some 50% of UK crushed rock sales. This amounts to a market size of some 59mt/year. It is widely used in North Wales for general fill and road building and these applications represent the major future use of slate waste. Penrhyn quarry has recently started to send slate waste by sea from Port Penrhyn to Liverpool and Manchester and it is anticipated that up to 200,000t per year could be sent to each destination. It is also planned to establish a rail terminal at Blaenau Ffestiniog from where slate waste from Oakeley quarry will be sent to English markets.

Recycled & Secondary aggregates - England	Million tonnes / year	% supply of secondary and recycled aggregates	% total aggregates supply (207.2mt)

A-4 Dredged materials for a STP scheme (preparation works)

Dredged aggregates from preparation works

Extensive dredging would be required along the alignment of the barrage or the lagoon to provide not only a level foundation on sound rock but also a sufficient submergence for the turbines; dredging would be required as well for navigation channels (to provide access to and from the new navigation lock) or for caisson towing channels from construction yards.

The materials dredged should comprise mainly sand, gravel, soft rock (mudstone) and hard rock (limestone); mud and soft clay should also be dredged and disposed of as they would not be suitable for construction works. Due to their grading and potential contaminants (silt, clay...), these dredged materials in the Severn estuary would not meet the necessary high quality specifications for concrete aggregates; this is why they are not taken into account as a source of concreting aggregates for the STP schemes.

The sand and gravel marine aggregates would be the main materials suitable for embankment construction and caisson ballast. We assume in this survey that 80% of sand and gravel dredged for the preparation works could be used for embankment fill and ballast.

All the soft and hard rock dredged are likely to be weak materials which would break down and soften when worked as concrete aggregates. They could be used as fill materials for the landing areas for locks (Cardiff-Weston and Shoots barrage) or for the construction of compensatory habitat areas in the estuary.

According to the geology data and the optimisation of each alignment, the following tables set out the estimates of volume (and tonnage) of dredged materials as well as their category:

Dredging - Barrages	Cardiff-Weston		Shoots		Beachley	
Navigation channels	<i>million m³</i>	<i>million ton</i>	<i>million m³</i>	<i>million ton</i>	<i>million m³</i>	<i>million ton</i>
Mud and soft clay	0	0	0	0	0.043	0.073
Sand and gravel	22.340	33.510	3.600	5.400	1.200	1.800
Rock - soft (mudstones)	12.170	26.774	4.400	9.680	0.800	1.760
Rock - hard (limestones)	0.620	1.178	0	0	1.940	3.686
Caissons (incl. Lock) & embankments	<i>million m³</i>	<i>million ton</i>	<i>million m³</i>	<i>million ton</i>	<i>million m³</i>	<i>million ton</i>
Mud and soft clay	2.140	3.210	0	0	0.014	0.021

Total dredged materials likely to be used (ballast, land fill...)	5.106	9.766	1.811	3.984

Source: Parsons Brinckerhoff & DECC

These tables show that for Cardiff-Weston barrage and Beachley barrage, dredged sand and gravel could relieve significantly the demand for construction aggregates or ballast on the market (provided their quality meets the requirements). For the other schemes, dredged sand and gravel would not be considered as a major substitution of construction aggregates and for Bridgwater Bay lagoon, these dredged materials are purely and simply not available.

Main constraints for marine dredging in the Severn Estuary

Dredging and disposal licenses are highly regulated under a full range of policy and legislation. The main policy and guidance documents are: Welsh Assembly Interim Aggregates Dredging Policy; Marine Minerals Guidance Note 1: Guidance on the Extraction by Dredging of Sand, Gravel and Other Minerals from the English Seabed; Marine Minerals Guidance Note 2: The control of Marine Minerals Dredging from the British Seabed. The legislative control for marine aggregate is the Marine Mineral Dredging regulation 2007, for which there are separate pieces of legislation in England & Wales.

Capital dredging requires consent under Coastal Protection Act (CPA – 1985) and disposal of dredged materials are currently regulated together under the Food and Environmental Protection Act (FEPA – 1985). These consents are subject to the satisfactory completion of an Environmental Impact Assessment (EIA), stakeholder consultations etc.

However, this system is in the process of being rationalised into a new marine licensing regime under the Marine and Coastal Access Bill which is scheduled to be adopted in winter 2009. The proposed Marine Bill will introduce a new system of marine spatial planning that is considered essential for sustainable use of the sea and to deliver an effective and coherent approach to the management of the marine environment. Therefore the construction dredging and disposal operations for a Severn Tidal Power scheme would require a Marine Licence from the new Marine Management Organisation (which will be 2 separate bodies, one in England and one in Wales; new licensing regime is expected to be in place in Q.1 2011).

The main constraints with respect to marine aggregate extraction, capital dredging and disposal operations for the construction of the schemes, particularly for the Cardiff-Weston Barrage, are as follows:

- Finding and licensing new dredging areas mainly in the Severn Estuary (or the Bristol Channel) in order to supply additional marine aggregates for embankment construction (see chapter A-5).
- Finding and licensing suitable sites for the disposal of any dredged material that cannot be used within the construction works. The scale of the constraint would depend on the volume and nature (including type and quality) of the dredged material and the location and characteristics of the disposal site.
- Finding cost-effective beneficial uses for soft rocks (particularly mudstone): compensatory habitats works?
- Impacts of dredging and disposal on conservation features of the Severn Estuary SAC, SPA and Ramsar would need to be assessed, mitigated and compensated under the Habitats Regulations, for example loss/damage of sandbank resource, intertidal habitat and impact on *Sabellaria* reefs. Conservation agencies, generally, have a preference in the Severn Estuary for surficial (fine) sediments to be kept within the estuary system in order to maintain intertidal habitats
- Dredging operations in the vicinity of the main navigation channels would need to be carefully managed to ensure safety of navigation.
- Other constraints include impacts on coastal processes and sediment transport, ecology, water and sediment quality, marine archaeology, aggregate dredging, fisheries ...etc.

Main constraints for spoil or temporary disposal in the estuary

Limited options are available for disposing surplus spoil in the estuary or at sea. The best option would be to create a reclamation area within the vicinity of the works to be used as a lay down or processing area for the works. The reclamation area would require a marine facility for the import of materials.

The condition of untreated dredged material presents various problems for storage, principally the saturated nature of the material that requires suitable time and areas of land to enable dewatering to take place (which would vary depending on the type and amount of material). Direct transfer from excavation to final position is a preferable option, although may have implications on the construction programme. Storage would have to be carefully considered for any of the schemes at any location. Storage, and possibly treatment, of material on land would require licensing and consents, including by the Environment Agency under the Waste Management Regulations/Land Drainage Act.

Finding a suitable disposal site would depend on the type and quantity of dredged material. The key constraint would be in finding a suitably deep area of the Severn Estuary/Bristol Channel relatively close to the construction works; with a capacity to hold the required quantity of material to be disposed of; and without presenting a risk to navigation or the designated conservation features in the Estuary. In addition other constraints which would need to be given full consideration include impacts on coastal processes (sediment transport and budgets), ecology, water and sediment quality, marine archaeology, aggregate dredging, fisheries etc.

There are a number of licensed disposal sites in the Severn Estuary for the placement of maintenance dredged materials from the entrances and immediate approaches to ports. These disposal sites are licensed specifically for the disposal of relatively small quantities of maintenance dredged material (predominantly silts, some sands). It is unlikely that these sites would be suitable for the disposal of large quantities of capital dredged materials. There is a (now disused) disposal site that was used during the construction of the Cardiff Barrage. There is also a proposed disposal site in the outer estuary (Holm Deep) for the disposal of capital dredged material during the construction of the Bristol Deep Sea Container Terminal, which may possibly have capacity following the construction of the terminal. Detailed assessment would need to be undertaken in order to determine whether or not these sites would be suitable for the disposal of dredged material from the construction of the Cardiff-Weston Barrage.

We should be aware that baseline conditions in the Severn Estuary against which to consider disposal operations and the dispersal of material from existing disposal sites would change during and following the construction of the Cardiff-Weston Barrage, and to a lesser extent the other schemes. Careful consideration would need to be given as to whether dredged material is disposed upstream of the barrage within the Severn Estuary or downstream of the barrage in the Bristol Channel. The Conservation Agencies and CEFAS (Centre for Environment, Fisheries and Aquaculture Science) would be among the key advisors in making this decision.

As for the temporary disposal of dredged materials used for construction works, solutions exist to avoid large storage areas. Sand fill would not need to be landed onshore, techniques are available for placing the material directly into the works after being dredged; nevertheless it would require an efficient synchronisation between the dredging works and the embankment construction. Retaining bunds of rockfill construction with a central sealing zone can be formed initially to contain the dredge arisings.

Re-handling materials should be minimised as it would significantly increase the overall project cost. “Just in time” logistics should be adopted to ensure that materials are optimally used throughout the project.

A-5 Aggregates and armour stone for a STP scheme:

Introduction

At this stage, it is difficult to estimate the ratio of primary aggregates that would be sourced either from quarries or from dredging (including dredged materials from foundation preparation and navigation channels). Further work is necessary to consider the suitability of the aggregate sources and the associated transport links.

The local authorities which help regulate the industry and are responsible for approving (or not) applications for aggregates extraction have to operate in accordance with national policies and policy guidelines. These guidelines (in England) include assumptions about future aggregates demand so that the local authorities plans can make sufficient provision for future aggregates supply.

According to the Mineral Products Association (MPA), existing plans should have sufficient capacity to meet the aggregates needs of all the options – with the possible exception of the lagoon schemes. Given the scale of potential demand for concrete aggregates, crushed rock and fill materials there would need to be further analysis to determine if existing Government plans included sufficient supply capacity to meet the demand of this option. The Government’s policy guidance is regularly reviewed and there is the opportunity to revise forecasts of future aggregates demand to reflect the Severn Tidal Power scheme requirements. Moreover, very large schemes would have to be considered separately in terms of aggregates supply and exemption clauses for such projects could be applied.

The choice of the best quarries will depend also on the location of the caisson construction yards. For saving and for environmental reasons, these quarries should have a marine access for waterborne transport or even a good rail or road connection. Glensanda in Scotland, but also other smaller quarries in Great Britain, has access to marine wharves. Raynes quarry in North Wales supplies some crushed rock limestone into the South East and igneous rock from coastal quarries in Cornwall also supply small amounts to the South East. Nevertheless, the local ports may not have the infrastructure to assist in the movement of the bulk material and some upgrading works would be needed.

The demand for construction aggregates for each STP scheme has been compared to the future (2015-2020) regional and national annual output capacity based on the 2007 data slightly increased. This demand will be split during the construction timescale and at this stage of the study, it has been assessed that the average annual demand is equal to the total demand divided by the number of years required for civil engineering construction (this assumption is optimistic because at the beginning of the works a peak demand is likely to occur). This comparison only gives an idea of the impact on the current market.

For each type of aggregates (concrete aggregates, aggregates for embankment fill or for ballast), the demand has been compared to the regional and national breakdown capacity by end-use (assumption: the breakdown of primary aggregates production by end-use remains the same – see 2007 figures from table p29).

Due to the lack of available detailed data on aggregates production and end-use breakdown in Northern Ireland, the demand for materials of each STP scheme has been compared only to the Great Britain market and not the UK's.

Aggregates for concrete

In 2007, Great Britain produced 78.5mt of aggregates for concrete (72.7mt in 2005), including: 24.7mt of crushed rock and 53.8mt of sand and gravel (including marine dredged materials landed at British ports). By the time a STP scheme would be constructed (around 2015-2020), the production of concrete aggregates is estimated as: 5mt/year in Wales, 10mt/year in South West and 80mt/year in Great Britain.

The impact of the overall annual demand for concrete aggregates (caissons, crest wall, ballast, precast armour units...) of each STP scheme is as follows:

Demand for aggregates for concrete (structures, ballast & precast armour units)	Total demand for aggregates for concrete	Duration of civil engineering construction	Annual demand for aggregates for concrete	% of annual average production of concreting aggregates (forecast - 2020)		
				Wales Total average production	South West Total average production	GB Total average production
				5mt/y	10mt/y	80mt/y
Scheme	mt	Year	mt/year			
Cardiff-Weston barrage	11.71	6	1.95	39.0%	19.5%	2.4%
Shoots barrage	1.28	4	0.32	6.4%	3.2%	0.4%
Beachley barrage	0.64	4	0.16	3.2%	1.6%	0.2%
Welsh Grounds lagoon	2.02	5	0.40	8.1%	4.0%	0.5%
Bridgwater Bay lagoon	6.06	5	1.21	24.3%	12.1%	1.5%

Impact of the demand for aggregates for concrete (structures, ballast and precast armouring) on the national and regional market

Source: Parsons Brinckerhoff & DECC

If aggregates for precast armour units are not taken into account (i.e. these precast armour units could be directly imported from overseas facilities), the impact becomes:

Demand for aggregates for concrete (structures & ballast)	Total demand for aggregates for concrete	Duration of civil engineering construction	Annual demand for aggregates for concrete	% of annual average production of concreting aggregates (forecast - 2020)		
				Wales Total average production	South West Total average production	GB Total average production
				5mt/y	10mt/y	80mt/y
Scheme	mt	Year	mt/year			
Cardiff-Weston barrage	11.37	6	1.90	37.9%	19.0%	2.4%
Shoots barrage	1.28	4	0.32	6.4%	3.2%	0.4%
Beachley barrage	0.64	4	0.16	3.2%	1.6%	0.2%
Welsh Grounds lagoon	2.02	5	0.40	8.1%	4.0%	0.5%
Bridgwater Bay lagoon	3.49	5	0.70	13.9%	7.0%	0.9%

Impact of the demand for aggregates for concrete (structures, ballast) on the national and regional market

Source: Parsons Brinckerhoff & DECC

In both cases, these tables show that the demand for concrete aggregates for Cardiff-Weston barrage (and to a lesser extent for Bridgwater Bay lagoon) has a significant impact on the Welsh and South West production. On the other hand, the demand on the Great Britain market is much less.

The demand for concreting aggregates for the other schemes can be easily sourced in Great Britain and to a certain extent in Wales and in the South West.

As the current production of aggregates for concrete represents around 30-35% of the overall production of primary aggregates in Great Britain (total 229.8mt in 2005 and 204.2mt in 2007), this percentage could be slightly increased by shifting the end-use of aggregates extracted so as to better adapt the production to the demand (in particular for Cardiff-Weston barrage).

At this stage of the study, the % of sand and gravel for concrete sourced from marine aggregates cannot be easily assessed; nevertheless, as the tonnage required remains within the current dredging capacity, it is unlikely that additional dredging licences would be needed for concrete aggregates (unless marine dredging close to caissons construction yards would be more cost effective than transporting aggregates from distant quarries).

Nevertheless, the choice of these sources (quarry or marine dredging) will depend heavily on the location of the caisson construction yards. At this stage of the study, it is difficult to identify the exact regional or even national sources.

Primary aggregates for embankment/breakwater fill and sand ballast (caisson)

For each STP scheme, the impact of the overall demand for primary aggregates for embankments and breakwaters fill (excluding armour stone), ballast and seabed sand to the forecast (2015-2020) regional and national annual output capacity of all construction and fill aggregates is set out in the following table:

Demand for primary aggregates for embankment & breakwater fill, sand ballast & seabed (sand, gravel & crushed rock)	Total demand for aggregates	Duration of civil engineering construction	Annual demand for aggregates	% of annual average production of aggregates for construction fill (forecast - 2020)		
				Wales Total average production	South West Total average production	GB Total average production
Scheme	mt	Year	mt/year	9mt/y	10mt/y	63mt/y
Cardiff-Weston barrage	33.33	6	5.56	61.7%	55.6%	8.8%
Shoots barrage	14.25	4	3.56	39.6%	35.6%	5.7%
Beachley barrage	2.20	4	0.55	6.1%	5.5%	0.9%
Welsh Grounds lagoon	60.36	5	12.07	134%	121%	19.2%
Bridgwater Bay lagoon	76.31	5	15.26	170%	153%	24.2%

Impact of the demand for primary aggregates for embankment & breakwater fill, sand ballast & seabed on the national and regional market

Source: Parsons Brinckerhoff & DECC

This table shows that only the Beachley barrage has a small impact on the regional production of aggregates for construction and fill. For the other schemes, aggregates for construction and fill cannot be sourced on the regional markets and for the lagoon schemes, the impact on the national market is also very high.

We should also bear in mind that the classification “aggregates for construction fill” in the current surveys and statistics does not only encompass materials for embankment fill or ballast; therefore this comparison is likely to be pessimistic because the breakdown of end-use of all the aggregates produced in the regional and national market could change by the time a STP scheme is scheduled. Nevertheless, this comparison provides a relevant approach to the problem of aggregates supply.

The impact of the overall demand for sand and gravel for construction fill (ballast, embankment and breakwater core, seabed) is as follows:

Demand for sand & gravel for ballast, embankment core and seabed	Total demand for sand & gravel for construction fill	Duration of civil engineering construction	Annual demand for sand & gravel for construction fill	% of annual average production of sand and gravel for construction fill (forecast - 2020)		
				Wales Total average production	South West Total average production	GB Total average production
Scheme	mt	Year	mt/year	0.3mt/y	2mt/y	13mt/y
Cardiff-Weston barrage	27.65	6	4.61	1536%	230%	35.4%
Shoots barrage	9.66	4	2.42	805%	121%	18.6%
Beachley barrage	1.72	4	0.43	143%	21.5%	3.3%
Welsh Grounds lagoon	39.71	5	7.94	2647%	397%	61.1%
Bridgwater Bay lagoon	55.31	5	11.06	3688%	553%	85.1%

Impact of the demand for sand & gravel for embankment & breakwater fill, sand ballast & seabed on the national and regional market

Source: Parsons Brinckerhoff & DECC

And the impact of the overall demand for crushed rock for construction fill (embankment and breakwater fill) is as follows:

Demand for crushed rock for embankment and breakwater fill	Total demand for crushed rock for construction fill	Duration of civil engineering construction	Annual demand for crushed rock for construction fill	% of annual average production of crushed rock for construction fill (forecast - 2020)		
				Wales Total average production	South West Total average production	GB Total average production
Scheme	mt	Year	mt/year	9mt/y	8mt/y	50mt/y
Cardiff-Weston barrage	5.69	6	0.95	10.5%	11.8%	1.9%
Shoots barrage	4.59	4	1.15	12.8%	14.3%	2.3%
Beachley barrage	0.48	4	0.12	1.3%	1.5%	0.2%
Welsh Grounds lagoon	20.65	5	4.13	45.9%	51.6%	8.3%
Bridgwater Bay lagoon	21.00	5	4.20	46.7%	52.5%	8.4%

Impact of the demand for crushed rock for embankment & breakwater fill on the national and regional market

Source: Parsons Brinckerhoff & DECC

These tables highlight the very high impact of the demand for sand and gravel not only on the regional markets but also on the national one. Only sand and gravel required for the Beachley barrage for construction and fill could be easily sourced on the national market (mainly from dredging).

As for crushed rock, the demand for the lagoon schemes has a significant impact on the regional markets and to a lesser extent on the national one. Beachley barrage has less impact on the regional and national markets; for the other barrages, the demand for crushed rock could be easily met on the national market. The demand for crushed rock for the lagoon schemes could also rely either on an increase in the output capacity of existing quarries (e.g. Glensanda) or on additional imports from European quarries (e.g. Norway).

The use of dredged materials for the foundation preparation works and the navigation channels could relieve this high demand. As already mentioned, mainly sand and gravel dredged are likely to be suitable for construction aggregates.

Assuming that 80% of sand and gravel dredged for the preparation works could be used for embankment fill and ballast or seabed, the net demand for sand and gravel for construction and fill is as follows:

Demand for sand & gravel for ballast, embankment core and foundation preparation	Total demand for sand & gravel for construction fill	Dredged materials for foundation preparation used (80% sand & gravel)	Net demand for sand & gravel for construction fill	Duration of civil engineering construction	Net annual demand for sand & gravel for construction fill	% of annual average production of sand & gravel for construction fill (forecast - 2020)		
						Wales Total average production	South West Total average production	GB Total average production
Scheme	mt	mt	mt	Year	mt/year	0.3mt/y	2mt/y	13mt/y
Cardiff-Weston barrage	27.65	33.25	0	6	0	0%	0%	0%
Shoots barrage	9.66	4.97	4.69	4	1.17	391%	58.6%	9.0%
Beachley barrage	1.72	1.54	0.18	4	0.045	15.1%	2.3%	0.3%
Welsh Grounds lagoon	39.71	3.99	35.72	5	7.14	2381%	357%	55.0%
Bridgwater Bay lagoon	55.31	0	55.31	5	11.06	3688%	553%	85.1%

Impact of the demand for sand & gravel for embankment & breakwater fill, sand ballast & seabed on the national and regional market after deducting 80% sand and gravel dredged

Source: Parsons Brinckerhoff & DECC

When 80% of sand and gravel dredged for preparation works are used as aggregates for construction and fill, this table indicates that these dredged materials can relieve significantly the demand for sand and gravel for the barrage schemes. For the Cardiff-Weston barrage they can substitute for 100% of them.

As for the lagoons, due to the lack of sand and gravel on the seabed (particularly for the Bridgwater lagoon), the use of dredged materials has little or even no impact on the demand. Therefore, in order to meet this high demand, the alternative solutions are as follows:

- increase in the output capacity of existing sources of sand and gravel including marine dredging (within the current licensing framework)
- intensive use of secondary and recycled aggregates, in particular for ballast and seabed (e.g; china clay waste or slate waste)
- more imports from overseas sources
- additional dredging licenses, in particular in the Bristol Channel, so as to avoid transportation costs

Armour stone for embankment and breakwater

The second main concern for embankments and breakwaters in terms of materials is the availability of armour stone: rip rap or rock armouring (Class A or B rock). The annual demand for the largest STP schemes is between 1.4 and 2.3mt whereas the average imports of armour stone in Great Britain is about 1.5mt/year.

If we assume that by the time a STP scheme would be built about 2mt of armour stone can be produced and imported per year in Great Britain, the impact of this demand on the national market is set out in the following table:

Demand for armour stone for embankment & breakwater	Total demand for armour stone	Duration of civil engineering construction	Annual demand for armour stone	% of annual average production & imports of armour stone in GB (forecast - 2020)
Scheme	mt	Year	mt/year	2mt/y
Cardiff-Weston barrage	9.76	6	1.63	81.3%
Shoots barrage	2.18	4	0.55	27.3%
Beachley barrage	0.24	4	0.06	3.1%
Welsh Grounds lagoon	11.29	5	2.26	113%
Bridgwater Bay lagoon	7.33	5	1.47	73.3%

Impact of the demand for armour stone on the national and regional market

Source: Parsons Brinckerhoff & DECC

This table shows that for the Cardiff-Weston barrage and the lagoon schemes, the demand for armour stone is very high and would require additional sources or significant increases in extraction capacity.

Most of the rock armouring materials would be sourced from Scotland (Glensanda), provided the current size of extracted rock would be increased, and also from overseas quarries already specialized in rock armouring supply (Norway...). The total amount required cannot be extracted from the existing specific quarries without significant increase in delivery rates; the current volume of imported armour stone (1.5mt/year) would also be increased by a maximum of 50% (based on 3-year consumption of armour stone).

In order to cope with the shortage of rock in Great Britain, it would be worth comparing the use of precast armour units (fabrication, transport and placing cost) to the extraction and transportation of rock armouring from overseas.

Conclusion – Aggregates & armour stone

In order to meet the demand for aggregates for concrete, embankment fill and sand fill (caisson ballast) the existing UK sources (marine dredging and quarries) would have to take part in the delivery chain, provided their location is compatible with the construction sites. A more detailed study needs to be undertaken so as to identify the various sources in Great Britain and even in Europe, taking into account transportation (sea and land), materials quality and technical characteristics, as well as availability of permitted resources – on land and offshore.

In Great Britain, these aggregates could be extracted from existing quarries in South Wales and the Mendip Hills or even from coastal quarries in Southern Ireland (Arklow) and West coast of Scotland (mainly from the Glensanda coastal quarry). The large volume of aggregates needed would require a significant increase in the current UK delivery rate which could be reached either by stepping up the extraction output or by importing more aggregates from European quarries.

The location of the caisson construction yards would also determine the most suitable sources for concreting aggregates so as to optimise transportation.

The proportion of dredged materials from preparation works which could be used for construction aggregates has to be confirmed in particular for the Cardiff-Weston barrage and the lagoons.

Nevertheless, these global results do not highlight in detail the disparities of the impact of each type of aggregates (sand, gravel or crushed rock) on the regional and national market according to the current end-use of these materials. At this stage of the study, the volume of concreting aggregates cannot be assessed for each component (sand, gravel or crushed rock) and the official records of production of aggregates for construction and fill do not distinguish sand from gravel.

If we assume that the breakdown of end-use of aggregates extracted in the regions and in Great Britain cannot be significantly modified therefore, the impact of the demand of each type of aggregates can be summarized as follows:

- Concreting aggregates: the Welsh and South West market could provide these materials for the smaller barrage schemes and to a certain extent for the Welsh Grounds lagoon. For Cardiff-Weston barrage and Bridgwater bay lagoon, these materials would be sourced from the Great Britain market (quarries and land-won or marine dredging).
- Crushed rock for embankment and breakwater fill: only the demand for the Beachley barrage could be met on the regional market; for the other schemes, the Great Britain market could provide enough materials and additional imports from overseas could be envisaged for the two lagoons (or an increase in the output capacity of existing UK quarries).
- Sand and gravel for embankment and breakwater fill and for ballast or seabed: dredged materials for preparation works would relieve significantly the demand for the barrages and the Great Britain market would provide enough materials. As for the lagoons, additional sources would be required, including overseas imports (provided sea transport remains cost effective) or new dredging licenses (provided this way of supply is easier to set up and cost effective). The use of significant volumes of secondary and recycled aggregates would also be part of the possible solutions, in particular for ballast (e.g. china clay or slate waste).
- Armour stone for embankment and breakwater: only the demand for Beachley barrage can be met on the Great Britain market; for the other schemes, an increase in the capacity and delivery rate of existing quarries (e.g. Glensanda) would not be sufficient and a significant rise in imports from European rock quarries is likely to be the only solution.

B – Caisson construction yards

Introduction

The number of caissons for each scheme is as follows (Phase 2 estimates):

Number of Caisson	Turbine, sluice and plain caisson	Navigation lock caisson	Breakwater caisson	Total caisson
Scheme				
Cardiff-Weston barrage	129 (54/46/29)	18	17	164
Shoots barrage	46 (15/25/6)	4	2	52
Beachley barrage	31 (13/9/9)	4	2	37
Welsh Grounds lagoon	32 (10/14/8)	4	2	38
Bridgwater Bay lagoon	42 (36/0/6)	4	2	48

Number of caisson
Source: Parsons Brinckerhoff

The caissons would be constructed in dry dock, towed and floated out to their location on the barrage, lowered onto the pre-prepared foundations and ballasted with sand and/or concrete for stability. It might also be necessary to make provision for bringing the caissons to the site by sea tows, or semi submersible barges. The caissons might then be sunk at a nearby location, for re-floating and rapid deployment to their final locations during suitable weather windows.

The caissons can be built year-round in the yards and their shipment and installation on the site would mainly depend on the tides. Installation methods would be designed to allow placement throughout the year when the tides are suitable, subject to favourable weather. The caissons would be suitable for open sea tow.

For the Cardiff-Weston scheme, caisson manufacture would require coastal sites close to deep water and if possible, with good road and rail links so as to ease material and equipment delivery (to a certain extent, improvement of transportation network could be envisaged). Caisson floating draughts (which would vary from 10m for the shallowest plain caissons to 21m for the turbine caissons) would limit the choice of sites.

A typical site would contain 3 basins each large enough to accommodate 4 caissons and would have a total area of 140 hectares (dry and wet docks). STPG report mentioned 4 sites in the vicinity of the barrage and others in Scotland or England (see map).

Such caisson yards should be located in areas where key components could be easily sourced so as to reduce transport costs (e.g. sources of construction aggregates).

For the Shoots barrage, due to the proximity of Second Severn Crossing, and in order to avoid any collision of towed caissons on the bridge piers, the caisson yard should be located downstream of this bridge. Part of the English Stones embankment could be used as one side of the dry dock for caisson construction.

As for the Beachley barrage, for the same reasons (M48 bridge located downstream), the caisson yard should be implemented upstream of the barrage.

It is interesting to note that the Belgium Marine Consultant DEME (Dredging, Environmental & Marine Engineering) mentioned in its response a solution for the caisson construction yard. The solution would consist of building a very large casting yard within a cofferdam (like the one used for the construction of the Cardiff Bay Barrage). This casting yard would be implemented within the footprint of the future locks, where deep dredging would be required. In a final stage, the locks could then be built in a dry enclosure. However, the impact of this solution on navigation routes during the construction would need to be considered.

Potential coastal sites in UK/Europe suitable for the construction of caisson yards facilities

The feasibility of the caisson design depends heavily on the possibility of construction yards along the UK coast or even in Western Europe. It is certainly one of the major constraints for each scheme.

According to the responses, a detailed assessment is required to consider available draught, land and equipment and the associated supporting infrastructure. There would be issues to be addressed in relation to the environment and the cost, carbon footprint... associated with moving the caissons from the production facility to the site. The consent and permit process might lead to delay in the construction programme and therefore, the choice of the most suitable caisson yards sites must be studied and confirmed well in advance.

The 1989 STPG study found 11 caisson yard sites available around the UK (able to accommodate 12 caissons per site), but only 4 sites are located within the South West and Wales. Some respondents estimate that only about 35-40% of the caisson construction works could be done within Wales and South West region in the case of Cardiff-Weston Barrage, and smaller barrages or lagoons would need up to 3 and 4 caisson yards which may potentially keep all caisson yards within the South West and Wales area. However, this will largely depend on the economic conditions impacting the availability of such sites and therefore there still can be a leakage to the rest of the UK.

Several of the coastal sites identified in the STPG report still exist (but some of them are located on the east coast):

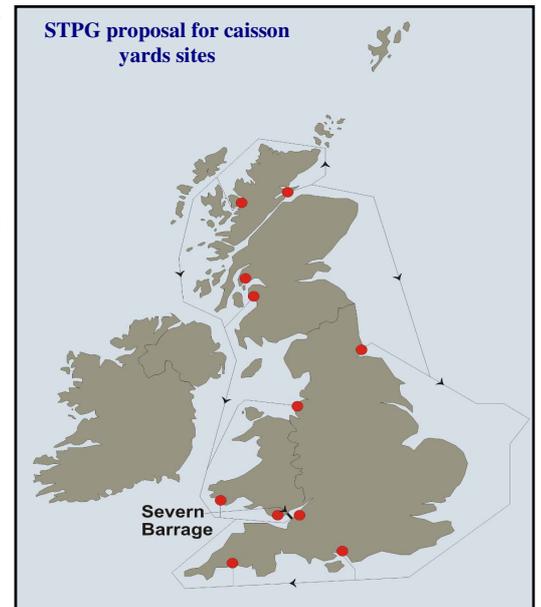

- Arnish, Isle of Raasay - Highland
- Campbeltown - Argyll
- Methil, Firth of Forth
- Nigg, Cromarty Firth
- Mostyn, Dee
- Swan Hunter - Middlesbrough

Suitability of existing port (in the UK or in Europe) for the implementation of a caisson yard facility

A further study would be required to consider the contemporary situation at candidate ports. Market demands at ports regularly change land-use patterns and it seems likely that once potential sites for a caisson yard facility (or facilities) have been identified it may be necessary to secure the site with a financial commitment. The availability of land and equipment to serve a caisson yard facility may exist at the time of a recession but would quickly disappear when trade increases and there is further demand for port facilities to move and store cargo. Access to Ports is restricted in relation to the draught, beam and length of the vessels that they can accommodate and these issues would limit the location of existing ports able to deal with the production and movement of caissons. The size of existing dry docks for caisson construction is also a constraint.

The DECC study on UK ports for the Offshore Wind Industry (2009) mentions some ports which might be suitable for the construction or the storage of caissons (further investigation is required so as to check water depth, locks, available space, sea conditions...):

- Hunterston Terminal (Firth of Clyde): former oil rig site, one of the deepest sea entrances in Northern Europe (water depth at LAT: 20m); available for redevelopment; maybe suitable for large caissons construction (operational dry dock)
- Swansea and Port Talbot: located in the vicinity of the project; as depth is limited, maybe suitable for smaller caissons construction
- Nigg Yard (Cromarty Firth): offshore platform yard, floating caisson opening; maybe suitable for large caissons construction (water depth at LAT: 9.14m)
- Harland & Wolff in Belfast: could be suitable for smaller caissons in the dry dock (water depth at LAT: 8.6m)
- Milford Haven (Wales); one of the deepest port.

Nevertheless, these ports would probably not have sufficiently large areas for the caissons to be mass produced in. The need for large working space, might mean that the only viable casting yards would be the sites of former oil field fabrication yards.

The suitability of European ports (e.g. Cherbourg, Le Havre, Rotterdam...) depends on transport conditions and possibilities of towing the caissons through the Channel. East European ports on the Baltic may not be suitable as water depths are very limited.

Former yards used for oil and gas platform construction are still existing and could be re-used:

- Ardyne Point at the mouth of the Clyde (owned by Sir Robert McAlpine): 3 docks used for constructing North Sea oil platform in the 1970s, each big enough for the largest caissons. Investments for upgrading and refurbishment should be required so as to re-use it (provision of docks gates...)
- Kishhorn Yard (West coast of Scotland): also developed for oil platform construction in the 1970s

Also, sites in Western Europe could be considered, in particular some which have been used for offshore structures in Norway, Holland, France and Spain.

Conclusion – Caisson construction yards

The possibility of implementing caisson construction yards (location, consent...) is considered as a major issue for each STP scheme and more particularly for the Cardiff-Weston one which would require several sites.

More detailed studies have to be undertaken later in order to confirm the availability of the potential sites, taking into account environmental impacts, consent process, caisson transport (tug) cost, sites characteristics (e.g. water depth, transport network for material and equipment delivery...) and carbon footprint.

Innovation in caisson construction and transport could also be envisaged so as to optimise the size and number of yards. More yards could reduce construction risk (by reducing the effect of a delay at one yard) and would also result in lower total yard costs, provided more existing yards could be used without much modification.

C – Concrete

Introduction

Concrete is also a major concern due to the large volume required and their impact on the UK market. Each component of the concrete must be taken into account so as to anticipate any bottleneck in the supply chain. For large projects, materials required for concrete fabrication and works (rebar, formwork, cement...) are procured through national and international markets (rather than regional markets). It is difficult to predict availability in 5 to 10 years time, however pre-ordering well in advance would be the key to availability.

Aggregates for concrete

See section A-5 “Aggregates & armour stone for a STP scheme”.

Cement

Finished cement production in Great Britain was 10mt in 2008 (11.9mt in 2007). This is a notable drop as cement production has remained above 11mt for the last 5 years. Increasing competition in overseas markets has led to a decline in cement exports in recent years, with UK exports of cement falling to 487,000t in 2007, compared with 613,000t in 2006 and 826,000t in 2000. The UK has become a net importer of cement due to insufficient domestic production capacity, importing more than 2,370,000t of cement in 2007.

Year	Cement clinker		Portland cement	
	Exports	Imports	Exports	Imports
2000	256	351	570	1,420
2001	169	387	327	1,182
2002	161	290	306	1,143
2003	61	506	216	1,715
2004	83	377	214	2,034
2005	135	406	321	1,645
2006	91	517	522	1,397
2007	28	836	459	1,534

UK imports and exports of cement clinker and Portland cement
Source: HR Revenue & Customs

The 5 largest cement manufacturers in the UK are Hanson (Heidelberg Cement Group; 3 plants), CEMEX UK Cement (3 plants), Lafarge Cement UK (7 plants), Tarmac Buxton Lime and Cement (1 plant) and Quinn Group (1 plant) operating 15 cement plants. Due to high energy prices and deteriorating market conditions, Lafarge has suspended operations at its Westbury cement production facility (Wiltshire) and CEMEX has closed Barrington plant (Cambridgeshire).

Cement plants have cement capacity of between 0.3mt/year to 1.4mt/year. Cement is transported mainly by road and sometimes by rail.

Company	Cement Plant	Cement capacity (thousand tonnes/year)	Transport
Lafarge Cement UK	1. Dunbar	1000	Road/Rail
	2. Hope	1300	Road/Rail
	3. Cauldon	1000	Road
	4. Aberthaw	500	Road
	5. Westbury	700	Road/Rail
	6. Northfleet	1000	Road
	7. Cookstown	500	Road
CEMEX UK	8. South Ferriby	800	Road
	9. Rugby	1250	Road
	10. Barrington	300	Road
Hanson Cement	11. Ketton	1400	Road/Rail
	12. Padeswood	800	Road
	13. Ribblesdale	1400	Road
Tarmac Buxton Lime & Cement	14. Tunstead	800	Road/Rail

Assuming that 13mt/year of cement could be produced in the UK by the time a STP scheme is likely to be constructed, the impact of the total demand for cement (civil structures, concrete ballast and precast armouring) on the national market is as follows:

Demand for cement (structures, ballast & precast armour units)	Total demand for cement	Duration of civil engineering construction	Annual demand for cement	% of annual average production & imports of cement in the UK (forecast - 2020)
Scheme	mt	Year	mt/year	13mt/y
Cardiff-Weston barrage	2.98	6	0.50	3.8%
Shoots barrage	0.33	4	0.08	0.6%
Beachley barrage	0.16	4	0.04	0.3%
Welsh Grounds lagoon	0.51	5	0.10	0.8%
Bridgwater Bay lagoon	1.49	5	0.30	2.3%

Impact of the total demand for cement on the national market

Source: Parsons Brinckerhoff & DECC

If only civil structures (caissons, crest walls...) and concrete ballast are taken into account, the impact becomes:

Demand for cement (structures & ballast)	Total demand for cement	Duration of civil engineering construction	Annual demand for cement	% of annual average production & imports of cement in the UK (forecast - 2020)
Scheme	mt	Year	mt/year	13mt/y
Cardiff-Weston barrage	2.90	6	0.48	3.7%
Shoots barrage	0.33	4	0.08	0.6%
Beachley barrage	0.16	4	0.04	0.3%
Welsh Grounds lagoon	0.51	5	0.10	0.8%
Bridgwater Bay lagoon	0.89	5	0.18	1.4%

Impact of the demand for cement (structures & ballast) on the national market

Source: Parsons Brinckerhoff & DECC

Only the Cardiff-Weston barrage would have a relative impact on the UK demand for cement production. There are two Lafarge cement plants in the vicinity of the Severn Estuary: Aberthaw (0.5mt/year) and Westbury (0.7mt/year; provided this facility would be re-opened after the economic recession), and the other plants located in the UK are likely to be able to meet this demand.

In case of shortage of cement supply in the UK, cement importation from overseas plants (Europe) might be envisaged from cement plants located close to European ports so as to optimize transportation. Pre-ordering well in advance would be the key to availability.

Concrete production

The average UK production of ready-mixed concrete is about 11mt per year. The location and limited capacity of existing concrete plants is unsuitable for the largest STP schemes (from 3mt/year to 2.2mt/year). The existing UK cement plants typically supply less than 300m³ each per day; there are about 1,300 ready-mixed concrete plants in the UK (a number of concrete production plants closed during 2008).

Moreover, there will be insufficient plants within range of the construction yards to be able to supply these sites. The quantities of concrete required will justify the setting up of concrete batching plants at most of the caisson construction sites. This is a normal practice for projects requiring large quantities of concrete. These will probably have a quay besides the plant to accept cement, sand and aggregates brought in by sea directly to the site. This would greatly cut the burden on the local transport infrastructure, and would enable bulk deliveries by water which would be cheaper than by rail or road.

The overall impact of concrete demand for civil structures, ballast and precast armouring on the UK market is as follows (assuming that in the future, 12mt/year of concrete could be produced):

Total demand for concrete (structures, ballast & precast armour units)	Demand for concrete			Total demand for concrete	Duration of civil engineering construction	Annual demand for concrete	% of annual average production of concrete in the UK (forecast - 2020)
	Structures	Ballast	Precast armour units				
Scheme	mt	mt	mt	mt	Year	mt/year	12mt/y
Cardiff-Weston barrage	18.32	2.36	0.61	21.29	6	3.55	29.6%
Shoots barrage	2.09	0.24	0	2.33	4	0.58	4.9%
Beachley barrage	1.05	0.11	0	1.16	4	0.29	2.4%
Welsh Grounds lagoon	3.57	0.11	0	3.68	5	0.74	6.1%
Bridgwater Bay lagoon	5.79	0.54	4.69	11.03	5	2.21	18.4%

Impact of the demand for concrete (structure, ballast & precast armouring) on the national market

Source: Parsons Brinckerhoff & DECC

Without taking into account the concrete for precast armour units, the result is as follows:

Demand for concrete (structures & ballast)	Total demand for concrete	Duration of civil engineering construction	Annual demand for concrete	% of annual average production of concrete in the UK (forecast - 2020)
Scheme	mt	Year	mt/year	12mt/y
Cardiff-Weston barrage	20.68	6	3.45	28.7%
Shoots barrage	2.33	4	0.58	4.9%
Beachley barrage	1.16	4	0.29	2.4%
Welsh Grounds lagoon	3.68	5	0.74	6.1%
Bridgwater Bay lagoon	6.34	5	1.27	10.6%

Impact of the demand for concrete (structures & ballast) on the national market

Source: Parsons Brinckerhoff & DECC

Mainly the largest schemes (Cardiff-Weston barrage and Bridgwater Bay lagoon) would have a significant impact on the national concrete production.

Steel reinforcing bars

Most of the manufactured steel reinforcing bars are currently made from recycled scrap metal. In 2007, the production of rods and bars for reinforcement in the UK was 0.785mt for home delivery + 0.327mt for exports (total output capacity: 1.112mt); 0.575mt were imported.

The overall impact of rebar demand for civil structures and precast armouring on the UK market is as follows (assuming that in the future, 1.5mt/year of rebar could be manufactured):

Demand for rebar (structures & precast armour units)	Total demand for rebar	Duration of civil engineering construction	Annual demand for rebar	% of annual average production & imports of rebar in the UK (forecast - 2020)
Scheme	mt	Year	mt/year	1.5mt/y
Cardiff-Weston barrage	1.55	6	0.26	17.3%
Shoots barrage	0.17	4	0.04	2.8%
Beachley barrage	0.08	4	0.02	1.4%
Welsh Grounds lagoon	0.29	5	0.06	3.9%
Bridgwater Bay lagoon	0.87	5	0.17	11.5%

Impact of the demand for rebar (structures & precast armouring) on the national market

Source: Parsons Brinckerhoff & DECC

The UK steel making facilities (in particular Celsa Steel Ltd in Cardiff which produces about 0.89mt/year of reinforcing and wire rod products and recycles 1.3mt of the 3.3mt of steel scrap used by UK steelworks) are likely to be able to meet all the demand for rebar for the smaller schemes (annual demand: 0.02 to 0.06mt).

As for the Cardiff-Weston barrage (total demand: 1.55mt) and the Bridgwater Bay lagoon (total demand: 0.87mt), overseas importations could be required; this is a classical practice for large construction projects.

Precast concrete units manufacturing

The main demand of precast concrete (PC) units includes PC protection armour units for embankment or breakwater (Dolosse for the base case). The UK precast concrete industry has a capacity of around 40mt/year.

The organisations that hold the patents for precast armour units such as Accropodes or Dolosse fulfil a design function but do not manufacture the units. They allow the units to be produced under license for given projects. The fabrication of moulds and the production of the units are the responsibility of the project.

Existing precast concrete facilities are generally capable of satisfying usual demand and have the capacity to deal with small fluctuations but they are almost all located inland. The need for a substantial increase in production can be addressed in a number of ways and these can be managed with sufficient time and resource. Production alternatives might include: the use of various existing plants in Europe (or further afield) and transport by sea to the site; expansion of existing plants (and associated transport links); or the provision of a new dedicated but temporary facility to produce the units specifically for the STP scheme.

It is likely that the preferred solution would be the construction of purpose built casting yards set up at a coastal location in the Severn Estuary for manufacture of precast concrete armour units or wall, both because of the quantities required and for ease of transport to the embankment. The construction of these precast armouring units could also be envisaged within existing port facilities (e.g. Port Talbot or Avonmouth), using sea or rail transportation.

Precast concrete armour units are only proposed for the Cardiff-Weston and Bridgwater bay schemes, based on 5t Dolosse units. The impact on the UK precast units manufacturing market is rather low.

Demand for precast armour units (Dolosse – 5t/unit)	Total number of units (Dolosse)	Total weight	Duration of civil engineering construction	Annual demand for Precast armour units	% of annual average production of precast units in the UK (forecast - 2020)
Scheme		mt	year	mt/year	40mt/y
Cardiff-Weston barrage	60,501	0.303	6	0.040	0.13%
Bridgwater Bay lagoon	468,667	2.343	5	0.468	1.17%

Impact of the demand for precast armouring on the national market

Source: Parsons Brinckerhoff & DECC

There is limited equipment to handle precast units but the construction industry should respond to new demands and thus adequate fore-warning of the needs for plant would enable new requirements to be addressed. Trucks and cranes to move and handle such units are widely used in the construction industry and would not be a problem.

Conclusion - Concrete

The main constraint for concrete supply is the availability of aggregates already mentioned in chapter A. The other concrete components (cement, steel...) can be sourced from the national market or even from overseas and the key to success is anticipation.

Like other large projects, on-site concrete batching plants have to be installed.

D – General points

Competition from other concurrent large construction projects in the UK or in Europe

Competition from concurrent large construction projects would increase costs as demand for the resources of plant, labour and materials surpasses supply. Nevertheless the global resources required to meet the project objectives do exist. Major civil engineering projects comparable with a STP scheme (e.g. Channel Tunnel) have been successfully constructed despite other opportunities being available for the labour plant and materials required. Early involvement of the contractors and suppliers would contribute to the project's success by engaging those parties in the development process and providing, at the relevant stage, certainty.

In terms of aggregates and concrete supply, the possibility of other major projects is not a significant constraint on supply to Severn Tidal Power schemes. The UK markets would take a number of years (from 5 to 10 according to the MPA) to recover from the current recession and individual projects such as Crossrail and Nuclear power stations account for only small proportions of total demand (for example the Olympics project is accounting for no more than 1% per year of national aggregates and concrete demand).

Nevertheless, aggregates, cement, and ready-mixed concrete volumes fell sharply during the second quarter of 2009 as the construction recession intensified, according to the latest quarterly survey of construction material trends by the Mineral Products Association (MPA). Compared with the same period of 2008, sales volume of crushed rock and sand and gravel aggregates fell by 29% and 27% respectively, cement and ready-mixed concrete by 32% and 37% respectively, and asphalt by 24%. The MPA says these rates of decline are broadly similar to the first quarter, and are likely to moderate slightly in the second half of the year, as industry demand dropped dramatically in the third and fourth quarter of 2008, so the comparative base is reduced. By the time a STP is scheduled to be constructed, the economic situation is likely to be more favourable for construction projects.

Impact on existing transport infrastructure

The location of all the five STP proposals that are currently under consideration would require improvements to the local transport infrastructure to link the proposed works with the existing network. The demands on the road network could be reduced by maximising the potential use of rail and sea delivery of materials. For the larger schemes the improvements would be more substantial and extensive and have a significant, albeit possibly temporary, impact upon the environment. Given the limitations on the existing road network it is inevitable that some upgrading and strengthening work would be required. The location of the sites for preparatory works would be a key issue and the opportunity to use seaborne transport would have a significant impact upon the extent of landside infrastructure that needs to be provided and improved. The location of the quarries for aggregates supply, far from the construction sites, could lead to transport constraints as well as the location of precast facilities or other materials suppliers.

In any case, the closeness to the sea offers a far better solution to moving most materials than would be possible by land; it makes more sense to install temporary quays, and jetties and to take the transport burden off the existing infrastructure. Within the responses, it is also mentioned that the creation of a new or the enhancement of an existing port in the Severn estuary that would be used as a base for sea-borne transport, would be a suitable solution to minimize long-haul road transport.

Moreover, rail transportation would be prioritized when possible. For example, when the second Severn crossing was built most of the aggregates and fill material requirements for the embankments and approach roads were sourced from large quarries in Somerset and delivered by rail to the project.

E - Conclusion

The proposed civil engineering works for all the selected STP projects are not particularly innovative and would generally involve proven techniques (e.g. port and marina construction or extension, storm surge barrier construction...). Only the scale of the largest schemes is considered a technical challenge. The civil engineering issues that might delay completion are all predictable and, subject to appropriate management and assessment, can be accommodated.

The main issues would be the location of caissons construction yards, the supply chain for sand and gravel and armour stone and... the weather. Innovative design and construction process could be one of the keys to success.

IV - MAIN MECHANICAL AND ELECTRICAL EQUIPMENTS

A – Turbines and Generators

Introduction - Background

Turbine units are the main mechanical concern; only two existing horizontal axis turbine designs are suitable for a tidal power plant: bulb turbine (the name "bulb" comes from the shape of the upstream casing which contains a generator located on a horizontal axis) and Straflo turbine ("Straight Flow"; the concept is based upon a rim driven generator of the former Escher Wyss company – now Andritz Hydro; the patent has already expired). The turbines envisaged for each shortlisted STP scheme are set out as follows (base case from Phase 2 Optimisation study):

Barrage: Turbines + Generators	Units	Cardiff-Weston	Shoots	Beachley
Bulb-Turbines rated 40MW (base case)	No	216		
Straflo-Turbines rated 35MW (base case) <i>or variant Bulb-Turbines</i>	No		30	
Straflo-Turbines rated 12.5MW (base case)	No			50

Lagoon: Turbines + Generators	Units	Welsh Grounds	Bridgwater Bay
Bulb-Turbines rated 25MW (new base case)	No	40	144
<i>Bulb-Turbines rated 12.5MW (previous base case)</i>	No	108	108

Bulb turbines for tidal barrages were developed specifically in the 1960s for the La Rance barrage built and operated by EDF (24 units rated 10MW; 5.3m diameter; 93 rpm). Bulb turbines are able to generate electricity in two directions of flow and can also be used as pumps. Bulb turbines have been installed in many low head hydro power plants worldwide but after La Rance, only in smaller tidal power plants: Jiangxia (China - 5 bulb units rated 0.5, 0.6 and 0.7MW - total 3.2MW - 1980) and Kislaya Guba (Russia - 1 bulb unit rated 0.4MW - 1968). The Sihwa barrage in South Korea is the latest large tidal barrage project in the world and the 10 bulb turbines rated 25.6MW are scheduled to be commissioned in mid-2010.

Bulb units are manufactured by the following main turbine manufacturers:

- Alstom Hydro (France)
- Voith Hydro (Germany)
- Andritz Hydro (Austria/Germany)
- Hitachi (Japan)
- Dongfang Electrical Machinery Company Ltd (Dongfang Electric Corporation - DEC - China)
- Harbin Electric Machinery Company Ltd (Harbin Electric Inc. - HEC - China)
- Bharat Heavy Electrical Ltd (India)

Only Alstom, Andritz and Voith have the expertise and know-how to handle large projects, are able to meet the technical requirements for a STP scheme (size, output capacity...) and can deliver large numbers of units. For the other turbine manufacturers, bulb units are not considered as their core activity.

The main bulb and Straflo turbines manufactured by the 3 major turbine suppliers are set out in the following tables:

Country	Scheme	Power (MW)	Head (m)	Runner Diameter (m)	Number of Units	Year of completion	Manufacturer

Main large bulb-turbines (diameter > 6m) installed in the world

*Karkamis: consortium led by Andritz hydro with Voith Hydro

Straflo turbines were designed mainly for low head run of river hydro plant and around 100 units have been installed in the world. Only one Straflo turbine (Rated 20MW – 7.6m diameter – 50 rpm) was installed in 1984 for the Annapolis demonstration tidal power plant (Nova Scotia – Canada). To date, due to the previous patent, the Straflo turbines were only manufactured by Andritz Hydro. As the patent has expired, other turbine manufacturers can now use this technology but they are likely to be reluctant to manufacture Straflo turbines for fear of encountering higher costs and technical shortcomings.

Country	Scheme	Power (MW)	Head (m)	Runner Diameter (m)	Number of Units	Year of completion	Manufacturer

Examples of Straflo turbines installed in the world

It is important to bear in mind that Alstom, Andritz and Voith are also able to design and manufacture generators, governors, protection system, excitation, control and monitoring system as well as gates, stoplogs and valves (Alstom and Andritz).

In the following presentations of the 3 major turbine manufacturers, a summary of the technical discussions on the Severn project and recommendations are also set out (meetings held in DECC office and also in their headquarters offices).

Alstom Hydro

Alstom Hydro (5500 staff in 19 countries) is a 50/50 joint venture (set up in 2006) between Alstom (Alstom Power and Alstom Transport) and the Bouygues Group (2 main sectors: construction and media/telecoms). Alstom Hydro is now one of the major suppliers of hydroelectric equipments and services, having installed turbines and generators capable of providing more than 400GW of electricity (25% of global hydroelectric generating capacity; 310 GVA generators and 155GW turbines). Alstom Hydro operates in more than 70 countries worldwide.

With more than 250 bulb turbines (runner diameter varies from 3m to 7.5m) installed worldwide (total output: 5,000MW; including more than 35 large units commissioned in China alone during the last ten years), Alstom Hydro has gained wide knowledge and experience in design, manufacturing, installation, commissioning and management of complex bulb projects, whatever the environmental conditions. The former Neyrpic and Alsthom companies (now Alstom Hydro) were involved in the design of La Rance bulb turbines and they supplied 12 units (the other units were manufactured by Jeumont-Schneider and the Société des Forges et Ateliers du Creusot). Alstom Hydro (former GEC Alsthom Turbine Generators Ltd), as a member of the STPG consortium, was also involved in the Severn studies carried out in the 1980s. Therefore, Alstom Hydro has perhaps the best expertise in bulb turbine design for tidal barrages.

Alstom Hydro is committed to developing a more “fish-friendly” turbine (fewer but longer blades for Kaplan and Bulb turbines so as to reduce fish mortality + spherical design of the hub) and to mitigate environmental impacts (e.g. oil-free operation thanks to runner bearings lubricated by water for Kaplan turbine).

Alstom Hydro has 2 development and test facilities:

- Turbine Technology Centre in Grenoble (France – 140 staff) including 7 test rigs for all type of turbines (Francis, Kaplan, Bulb...). Modelling (Computational Flow Dynamics - CFD) is used to improve turbine efficiency and performance as well as model tests. Two recent test rigs, one of which has been in operation since 2003, are used for bulb turbines.
- Generator technology Centre in Birr (Switzerland)

Alstom Hydro has several turbine/generator manufacturing facilities in the world: Taubaté (Brazil), Tracy (Canada), Tianjin (China), Baroda (India) and Grenoble (France). Large turbines are mainly manufactured in China, India and Brazil; bulb turbines and Kaplan are currently built in the Taubaté, Tianjin and Tracy facilities. Other generator manufacturing facilities are: Bilbao (Spain), Birr (Switzerland).

Alstom Hydro estimates that 65,000 hours are reported to be needed to produce a large bulb turbine (>50MW) and around 35,000 hours for smaller units. For instance, in the Taubaté facility where bulb turbines are manufactured for the San Antonio and Jirau hydro power plant in Brazil (see below), the annual working hour capacity is 1.25 million (780 staff); currently 2 bulb turbines per month are delivered in this facility. It would be possible to increase the bulb turbine delivery rate by a further 2 units per month provided there is no higher demand in Brazil and South America for other types of turbine. Nevertheless, there are point constraints in the manufacturing cycles, particularly the use of limited boring machines, blade sourcing and manufacturing. A delivery rate of 44 turbines per year, as proposed in the original STPG studies, could not be achieved without an improvement in the existing international facilities (expansion of existing facilities or even a possible construction of a dedicated facility in the UK so as to meet not only the Severn demand but also the other future tidal schemes in the North West Region). For example, for the Three Gorges scheme, runners were constructed at site due to their large size and transport issues.

According to Alstom, the main constraints from the turbine supplier point of view is the pace of civil work and the final client processes on design/drawings approval, that have to be in line with what will be requested as the pace for manufacturing and engineering. As a precondition, Alstom Hydro recommends a very early kick-off meeting clearly defining interfaces and critical path of components with payment events and deliverables in a logical sequence to avoid non added value work being done in different phases of the project. In its experience, issues on time schedules are mostly due to interfaces and decision-making processes.

Alstom Hydro has developed a Plant Integrator™ concept so as to provide complete and optimised power solutions to customers. Improvements in manufacturing process have been achieved and up to 25% lead time savings are possible.

All the key components of a turbine unit are designed and manufactured by Alstom itself so as to control the quality and manufacturing process. Alstom uses a Primavera planning tool which can take into account existing orders plus 3-year workload and 5-year marketing forecast.

In terms of size of the bulb turbines, nowadays an 8m runner diameter is considered as the upper limit due to existing machine size (in particular boring machine). A 9m diameter bulb turbine could be envisaged but it would be a technical challenge and it would require further investments for the machine tools. Alstom Hydro is also constrained by lack of large boring machines and machining centres where turbines are made.

Alstom Hydro also points out possible constraints in terms of steel and nickel supply. Steel availability depends on the world-wide steel consumption, among other things, in competing projects. The situation in a few years depends on the economic situation, local and global policies, and can vary considerably in terms of costs and delay for material procurement.

Alstom Hydro optimizes the material procurement process depending on the market situation, taking into account all suitable materials for turbine construction. The Alstom global supplier panel, based on framework agreements for key commodities such as carbon and stainless steel plates, castings, forgings, copper and silicon steel plates among others, forecast through a very strong load analysis process, makes it possible to anticipate its load and also the load of its suppliers through a very close scanning process undertaken by its Key Commodity Managers for each strategic commodity.

In Alstom's experience of working on projects such as Rio Madeira and large Chinese projects, they have never been in a situation of material shortage. This is largely due to having in place a strong material procurement process and ensuring that material specifications are in line with supplier capacities and technology needs.

Andritz Hydro

Andritz Hydro (formerly VA Tech Hydro) has been part of the Andritz Group (Pulp & Paper, Hydro, Metals, Environment & Process and Feed and Biofuel) since 2006.

Andritz Hydro is a leading global supplier of turnkey electromechanical systems and services to hydropower plants and offers new hydroelectric power stations as well as services, rehabilitation and upgrading of existing plants.

Thanks to several acquisitions of European turbine manufacturers (Escher Wyss, ELIN, Vevey, Bouvier, Charmilles...) and recently General Electric Hydro (2008), Andritz Hydro has more than 160 years of expertise in hydropower.

Before the acquisition of GE Hydro, VA Tech (4,500 staff) had large turbine manufacturing workshops in Ravensburg (Germany), Linz (Austria), Kriens (Switzerland), Schio (Italy), Madrid (Spain), Morelia (Mexico) and Faridabad (India). Three large generator and electrical manufacturing workshops are located in Weiz and Vienna (Austria) and in Bhopal (India). Three R&D laboratories are located in Linz (Austria) and Vevey and Zurich (Switzerland). There are several sales and services offices in the world (25 countries).

The acquisition of GE Hydro (400 staff, 9 very large facilities in Canada, China, Brazil, Sweden, three Hydraulic laboratories in Brazil, Canada and Finland) is a key milestone in Andritz Hydro development and this company is becoming one of the key global hydro turbine manufacturers. There are now several Andritz hydro facilities all around the world and in particular in countries where the hydro demand is high (China, South America, India...).

VA Tech Hydro has installed around 26,000 turbines (245GW) and 51GVA generators; GE Hydro has installed a total of 152GW turbines and 107GVA generators.

More than 300 bulb units have been supplied by Andritz Hydro for heads up to 27m, a maximum runner diameter of 8.2m and outputs up to 55 MW (77MW for the current Rio Madeira project). The total installed capacity amounts to 4,500 MW approximately. Andritz Hydro is one of the leaders in Bulb turbine/Generator units with more than 50% market share in the last decade.

Andritz Hydro has been involved in 2 tidal schemes:

- Annapolis (Nova Scotia-Canada): 1 Straflo turbine (Sulzer Escher-Wyss; 7.6m runner diameter) rated 20MW (1984)

- Sihwa (South Korea): 10 Bulb turbines (7.5 runner diameter) rated 25.4MW (order in 2005 – completion originally due by the end of 2009 but power plant commissioning delayed to mid-2010)

Andritz Hydro has no specific experience of reversible bulb turbines as proposed as a variant for Cardiff-Weston barrage or the lagoon schemes which may require some development work.

For the Sihwa project, the owner Korean Water Resource Corporation (K-Water) selected Daewoo Engineering and Construction Co. as a prime contractor. Andritz Hydro was a Daewoo subcontractor and the scope of work comprised: detailed design of the bulb turbines/generators and their ancillaries, supply of all major electromechanical equipments (turbine runners, turbine shaft seals and bearings, oil heads, guide vanes, governors, stator cores and windings, rotor poles and combined bearings). Key components (e.g. turbine runners, bearings, generators) were manufactured mainly in Germany and Austria at Andritz workshops and shipped to site, while the bulk of steelwork and Balance of Plant were made in Korea. Due to the scheme configuration, the turbines operate only on flood generation mode, and during ebb they operate on sluicing mode. Andritz Hydro carried out many hydraulic studies so as to optimise the efficiency of these bulb turbines and to adapt them to the unusual context for a tidal scheme (flood generation). As a matter of fact the available basin volume has to be filled within a given time so as to assure maximal energy production and therefore the start of the turbines has to be well estimated for each cycle. Thanks to this project, Andritz Hydro has acquired updated expertise in tidal generation and bulb turbine design.

Andritz Hydro can manufacture bulb turbines of around 7.5 to 8m diameter, but above that size, they say they are not economic to produce nor very stable in operation. As for Straflo turbines, they can also manufacture large fixed blades machines; despite this they do not have many orders. For large hydro projects it can take 12 months to do the design and model testing of a single turbine, a further 22 months to manufacture and then 10 months to ship, install and commission, i.e. a total of 40 months. However, it is possible to shorten this time with a large order, and of course a number of turbines can be processed in parallel.

Shipping and transporting the turbines to the construction sites is also considered as a challenge. For example, from the Ravensburg manufacturing facility, Andritz Hydro transports the turbines on specified heavy load/width roads to the Neckar river, where they are transported by barge to the coastal ports on the Baltic.

Andritz Hydro offers a warranty of 2 years with their hydro turbines, and they have a design lifetime of 40 years with a recommended major overhaul after 20 years. For tidal turbines they thought these periods would be considerably longer as they are not in such continuous use. They do not offer any ongoing maintenance contract but offer to train the engineers of the operating company to handle any normal faults. If anything more serious goes wrong they would agree a separate contract for that.

In conclusion, Andritz Hydro thought they would be able to supply turbines for the lagoon and smaller barrage options, provided they were given an order a couple of years ahead, and they would probably do it as part of a European consortium in order to spread the risk and make the delivery time more acceptable. They did not think the turbines for a Cardiff –Weston barrage could be delivered on the expected timetable without a major expansion in manufacturing capacity, and they would need some confidence that the project would go ahead before taking this investment risk.

Voith Hydro

Voith Hydro (formerly Voith Siemens Hydro Power Generation – joint venture with Siemens in 2000) is a division of the Voith Group (Voith Paper, Voith Hydro, Voith Turbo and Voith Industrial Services). Voith Hydro core activity is turbine and generator manufacturing; they have design capabilities but are less involved in the manufacturing of other mechanical equipment (e.g. gates...) but they work closely with other mechanical manufacturers in hydro mechanical equipment.

Voith Hydro has installed about 40,000 turbines and generators in the world (total capacity around 300GW) and has more than 135 years of hydro expertise.

Voith Hydro (4000 staff) has 5 main facilities (there are also worldwide service and sales offices):

- Heidenheim (Germany): headquarters, R&D laboratory and facility mainly devoted to turbines rehabilitation
- York (USA): North America headquarters and large engineering, manufacturing and servicing facility and also R&D laboratory for mechanical equipment

- Sao Paulo (Brazil): manufacturing facility, capable of handling the largest turbine runners in the world (crane capacity of up to 300t); R&D laboratory for generators and electrical equipments
- Shanghai (China): manufacturing facility focusing on high-performance turbines and generators (China and East Asia market)
- Kawasaki (Japan): facility dedicated for new and modernization projects (turbines, generators, auxiliaries, control & automation equipment, transformers and high-voltage switchgear)

Since 1955, Voith Hydro has installed over 180 bulb turbines in the world with outputs to nearly 50MW and diameters up to 8m.

Voith Hydro has no experience in tidal turbines but its know-how in bulb design would allow the company to undertake design studies and to manufacture such turbines. Voith Hydro is also used to working closely with Andritz Hydro (they share a facility in Ravensburg) and Alstom.

Voith Hydro can currently deliver 6-15 bulb turbines per year with a maximum delivery rate of 1 unit/month. The average manufacturing lead time for one large bulb unit (from manufacturing to site delivery) would be 19 – 20 months (without preliminary design study and modelling test); it would be 15-16 months for smaller bulb units.

Voith Hydro have a long experience of handling supply chain constraints; they are used to manufacturing the bulb components in various places in the world (China, Brazil...) with the right manufacturers and then they assemble them in one place, sometimes in a new purpose-built facility close to the construction site. For instance, a new assembly facility has been built in China (Shanghai) for a large hydro scheme (Francis turbines) where welding, heat treatment and final assembly are undertaken by local workforce. The facility and equipment cost €10m. Voith Hydro suggests that for the Severn, a new specific assembly facility could be built (instead of a full manufacturing facility)

A 9m bulb diameter is not considered as a technical challenge; Voith has already manufactured 8.5m bulb for the USA.

Voith Hydro also confirms that delivering between 100 and 220 turbines is a challenge which can be overcome thanks to a consortium set up between the 3 major European suppliers; the Madeira experience shows that such cooperation works well. A delivery rate of up to 3-4 bulb/month could be achievable for the larger Severn schemes.

Voith Hydro seems to be reluctant to work with Chinese turbine manufacturers (subcontractors) for bulb turbines because of the lack of Chinese experience in bulb and also due to problems of quality.

Voith Hydro suggests that as soon as the decision of the Severn scheme is taken, a pre-design contract would be set up between the 3 turbine leaders so as to start the design study of the turbines (3-6 month preliminary studies); an independent hydro consultancy could be asked to supervise the design study, particularly for the interface with civil-works (e.g. Coyne & Bellier, Lahmeyer International, Stucky...)

Case study: the Brazilian Madeira Hydro project. Example of a turbine manufacturers consortium

In Brazil, 2 large run of river hydro dam projects on the Madeira river were launched in 2008. In order to meet the demand for the numerous bulb turbines & manufacture), a consortium between Alstom Hydro (leader), Andritz Hydro and Voith Hydro was set up.

- San Antonio (3,200MW): 20 bulb-units rated 71MW and 24 bulb-units rated 75.5MW - 7.5 runner diameter (to be commissioned in 2012)
 - Alstom will provide 19 bulb turbines + 22 generators + 50% of the project's hydro-mechanical and lifting equipments
 - Andritz will provide 12 bulb turbines + 12 generators + 24 voltage regulating systems
 - Voith will provide 13 bulb turbines + 10 generators
- Jirau (3,300MW): 28 bulb-units rated 75MW - 7.5 runner diameter (to be commissioned in 2015)
 - Alstom will provide 10 bulb turbines + 17 generators + 28 speed governors, monitoring systems, bus bars and surge/neutral devices
 - Andritz will provide 8 bulb turbines + 8 generators + 28 voltage regulating systems
 - Voith will provide 10 bulb turbines + 3 generators
 - The remaining 16 bulb turbines are not included in this contract and they will be manufactured by DEC (China)

The magnitude of these projects and the turbine manufacturer consortium will provide an interesting example for the STP schemes.

The Alstom-led consortium has set up a manufacturing process as follows:

- Study, design and delivering of the first bulb unit: around 32 months
- Total timescale for the supply of the turbines for each scheme: 88 months after main order to proceed
- San Antonio will be the first scheme to be constructed; construction of the Jirau scheme will be launched 36 months later (52 months of common works on both schemes)
- Average delivery rate: Alstom 1.5 turbine/month; Andritz and Voith: 1 turbine/month

The design of the bulb units is based on shared design, in particular combined hydraulics and mechanical design for the turbine and shared generator design. San Antonio is to use 4 to 5 bladed turbines and Jirau will use 4 bladed turbines.

Chinese turbine manufacturers

Harbin Electric Machinery Company Ltd - HEC, established in 1951, manufactures generating equipment for hydro and thermal power plants. HEC has manufactured more than 500 turbines units for about 200 hydropower plants in China (40% of large hydropower units in China have been supplied by HEC), in particular 700MW turbines for the Three-Gorges scheme. To date, HEC has already exported 138 turbines (total capacity: 12GW; 138 units) to 24 foreign countries (USA, Canada, Pakistan, India, Brazil, Iran...).

Dongfang Electrical Machinery Company Ltd - DEC, established in 1984, is involved in nuclear, thermal and hydropower. DEC is the 2nd hydro turbines supplier in China (40% of the national market, including also 14 x 700MW turbines for the Three-Gorges left bank power plant) and the company has already manufactured 60 large and medium generating units in China and abroad (USA, Peru, Philippines, Turkey, Indonesia, Canada, Pakistan, Iran...). DEC will also deliver the remaining 16 bulb turbines (75MW) for the Jirau hydropower scheme.

These two Chinese turbine suppliers only manufacture Francis and Kaplan turbines but they are already involved in large bulb units projects (7.5m diameter) in China. They are likely to have the necessary manufacturing capacity to deliver large bulb turbines for tidal schemes. Under the supervision of one of the 3 major European turbine manufacturers (consortium or subcontractor), in particular to improve the quality of their products which remains an issue, they could offer additional manufacturing capacity for bulb turbines (mainly non reversible units). HEC have far larger machining centres available in China (up to 16m diameter boring machines, compares to 8m limit at Alstom for example). HEC has also 2 coastal manufacturing bases for large size manufacturing and assembling.

Main issues

Due to the high and steady worldwide demand for hydro turbines (average 50GW/year), most of the turbine manufacturers have a reasonably full order book with around two years of firm production and are running at near capacity. Moreover, the size of the turbines is growing (>700MW; 1000MW turbine projects in China) and requires further investment, in particular for machine tools. The bulb-turbine market is also soaring because run of river schemes seem to be easier to build.

Tidal turbines for barrages are still considered as a niche market and turbine manufacturers are waiting for further projects before modifying their organisation. Due to the economic recession, even the large tidal projects in South Korea were delayed in 2009 by the owners and investors (Garolim...). But the situation has already evolved due to the country's commitments to developing renewable energy and South Korea has just confirmed the launching of the 1.32GW Incheon tidal barrage which is scheduled to be completed in June 2017. In the UK, the development of tidal projects like the Mersey or the Solway, scheduled to be commissioned by 2020, would also change the turbine manufacturers' strategy.

It is difficult for the three main turbine manufacturers to provide relevant information on their ability to meet the demand for hundreds of bulb turbines... It is likely that a consortium would need to be set up in order to share the financial and technical risks and to be able to deliver in time the high number of units for a Cardiff-Weston scheme, and even for the smaller schemes.

The overall turbine unit delivery rate for these three turbine manufacturers could reach between 3 and 6 units/month but this increase in capacity would also depend on the short and long term demand for conventional hydro turbines. If

China (and also another country like India or Brazil) confirms its commitment to building more very large hydro schemes, the market will be very strained and all the turbine manufacturers will have to make strategic choices.

It is too early at this stage to compare the two following manufacturing strategies:

- Using existing worldwide facilities and transporting the bulb units by sea to the construction site
- Developing a new facility (or more) in the vicinity of the construction site so as to mitigate cost of transportation and to meet the delivery rate

Shipping the turbines from the facilities to the construction site is also challenging due to the size and weight (a 7.5m turbine weighs around 200t) and requires vessels or barges, and perhaps heavy load/width roads. A specific study could be undertaken so as to compare the transportation solutions.

The decision to invest in one or maybe two new manufacturing facilities in the Severn area would require a high degree of certainty for the turbine manufacturers (probably signed contract for the number of turbines required). Some possible locations would be possible either close to the future caisson construction yards or within existing ports facilities (e.g. Port Talbot or Avonmouth).

The Madeira Hydro project highlights the fact that the STPG assessment for the Cardiff-Weston turbines delivery rate (44 turbines/year – 5 years) is very challenging; the current situation among the 3 major turbine manufacturers (delivery rate: 2-3 turbines/month) means that it would take between 6 and 9 years to supply the 216 Cardiff-Weston turbines. Therefore, additional facilities for manufacturing or assembling are essential for the improvement of the delivery rate.

Turbines and caissons

The use of caissons for river and sea civil works construction is now a standard practice (barrier, embankment, bridge, marina, port, lock...). During the Delta Plan projects in the Netherlands, many embankments and dams were built with caissons (e.g. Volkerak dam, Veerse Gat dam, Zandkreek dam...) and construction and installation processes were improved. The replacement of the Braddock Dam (Pennsylvania – USA) in 2002 by a new gated dam (4 radial gates) was a technical breakthrough (largest float-in navigation structure built in the USA): the 190m long dam was divided into 2 caissons built in a construction yard (27 miles downstream from the dam site) and towed to the site after foundation preparation.

There are very few examples of caissons used for hydro power plant housing turbines. Generally turbines and generators are assembled when the caissons are on site and perfectly positioned. The first example of turbines and generators assembled in the construction yard and floated into position was the 400kW experimental Kislaya Guba tidal power plant in the early 1960s. Later, Alsthom Atlantique and Neyrpic built three 25MW bulb turbines and installed them in two steel caissons which were transported across the Atlantic in a submersible load-carrying ship, off-loaded and towed up to the Mississippi and Ohio rivers into an existing dam (Greenup project). Then the caissons were sunk in their final position within a temporary cofferdam which was dewatered and the caissons were concreted in. In 1980, Boving & Co. were awarded a contract for a single steel caisson housing height 8.2m diameter bulb turbines (Vidalia scheme – USA).

The STPG report mentioned that the turbines should not be installed in their caisson in the construction yard so as not to delay the installation rate of caissons on the site. During the discussion with the turbine manufacturers, the suppliers did not make many suggestions on the turbine installation process, and conventional methods on the final site had been assumed.

The installation of the turbines inside the turbine-caissons is also considered to be a very delicate task using heavy-lift crane barges and previous experiences (in particular installation of large sluice-gates for storm surge barriers) has shown that a good installation and management process is the key to success.

Conclusion - Turbines

The turbine delivery for the smaller schemes can be achieved by the three leading turbine manufacturers using a consortium so as to mitigate risk and to tackle manufacturing issues. Lessons learnt from the Madeira project should provide interesting feedback. Only the 30 turbines for the Shoots barrage scheme and to a certain extent the 40 bulb turbines for the Welsh Grounds lagoon could be sourced from only one turbine manufacturer in the timescale envisaged.

As for the Cardiff-Weston barrage (and to a certain extent for the Bridgwater Bay lagoon), delivering such a large number of turbines is considered as very challenging by the manufacturers, if they were to use only the existing manufacturing facilities. A consortium between them is not the only key to success. In order to increase the delivery rate and the manufacturing capacity, a development and procurement strategy is likely to be set up by these manufacturers and investment in a new plant could be envisaged, provided contracts can be signed in advance.

B – Gates-Cranes-Bascule bridge

The overall demand (in thousand tonnes of steel) for steelwork for sluice gates, lock gates, stoplogs, gantry cranes, stoplog handling cranes and temporary bulkheads is as follows:

Scheme	Total demand for fabricated steelwork
	Thousand tonnes
Cardiff-Weston barrage	200
Shoots barrage	65
Beachley barrage	47
Welsh Grounds lagoon	45
Bridgwater Bay lagoon	50

Demand for fabricated steelwork

Source: Parsons Brinckerhoff

It is very unlikely that these items of mechanical equipment will be supplied from the UK, but the UK could provide a significant amount of steel components manufactured in its facilities (e.g. Corus). The specialist nature of the design, manufacture and installation of gates, bascule bridges and similar equipment limits the number of providers. Such equipment is often sourced from suppliers based in the Netherlands who have the experience and capacity to produce and install these facilities.

Regarding the gates, they could be provided either by turbine manufacturers or by international suppliers (in particular from the Far East). Cranes can be sourced from worldwide manufacturers, in particular in Asia. Bascule bridges are more specific equipment and the demand is low.

Sufficient time should exist to identify suppliers, procure the materials and design, manufacture and install all the equipment. These should not be critical path items.

Transportation of these pieces of equipment would be the main issue due to their size. The installation process would have to be optimised so as to avoid too large land area for stockpiling these equipments (which means ports infrastructure availability) and to install them directly on the construction site.

In terms of raw material, as all this equipment is made of steel, variation in prices on the market is likely to be one of the major issues.

C – Other technical equipment

With the possible exception of the large transformers and switch gear equipments (and cables to a certain extent), there are few other electrical items that would cause undue concern. With a project of this nature with long lead-in times, securing the necessary equipment should not be a particular problem, provided the process is adequately managed.

Some electrical components can also be provided by turbine manufacturers (e.g. control systems...).

Given the current and ongoing need to overhaul the UK's electricity grid network, and parts of the associated infrastructure, to meet increased demand and changes in connection requirements (wind energy, biofuel power stations, etc) there are many competing schemes for suppliers and contractors. There is a similar requirement in parts of Europe. These demands are likely to increase costs.

Aside from the competing schemes, other concerns are the availability of sufficient suppliers to provide the electrical equipment, a sufficient work force of skilled designers and contractors and the dependency upon the supply chain from the designers to the provision of base materials to the installation. Given the extent of the demand for electrical equipment, international resources would be required to address the supply requirement. Appropriate management of the supply chain would be necessary to ensure sufficient time for design, manufacture and installation of the equipment.

D – General points

Competition from other concurrent large construction projects in the UK or in Europe

Competition from concurrent large construction projects may increase costs as demand for the resources of plant, labour and materials surpasses supply. Nevertheless the global resources required to meet the project objectives do exist. Major engineering projects comparable with the STP have been successfully constructed despite other opportunities being available for the labour plant and materials required. Early involvement of the contractor(s) and suppliers would contribute to the project's success by engaging those parties in the development process and providing certainty at the relevant stage.

For the mechanical equipment, the main competition is the demand for large hydro schemes (mainly turbines + generators, gates...) and for the electrical components, the ambitious European target on renewables could result in possible bottlenecks in the delivery rate of suppliers.

Impact on existing transport infrastructure

The abnormal load routes on the national and local road network are of limited extent and it is likely that each of the five STP options under consideration would require some upgrading and/or strengthening to accommodate heavy loads and dense road traffic.

The opportunity to transport equipment by sea directly to the point of installation would reduce the need for road improvements and as most of the heavy equipments (transformer, bulb-unit...) are likely to be sourced outside the UK, sea transportation is likely to be the preferred solution. For example, for the future Hinkley Point nuclear station, EDF Energy favours sea transportation so as to mitigate the impact on the road and bridge network.

The need to deal with maintenance and replacement of heavy and large components (e.g. generator or transformer) needs to be considered in overall project/life costs.

E – Conclusion

The magnitude of a STP Scheme would pose constraints in terms of the supply chain for mechanical and electrical equipment, especially a Cardiff-Weston barrage and to a lesser extent Bridgwater Bay lagoon due to the number of turbines and electromechanical equipment associated.

There are a number of concerns that could delay the completion of a scheme. These are the availability of sufficient suppliers to provide all the mechanical and electrical equipments required and the dependency upon the supply chain from the designers, to the suppliers of base materials to the final installation.

Therefore early involvement of potential suppliers is essential to determine a feasible construction programme for these pieces of equipment.

Most of the supply chain issues could be addressed via a procurement strategy and firm orders.

V – LABOUR AND SKILLS

A Severn Tidal Scheme will support temporary employment in the industry during the development and construction period. The core phases of development for each scheme require a range of skill sets and construction tasks, in particular for the following areas:

- site investigation, design, supervision and site overheads...
- marine engineering: dredging, marine heavy lifting operation...
- civil engineering and construction: caissons, embankments, navigation lock, surface building...
- mechanical engineering and manufacturing: turbines, gates, cranes...
- electrical engineering and manufacturing: generators, transformer, control system...

During the operational phase, various skills will be required, in particular for the maintenance.

Previous estimates have been made of employment creation and skills required to construct a Severn scheme (STPG 1989 report). The DTZ Regional Economic Impact Study also provides some estimates based on engineering data generated during the first phase of the STP feasibility study and was used as the basis for the questionnaire (http://severntidalpowerconsultation.decc.gov.uk/supporting_documents). However, it should be noted that updated data on construction cost and labour requirements have been provided by Parsons Brinckerhoff during Phase 2. These are provided below.

Many respondents found questions posed relating to labour and skills difficult to answer given the strategic nature of the study. However some respondents usefully provided additional information from existing surveys from various Sector Skills Councils (e.g. Sector Skills Council for Science, Engineering and Manufacturing Technologies and the Engineering Construction Industry Training Board).

The following information is a summary of responses received and data from existing reports and surveys (see Appendix 3 – Sources of Information).

Parsons Brinckerhoff updated data on construction employment estimate (Phase 2)

During its optimisation study (Phase 2), Parsons Brinckerhoff (PB) has updated the construction cost of each scheme (results provided after the questionnaire responses). DTZ estimated that the value earned per employee ranged between £139,000 and £144,000. Using this as a basis, the overall construction employment estimates are given in the table below. It should be noted that these figures may change as scheme costs are further refined and methodologies are reviewed.

As operating and maintaining a Severn Tidal Scheme will require various specific skills, a first assessment of local labour share and capacity to deliver these future jobs has also been made.. The composition of operating employees by discipline is as follows (Parsons Brinckerhoff assessment):

- 10% manager
- 35%-45% skilled technicians
- the remainder would consist variably of unskilled workers, trainees and administrators.

Schemes	Total Cost (incl. Contingency excl. compensatory habitat) £bn	Overall no FTE jobs
Cardiff-Weston Barrage	20.832	140,000 to 150,000
Shoots Barrage	3.931	25,000 to 30,000
Beachley Barrage	2.659	Around 20,000
Welsh Grounds Lagoon	5.501	35,000 to 40,000
Bridgwater Bay Lagoon	10.643	70,000 to 80,000

STP schemes – Total cost and overall number of FTE jobs

Source: Parsons Brinckerhoff (phase 2)

How many of the above jobs would be realised in South West England and Wales, or even the UK, will be dependent on a number of factors previously discussed by DTZ. The full range of assumptions underpinning regional

employment estimates are under review at the time of writing but phase 2 studies by PB suggest that the following should be considered:

Assumptions:

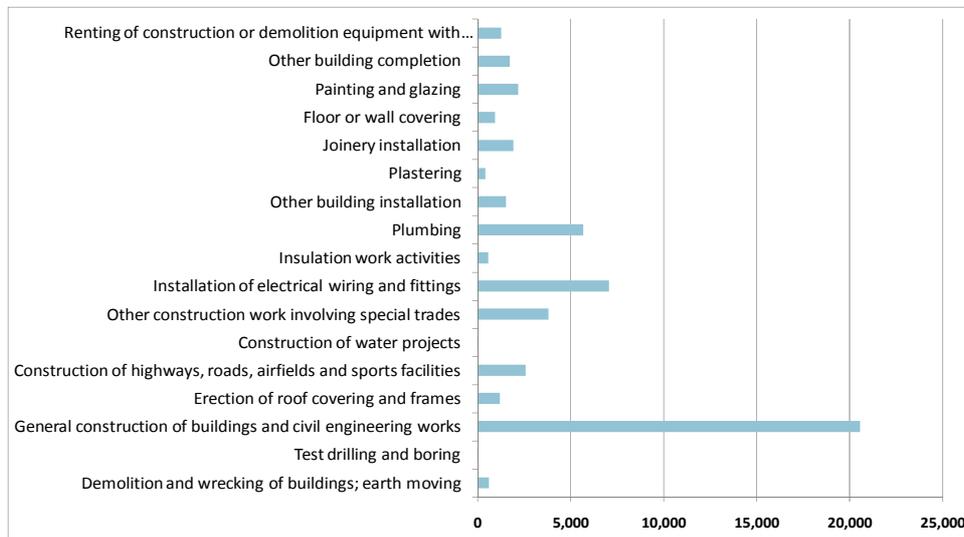

- Cardiff-Weston barrage caisson yard employment in the region would represent one third of total UK caisson yard employment.
- For Shoots and Beachley barrage and for the lagoons, all caissons could be built in the region, with concrete aggregates sourced within the region.
- For Shoots and Beachley barrage and for the lagoons, labour employment in material manufacture is assumed to be related only to transmission equipment and cranes, not turbines equipment and gates
- For Shoots barrage, civils employment should be split 50:50 between shores; 90% of M&E employment assumed on English shore.
- For Shoots and Beachley barrage and for the lagoons, the regional employment required for material supply is assumed to be the same as Cardiff-Weston barrage. There is considerable uncertainty over this estimate due to uncertainty in material sources.

These assumptions in addition to the points raised below and those made in the peer review of the DTZ study will be fed in to work to revise the regional employment estimates.

Local Area and Regional construction labour capacity

The NOMIS employment data for 2006 suggests that Construction Broad Sector (SIC F) employed 51,300 people in the Local Area as defined by DTZ in 2006, and 52,200 in 2007. However 2008 and 2009 data are expected to show decreases in new entrants to the Construction industry due to the economic recession.

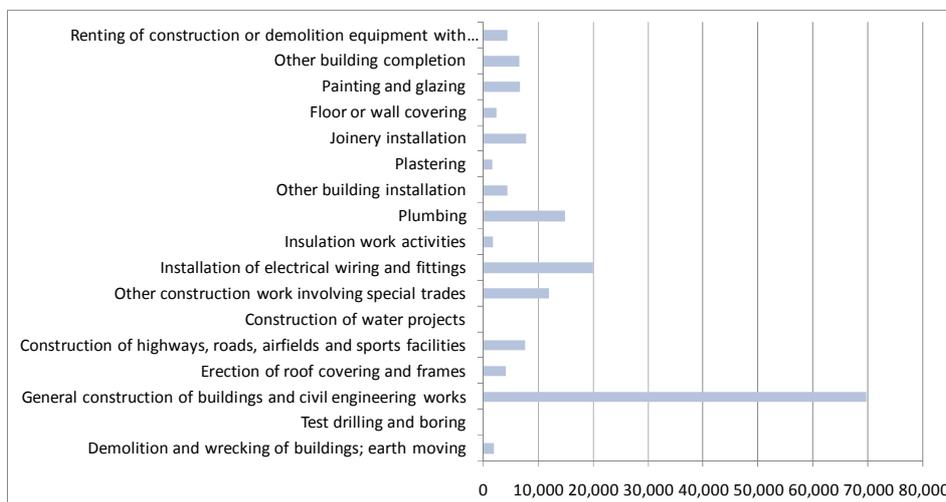

The profile of construction workforce in the Local Area is shown below in the following Figure. As shown in this Figure, not all of the 52,200 employees in Construction in the Local Area will be available or will have skills to work at both Hinkley Point Nuclear Plant and Severn Tidal Project sites.

Total employment in Construction (SIC 45) and Architectural and Engineering and Related Activities (SIC 74.2) by Occupation type in the Local Area in 2007

In fact, between 25,000 and 36,000 employees will have relevant sector skills for the majority of works excluding those in occupations related to residential construction and repair works.

Within the South West and Wales there have been 167,113 employees in the construction industry in 2007. The breakdown by occupation types is shown in the Figure below.

Total employment in Construction (SIC 45) and Architectural and Engineering and Related Activities (SIC 74.2) by Occupation type in the South West and Wales in 2007

In a similar way as analysed for the Local Area, we can assume that the number of employees with relevant sector skills in the South West and Wales was between 118,000 and 134,000. This is a large pool of construction workforce; however it reflects the current level of demand from construction projects and doesn't take into account future requirements. Obviously lesser number of employees will be available from outside the Local Area the longer it takes to travel to the construction site.

The current recession has seen major redundancies in many sectors of the economy including the Construction sector. The South West has the second lowest unemployment rate among all UK territories at 5.7% in 2009, whereas unemployment has reached 7.7% in Wales – higher than England, GB, and UK averages. The number of jobs in the construction industry in the South West has decreased by 1.4%, and in Wales by 0.8% by December 2008 compared to 2007. These figures will increase as the situation has worsened in 2009. Whilst the pool of unemployed may be good news for current construction projects as this drives the cost of labour down and means that skills are easier to find, the situation will be changing in the medium to long-term as these unemployed workers will be absorbed into other industries and their skills will not be up-to-date anymore.

The Construction Skills Network (CSN) reports acknowledge that Major Infrastructure Projects (MIP) led and financed/part-financed by the government will serve as a cushion in the difficult times for the industry.

The CSN outlook (2009-2013) for construction in Wales and in the South West Region is summarized as follows:

Wales Total employment and annual recruitment requirement (ARR) by occupation: 2009-2013				South West Total employment and annual recruitment requirement (ARR) by occupation: 2009-2013			
	Employment		ARR		Employment		ARR

Source: Construction Skills Network (CSN) outlook (2009-2013)

* nec - not elsewhere classified

In Wales, during the period 2009-2013, total new infrastructure construction output is forecast to grow at an annual average rate of 5.2%, driven in particular by transport and energy projects (£84m Port Talbot Peripheral Distributor Road, £320m Private Finance Initiative scheme to expand the M4 and a new bridge across the Menai Strait, £400m wood-chip fuelled electricity station at Port Talbot...). Total construction employment of 113,510 in 2007 is forecast to fall to 107,920 by 2009, and then rise by 4.6% to 112,860 in 2013. In order to meet this demand, and after taking into account those entering the construction industry other than from training and those leaving, 2,330 new workers will be required to join the construction field each year.

In the South West, during the period 2009-2013, the prospects for growth in new infrastructure construction are poor. Total construction employment is projected to remain static between 2009 (221,830), and 2013 (221,810), after falls between 2007 and 2009. After taking into account those entering the construction industry other than from training and those leaving, 1,450 new workers will be required to join the construction field each year.

It is interesting to note that the Severn tidal scheme is only mentioned in the CSN Wales report. The possible Hinkley Point Nuclear Plant is not mentioned in the South West report.

If approved, construction of a new nuclear power plant at Hinkley Point will start, according to the current plans sometime in 2013-2014. nPower has been acquiring rights for sites, which are suitable for nuclear power stations in Wales, and plans to build at around the same time as planned by EDF Energy for Hinkley Point. The new Oldbury nuclear plant could also be launched by E.ON later.

The 2005 Wales and South West Workforce Mobility reports by IFF Research (*Workforce Mobility and Skills in the UK Construction Sector prepared for Construction Skills, DTI and ECITB*) found that only 41% of Construction industry workers in Wales worked on projects in more than two types of Construction sub-sectors (out of five total). In the South West 65% of workers worked on projects in more than two types of sub-sectors. However this does not represent great changes in skills or qualifications. The report further shows that 65% of workers in the Construction sector in the South West had always worked in the same occupational area as their current job. Overall, just over a third (35%) had ever switched roles – this would amount to 48,000 workers in the South West region in 2007 across all occupations. In Wales only 25% of workers in the Construction sector had ever switched roles, which would represent 18,000 of workers across all occupations in the country in 2007. Propensity to gain new skills and qualifications required to switch roles is therefore quite low in Wales.

Construction workers mobility (IFF Research)

The above table shows that 67% of construction workers in the South West are originally from that region whereas the ratio is 81% in Wales. A relatively high proportion of the South West construction workforce comes from other region.

The South West and Wales are likely to be unprepared to supply labour for a nuclear power station and a Severn Tidal scheme (especially the largest barrage option) together because the industry will be adjusting after the economic recession in the years leading to the start of the construction work of the new nuclear plant (Hinkley Point?) and the Severn Estuary.

Labour supply in the UK

Since July 2008, 128,000 people were made redundant in the Construction sector across the UK according to ONS. The number of redundancies in the 1st quarter of 2009 increased by 195% compared to the 1st quarter in 2007 and even in 2008. At the same time the number of vacancies nationally has been steadily decreasing since March-May 2008.

The Construction Skills Network (CSN) report predicts that the workforce expansion in construction industry in the UK will re-start in 2011 (in 2.5-3 years from now), and that the employment will increase by about 74,000 starting from 2010, which will see 18,500 employees a year on average. The annual recruitment requirement for this level of growth is about 37,000 excluding new entrant trainees in the UK. Overall 37,000 people have entered into construction employment in 2007. A slowdown was felt in Wales and Scotland and the total expansion of the workforce in Great Britain stood at 32,800 employees. CSN and other Sector Skills Councils recognise the difficulty of training and delivering new recruits and upgrading the skills of the current workforce.

The economic recession will have a profound impact on the availability of labour for projects starting after 2011. In the short-term, i.e. for any projects starting in 2009-2010, the construction workforce will be available and cheaper due to redundancies. In the long-term this outflow of workers will mean losses of skills and experience and the actual losses of labour, which will transfer into other industries. At present skills shortages are some of the highest in the Construction Industry according to the Learning and Skills Council (LSC). The workforce made redundant from the industry will be harder to reach for any training programmes run by LSC and Skills Councils, which will exacerbate the problem.

The Severn Tidal Project is one of the many new plants required to both replace the ageing energy infrastructure in the UK and meet the renewable energy targets. Some 30-40GW of generating capacity in the UK has to be replaced by 2030, of which around 15GW is needed by 2016 and much of the transmission and distribution network will need to be renewed or upgraded.

The UK has committed to sourcing 15% of its energy from renewable sources by 2020 which means delivering around 30% renewable electricity (5.5% today) so as to reach a total output of 38.5GW.

The Government's ambition is to deploy 25GW of offshore wind on top of the already planned 8GW. However a BERR paper on supply chain constraints (*BERR Supply Chain Constraints on the Deployment of Renewable Electricity Technology – Douglas Westwood 2008*) analyses only 18GW planned capacity as, given the timescales, it is a more realistic target. Offshore wind farms are considered as the most viable option due to several factors including planning constraints. However, they are facing some of the supply chain obstacles: for example, increasing skills shortages due to “experience and desire to work offshore becoming increasingly scarce”.

The BERR report also found that if the 2020 target of 35.8GW for all types of renewable energy projects is met, this is expected to require 122-133,000 jobs from current levels of 16-26,000 to manufacture, construct, and operate. The report further indicates that construction of biomass power stations is experiencing “growing lead-times due to levels of power plant construction both inside and outside the UK”.

Other infrastructure projects include Crossrail, which requires 8,700 FTE jobs during construction phase. Crossrail services will start in 2017 as currently planned, and therefore this project will also compete for resources with other construction projects nationally during the next decade.

Across the UK there are 11 sites (3 of them in the South West and Wales), which have been proposed for possible nuclear power station development. It is anticipated that only one nuclear station will be built before 2020. Even if a nuclear power station is built outside the South West and Wales it will still have an impact on the availability of construction and civil engineering workforce for the Severn Tidal Power Project.

United Kingdom Total employment and annual recruitment requirement (ARR) by occupation: 2009-2013

Source: Construction Skills Network (CSN) outlook (2009-2013)

Among competing barrage schemes equivalent to a small STP scheme, two tidal barrages over the Solway Firth and the Mersey are currently being studied, and are initially planned to be completed within similar time scales (The Mersey Tidal Power scheme is scheduled to be commissioned in 2020 and construction should start in 2014). If these projects are confirmed and launched, they could add supply chain constraints, in particular for the turbines delivery (unless, turbine manufacturers take the opportunity to invest in a shared facility for all these schemes).

The BPC therefore concludes that the UK capacity for MIP construction will be under high pressure from 2013 and onwards, which will definitely have major implications for labour availability and cost. This may cause delays, and not only for Severn Tidal Project but for other MIPs.

International labour capacity

Internationally, many countries are facing similar problems in terms of depleting energy production facilities, and many have significant plans to build more power stations and renewable energy generating projects.

Nuclear power plants require a lengthy construction process due to complexities of technology and safety requirements that need to be met. The latest average construction time for nuclear plants is 6-7 years according to International Atomic Energy Agency (IAEA) statistics for projects initiated between 2001 and 2007 (based on 25 reactors). During 1996-2000 the average construction time was 12 years (based on 23 reactors).

Therefore, if construction of the first new nuclear power plant will start in 2-3 years, it will run through 2011/2012 to 2017/2018. However many commentators consider the start of a project/s in 2-3 years as being overly optimistic and many others point to new case studies of nuclear power plant construction available from France and Finland where Areva supplied plants are currently being built (EPR). Both construction projects have suffered delays: Finnish power plant in Olkiluoto is three years behind the schedule to be completed in 2012; and EDF French plant in Flamanville in Normandy has been reported to be nine months behind schedule.

The main competition for international skills is coming from neighbouring EU countries where more than 29 nuclear projects are planned to be completed before 2020. Not only does this put high pressure on the availability of engineering, mechanical, and electrical components of nuclear projects but also on the availability of experienced international experts in nuclear engineering, as well as in construction of major projects.

Internationally there are skills to build large scale projects but the world has embarked upon a simultaneous nuclear power build programme, which will put the strain on both supply chain and human resources available and thus will put even more strain on availability of project management and skilled construction labour for the UK MIPs. Tidal engineering skills are also in a nascent stage in terms of availability as they are being built up by a handful of companies across the world through the ongoing research and demonstration projects.

Possibility of transferable skills from other industries

Project management skills are available outside the construction and engineering industry and potentially many consulting companies have people with project/programme management skills, who could be re-trained for construction and engineering projects to be able to deal with technical issues. They would however, lack relevant experience and will need specific support. Re-training may potentially be less than one year. Very often consulting firms suffer skills shortages themselves, and therefore availability of the workforce willing to transfer to another industry may be limited.

Manufacturing is experiencing overall decline in the UK and is likely to continue to do so in the future. This may provide a good source of labour especially for lower and medium skilled jobs. Retraining may take up to 1-2 years depending on qualifications.

In particular, it is likely that industries such as mining and shipbuilding could provide a labour force with both transferable skills and the potential to be re-trained. The main areas for re-training are: caisson construction, marine heavy lift operation and turbine manufacture. The re-training periods could range from 3-18 months, depending upon the level of skill in the initial workforce and the required level of competence (i.e. a training in a skill combined with experience of applying that skill).

Assessment of the % of works which could be directly done within Wales and South West region (% of construction cost)

The questionnaire asked respondents to fill in a table setting out the main construction cost for each scheme (based on Phase 1 construction cost data) and to estimate the % of works directly done in the two Regions, in the UK and abroad. The Bristol Port Company (BPC) and the Severn Tidal Power Group (STPG) both carried out this assessment (see the tables below). As the construction cost data have been revised in Phase 2 study, these tables only give a first assessment of possible workforce breakdown. They should be interpreted and applied to the updated scheme cost and employment estimates.

Construction stage	Cardiff-Weston Barrage	% of work done in the Regions or in UK or Abroad				Shoots Barrage	% of work done in the Regions or in UK or Abroad				Beachley Barrage	% of work done in the Regions or in UK or Abroad				Welsh Grounds Lagoon	% of work done in the Regions or in UK or Abroad				Bridgwater Bay Lagoon	% of work done in the Regions or in UK or Abroad

% of work done in the Regions or in the UK or abroad for each scheme – The STPG assessment (Phase 1 data)

Possible skills shortages

STPG has identified three primary areas of skills shortage for the construction stage activities. They do not believe that there will be a significant shortage of skills in the design/development stage activities, principally due to the globalisation of the design supply chain. The three construction stage activities with skills shortages are:

- Caisson construction, whether this is undertaken in a dry dock or in-situ, slip-formed or otherwise, there is very little local capacity. Probably the nearest and most recent slip-forming works were at the LNG storage facility, constructed by Taylor Woodrow, for CB & I, at Milford Haven., these were on-shore, fixed facilities.
- Marine heavy lifting operations – most marine heavy lifting operations in the UK are undertaken using suppliers from mainland Europe. Developments in off-shore wind farms could result in an increase in the capacity of this market within Europe.
- Turbine manufacture due to the reduced number of companies able to supply these specific turbines

The consequences of other concurrent works will largely be determined by their location. STPG does not believe that projects such as Crossrail will have an adverse impact on any of the schemes in this study, as it is too far away geographically, and the skill sets are somewhat different (Crossrail is almost all below ground construction and tunnelling).

However, if the proposed new nuclear power stations at Hinkley Point and Oldbury run concurrently with any of these schemes they could generate significant risks to:

- Locally available labour
- Accommodation for the migrant workforce
- Availability of high quality concrete
- Availability of raw materials

The scale of the risk will vary, depending on the scheme, but even the smallest scheme, Beachley Barrage, if under construction at the same time as a nuclear power station at Oldbury, could effectively double the demand for local labour and accommodation.

Off-shore wind projects may limit the availability of marine heavy lifting resources (people and plant).

Skilled labour for operation and maintenance

During the operational phase, according to respondents, the key skills required in a tidal power plant are as follows:

- Management skills:
 - HR and people management
 - Leadership, team management, coaching and mentoring
 - Project and Contract management (e.g. maintenance works)
 - Quality management
 - Risk management
 - Collaboration and operating across businesses
- Engineering skills: a wide range of technical skills at varying levels from semi-skilled, through craft and technician, to skilled engineer
 - Electrical and electronic engineering
 - Mechanical engineering
 - Control and instrumentation engineering
 - Telecommunications engineering
 - Civil engineering
 - Software/Systems engineering
- Commercial skills:
 - Budgeting
 - Customer care and service

- Trading awareness

These skills are applied across key engineering activities such as:

- Plant operation
- Plant maintenance
- Specialist areas such as power system protection

However, the Electricity Industry is experiencing significant recruitment difficulties and skills gaps in the workforce (in particular in technical and craft jobs). The main reasons of recruitment difficulties identified as being the most important by Electricity Industry employers are:

- Shortage of appropriately skilled/qualified people in the marketplace
- Competition for skills from other employers
- The poor image of engineering industries
- Low number of applicants

Conclusion

Based on the analysis of research published by different Sector Skills Councils (Construction Skills, ECITB, SEMTA) and the BPC and STPG responses, some skills shortages are likely to occur in engineering (design, construction and supervision), in particularly in civil, marine and electrical engineering.

Nevertheless, most of the supply data mentioned in this survey do not take account of students coming out of college or university or transfers of workforce from other industries. Therefore, the net requirement is likely to be lower than shown in the figures.

The various scheduled MIPs schemes (nuclear plant, infrastructure works, wind farm...) will all be competing for similarly skilled employees, however, with the general down turn in work in the construction sector, and the impact of the Credit Crunch, it is likely that several of these schemes will be shelved or delayed, so that the peaks in resource demands predicted a year or so ahead may be much less severe than might have otherwise have been the case. However, demand may peak again in 5-10 years.

For the barrage schemes, most of the labour demand will be used for the construction of the caissons. If this work was done at existing shipyard or port sites there is unlikely to be a shortage of suitable labour. On the other hand, if the construction was located in a purpose built caisson yard, the amount of labour required and available would be an important factor in the choice of location of the yard.

For the lagoon schemes, not only will there be a need for caissons but there will also be a greater labour demand for the embankment, including marine expertise to handle the construction vessels (barges...). Such operations will use relatively little labour, and companies tend to use their own carry teams of specialists who travel from project to project. They would act as a cadre to which locally trained labour could be added.

There will be a further discussion of employment issues in the revised regional economic impacts study, the options definition report and the SEA Communities topic paper.

VI – POSSIBLE FURTHER STUDIES

The report highlights the need for further study or analysis in the following main areas (for each scheme):

Vessels

- Need for purpose-built vessels due to innovative construction or installation process.
- Assessment of the various vessels required (number, size, type...) and location of ports able to accommodate them (including possible improvement and refurbishment).

Aggregates

- Location of potential additional dredged areas required for marine aggregates supply (lagoon schemes): Bristol channel or other UK coast.
- Assessment of the volume of recycled and/or secondary aggregates required and location of the corresponding sources.
- Analysis of Government plans for aggregates extraction forecast and proposal for changes.

Concrete

- According to the demand of cement, location of the cement plants, including overseas imports (the result is also linked to the choice of the caisson construction yards).
- Precise assessment of the volume/tonnage of concrete aggregates required for each component: sand, gravel and crushed rock. These figures would enable choice of the most suitable quarries (delivery, location, transport...) including overseas imports (the result is also linked to the choice of the caisson construction yards).
- Accurate volume of precast concrete units (protection armour...) required and location of the plant including imports.

Caisson construction yards

- Confirmation of the availability of the sites mentioned, including existing ports according to the technical requirements.
- For each scheme, optimization of the location of the caisson construction yards.

As for the other mechanical and electrical equipments, at this stage it is too difficult to know where these components could be sourced because most of them are likely to be delivered from overseas manufacturers. However, the impact on existing transport infrastructure will be better assessed by these additional studies on civil works which represent the largest potential transport burden.

The scope of further studies would also address the potential environmental impacts of each technical choice in terms of location of sources of materials and equipment, transportation, temporary storage, disposal of materials (e.g. dredged materials unsuitable for construction use), road/bridge improvement, harbour upgrading...

APPENDIX 1

SEVERN TIDAL POWER QUESTIONNAIRE

A - VESSELS

For the construction of each scheme, various vessels should be required for the following tasks:

- dredgers (trailer suction hopper dredgers, large cutter suction dredgers, grab dredgers...),
- jack-up barges (for rock dredging pre-treatment by drilling and blasting),
- tugs (for caissons towing),
- vessels for caissons ballast filling,
- floating cranes (equipments installation, bulkheads removal...)
- heavy load crane barges (e.g. heavy derrick barge) for turbine, transformer, gates installation,
- side dumping barges/split hopper barges for embankments construction,
- rock transport (pontoons, barges...) for embankments and armouring construction,
- ...

Q1: what is the availability of these types of vessels in the national and international market? What are the most critical type of vessels in terms of availability

Q2: how do you envisage this availability changing over the next ten years?

Q3: where can these vessels be sourced (country, main owner-charterer...)?

Q4: will some additional specific vessels have to be built or retro-fitted? If yes, where (country...) and what are the likely timeframes for doing so?

Q5: what are the consequences of competition from other concurrent large offshore construction projects in UK or in EU (e.g. offshore wind farms...) in terms of vessels availability?

Q6: could the harsh site conditions (tidal stream velocity, waves) be incompatible with conventional vessels, in particular for the caissons installation?

Q7: is the capacity of the existing port facilities in the Severn estuary appropriate for these vessels? Do these ports need to be upgraded so as to accept these vessels (berth size, crane capacity, mooring...)?

SEVERN TIDAL POWER QUESTIONNAIRE

B – CIVIL WORKS

Dredging

Q1: according to the existing policies and legislation on marine dredging in the Severn Estuary, what are the main constraints?

Q2: what are the main constraints for getting additional licences for dredging in the estuary?

Q3: where can the dredged materials be stored before being re-used for civil works (ballast, construction...)?

Q4: what are the main constraints for getting licences for spoil disposal in the estuary? Are there already areas suitable for this spoil disposal?

Caissons yards

Q5: what is the up to date list of potential coastal sites in UK/EU suitable for the construction of caisson yards facilities?

Q6: is there any existing port (in UK or EU) suitable for the implementation of a caisson yard facility?

Q7: what are the main constraints for manufacturing, building and installing equipments/assembly facilities required for each caisson yard (cranes, quays...)?

Concrete

Q8: are the existing national and regional policies that prescribe volume and location of aggregate extraction compatible with the aggregates demand (gravel, sand...)?

Q9: are the existing national and regional policies that identify, or have the secondary outcome of production of, suitable secondary aggregates (e.g. bottom ash from waste incinerators) compatible with the recycled aggregates demand?

Q10: what is the availability in the regional, national or international market of:

- steel bar reinforcement
- cement (Portland)
- additive compounds (fly ash...)
- formwork/shuttering?

Q11: pozzolanic cements and cements using more than 60% of slag as aggregate are more resistant to sea water. If these were used instead of pure Portland cement, are there likely to be significant constraint in their supply?

Q12: are the existing UK concrete plants suitable and appropriate?

Q13: what is the availability of dumper trucks, cranes for precast concrete armour units installation...?

Q14: what is the compatibility of precast concrete armour units manufacturing (0.78 million tonnes for Cardiff-Weston scheme) with existing precast production and facilities in UK or EU?

Materials for embankments & breakwaters

Q15: are the existing national and regional policies that prescribe volume and location of aggregate extraction compatible with the materials demand for embankments/locks breakwaters (rock, sand...)?

Q16: what are the main constraints in terms of sources of rocks in UK and EU?

Q17: where are the most suitable sites for materials sourcing (quarries...)?

Q18: how to cope with the shortage of rock sources?

General points

Q19: in civil works, what is the major concern which could delay the completion of the scheme?

Q20: what are the consequences of competition from other concurrent large construction projects in UK or in EU (e.g. nuclear plant, Crossrail...) in terms of civil engineering and works?

Q21: what is your assessment on the capability of existing transport infrastructure to cope with increased construction traffic? Does the transportation of materials from regional and national sources require upgrading or strengthening the existing roads or bridges?

SEVERN TIDAL POWER QUESTIONNAIRE

C – MAIN MECHANICAL EQUIPMENTS

Total weight of fabricated steel components: about 200,000 tonnes for Cardiff-Weston scheme.

Turbines

The following questions are also appropriate to the supply of generating equipment.

Q1: what are the main constraints in terms of manufacturing/design? Can the demand of large number of units be easily met within the timeframe available?

Q2: in particular, for Straflo turbines, as there is only one European manufacturer (due to patents), what are the main specific constraints (ability to provide the number of turbines, risks of time delays to completion...)?

Q3: what are the best locations for turbine assembly facilities? New facility built close to the turbine caissons yard or existing facility?

Q4: is the installation solution suggested in the STPG report still appropriate?

Q5: is there a risk of shortage of specific materials (e.g. stainless steel...) required for the construction of the turbines? If yes, are there any alternative solutions?

Q6: what are the main constraints in terms of turbines supply?

Gates (dam, turbines and locks) and bascule bridges

Q7: can the regional or national manufacturers meet the demand of gates and bascule-bridges supply?

Q8: what are the main constraints in terms of gates/bridges supply?

General points

Q9: in mechanical engineering, what is the major concern which could delay the completion of the scheme?

Q10: what are the consequences of competition from other concurrent large construction projects in UK or in EU (e.g. nuclear plant, Crossrail, hydro power plants...) in terms of mechanical engineering and procurement?

Q11: what is your assessment on the capability of existing transport infrastructure to cope with increased construction traffic? Does the transportation of heavy or large components from regional or national facilities require upgrading or strengthening the existing roads or bridges?

**SEVERN TIDAL POWER
QUESTIONNAIRE**

D – MAIN ELECTRICAL EQUIPMENTS

Electrical equipments

Q1: what are the key electrical components whose supply could be challenging?

Q2: can the regional or national suppliers meet this electrical equipment demand?

General points

Q3: in electrical engineering, what is the major concern which could delay the completion of the scheme?

Q4: what are the consequences of competition from other concurrent large construction projects in UK or in EU (e.g. nuclear plant, Crossrail, hydro power plants, wind farms...) in terms of electrical engineering and procurement?

Q5: what is your assessment on the capability of existing transport infrastructure to cope with increased construction traffic? Does the transportation of heavy or large components from regional or national facilities require upgrading or strengthening the existing roads or bridges?

**SEVERN TIDAL POWER
QUESTIONNAIRE**

**E – LABOUR & SKILLS
(MARINE, CIVIL WORKS, MECHANICAL AND ELECTRICAL)**

Q1: indication of the number of jobs (for each field) that might be directly created in Wales and South West region during the construction works.

Q2: in case of regional (Wales and South West) job creation, assessment of the % of resident and new resident labour force (level of employment displaced in the region).

Q3: assessment of the particular skills required for the studies (site investigation, design studies...) and the construction works in each field. In what study and construction fields is there a risk of shortage of skills and/or workforce?

Q4: given the likely work force demands outlined in Part 1, to what extent do you think there is likely to be spare capacity in the following markets to meet this labour demand:

- Regional (South West and Wales)
- National
- International

Q5: in case of shortage of particular labour supply, are you aware of industries with transferable skills that may be able to fill these gaps? If so, give estimates of likely period to re-train.

Q6: assessment of the % of works which could be directly done within Wales and South West region (% of construction cost).

Q7: what are the consequences of competition from other concurrent large construction projects in UK or in EU (e.g. nuclear plant, Crossrail, hydro power plants, wind farms...) in terms of labour and skills?

Q8: indication of the number of jobs (for each field) that might be directly created in Wales and South West region for the operation and maintenance of each scheme.

Q9: in what operation and maintenance fields is there a risk of shortage of skills and/or workforce?

Q10: do you have any comment on DTZ data and figures presented in Part 1?

UK Infrastructure: The challenges for investors and policymakers

White paper 2013

About Pension Insurance Corporation

Pension Insurance Corporation ("PIC") provides tailored pension insurance buyouts and buy-ins to the trustees and sponsors of UK defined benefit pension funds. A market leader, PIC brings safety and security to scheme members' benefits through innovative, bespoke insurance solutions, which include deferred premiums and the use of company assets as part payment. Clients include FTSE 100 companies, multinationals and the public sector.

PIC has almost £9bn in assets primarily invested in investment grade corporate bonds, UK government debt and cash. Within this, housing association and infrastructure debt is expected to play an increased role in helping the company diversify its asset portfolio. In 2012 PIC completed the first ever UK publically-listed solar finance bond, investing £40 million as the sole buyer in a Solar Power Generation Ltd bond, as well as directly funding Raglan Housing Association as the sole buyer of a £50 million bond issue.

PIC is authorised by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and Prudential Regulation Authority (FRN 454345). For further information please visit www.pensioncorporation.com

About Llewellyn Consulting

Llewellyn Consulting is a niche 'macro-plus' economics advisory, based in the City of London. We provide high-level bespoke services to a strictly-limited number of clients. We look at macroeconomics from the top down, with a particular emphasis on policy, so as to determine the economic and market implications that flow from contemporary events, as well as from longer-term drivers.

For further information, please see www.llewellyn-consulting.com

Executive Summary

- The UK economy is experiencing a chronic shortage of aggregate demand
- Meanwhile the share of both public and private investment in UK GDP is low, at a time when its infrastructure is widely recognised as poor
- More infrastructure investment would make economic sense, both for cyclical and for structural reasons
- Greater private sector involvement could address the shortfall that is due to Government hesitancy to engage in public sector investment
- Pension funds are already significantly invested in infrastructure, including importantly through the listed bond markets
- However, they continue to have a large and growing need for secure, stable, and predictable long-term cash flows better to match liabilities
- Infrastructure could offer pension funds and insurance companies further investment opportunities through new debt or ungeared equity investment structures
- Such investment would mobilise previously unused funding, helping to expand the economy both near – and longer-term
- This requires a constructive institutional environment that, inter alia, tempers upfront financial risks, particularly for large projects
- Regulations inhibiting institutional investors require particular attention
- New legal/financial frameworks would be particularly beneficial for smaller projects
- Shaping the institutional environment and creating new legal/financial frameworks represents an important role for Government
- It is desirable to find ways to pool the resources of smaller pension funds
- Enhancing private sector infrastructure investment in aggregate requires a more stable, long-term, national strategy for the UK's infrastructure
- Additional expenditure on infrastructure of 1% of GDP could expand GDP by as much as 1.4% – over £20bn
 - The £310bn Infrastructure Plan if fully implemented could, over a run of years, end up contributing over £400bn to UK GDP (currently £1.6tr)
- The national accounts should make a clear distinction between public debt that is backed by saleable assets, and general public debt that is not
- The situation could be addressed piecemeal; but it would be better to take a more coherent approach
- It is recommended that this be done by a combination of:
 - 'Invest and sell' asset transfers
 - Reanimation of the Private Finance Initiative
 - Creation of a National Investment Bank or Fund

I. Introduction

The UK's infrastructure is under duress

In the wake of the Global Financial Crisis (GFC), most of the advanced economies are recovering only slowly, and public sector balance sheets are under duress. This has led governments to cut back on public spending, and not least on infrastructure investment.

Notwithstanding a slight shift of emphasis in favour of public investment outlays, and in particular the prominence of a few high-profile projects in its latest public spending plans, the United Kingdom is no exception; and nor are its macroeconomic conditions likely to normalise any time soon. The recovery seems set to remain hesitant, fragile, and uneven.

Increased investment in infrastructure can contribute positively: not just to the recovery process, through the boost that it provides to aggregate spending, but also to the economy's longer term performance and competitiveness. Moreover, the UK has for some time tended to spend comparatively little on this key component of GDP and catalyst for development.

The UK's global competitiveness ranking for 'quality of overall infrastructure' was 24th in 2012-13, equal to the US, and below all the other G7 economies except Italy.¹ In 2007 the UK ranked 19th (Figure 1). In a 2012 survey by the Confederation of British Industry, nearly two thirds of companies judged the UK's infrastructure unfavourably relative to that of other EU countries; only a minority of companies were confident that the UK's transport, energy, and water networks will improve in the near future; and nearly half rated the UK's transport networks as well below average international standards.² And, notwithstanding the government's recent claims about transformational plans for road building and the railways, and talk of lengthening the government's policy horizon in this area,³ its latest initiatives are in significant part a repackaging of previous ideas.

Pension funds could help to address the shortfall

One increasingly talked-about way to achieve a higher level of infrastructure investment has been to encourage greater private sector financing. This is consistent with the objective of institutional investors, such as pension and insurance funds, to increase the diversification of their portfolios, and enhance their long-term asset-liability management. There is a lead role for Government here in setting the necessary framework.

In short, there are huge infrastructure demands, and increasingly interested and cash-rich institutional funds. A key challenge therefore is to bring the two together. This paper considers some of the problems involved, and the options available to overcome them.

II. Infrastructure's role in the economy

Infrastructure is important for economic success

A country's infrastructure is central to the functioning of its economy and to the welfare and development of its population.

A broad definition of infrastructure includes both physical (tangible) and non-physical (non-tangible) assets. Infrastructure can be thought of as the economic arteries and veins that enable people, capital, manufactured goods, commodities, water, energy, information, and more to move efficiently both within, and into and out of, the country. It includes the assets that underpin the economy's networks for transport; energy generation, distribution and storage; communications; waste management; and water distribution and treatment.

Arguably, the most important elements extend to major roads, railways, airports, seaports, power lines, pipes and wires; electricity and gas; electronic communications, including broadband; water, sewerage and waste; flood defences; and intellectual capital.

Most economists would also include 'social infrastructure' in the list, namely housing; hospitals; schools; universities; the legal system; government research institutions, and more.

From the institutional investor's point of view, there is little doubt that 'social infrastructure' should indeed be included in the definition. For such investors, it is the associated long-dated cash flows that matter most, and 'social infrastructure' is just as capable of delivering these.

Thus infrastructure facilitates the delivery of goods and services that promote prosperity and contribute to quality of life; and it adds to the productive capacity of the economy. But empirical analysis suggests that it can also have effects on economic growth over and above those arising from simply adding to the capital stock. It also facilitates:

- Trade and the division of labour;
- Competition in markets;
- More efficient allocation of activity across regions;
- The diffusion of technology;
- Better organisational practices; and
- Access to new resources, both physical and human.

Infrastructure can also help to address the burgeoning global challenges of climate change, and encourage the 'greening' of the economy.

(For more, see Box: *Macroeconomic effects of infrastructure spending*).

Infrastructure boosts aggregate demand and aggregate supply

III. The legacy of the Global Financial Crisis

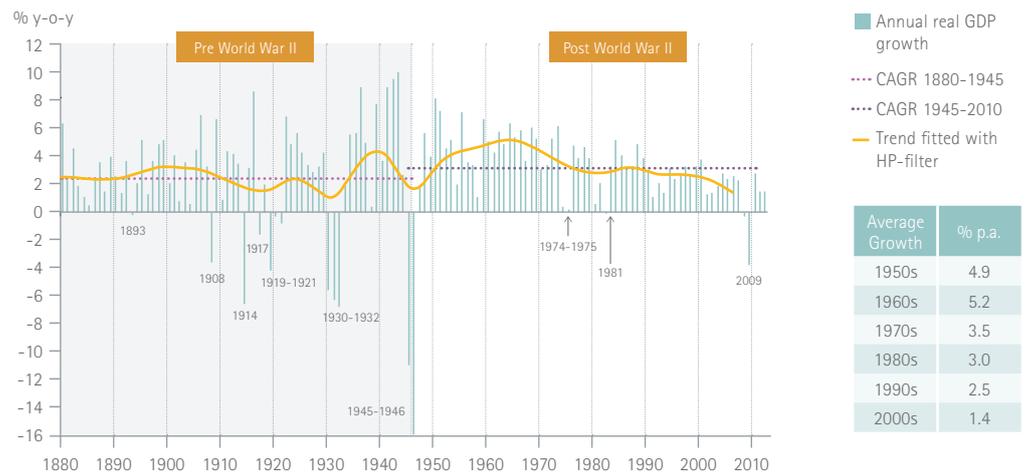

The global crisis sparked the worst downturn since WWII

In the aftermath of World War II, economic growth, even if it began to trend downwards from the 1960s, was markedly less volatile, and subject to fewer major setbacks, than it had been in the pre-war period. Indeed, the major economies went more than 60 years without experiencing a major decline in real GDP (Figure 2).

All this changed, however, with the Global Financial Crisis (GFC) in 2009, which saw a major decline in output right across the advanced world – in the case of the UK a fall in GDP of 7.2%, peak-to-trough. The subsequent recovery has been slow in coming, hesitant, and uneven.

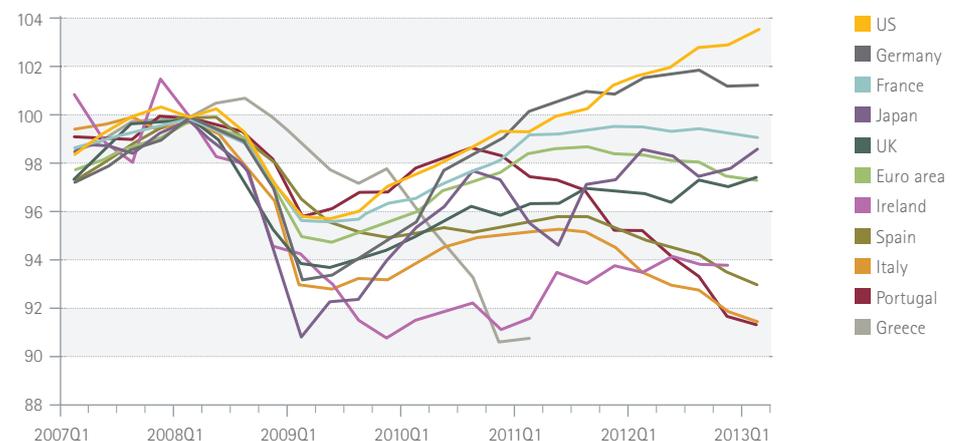

The United Kingdom's cyclical upswing has, if anything, been less impressive than most of its major competitors: output (GDP) is still some 4% below its previous high, particularly disappointing when compared with the US. Indeed, only those economies at the periphery of the euro area that have suffered extended sovereign debt crises have fared worse (Figure 3).

III. The legacy of the Global Financial Crisis

Demand has slumped and the supply-side is at risk of damage

Major financial crises are always expensive, and exact an enduring cost on economic activity. The experience of developed economies of such episodes is that the loss of output, relative to the previous extrapolated trend, can run ultimately to between 50% and 100% of one year's GDP.

Seven years after a financial crisis, GDP is typically 10% below trend, most of the 'lost' output reflecting the fact that investment spending is on average around 30%-odd below where it would normally have been expected to be in normal times. There can be other longer term effects on productive potential too, if the weakness in investment spending persists, and labour skills atrophy in an environment of extended unemployment. Financial crises can even depress an economy's underlying growth rate (Figure 4).

Perhaps the best way to describe the prevailing conjuncture in the UK and the other major economies is that there is a chronic deficiency of intended (so-called *ex ante*) investment relative to intended savings. Normally, during such periods of very weak aggregate demand, the public sector is able, in conjunction with other efforts to stimulate the economy such as monetary policy easing, to at least partially fill the gap with additional government spending, not least on infrastructure investment.

Fiscal incontinence...

Since the Global Financial Crisis, however, public debt burdens, which were already historically elevated, have risen to peacetime highs (Figure 5). The average advanced-economy general government gross debt-GDP ratio now stands substantially above 100%, and is still rising. The IMF's forecast for the UK this year is 108.1%, and it is generally reckoned that this figure is unlikely to decline much over the coming five years.⁴ Moreover, the advanced economies, including the UK, are confronted by ageing population structures that will require increasingly large outlays on pensions and healthcare.

Following the short burst of discretionary fiscal stimulus in 2009, Western governments have proved reluctant directly to boost demand through sustained budgetary activism, for fear of eliciting a negative response from markets and the rating agencies. Rather, the emphasis has been on fiscal restraint, and it is public investment that has often been the prime casualty. In the UK, public investment fell 6% in quarter-on-quarter terms in the January-March period of this year.

... and political philosophy ...

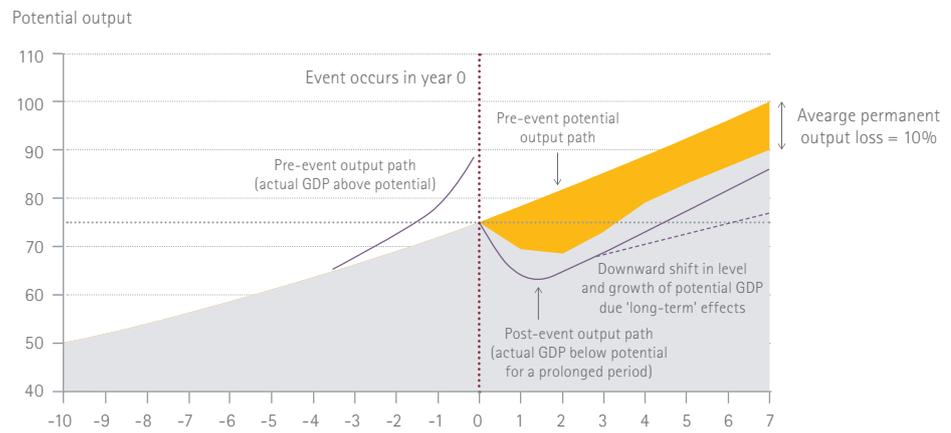

There has also been an ideological element to this restrictive fiscal policy stance, and not least in the UK. A widely-articulated view in Government has been that budgetary stimulus produces more costs than benefits, and that on previous occasions the public provision of infrastructure has failed to deliver efficient investment, with misallocations across sectors or regions. This conviction has led in turn to the twin conclusions that it is the private sector that should be responsible for the bulk of investment expenditure; and that, when government investment expenditure is reduced, private sector investment will 'crowd in' to fill the vacuum.

However, any hope that the private sector would rapidly fill the hole in aggregate spending has proved wide of the mark. Contractions in government expenditure have not in general led to a hoped-for rapid 'crowding in' of private expenditure, whether for infrastructure or otherwise. Confidence has been at too low an ebb, and too many market failures and other constraints have intervened. The private sector is the more likely to 'fill in the hole' the greater the extent to which it has clarity about the infrastructure in which it can invest pursuant to government's long-term strategy.

... have prevented a major effort to boost public investment

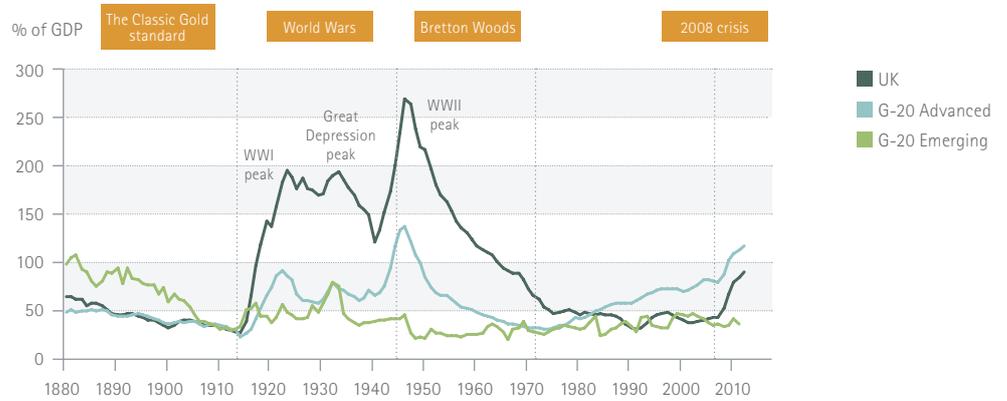

Hence, the UK has benefited neither from the ability of infrastructure investment to stimulate demand in the near term, nor from its capacity to raise potential over the longer term.

IV. The United Kingdom: a serial under-investor

The UK's share of total investment in GDP is low...

The Organisation for Economic Cooperation and Development (OECD), variously in its *Going for Growth* series and its regular *Economic Surveys*, has consistently identified investment in infrastructure, and especially in transport, as one of the main priorities for the UK.⁵

... as is its share of public investment in GDP...

The UK's shortcomings are perhaps most succinctly captured in the economy's low share of both total investment and public sector investment in GDP. Since the 2008 global financial and economic crisis, total investment-to-GDP ratios have fallen in all the major economies, to well below historical norms: the UK is thus not alone in this regard. However, in 2012 the UK's total investment ratio was a mere 14% of GDP, compared with 16% in the US, close to 20% in the euro area, and slightly above 20% in Japan. Moreover, the UK has had a relatively low investment share for many years (Figure 6).

Much the same is true of investment by the UK government (Figure 7). Over the past twenty years, the share of gross public investment in GDP has been lower than in most of the UK's major advanced-economy trading partners. While the ratio did increase significantly in 2008-09, in response to the emergency policy action by the then government, public investment has since fallen back to its pre-crisis level.

Moreover, according to the Office of Budgetary Responsibility, the share of public sector *net* investment in GDP (i.e. excluding depreciation) is set, on announced plans, to fall further, from 2.6% in 2010-11 to just 1.1% in 2016/17, the lowest level since 2001/02 and a mere one-sixth of the figures recorded in the late 1960s.⁶

... resulting in a major 'infrastructure gap'

Thus the UK is clearly suffering from a major 'infrastructure gap'. Resolving this requires a sophisticated interplay between Government and the private sector.

V. Financial characteristics of infrastructure projects

Infrastructure projects have a number of distinct characteristics (Figures 8, 9 and 10). In particular, such projects:

- Produce cash flows that are determined by a regulatory regime set by government, or sponsored by a government or quasi-government body
- Frequently are monopolistic or quasi-monopolistic;
- Require a large initial capital outlay;
- Have to satisfy the double imperative of ensuring financial sustainability and meeting user needs and social objectives;
- Involve contracts that are complex and of long duration;
- Offer extended duration, stretching to 25 or 30 years and in some cases even longer;
- May provide inflation protection, in that the associated revenues are often combined with an inflation adjustment mechanism, whether via regulated income clauses, guaranteed yields, or other contractual guarantees;
- Yield stable and predictable long term cash flows that can support significant leverage; and
- Yield a return that is predictable, inelastic, and relatively uncorrelated with the business cycle.

... not least because of the structure of cash flows

'Greenfield' investments – defined as first time usage at a site – involve considerable planning, development financing, a procurement phase, and extended construction stages during which investors rarely make a profit. The cash flows associated with 'Greenfield' sites demonstrate a distinct 'J' curve pattern. By contrast, however, the later, revenue-generating, stages can offer high and stable cash flows similar to standard fixed income investments or real estate.

'Brownfield' sites – those already operational in some sense or other, or that have a predecessor – involve reconstruction, renovation, or expansion but are generally less expensive in the early stages. Hence, there is less of a 'J' curve effect.

Various financing structures are available

Given these characteristics, two broad options are available to investors: equity (which in turn can be subdivided into geared pooled investor funds and non-geared direct investor funds); and debt (bonds).

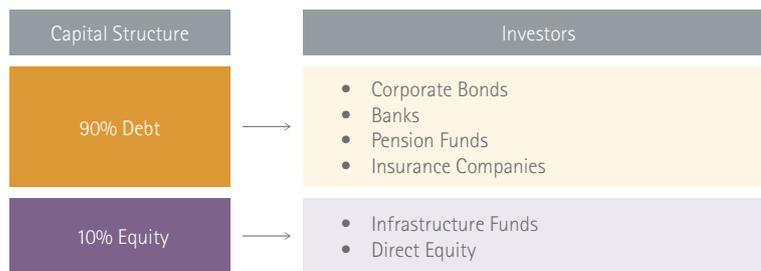

- **Equity.** Listed shares can be bought in large companies, and in particular those in the larger utility, energy, and transport sectors. Investor funds can be bought from managers with in-house expertise who can finance individual projects and who may hold the equity of smaller infrastructure projects which are not listed.
 - Geared pooled direct investor funds are typically based on the private equity model. Prior to the GFC, they were often highly geared and promised exits after seven years, though there is little evident economic rationale for that particular time frame. There are therefore question marks over the appropriateness of these funds for the infrastructure sector.
 - Non-geared direct investor funds often follow the model developed in Canada, not least by Borealis, the investment arm of the Ontario Municipal Employees Retirement System (OMERS) that boasts C\$55.7bn in total assets, uses specialist teams of managerial and operational expertise to manage C\$8.5bn of infrastructure investments, and not just in Canada – some of their interests are in the UK. It embraces a long-term 'buy and hold' strategy; takes direct control of the assets of the project; and seeks to avoid any agency issues with fund managers.
- **Debt.** Most infrastructure projects can be highly geared and sub-divided into 85-90% debt and 10-15% equity financing, depending on the project. The debt financing is generally:
 - Investment grade;
 - Secured on physical assets or contracts;

- Issued by states, municipalities, utility companies, other large corporates, or Special Purpose Vehicles (SPVs); and
- Offers returns that may be linked to inflation and/or to project revenue.

Where individual projects are of sufficient scale to warrant public-debt financing – typically £200 million or more – a public listed bond can be issued. Often this will be the cheapest form of debt financing, because investors put a value on the liquidity of a public bond that can be traded in the secondary market. Often the bonds are issued only once the initial construction stages have been completed and the associated risks have declined.

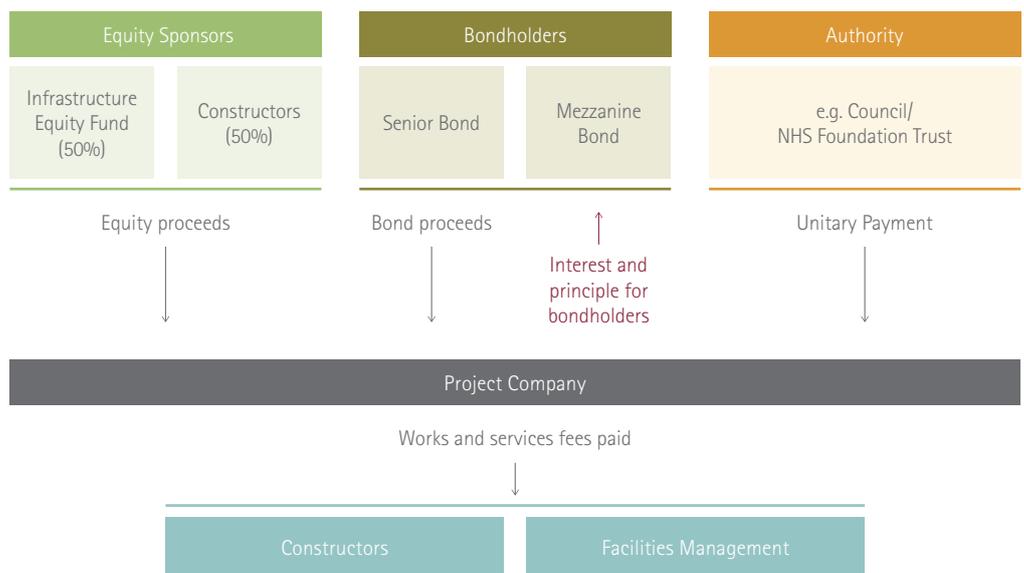

For smaller projects, private debt deals can be arranged. These can take the form of loans, and be sold to individual debt investors or clubs of debt investors.

VI. Macro constraints on private financing

The travails of the banks have hurt private financing

In the run-up to the GFC, fierce competition and abundant cheap credit encouraged infrastructure asset values to rise sharply in an environment where there was a widespread 'stretch for yield'. The credit quality of many infrastructure deals declined. There were also issues with increased gearing. Some investors, and not least the banks, which had been seeking stable incomes by investing in infrastructure, found themselves owning over-priced and over-leveraged assets with very different risk profiles from those initially hoped for and expected.

Since the GFC, the options available for the private financing of infrastructure have been severely curtailed, in large part the result of the pressures exerted on the banks. In principal, banks remain the most flexible source of funding. Such flexible funding is particularly useful in the construction phase, when the exact timing of the various financial requirements is unknown. But latterly they have faced serious capital and liquidity issues, if not of outright solvency. Banks have become risk averse, and focused on shedding assets and restraining credit growth, especially over longer maturities. It has also become more difficult for them to shift credit risk from their balance sheets. There is every likelihood that regulation, in the form of Basel III, will only add to this conservatism in the near term.

Some banks have withdrawn from the sector altogether

Some of the banks which were most active in UK infrastructure financing, including Depfa, Espirito Santo, Commerzbank, and Mizuho, have either substantially cut back their activities in these areas or have withdrawn altogether. Meanwhile, considerable infrastructure project expertise has been lost elsewhere in the sector.

The banks' difficulties have also affected Public Private Partnerships (PPPs), whereby project risks are shared across the private and public sectors. The government (often local or municipal) typically specifies the quantity and quality of the service it requires from the private partners, which are coalesced into a consortium, and which capitalises a Special Purpose vehicle (SPV) with varying recourse to debt and equity. The consortium is tasked with the design, construction, financing, operation, and management of the infrastructure asset, as well as delivery of the resulting service, whether to the government or the public. The group may benefit from some equity contribution from the public sector sponsor, but it will also receive either a stream of payments from the government or user charges levied on end users, or a combination of both.

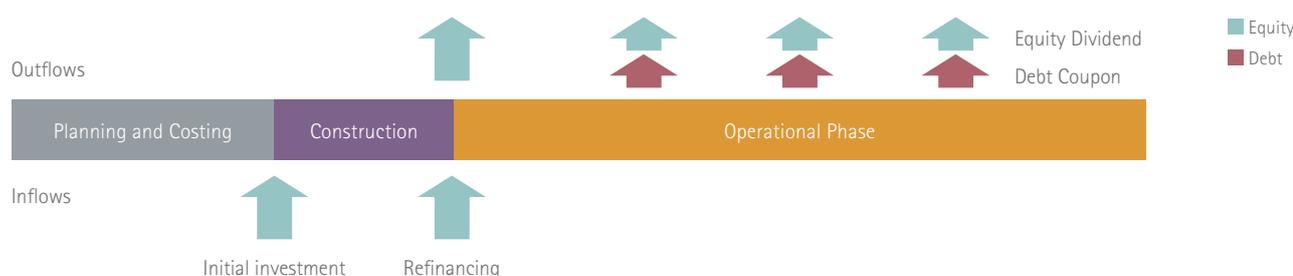

In the UK, which was something of a global pioneer in this area, these schemes have been bracketed under the term Private Finance Initiative (PFI). The PFI contributed considerably to infrastructure spending over the 15 years leading up to the GFC. More than 700 such partnerships were assembled, with a capital value of more than £50bn. This included almost 100 hospital schemes, more than 100 education projects, and around 40 transportation projects and initiatives in areas as diverse as defence and culture. Overall, they were associated with some 12% of total annual capital expenditure over the latter part of that period.⁷

Bank and insurance troubles have hit the UK's PFI hard

However, the PFI has been a major casualty of changing political priorities, as well as the banks' more conservative attitudes to lending, an attitude that has been further encouraged by the losses some banks have made on these projects. Smaller PFI projects in particular were highly dependent on bank finance. The PFI was dealt a further blow by the collapse of the involved insurers that had hitherto conducted much of the project risk evaluation spadework and lent their stamp of approval to the bonds issued to finance larger projects.

Moreover, the more cost-conscious, post-GFC, period saw a growing focus on whether these initiatives were offering sufficient value for money for taxpayers. The net result is that PFI activities have tapered off decidedly since 2008. The current government has tried to address some of these issues with its PF2 programme, but this effort has yet to reach critical mass.

Figure 10: Infrastructure financing timeline and cashflows

Box: Macroeconomic effects of infrastructure spending

The evidence points to relatively large effects, particularly in conditions similar to the present conjuncture.

The relationship between infrastructure and output is difficult to estimate precisely and causality can be hard to determine empirically. Important influences on the observed relationship, both in the near term and over the longer term, include:

- The precise nature of the spending;
- Its longevity;
- The stance of monetary policy;
- The state of the business cycle;
- The health of the financial sector and prevalence of credit constraints on the household and business sectors; and
- Externalities and spill-over effects.

Such caveats aside, there is suggestive evidence that infrastructure enhances growth in ways that go beyond the direct effect on the capital stock. These include economies of scale, network externalities, and the potential for increased competition. The construction of a new airport for example, could be expected to generate benefits to the economy that go way beyond the initial capital outlay.

The results of empirical studies suggest that effects differ both across countries and sectors, and that they vary over time, with episodes of under- and over-provision, and efficient and inefficient use of investment. But, as is to be expected, infrastructure appears to exert a stronger long-term impact on growth at lower levels of provision. (See: Egert, B., Kozluk, T. and Sutherland, D, 2009. *Infrastructure and growth: empirical evidence*. OECD Economic Department Working Paper No. 685.)

In practice, achieving a value for the multiplier – defined as the increase in GDP following a 1% increase in infrastructure spending – of much above 1 will depend on the nature and quality of the investment, and in particular on the potential for long term impacts on productive potential and productivity.

It is, however, likely that multipliers are larger for public investment than for other fiscal policy measures, and that they are also likely to be larger when, as in current circumstances, the stance of monetary policy is easy, the private sector is unable or unwilling to borrow, unemployment is high, and the economy is working below full capacity.

A survey of a broad range of the pre-crisis literature on infrastructure suggests a multiplier range of between 0.5 and 1.5. However, more recent, post-crisis, estimates have put the value as high as 2.0 or more, the suggestion being that the particular circumstances characterising the current conjuncture have if anything enhanced the impact of infrastructure-related fiscal stimulus. (See: IMF, 2010b. *Effects of Fiscal Stimulus in Structural Models*. IMF Working Paper 10(73)).

Simulations for the UK economy conducted by the UK's National Institute of Economic and Social Research (NIESR) concluded that, in the wake of the crisis, a 1% of GDP increase in infrastructure investment not only increases GDP by close to 1% in the near term, but also increases potential GDP by a further 0.2 and 0.4% over the longer term. (See: Fic, T. and Portes, J. 2013. *Macroeconomic impacts of infrastructure spending*. National Institute of Economic and Social Research).

(For more on the UK government's National Infrastructure Plan, see Box: *The National Infrastructure Plan*).

VII. Pension funds and alternative sources of funding

Pension funds offer an alternative source of funding

So far they have little direct exposure to these investments...

With the banks under duress and much more cautious in their approach, there is a need for new and alternative sources of funding for infrastructure. Fortunately, the diversity of the non-bank financial sector is such that there are numerous other sources, including insurance companies, family offices, sovereign wealth funds and, in particular, pension funds.

UK pension fund assets are particularly large, equivalent to around 112% of GDP in 2012 (Figure 11). Only the Netherlands and Switzerland have larger pools of pension assets relative to the size of their economies, while for most other advanced economies the figure is much lower.

UK pension funds are heavily skewed towards defined benefit (DB) schemes, which account for almost three quarters of the total (Figure 12). This is changing, but DB schemes will retain the largest pool of assets for some time, although a significant portion is expected to pass across to insurance companies via buyouts. An issue for Defined Contribution (DC) pension fund investment in illiquid assets such as unlisted infrastructure is that people have the option to switch funds easily.

The asset allocation split of UK pension funds has historically been dominated by equities, although the proportion allocated to bonds, now 37%, has been increasing, both in an effort to reduce the volatility of returns and because of investor conservatism following the GFC.

Currently, in most countries and including in the UK, most pension funds carry some exposure to the infrastructure sector. This is predominantly indirect, via equity and corporate debt issued by the infrastructure project or company and traded in listed markets. Some investments are made through financing vehicles such as SPVs or private equity funds but, in the main, and certainly beyond the largest pension funds, direct investment asset allocations to infrastructure remain limited.

Most UK pension funds will hold listed utility equities. And the typical non-Gilt fixed income portfolio will include 10-15% in utilities and perhaps a further 20% in broader exposure to infrastructure of one sort or another, including in particular bonds issued by the major airports, or PFI consortia. A key requirement of all such investments is that the infrastructure projects be of sufficient scale to merit the financial instruments being listed.

The 'other investments' category, which is designed to encourage the diversification of portfolios, and which captures direct exposure to infrastructure equity, accounts for only 17% of total assets, and the direct infrastructure allocation itself is estimated at less than 5%. It is the larger pension funds that tend to dominate this category: many, perhaps most, UK pension funds have little direct investment in infrastructure equity.

The large pension fund holdings of infrastructure cover a range of project types, with different investment characteristics. Based on risk/return profiles, these portfolios often divide into two segments:

- A core holding, where cash yield is dominant; and
- A value added/opportunistic holding, where capital appreciation is the dominant focus.

Large pension funds can also focus more on 'Greenfield' sites and relatively untested technologies, though such investments generally represent only a tiny proportion of the total infrastructure holding.

The clear inference is that there is considerable scope in principal for UK pension funds, and in particular smaller pension funds, to increase their exposure to infrastructure. The long-term alternative sources of funding represented by pension funds may also be preferable for infrastructure project managers in search of patient, stable, long-term funding.

... but the prospect of predictable real returns is attractive...

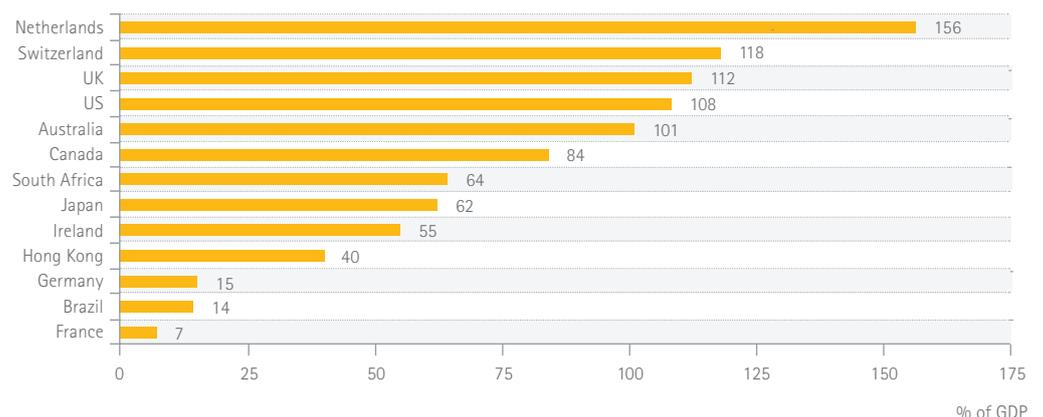

... especially while index-linked Gilt yields are negative

The risks associated with the illiquidity of the equity-financed portion of infrastructure projects are one of the major constraints on the pension fund involvement, especially for the smaller entities (see Box: *Some specific problems faced by small pension funds*). But on the other hand, the more secure and predictable stream of income flows that infrastructure assets can provide, via fixed income instruments and other conduits, is attractive in terms of liability matching. And this is particularly so given the consequences of the Bank of England’s persistent resort over recent years to unconventional monetary policy (Quantitative Easing), which has depressed Gilt yields and thereby widened pension fund deficits. Data from the Pension Protection Fund (PPF) indicate that the collective deficit of the 6,316 schemes it covers stood at £186bn in May 2013.⁸ It has also been estimated by Pension Insurance Corporation that the initial round of UK Quantitative Easing increased pension fund deficits by some £74bn.

Long-term interest rates in the UK, as in many advanced economies, have declined sharply since the GFC, falling to historical lows in nominal terms, and into negative territory in real terms (Figure 13). With normalisation of monetary policy likely to prove slow, and governments, because of their onerous debt burdens, increasingly resorting to variations on the theme of financial repression to contain borrowing costs, this situation is unlikely to change dramatically any time soon. Real returns on sovereign bonds, both in the UK and more broadly, seem set to remain paltry at best for a number of years.

Moreover, these difficulties are exacerbated by the fact that pension liabilities are generally only partly hedged, and so are highly sensitive to falling interest rates and the particular structure of UK pension liabilities. Obligations in excess of 25 years account for about 30% of the total, and some 60% of the overall interest rate sensitivity of liabilities (Figure 14).

Box: Some specific problems faced by small pension funds

Helping smaller pension funds pool their resources stands to increase direct investment in infrastructure projects.

By international standards, the UK pension fund industry is quite fragmented. Smaller pension funds face some especially-thorny issues in investing in infrastructure:

- They lack the necessary expertise, and often depend on third-party advice;
- They are reluctant to invest in illiquid assets, especially when they can be confronted by short-termism and the possibility of buy-out, with all its uncertainties over price, within a few years;
- The focus of private equity funds on a 7-year investment horizon and the growth- or return-seeking parts of investment portfolios are ill-suited to smaller pension funds seeking secure long-dated credit-like assets; while
- Private equity governance and fee structures such as the 2+20 model are a further disincentive. However, fees have fallen since the GFC.

The recently-created UK Pensions Investment Platform (PIP) is intended to overcome at least some of these issues. Established by the National Association of Pension Funds (NAPF), which represents some 1,200 entities, with assets of £800bn, and the Pension Protection Fund (PPF), it is designed to be an aggregated infrastructure fund "for pension funds, managed by pension funds".

The UK PIP was modelled on Australia's Industry Funds Management (IFM). It aims to pool pension assets and invest them directly in infrastructure projects, with a view to generating long-dated, low-risk, inflation-linked returns of the order of RPI inflation plus 2-5% on relatively low leverage. The complexities of coordinating the views of such a large number of players with limited experience and resources, however, should not be underestimated, especially when decision times can be a key factor. A target size of £20bn in ten years has been set, and can already boast ten pension funds as founding members. However, thus far, it has raised just £2bn.

Investment in water, for example, could be particularly attractive to smaller pension companies. Given that population sizes and structures typically evolve only slowly, and that trends in water demand are strong, confidence in future cash flows would seem warranted.

VIII. Overcoming the barriers to infrastructure investment

The barriers to private infrastructure are many and various

A number of important hurdles need to be overcome before a significant number of UK pension funds and insurance companies can consider taking a significant direct exposure to infrastructure investment.

These hurdles fall into three categories which, in order of importance, are: investment opportunities; investor capability; and the conditions for investment.

Investment opportunities

Limitations on opportunities at present include:

- The small number, and sporadic nature, of projects – including a lack of privatisation programmes;
- A shortage of political commitment to particular projects over the long term;
- Regulatory instability;
- Fragmentation of the market across different and uncoordinated levels of government;
- High initial bidding costs – partly the result of the absence of a clear, consistent, simple bidding process; and
- Other risks – constructional, operational, business, gearing, legal, and environmental.

Investor capability

A number of other limitations also inhibit investors. These include:

- Lack of investor expertise in infrastructure; and consequent dependency on the due diligence of third parties, such as private equity funds, that may prove difficult to oversee;
- Size of investment fund – smaller pension funds face particular issues (see Box: *Some specific problems faced by small pension funds*);
- Regulatory barriers – e.g. moves to risk-based solvency standards; and
- A culture of investor short-termism.

Conditions for investment

Furthermore a lack of understanding of infrastructure investment is also a limitation. These include:

- Negative perceptions of the value of infrastructure – deriving from novelty and general unfamiliarity;
- A lack of transparency in the sector and/or a scarcity of data needed to assess risk and return profiles of projects, or separate project tranches; and
- Financial processes that are run by banks and geared to banks' products.

Government's role is central, both for large and small projects

A range of policy responses is warranted...

Policy responses

Enhancing investment in UK infrastructure will require a range of integrated policy responses. Government has to be involved.

As regards the largest, most complex, projects, the experience, both in the UK and other advanced economies, is that many of these, such as airports and major railway routes, need a (government) sponsor, even though the bulk of the financing may come ultimately from existing public markets. Government cannot avoid planning, delivering and, to some extent, partially financing projects, at least in their early stages.

For smaller projects too, such as individual hospitals, schools, or renewable energy plants the government is also important, albeit for somewhat different reasons. Historically, equity for a small infrastructure project, such as a PFI deal came from the sponsor and potentially the constructor, with the debt component supplied largely by the banks. But with the banks now deleveraging, this financing component is in short supply, even though the potential equity providers are still present.

Hence to encourage equity funds and capital market conduits in general there is a burgeoning need for Government to involve itself in:

- Developing appropriate new legal frameworks for such projects;
- Managing the procurement process so as to ensure that the debt is delivered to (non-bank) investors in a suitable form, and with feasible timelines in respect of pricing and delivery of funds;
- Developing risk transfer systems, such as guarantees and stand-by lines of credit; and
- Incorporating into the overall financing assessment the setting of tariffs and user charges for which it is responsible, whether directly or indirectly.

In terms of governance, a stable and accessible long term programme of infrastructure investment will need to be:

- Co-ordinated across different departments and levels of government;
- Devoid of frequent policy reversal and prevarication over key decisions;
- Supported by regulatory stability (especially in relatively regulation heavy sectors such as energy and utilities); and
- Dovetailed with the ability of construction firms to supply the necessary resources to do the job.

... as is a major change in attitude and approach...

Clearly, a vibrant and revived PFI could help in the latter regard.

To facilitate all this, infrastructure will need to be elevated in the political debate, and there is a need for cross-party buy-in. There has been some evidence of this lately in the UK, in that both the government and the opposition have expressed support for an increased emphasis on capital spending at the expense of current spending.

However there has, as yet, been little attempt to build a formal political consensus on a list of priority projects. Agreed national infrastructure priorities could with advantage be championed more aggressively, perhaps using the 2012 London Olympics as a model for successful delivery. That was a large, complex, and diverse project, that involved numerous layers of planning and the engagement of all levels of government, and which at its completion generated numerous saleable assets.

Infrastructure investment needs to be disengaged from the electoral cycle, and with greater acceptance of an unavoidable, and sometimes large, role for government, especially in the initial stages of projects when risks are highest.

Investor responses

... among investors as well as within government

In addition to the direct requirements for government, the capability of investors needs to increase too. But even here, there is a role for government in creating the necessary preconditions for the development of the institutional sector's capabilities. In practice this includes:

- Developing a regulatory, supervisory, and tax framework that allows or encourages private sector entities to develop necessary expertise and professionalism;
- Improving pension fund governance through better pension trustee composition; and
- Fostering resource-pooling and collaborative strategies through the consolidation of smaller pension funds and the merging of fund resources to create entities of sufficient scale to be able to offer more effective risk management systems and implement a broader investment strategy.

Further broader initiatives that would bolster investor capability include:

- Developing the regulatory framework to reduce the focus on short-term performance;
- Encouraging transparency in business models; and
- Reforming funding regulations for defined benefit schemes.

Such measures would in total help to improve the alignment of interests between the pension funds and the infrastructure industry, particularly through the provision of a prudential framework more attuned to long term investment.

Data and performance metrics are also a priority

Conditions for investment could also be enhanced by:

- Specifying common definitions for types of infrastructure project;
- Encouraging the independent and objective collection of data that hitherto has been scarce and largely proprietary; and
- Implementing common performance measures for risk and return, including specified industry benchmarks.

Universities and research bodies, including the OECD, could be tapped for expertise on infrastructure. And the creation of an independent association of infrastructure investors to bring forward institutional investors' interests, together with a formal platform for dialogue between them, the finance industry, and Government would also be beneficial.

IX. The way ahead – three ideas

A comprehensive, overlapping, strategy is thus required

The manifest importance of infrastructure spending to the UK economy, both as regards its immediate prospects and its long-term development, together with the equally obvious shortcomings in the way that this core aspect of investment is planned, funded, and regulated, lead to the question of what is the best way forward to address these issues.

Arguably, even a piecemeal approach, embracing some of the suggestions outlined in the previous section, would be better than doing nothing. But much better would be a comprehensive long term strategy that put in place an improved institutional framework for the future delivery of infrastructure, and which helped to create a stable and more sympathetic investment environment.

Accordingly, three proposals are offered below. Each differs in degree of breadth and concentration. None is mutually exclusive. All could in principle be capable of delivering a greater degree of coherence to the solution of the UK's infrastructure investment conundrum.

'Invest and sell' asset transfers

'Asset transfers' could address the immediate shortfall...

This is a demand-side proposal, designed to provide a public-expenditure-related stimulus at a time, such as the present, when there is significant excess capacity in the economy, the monetary policy stance is easy, yet the public finances are under duress and there is sensitivity about any such initiative that might frighten the markets or the rating agencies. It also offers up new opportunities for investment by the private sector in the latter stages of infrastructure projects, when the related cash flows are more stable and dependable.

The proposal is that the government should borrow an additional sum, say in the region of £15-30bn (some 1 to 2% of GDP) to directly finance investment expenditure in projects that stand to produce marketable output, with the stated intention of subsequently selling these assets, either partially or wholly, when times are better. Potential examples include railway lines; sea ports; airports; bridges; toll roads; perhaps even social housing. The expectation, based on evidence from abroad, such as France's network of high speed trains (TGV) such schemes would, in due course, induce the private sector to spend more.

... need not upset the markets or rating agencies ...

To deal with potential market and/or rating agency concern at near-term increases in public borrowing, it is suggested that the national accounts be re-presented such that they make clear the fundamental distinction between public debt that is backed by saleable assets, and general public debt that is not. This makes explicit the idea that not all debt is created equal; not all debt is quite the dead weight on the economy that it is sometimes presented as being.

This idea was suggested to the UK government by John Llewellyn and Gerry Holtham from 2009. It was rejected at the time, on a number of grounds: one was that there were few available, 'shovel-ready' projects; another was that, if there really were demand for such investments, the private sector would already be advancing them.

Given that it takes considerable time for a major infrastructure project to reach its high-expenditure phase, it is necessary that planning – including public enquiries, the design of contracts, land procurement, and so on – be undertaken well in advance. This would mean that one or more projects could, when necessary, be launched at relatively short notice, and even subsequently be switched on and off in accordance with the balance of aggregate supply and demand, both regionally and across the economy as a whole.

The Llewellyn/Holtham argument at the time was buttressed by the evidence, from many other economies, that recovery from financial crises was always likely to be shallow, so that there would still be time enough for this preparatory work to be done and for projects still to be worthwhile.

Furthermore, given the generally-low level of business and consumer confidence and the travails and conservatism of the banking sector, expecting the private sector to show much initiative in regard to infrastructure, or indeed any investment, was considered to be wishful thinking? Hence the public sector had to look to catalyse the recovery: and, if it did so, the private sector would be 'crowded in', rather than 'crowded out'.

Given that the cyclical upswing has indeed failed to gather much momentum over the intervening period, the persistence of historically-low interest rates because of QE, and that monetary policy remains to some extent hamstrung by balance sheet adjustments in the financial and non-financial private sectors, recent periods have seen government attitudes to fiscal stimulus, and in particular public-investment-related stimulus, ease somewhat. For example, the government has recently announced increases in its infrastructure spending plans amounting to about 0.2% of GDP per year for each of the next five years.

However, the fear remains in Whitehall that too much fiscal largesse might produce a negative reaction on long term interest rates or Sterling. Hence the logic for the original Llewellyn/Holtham proposal, and its ability to deliver a more substantive kick to the economy while addressing the issue of market nervousness. What is more, there is no reason why it should not be combined with some of the other potentially positive long term stimuli to infrastructure investment and the increased resort to private sector financing outlined above.

The Private Finance Initiative

The PFI method of infrastructure funding ran into the sand in the face of financing difficulties and, in particular, a shortage of bank lending, although there are tentative signs this is changing.⁹ After reaching a rate of some £8bn per year prior to the GFC, PFI investment has subsequently slowed sharply.

The vexed issue of bank financing is unlikely to disappear anytime soon unless a more adventurous approach is taken to banking sector recapitalisation and reform. The economic case for this is strong, but the potential cost to an already overburdened Treasury is clearly a major constraint.

Beyond fixing the banks, however, more could be done to reanimate the PFI, not least by recalibrating it away from service infrastructure towards investments in energy, broadband, and transportation.

Government has already responded to National Audit Office (NAO) evaluations of the sector, and has taken steps to address its shortcomings, not least through an active process of information exchange and consultation with the industry. Moreover, its December 2012 PFI2 initiative, whereby it is proposed to take a minority stakeholding in project firms and then siphon off some of the profits, goes some way towards the simplifying funding in the most risky phases of projects. This should make the financial instruments easier for non-bank capital to invest in. However, with the results so far disappointing, there is a case for pursuing this more forcefully.

Efforts have also been made to accelerate PFI delivery by setting a limit on the tendering phase for projects, and moving towards centralised departmental funding. The government has further sought to bring greater transparency and accountability to the PFI financing through the release of a project approval 'tracker', and the publication of private sector equity returns. All of these improvements warrant being sustained.

... and could be dovetailed with other initiatives

Reanimating the PFI would pay dividends...

... via a switch in focus...

... and greater efforts by government to shoulder equity risk

Perhaps the key consideration with the PFI, however, is the need for Government to be willing to shoulder more equity risk in the early phase of a project's lifespan. The UK Guarantees scheme was announced in July 2012 with a view to providing backing for around £40bn of infrastructure projects that have struggled to access private finance because of adverse credit conditions. However, thus far the tangible results have been few, with just two contracts signed.¹⁰ Industry players consider that this initiative needs to go further in order to overcome market risk, with perhaps less stringent conditions attached to the structure of the guarantees, and a willingness to extend it to projects that are not entirely dependent on a guarantee.

Other potentially useful initiatives include additional co-lending, and a real effort to inject life into the embryonic Green Investment Bank.

Were PF2 ultimately to match the achievements of the original PFI, it would represent around £300bn of additional capital spending.

A National Investment Bank

A NIB would offer an all-bracing approach

By far the most comprehensive, as well as potentially controversial, option would be the creation of a National Investment Bank (NIB) or fund. This would in essence represent the creation of a single vehicle to address the majority of the government policy and other issues raised in previous sections.

A NIB is an idea with a long and impressive lineage, stretching back to the writings of John Maynard Keynes in the 1930s and '40s.¹¹ His concern at the time was of an extended period of underemployment, if not quasi-secular stagnation, when monetary policy was compromised and private sector (mainly household) spending was hamstrung by balance-sheet adjustments of one form or another.

Keynes' solution was a stable, long term, investment programme, both private and public in origin that would sustain aggregate demand and boost confidence.

Keynes' analysis and policy conclusions have echoes in the current environment of extended demand deficiency; structural shortage of infrastructure and investment spending more generally; and insufficient recognition of various market failures in the private capital markets, not least in the area of financing.

Moreover, a NIB could in principal be used to offset some of the short-termism of industry and politicians, encourage the rebalancing of the economy via a focus on competitiveness, help to foster green investment (perhaps by taking over the existing Green Investment Bank, created last year), help SMEs, and be an important mechanism to tap pension and insurance funding. What it would not do is swell the public sector deficit unsustainably.

It would provide guarantees and issue bonds...

A NIB would in essence operate in two ways, but it would not directly distribute public money:

- **First**, it would provide a partial or full guarantee to support the initial equity cost of project finance where the private sector is reluctant to invest, or a partial or full guarantee on the repayment of bonds issued directly by investment projects themselves. In this way it would assume some or all of the risks of projects, especially in their early stages, and reduce funding costs.
- **For the most part**, however, it would lend to finance investment projects and raise funds for lending from the capital markets by issuing 'national investment bonds' which could be expected to carry a modest premium over the interest rate on government securities. These would be attractive fixed income investment instruments for pension schemes, both large and small, and offer a set of benchmark interest rates for infrastructure.

... while providing a long-term vision for infrastructure

It is not without risks, not least of political capture

Its governance would have to be carefully configured

However, a NIB would also set out to deliver long-term policy stability, and ensure that the supply of credit would dovetail with the pipeline of projects. It would build confidence in individual projects, and it would act as a focal point for project preparation and management. It could help to develop financial (e.g. risk management) and other expertise pertinent to the sector; provide a repository of objective information and quality data; work closely with the PIP and PFI; and aim at simplifying planning procedures.

Naturally the establishment of a NIB, like any policy initiative, would not be without risks, and its interventionist ethos could prove politically concerning. There would clearly be a chance of its becoming merely an unwieldy and inefficient quango, at risk of being captured by narrow political interests, or indeed ending up crowding out private sector financing, if not cannibalising the entire market for infrastructure. Safeguards would have to be put in place.

A NIB would need to be operationally independent of government, perhaps in the manner of the Bank of England, yet have a strategic link to government set in published mandates in order to perform something of a countercyclical macro stabilisation policy role.

It would need a high credit rating, and therefore a quality loan portfolio, and be run on the basis of sound banking principles. This in turn means that the Chief Executive or other senior officials would need to be government-appointed, accountable to Parliament, and audited by the NAO.

There would need to be a conservative ratio of lending to funding, and no explicit government guarantee on loans. The NIB would also have to be prohibited from undertaking any form of current spending.

In short, the NIB's activities would need to be confined to the financing of investment in productive assets that generate a long term return. Its initial capital could be raised either by government bonds to be bought by the market or the Bank of England, or perhaps from the proceeds of sales of semi-nationalised financial institutions such as RBS or Lloyds. It could also usefully aim at making a small profit that could be used to accumulate reserves.

IX. The way ahead – three ideas

Box: The National Infrastructure Plan

The UK's infrastructure plan relies on private sector involvement, and lacks detail and credibility.

In an effort better to meet the nation's infrastructure requirements, and to encourage new private sector investment in infrastructure (not least from pension funds), the UK government has, since 2010, set out a National Infrastructure Plan (NIP), which it has updated annually as part of the regular budget process. The 2012 plan outlined a pipeline of 550 projects, worth some £310bn, an increase of £45bn on 2011, with energy and transport accounting for nearly 90% of that total. The intention is to deliver one third of the total amount over the 2015-20 Parliament.

Across the board, the private sector is assumed to finance some 60% of the total, although there is considerable variation across sectors, and little is said about how this is to be achieved, beyond reference to the potential offered by pension funds, sovereign wealth funds, and insurance companies. Energy, water, and communications investments are assumed to be almost entirely privately funded. For transport, waste, flood protection, and intellectual capital, however, the public sector is expected to be the overwhelmingly dominant source of funds.

Reactions to the NIP have been mixed. The Institute of Civil Engineers was broadly positive, commenting that it:

"... lays the foundations for a more structured approach to our infrastructure delivery"

by setting out what the UK needs, and praising the efforts to attract pension fund investment. Others have been more critical. The New Economics Foundation said it fell some way short of what was required, and described it as:

"... [a] cobbled together compendium of every scheme that the Treasury had on the stocks."

Professor Dieter Helm, the Oxford University economist and author of a 2009 Policy Exchange report on infrastructure, wrote in the Financial Times that, although the plan was in essence a good idea, it did not reveal much "system planning", and that it was in many ways merely akin to "a wish list of individual projects". Finally, Terry Morgan, the chairman of Crossrail has recently bemoaned the lack of "continuity" in UK infrastructure programmes, and contrasted the UK's "extremes of demand" with the much "smoother" profiles seen in Europe.

The overall conclusion appears to be that, while embracing a plan is something of a step forward, as currently configured it is more indicative than operational. There remains considerable uncertainty about the consistency and durability of the pipeline, and how the blueprint can become reality, given the current macro conjuncture and without major changes in the way that infrastructure investment is viewed and acted upon by government. Soundings of firms actively involved in the construction sector highlight these issues, and continue to bemoan the lack of "shovel-ready" projects. Indeed, such are the present day imponderables about UK infrastructure that construction skills are already in short supply, existing expertise is being denuded, and some specialist investment and engineering teams are apparently moving employees abroad:

"We will be demobilising our tunnelling capacity next year...It would be a crying shame if we weren't able to pass on what we have learnt". (Terry Morgan, CEO of Crossrail)

Clearly, the NIP could be improved and rendered more sympathetic to the attraction of private sector funding by moving from aspiration to greater certainty and a more acute focus on delivery. This requires, *inter alia*, detailed analysis of the barriers to infrastructure funding.

Investment in Social Housing:

How institutional investors are investing in local communities

PENSION INSURANCE
CORPORATION

About Pension Insurance Corporation

Pension Insurance Corporation ("PIC") provides tailored pension insurance buyouts and buy-ins to the trustees and sponsors of UK defined benefit pension funds. PIC brings safety and security to scheme members' benefits through innovative, bespoke insurance solutions, which include deferred premiums and the use of company assets as part payment.

At 30 June 2016, PIC had £18.4 billion in assets backing the pensions of more than 130,000 policyholders. These assets are primarily invested in investment grade corporate bonds, UK government debt and cash. However, as a specialist pension insurer with liabilities analogous to those of a defined benefit pension scheme, PIC also invests in other forms of secure, long-term cash flows.

To date we have invested more than £500 million in debt issued by Housing Associations through direct deals, backing affordable housing up and down the country. With asset growth of around £5 billion in the past 18 months, PIC is a growing business with the expertise, desire and capacity to partner with Housing Associations on future deals.

PIC is authorised by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and Prudential Regulation Authority (FRN 454345). For further information please visit www.pensioncorporation.com

Introduction

Housing Associations ("HAs") are independent, not for profit bodies that provide rented homes, some at sub-market rates, within a strong regulatory framework with implicit government support.

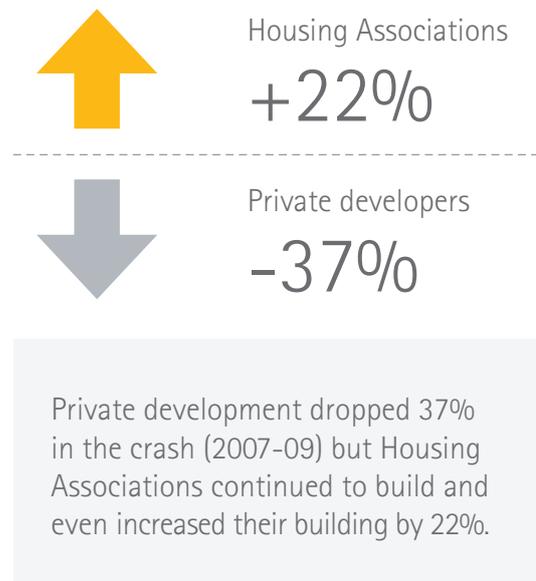

They can have a hugely positive role on the lives of residents and in the development of local communities, as well as the wider economy (see Figures 1 & 2). They can also be important partners for institutional investors, helping to support the pensions of millions of people around the country.

Figure 1.

Figure 2.

Source: National Housing Federation 'Housing Association Facts and figures'

In order to gather background and data for this document, PIC sent a survey to our HA partners in the summer of 2016. We asked them about their outlook for the sector, their pipeline of projects, as well as their views on planning processes. The responses we received were surprising in the extent and breadth of the activities they provide for residents beyond providing subsidised places of residence. We were also heartened by the levels of economic and social benefit they strive to bring to local communities. There are many examples of best practice in this area contained in this document.

From the responses we received, it's clear that all this doesn't happen by accident. At their very best, HAs really do design their projects around the needs of the community. This might include for example,

providing, at no cost, community buildings for use by charities involved in training, skills development, provision of childcare and bereavement counselling for local residents. It might also include the provision of leisure facilities such as allotments, urban farms or arts theatres.

The best HAs are developing crucial links to local businesses at the early stages of their development projects, helping to create local jobs and apprenticeships. Even once the development phase has finished, they are providing ongoing benefit to the local economy. Indeed, in 2015 one third of all houses developed in the UK were built by HAs, so they have a crucial role to play. One HA that responded to our survey provided opportunities for more than 50 residents to find employment in 2015. Others have specific measures for the overall success of their development projects in part on the jobs created and the businesses supported.

This document is, in part, designed to highlight the best practice we at PIC see in our work with HAs in order that this can be shared and developed more widely.

This document is also designed to highlight the perhaps surprising perspective of those who work in HAs about the importance of their relationships with long-term investors, especially as banks are no longer able to lend at the same pre-crisis levels. These organisations have been clear to us that without the long-term relationships and security of financing that can be offered by institutional investors, development plans would need to be cancelled or scaled back. This can have a significant impact on the local community. Links with the City and with institutional investors are therefore very important to HAs. These links feed directly into the wider social benefits that HAs bring to local communities.

What is clear from our conversations with the people who work for HAs is that they do not feel that story is well enough understood by important audiences, including politicians and indeed by their own residents.

Ultimately, this document is designed to provoke discussion and debate about this relationship and how institutional investors can best work with HAs, and vice-versa.

Partnering with institutional investors

From an investment perspective, HAs have become an increasingly important partner for institutional investors, such as pension funds and insurance companies. This is because institutional investors with long-term liabilities need to match their pension payments with secure long-term cash-flows. The long-term nature of HAs means that they are able to offer investment opportunities, in the form of high quality, secure debt, at rates attractive to these investors in a world of low returns.

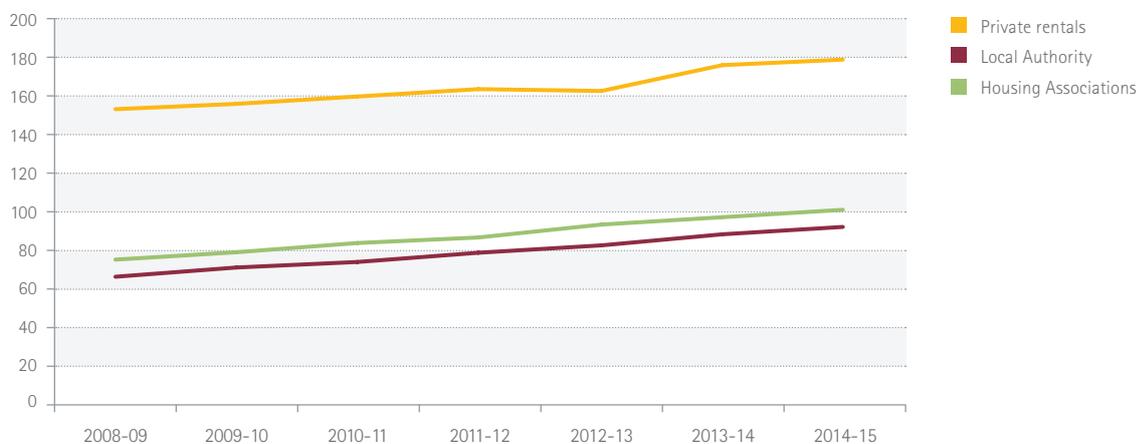

From the HA perspective, however, this is not a one way street: they need long-term relationships with stable lenders who are able to work with them to meet their funding needs with secure financing. This might include reducing the overall cost of borrowing, reducing the cost of carry and fully funding development aspirations.

There are certain steps that need to be considered on both sides if the relationship is to be a success.

Investors need to be clear why they are investing in HAs, and, as with other illiquid investments, need to put in time and effort to understand what they are investing in and the risks that are the counterpoint to the reward. Investors need to remember that just because a sector is regulated, there is no substitute for proper due diligence. To the contrary, regulations can be changed and, as we have seen over the past few years, this can change the investment case. For example, in his Summer Budget 2015, the then Chancellor, George Osborne MP, reversed a previously agreed policy of CPI plus 1% as the basis of rent increases for the subsequent decade. Instead, he announced that HA rents would decline on average by 12% over the four years to 2020-2021, forecast to benefit tenants by about £700 a year. Regulatory uncertainty has the potential to make some HAs appear a higher-risk investment.

Figure 4 shows how HA rent levels compare with other sectors, even in spite of the rent increases.

Figure 4: Rental incomes 2008-2015

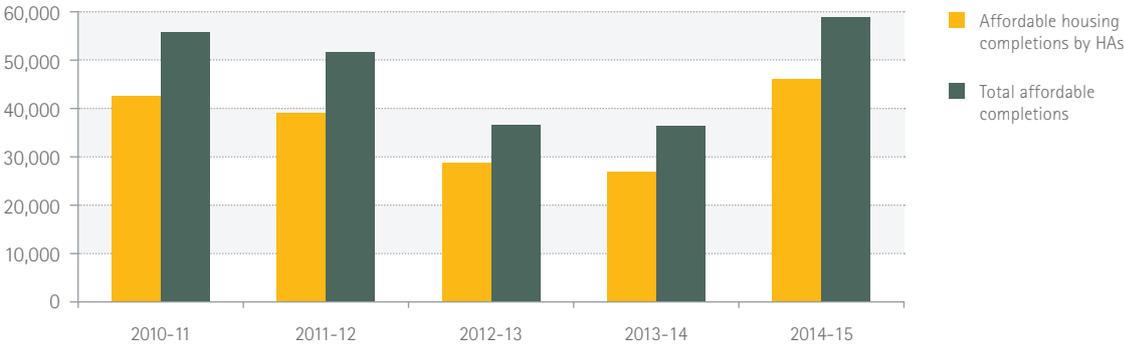

Source: DCLG English housing survey 2014 to 2015

Likewise, changes in the macro-economic environment can also impact, for better or for worse, the case for investing in HAs. For example, following the (Brexit) referendum result, the UK was downgraded by rating agencies. As HAs are supported by the overall UK rating for their own ratings, this means that they were also impacted. If a particular investor is only able to invest in debt with a certain rating, this could rule out investing in HAs.

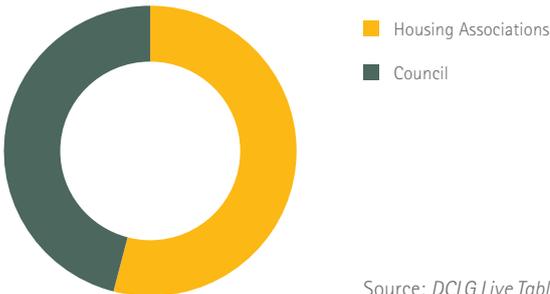

However, the fundamental investment case remains strong: the structural demand for housing (affordable or otherwise) in the UK. Indeed, in 2015 there were more than 1.2 million households on waiting lists for social housing in England, although this list is shorter than it might otherwise have been due to the effect of the Localism Act 2012. Ultimately, however, the sheer demand for housing helps to support the cash-flows generated by the underlying assets and HAs are a critical provider of housing in the UK (see Figures 5 & 6).

Case study – Pendleton Together

In 2013, PIC was the sole investor in £72 million of bonds backed by a project agreement with Salford City Council, to fund the New Pendleton Social Housing PFI project.

The funding is being used for the refurbishment of existing dwellings and associated infrastructure. The dwellings are a mix of high-rise blocks and low-rise terrace properties. The funds are being used by the project to refurbish about 1,250 existing dwellings in Salford, and to finance their maintenance over 30 years.

This project was delayed in the early days due to uncertainty of funding availability both of PFI credits and long-term bank financing, so having the funding from PIC in place at the start of the contract provided the certainty and security that the project needed. On the back of this, other private funding has been levered, allowing for significant additional investment, improving the local geographic area in terms of appearance, economic activity, health and wellbeing improvements and job creation schemes.

In choosing to work with any potential client/ borrower, the ability to build long-term relationships is critical to PIC.

Policy/ regulatory drivers

Institutional investors have to understand that the direction of policy and regulation can change quite suddenly, undercutting business models and affecting stakeholders in quite dramatic ways. A recent example of this is the Pension Freedoms introduced by the Government in 2015. This radically altered the way that savers were able to use their pension pot and completely removed the obligation to purchase an annuity, dramatically altering the business models of some insurance companies.

We have not seen anything this radical in the social housing sector. However, the general tone of government policy has been to encourage a shift from social housing renting to more home ownership. They have also been keen to encourage HAs to streamline their cost base and increase merger activity across the sector.

These changes, including the 1% rent reduction for the next four years on the majority of social housing units, present both challenges and opportunities for investors.

Perhaps the most important point is that fundamentally, the rent reduction and squeeze on benefit levels will put financial pressure on HAs. On the face of it this should make their debt less attractive to investors. However, this isn't necessarily the case as the sector responds in a variety of ways.

Those HAs with robust financials, good governance and sensible risk appetites should be able to successfully weather the changes, and indeed the sector is already showing signs of responding to the challenges. A strong case can be presented to potential financial partners by those HAs who can demonstrate they are well-prepared for the challenges ahead.

Others will be harder hit and the expectation is that we will see greater credit differentiation between HAs, as some will be better placed to respond to the changes than others. This may well lead to some HAs introducing more risk into their business model (e.g. through substantial development and sales exposure) to boost revenues. This means they will likely have to offer a higher yield on their debt. Whilst the increased yield versus government bonds on offer may be tempting to investors, especially in a world of negative sovereign bond yields, it is likely to be less attractive to institutional investors with a need to match assets and liabilities and strict regulatory frameworks with which they have to comply. Debt default is the greatest threat in this circumstance and whilst security structures can be negotiated (see section on *Working with prospective lenders*, pg.12), the balance of risk and reward will be carefully scrutinized on a case-by-case basis.

As a result of the policy changes, we would expect to see some further consolidation in the sector and an increased focus on higher levels of operational efficiency. Along with Right to Buy, which is generally considered credit positive as this may generate large cash windfalls for HAs, consolidation should be good for the sector as it will create larger, more stable HAs, and hopefully continue the trend of greater efficiencies being achieved by management across the sector.

Ultimately, whether consolidation happens or not, institutional investors will continue to work with HAs on their financing needs, despite the risk of further policy/ regulatory changes. They will try to manage some of this risk, however, by focusing on high quality credits which are well placed to withstand potential changes.

"Without doubt, these recent changes in policy have been factored into future strategies, risk appetites and financial appraisals. What is not in doubt is the demand for new homes. In view of this, ways will be found to procure new dwellings but the mix/ tenure might have to be altered to fit new political aims. When this is achieved, further debt funding will be needed."

Pendleton Together

Summary of policy/ regulatory change in the sector:

- 1% rent reduction for the next four years on the majority of social housing units
- Right to Buy – allows housing association tenants the right to buy their homes, albeit initial proposals have been watered down and it is now voluntary for HAs to sign up to this
- Pay to stay – requires higher income social housing tenants to pay increased levels of rent (HA participation is now voluntary)
- Benefit Cap – reduction in the benefit cap (the maximum amount of benefits that can be claimed) from £26k p.a. to £20k p.a. (£23k in London)
- Local Housing Allowance (LHA) caps – housing benefit will be capped for new entrants at the relevant LHA rate set for each area
- Deregulatory measures for the social housing regulator (the Homes and Communities Agency), to overturn the recent classification of HA debt on the government's balance sheet

Case study – Grŵp Gwalia Cyf

Grŵp Gwalia Cyf (now part of the Pobl Group) is a leading provider of social housing in south and mid Wales, managing over 10,000 high quality affordable homes and meeting the needs of a broad and diverse range of people in the community. Following a recent merger (with Seren), The Pobl Group has responsibility for 16,000 properties. Gwalia agreed a £35 million loan with PIC in 2012, through private placement, to invest in affordable and social housing projects across south Wales, building approximately 250 new homes.

For Gwalia, certainty of funding was critical at outset to allow them to put their plans in place. However, having certainty of funding was a risk management strategy to cushion them as far as possible from regulatory and policy changes. In particular, they were concerned about the risk of an extension of rent controls to Wales, following the 1% rent reduction seen in England, which does not currently apply in the Principality.

"When choosing a provider we are obviously focused on price. But of real importance is the ability to develop a long-term relationship with the funder, as well as their ability to be flexible in terms of structuring the finance package."

Gwalia

Working with prospective lenders

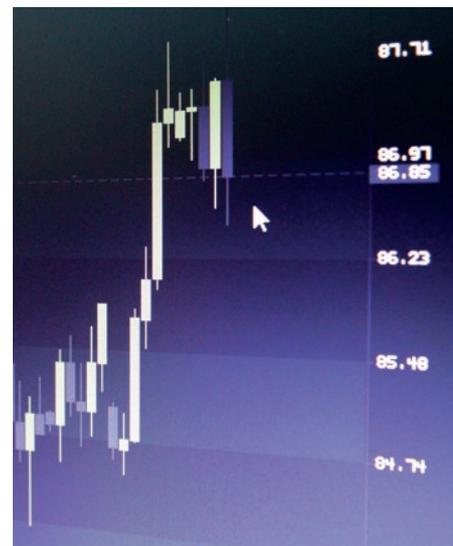

From a practical perspective, how should an HA work with a prospective lender to ensure that they complete the deal on the best possible terms for both parties?

HAs should ideally have the ability to:

- Be flexible in the types of debt structures that can be accommodated – the final structure should work well for both parties
- Secure the debt to social housing assets
- Accommodate inflation-linked structures as well as more traditional fixed rate debt
- Maintain a strong investment grade equivalent rating
- Offer flexibility on maturity of debt to allow lenders to better match their liability profiles

Preparation is also key to ensuring that HAs get the very best deal they can. In particular they should:

- Have a strong management presentation
- Offer transparency
- Have clear but flexible timescales
- Have a willingness to build a long-term relationship
- Be prepared to include prepayment protection for the lender

Likewise, what should an HA expect from a lender?

Lenders can often accommodate investing in a range of structures. For example, lending directly to HAs or funding social housing development and regeneration schemes through a PFI model. This will of course depend on the expertise and risk tolerance of the lender in question, but ideally there should be opportunity to at least explore both options.

In assessing the level of expertise that a lender has, and hence how beneficial the relationship might be, HAs should check whether the lender has the flexibility to apply their own internal rating. This is important from a borrower's perspective because it allows them to issue debt without having an external credit rating. This facility gives them flexibility around timelines for deal completion and indicates their level of sophistication and therefore the likelihood of them seeing the deal through to completion.

It is also worth seeing whether the lender can accommodate quite specific requirements, such as deferred draw down profiles. These offer flexibility to borrowers and provide certainty of funding whilst reducing the cost of carry. They are not, however, facilities which every lender will be able to accommodate.

When engaging on the direct side, lenders should be flexible on structure, to accommodate the needs of the HA. This might mean participating in public bonds, private placements, and loan structures. It should be noted that in most cases negotiation directly with an individual or club investor significantly reduces any potential execution risk from a transaction.

Institutional investors may also need the investment to be secured on social housing assets. This means that borrowers will be able to lend at a lower yield as there is ultimately less risk to the lender. For insurance companies this is particularly important.

Case study – mhs homes

In 2016, PIC invested £40 million in secured debt issued by mhs homes, a social housing provider based in Kent. Mhs homes are one of the largest independent landlords in Kent, owning and managing more than 8,500 homes in Medway, Maidstone and Dartford.

Key aspects of the transaction:

- £40m private placement, drawn in two stages over the next two years, giving mhs homes certainty of funding costs, whilst reducing the cost of carry
- Funding to help provide more than 400 new properties
- 34 year maturity (April 2050), to match PIC's liabilities
- Secured on social housing properties

"This funding will help provide over 400 new properties in the Medway and surrounding areas. The flexible arrangements agreed with PIC meet the requirements of our business plan and provides the long-term funding to match our aspirations."

Bruce Shelmerdine, Finance Director at mhs homes

Figure 7.

Building long-term relationships

Source: MHS Homes Data (2016)

Case study – Investment in Church of England's Housing Assistance for the Retired Ministry

In 2015, PIC invested £70 million in secured debt issued by CHARM Finance Plc, to fund retirement housing in the CHARM (Church's Housing Assistance for the Retired Ministry) scheme.

This scheme, provided by the Church of England Pensions Board ("CEPB"), offers subsidized retirement housing for clergy in the Church of England. The investment is linked to CPI and secured against a portfolio of residential assets. PIC was the sole investor.

For CHARM, the long-term certainty of funding allowed them to move from a rate reviewed three monthly on the rolling credit facility. They were also happy with the inflation linkage, which is a good match for inflation linked rents. The funds also allowed them to buy out the Church Commissioners' financial interest in properties that the Pensions Board considers to be long-term holds and means they will enjoy the rewards and risks of ownership.

Best practice highlighted by our partners

“ Ongoing estate management is contributing to lower anti-social behaviour, an increase in demand for dwellings. ”

“ The investment is resulting in new jobs and apprenticeships for local people. ”

“ New parks and allotments are bringing health and leisure benefits. ”

“ New jobs/apprenticeships in construction have been created but also in associated support areas such as catering and cleaning. Jobs have also been created in estate/management services. ”

“ When designing the overall project, the wider needs of the community are integral and the masterplan was subject to significant resident consultation. Input from local people help forge the long term plans. ”

“ Factors such as ease of access to services such as public transport, retail and healthcare are important. ”

“ Our environmental aims include energy efficiency as part of planned reinvestment. ”

“ 320 properties have been insulated over the past 2 years and 160 double-glazed windows and doors installed. ”

“ Aim to meet Decent Home Standards in newly acquired and re-let properties. ”

“ Our work plan over the next two years that link to our social and environmental activities will mainly fall into the following areas:

- To deliver great services
- To provide quality homes
- To help our customers achieve their potential
- To be financially fit and lean
- To have exceptional and diverse talent.

”

“ Our primary purpose is to alleviate the levels of homelessness and to provide a safe, affordable home to those most in need. Our added value activities often include personal support to help people with:

- Personal financial management
- Access to skills, training and employment
- Train people to engage with the digital world.

”

“ We are also corporate partners with Medway UTC (a new technical school for 14-19 year olds specialising in Engineering, Construction and Design) and for 2016/17 we will be hosting 20 students for work experience and working with Mid Kent College on an academy for apprentices for our own in house maintenance team.

”

“ For all our maintenance and development contracts we seek one apprentice for every £1m of contract value. These are local apprentices. We also have our own programme of work experience, apprentices and interns across different teams. For the year 2015/16 we provided opportunities for:

- 48 work experience placements
- 15 apprentices
- 56 residents into employment.

”

“ With any new homes development we research the likely demand, overall costs of construction vs the market value once completed. Certain locations are better suited to certain tenures (market rent/ and sale if e.g. close to commuter hubs, and older persons accommodation if close to shops and medical facilities). All refurbishment and new build opportunities are fully appraised before being proposed and approved to ensure that the business and our communities are well served.

”

West of England Response to the National Infrastructure Assessment: Call for Evidence

Rail

What is the proposed remedy?

For the background context see our response to 'What is the Issue?'

Our proposed remedy is as follows. A mechanism needs to be put in place by Network Rail and approved by the Office of Rail and Road, for sharing the costs and risks of third party rail schemes between the third party and Network Rail, on the following basis.

Joint Third Party/Network Rail Investment Mechanism (CP6)

Requirement	Details
Strategic & policy objectives	Schemes must demonstrate its contribution to rail industry strategic objectives and set out the strategic case for the scheme.
Value for money	Schemes must be WebTag compliant for their economic appraisal. The scheme economic case to be reviewed and approved by Network Rail.
Governance and Programme Control	Requirement for entry into the Joint Programme would be on the basis of completing GRIP2 and review and approval of the economic case at GRIP stages 3, 4 and 5.
Commercial and Contractual Model	The contractual model for the scheme to be determined on a scheme by scheme basis. The board options being: i) all GRIP stages procured via Network Rail through Development Services/Implementation Agreement, ii) all GRIP stages procured via external consultants and then validated by Network Rail, with construction and implementation delivered by a third party contractor iii) a hybrid of i) and ii) iv) A bespoke delivery mechanism, such as a special purpose vehicle.
Pre-construction phase	GRIP1 – 2 is funded 100% by the third party. GRIP3 & 4 is funded jointly by the third party and Network Rail, split 80% third party and 20% Network Rail. GRIP5 is funded jointly by the third party and Network Rail, split 67% third party and 33% Network Rail. All non GRIP costs ie, planning consent costs, land agent, highway design, etc are funded 100% by the third party.
Construction & implementation phase incl land acquisition, highway construction, environmental mitigation etc	GRIP6-8 and all other construction and implementation costs funded jointly by the third party and Network Rail, split 67% third party and 33% Network Rail.

Risks	<p>GRIP1 to 2 all risks are owned by the third party funder.</p> <p>GRIP3 & 4 risks are shared jointly by third party and Network Rail, split 80% third party and 20% Network Rail.</p> <p>GRIP5 risks are shared jointly by third party and Network Rail, split 67% third party and 33% Network Rail.</p> <p>GRIP6 to 8 all risks are owned by Network Rail. The GRIP5 cost estimate will fix the contribution of the third party to the construction and implementation of the scheme.</p>
-------	--

Worked example

Line re-opening scheme with a total delivery estimated cost of £100m (out-turn).

Cost Element	Total	Third Party contribution		Network Rail contribution	
	£m	£m	%	£m	%
GRIP 1-2 Feasibility including 7% Ind Fee & Risk Fund	£0.25	£0.25	100%	£0.00	0%
GRIP 3 & 4 Option Selection & Development including 7% Ind Fee & Risk Fund	£2.25	£1.80	80%	£0.45	20%
GRIP5 Detailed Design including 7% Ind Fee & Risk Fund	£4.50	£3.02	67%	£1.49	33%
Other pre-construction costs ie planning and other consents, land agent, highway design	£4.00	£4.00	100%	£0.00	0%
GRIP6-8 all Construction and Implementation costs including, land acquisition, highway construction, environmental mitigation etc including 7% Ind Fee & Risk Fund	£89.00	£59.63	67%	£29.37	33%
Totals	£100.00	£68.70	69%	£31.31	31%

The total contribution by the third party in this worked example is capped at £68.70m, based on the GRIP5 cost estimate.

The entry bar for the third parties would still be high as it would have to meeting all costs up to GRIP2 and most of the GRIP 3, GRIP4 & 5 costs. This would act to sift out highly 'aspirational' third party schemes, given the burden of cost to get to GRIP5 would remain very significant.

On the basis that the net contribution by Network Rail would broadly work out at around 30% depending on the scheme, an allocation by Network (via Control Period 6) of £300m would lever in third party investment of £700m, with a total investment in the network of £1bn.

Input to National Infrastructure Committee Call for Evidence, February 2017

To: NIAEvidence@nic.gsi.gov.uk

From the Linear Infrastructure Network – LINet

We would like to submit this response to the National Infrastructure Committee Call for Evidence on behalf of the Linear Infrastructure Network (LINet). This is an informal group of linear asset owning/managing sectors, with a shared aim to promote, embed and mainstream the use of green infrastructure (GI) as a tool for enhancing the resilience and reducing the whole life costs of national and local linear infrastructure assets.

Our input focuses on the strategic importance of green infrastructure being part of traditional or 'grey' infrastructure. Although this has relevance to question 11, 'How should infrastructure most effectively contribute to protecting and enhancing the natural environment, we see it is an over-arching strategic importance and a current gap, or missed opportunity in the approach and plan.

The value of increasing and incorporating green infrastructure is significant. We recommend that highest value should take into account the multiple benefits derived from incorporating well maintained and designed green infrastructure as an important part of infrastructure investment, such as quality of place, flood risk and air quality management, enhanced physical and mental health, energy and pollination.

The assessment and national infrastructure plan should promote the inclusion of green infrastructure such as trees and other planting, living roofs, walls and sustainable drainage such as swales and raingardens. This includes the incorporation of green infrastructure into new-build linear infrastructure assets, retrofitting it into existing linear infrastructure assets and its appropriate management and maintenance.

Green infrastructure is important in keeping the UK resilient to extreme weather by reducing rainfall run off rates and overall temperature. It contributes to tackling air quality, regenerative, resilient, green city. LINet members recognise the value of green infrastructure in enhancing the resilience of 'grey' infrastructure networks and improving reliability and reducing risk.

Benefits of including green infrastructure with linear infrastructure include

- storm and flood prevention by attenuating water flow
- bank stabilisation, as low water using vegetation stabilises soil
- perceived noise attenuation and visual barriers
- reduced leaf fall and tree and deer collision risk shading and cooling, which prevents track buckling

For evidence of demonstrating the above see:

<http://publications.naturalengland.org.uk/publication/5752930789490688>

<http://publications.naturalengland.org.uk/publication/6692039286587392>

http://www.plantlife.org.uk/publications/road_verge_management_guide

<http://www.susdrain.org/resources/ciria-guidance.html>

http://www.ciria.org/Research/Project_proposals2/Delivering_green_infrastructure_along_linear_assets.aspx?WebsiteKey=3f18c87a-d62b-4eca-8ef4-9b09309c1c91

The assessment and plan should promote the early inclusion of green infrastructure as when introduced early into the design they are often cheaper to install and maintain than traditional solutions. For example, installation of green roofs versus bitumen roofs and the associated (grey) positive drainage systems they need to cope with runoff, especially when valuing the other benefits they deliver such as drainage.

Many infrastructure companies, including LINet members, have adopted (such as Network Rail and Highways England) policies for securing 'net gain' from development (or are considering adopting this, such as Transport for London). Net gain projects deliver quantifiable and measurable benefits for biodiversity as well as providing a range of wider environmental enhancements, such as flood risk mitigation, enhanced air quality and opportunities for public engagement with the natural environment.

Examples of the role of infrastructure in delivering net positivity for biodiversity can be found here:

<http://www.wsp-pb.com/Global/UK/WSPPB%20Biodiversity%20whitepaper.pdf>
http://bbop.forest-trends.org/documents/files/network_rail_webinar_presentation.pdf

If the national Plan were to build on the pioneering work of LINet members by advocating the adoption of 'net gain' outcomes as business as usual across all infrastructure projects would secure significant environmental benefits.

It is important that the UK embraces this proactively and with a cross-sectoral engagement.

LINet would be very happy to give a presentation or further detail to the Commission if this would be helpful.

Yours sincerely

[name redacted]

[position redacted]

Maximising linear infrastructure resilience, environmental performance and return on investment.

Incorporating **well designed, managed and maintained green infrastructure** into linear infrastructure can enhance **asset resilience**, increase **asset efficiency and performance** and deliver an **improved return on investment**.

Well managed green infrastructure as an integral part of the UK's linear assets is the exception not the rule, causing costly disruption and with significant lost value from missed opportunities.

Whole life costs must be considered in soft estate performance and management assessments to secure more resilient, efficient and cost effective hard infrastructure.

400,000km of public roads

+

16,000km of Network Rail route

+

15,000km of energy networks

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London
EC3M 8UD

Dear Sir/Madam

Re: National Infrastructure Assessment Call for Evidence

Liverpool John Lennon Airport (LJLA) welcomes the opportunity to contribute information as part of the National Infrastructure Assessment Call for Evidence.

LJLA handled over 4.8 million passengers in 2016 with flights to over 60 destinations in the UK and across Europe and has seen passenger throughput grow by almost 10 times since the mid 1990's, firmly establishing the Airport not only as a gateway for Merseyside but for the North West and North Wales and the wider Northern Powerhouse.

Economic importance of regional airports

At LJLA, over £130m has been invested at the airport in recent years helping to grow passenger numbers and this on-going investment in Airport facilities will allow LJLA to continue to provide an efficient operation and high levels of customer service.

Successful regional airports bring clear economic and strategic benefits and a competitive advantage for the regions that they serve, which should not be underestimated. For example, LJLA is one of Merseyside's major employers, attracting inward investment and bringing significant tourism benefits, helping to boost the region's economy. A study undertaken in 2016 by York Aviation showed that LJLA is a significant driver of prosperity in the Liverpool City Region, currently supporting an estimated £250 million per annum in GVA and supporting 6,000 jobs in the City Region. Across the Northern Powerhouse, the GVA impact of the Airport increases to £440m with 11,900 jobs supported.

The York Aviation report also highlighted the long term potential of the airport, with future GVA predicted to be over £1bn across the Northern Powerhouse, supporting almost 23,000 jobs. Key to achieving these figures is the growth in air connectivity coupled with an efficient and seamless journey to and from the airport via road and rail.

Importance of efficient Surface Access

In responding to the call for evidence, it is important to highlight the fundamental economic role that regional airports play for the catchment areas that they serve; and key to maximising this benefit is the importance of investing in quality road and rail infrastructure that enables seamless journeys to the airport and makes LJA yet more attractive to new routes, and drive upwards its economic contribution to the area.

Maximising improvements to surface access is important for both inbound and outbound travelers and this will increase the UK's competitiveness globally through the following:

- Increasing the airport's catchment area and providing choice and competition not only to the travelling public, but also to airlines looking to establish routes into the UK – with a direct benefit in the ability of inbound visitors to fly closer to their end destination in the UK
- Enhancing air connectivity is a key factor in attracting inward international investment to the UK. Improving connectivity to Regional Airports such as Liverpool will provide a step change in the economic benefits for these areas
- Improved surface access impacts directly the inbound visitor economy, making the journey between the airport and the visitor's destination as seamless as possible.
- Allowing the Airport to maximise the benefits of the entire airport site and the adjacent land. An important part of the Airport's long term plan will be the future development of land to the south of Airport which will allow the airport to grow and to attract a broader range of aviation activities to support the growing freight market, supporting business aviation, and attracting support services such as maintenance and aviation training facilities that enhance the attractiveness of LJA as an airline base.

The recent independent report commissioned by Transport for the North on international connectivity highlighted the importance of surface access to the region's airports, and specifically stated improvements in road and rail access to LJA through the Eastern Access Road to the Airport, and the provision of direct rail links.

Importantly, such improvements to surface access not only benefit an airport but can also help to improve access to surrounding areas unlocking wider economic opportunities.

The Eastern Access Road scheme to LJLA has the potential to do just this, delivering multiple economic benefits. However, a lack of sufficient public sector funding has meant that bid submissions to both the Department for Transport's Large Local Major Schemes Fund and the Liverpool City Region Combined Authority Single Investment Fund, to progress this scheme have been unsuccessful.

Increased public sector funding support at a local and national level is needed in order to promote the pipeline of projects that can unlock a number of potential economic opportunities that will support post-Brexit international trade, drive inward investment and maximise the potential of the Northern Powerhouse.

Liverpool John Lennon Airport shares the Government's vision to build an industrial strategy that addresses long-term challenges to the UK economy. The success of this strategy would rely on investment in infrastructure projects that help to deliver economic growth.

In responding to this call for evidence, we have set out our thoughts relating to the economic importance of regional airports such as Liverpool, and the need for investment in improving the surface access infrastructure in order to realise the significant economic and social potential of the Airport. We would welcome further discussion with the Commission on issues specific to Liverpool but also regional airports, and would be happy to discuss this in more detail.

Yours sincerely

National Infrastructure Assessment – Call for Evidence

10th February 2017

1. About the Local Government Association (LGA)

The Local Government Association (LGA) is the national voice of local government. We work with councils to support, promote and improve local government.

We are a politically-led, cross party organisation which works on behalf of councils to ensure local government has a strong, credible voice with national government. We aim to influence and set the political agenda on the issues that matter to councils so they are able to deliver local solutions to national problems.

2. Summary

The LGA supports the work of the NIC and welcomes the production of the NIA. We believe that the document should take a holistic view of the UK's infrastructure and examine what is needed, what needs to be maintained and where responsibility should lie for this.

Whilst we have contributed specific evidence across a number of sectors where councils have an interest our comments across all sectors are characterised by the need for greater devolution of decision making and funding and less nationalised decision making.

Councils are strongly placed to make local decisions on how infrastructure is best provided and maintained. There are also areas in our submission where we believe capacity constraints could be alleviated with more powers for local authorities. This would be cheaper and simpler than building extra capacity. We strongly urge the commission to examine areas where this could be the case and include them in their report to Government.

3. Cross Cutting

What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

These will vary around the country depending on local circumstances. For many they will be connectivity infrastructure – such as transport and ultra-fast broadband. For other areas, flood prevention infrastructure to protect businesses and the workforce or more natural assets to promote tourism will be most important. As well as new infrastructure, maintenance and better use of existing infrastructure will provide better tax-payer value.

How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Submission

Good and well-maintained infrastructure will allow businesses to interact at lower cost with each other and their markets. For example, more manufacturers depend on just-in-time delivery, meaning that free-flowing roads and lower congestion will help them to be more globally competitive.

With regards to UK roads, it is one big network made up of the local roads network, managed by local authorities, and the strategic roads network, managed by Highways England. It is important that investment in one part of the network does not have an adverse impact on the capacity of another part.

How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Government must view housing investment in the same way that local government does: as a fundamental part of infrastructure that adds to the asset base and expands the economy. Housing provides a safe investment with rapid returns for local economies with every additional £1 of investment in construction generating an extra £2.84 of economic output and 56p of tax revenues. Housing construction can be 'shovel ready' more rapidly than other forms of infrastructure investment, it adds to gross domestic product (GDP) more rapidly, and is less reliant on imported materials. The LGA's Housing Commission report¹ sets out more than 30 recommendations for how local and national government can work together to build more homes, and to build homes that meet the diverse needs of people, partners and places.

The Housing Commission's key recommendations include:

Sustainable models for financing infrastructure long term

- Taking opportunities for joining up and devolving infrastructure and growth funding linked to local objectives to deliver homes.
- Exploring routes for capturing greater proportions of land value uplifts resulting from planning permission in order to finance infrastructure for homes.
- Increasing the contribution of Community Infrastructure Levy (CIL) - for instance making it simpler for councils to establish and by enabling them to borrow against future receipts.

Investment in infrastructure is critical to supporting the ambition for increasing housing supply by building community support for new development, as well as ensuring sites are commercially viable and do not constrain existing facilities. An OECD report in 2015² reported that UK infrastructure has suffered from under-investment compared with competitor countries, since the 1980s. Councils have found that local communities were on balance more supportive of housing development when it is accompanied with associated investment in new infrastructure³.

Infrastructure funding is an increasingly important concern for councils seeking to build homes.

¹ [LGA Housing Commission final report \(December 2016\)](#)

² OECD, UK economic survey 2015: Improving Infrastructure, February 2015

³ LGA: New housing developments survey 2012

Councils are increasingly working collaboratively to consider how new infrastructure could best deliver housing, however this can be held up due to lack of investment. The establishment of a Housing Infrastructure Fund of £2.3 billion⁴ to deliver infrastructure that enables housing growth is a welcome acknowledgement of the role of infrastructure finance in unlocking housing growth. Councils will work with the Government on the detail of the scheme to ensure it delivers maximum homes, and helps build prosperous places.

Looking ahead, devolution offers an opportunity to increasingly devolve infrastructure spending to places in ways that can link to commitments to deliver housing growth. Government departments and agencies investing in infrastructure – including the Homes and Communities Agency – should be required to work with local authorities to consider how it might be best targeted to deliver housing.

Local and national government should also take opportunities to test and develop models for forward funding infrastructure by capturing greater proportions of land value increases resulting from planning permissions. There might be a range of ways in which land value capture can be enabled. For instance the Land Compensation Act could be amended in ways that enable councils to acquire land through compulsory purchase order (CPO) at close to existing use value for sites that have been designated for infrastructure, including housing through the local plan process. This would then enable borrowing against the future uplift in land values to fund the necessary infrastructure investment. The current legislation guarantees that the landowner is entitled to the uplift in land value even when planning permission has not been granted, but would likely be granted if a planning application was submitted.

There is also scope to simplify and expand the use of existing infrastructure financing tools. The Community Infrastructure Levy (CIL) is one tool available to councils to raise funds to help deliver infrastructure, and should play a greater role into the future. Councils should be enabled to borrow against future CIL receipts which would allow, for example, councils to forward fund a developers' contribution element of major infrastructure schemes. Regulations should also clarify that the permission to pass CIL receipts to another body also applies where this is to reimburse expenditure already incurred by that other body; for example, when they have acted as a forward funder, in cases where a developer is unable to fund the required investment at an early stage of a development.

Furthermore, the proposals for full local retention of business rates include the power for elected city-wide metro mayors to be able to add a 2p premium⁵ to business rates to pay for new infrastructure, provided they have the support of a majority of the business members of the local enterprise partnership (LEP). This power should be extended to all councils.

Viability negotiations that provide infrastructure and affordable housing

- Establish a clear, robust and transparent viability procedure to help manage down the escalation of land values and ensure the delivery of affordable housing and infrastructure communities need to back development.

⁴ Autumn Statement 2016

⁵ <https://www.gov.uk/government/news/chancellor-unveils-devolution-revolution>

The assessment of economic viability of development is an important planning consideration for assisting with the development of Local Plans and plan policies and when determining individual planning applications. Councils have raised concerns about the viability process.

Councils raised concerns that the plan-led system is being undermined by the use of viability arguments from developers to avoid the need to meet local plan policy requirements including the provision of affordable housing and providing infrastructure contributions. Uncertainty in the viability process impacts on the price that developers pay for land, which can in turn impact on viability negotiations around affordable housing and infrastructure contributions. The Government, councils and the development industry should therefore work together to establish an agreed approach to viability assessment that reduces the incentives for developers to pay over the odds for land, and so supports subsequent viability negotiations to deliver the objectives agreed with communities in the Local Plan.

What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Councils play an important role in managing demand for infrastructure. The country's roads are facing a projected rise in congestion of up to 85% by 2040 and the answer is not to simply build more roads but to manage existing capacity better and to also manage demand. This could mean more people shifting modes of travel – such as from private cars to buses, or for shorter car journeys to be made by cycling or on foot. Much more can be achieved by local authorities if they had the right levels of funding, funding certainty and comprehensive decision-making powers over all national funding for local transport.

What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Much more can be achieved by local authorities if they had the right levels of funding, funding certainty and comprehensive decision-making powers over all national funding for local transport. LGA commissioned independent research found that there 8 different sources of funding for local transport in 2016-17. Greater certainty of funding enables councils to plan ahead, placing them in a better position to lever in private sector and third party investments, coordinate investment with national infrastructure, gain through economies of scale, and invest in innovation.

How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Through better coordination and planning across different network providers, such as rail, strategic and local roads and by placing local authorities at the heart of infrastructure investment decisions. Memorandums of Understandings (MoUs) between Highways England and combined authorities are a step in the right direction.

"How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?"

As well as the balance of maintenance spend as opposed to spending on new

infrastructure spend the commission should also consider the balance of maintenance spend within existing systems. For example, in particular the LGA has highlighted the huge disparity between the resources available in this parliament for the strategic road network (£1.1m per mile) compared to the local road network (£27k per mile). In an interconnected system like our road network a failure to adequately maintain any part of the system can result in delays across the network.

"Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?"

The Government should commit to long term funding certainty for local authorities in order for them to commit to financing infrastructure projects. Currently many viable infrastructure projects are affected by a council's ability to commit revenue resources in order to bid for capital funds made available by government departments. Infrastructure projects can often need to bid to multiple funding streams from a variety of providers each with different funding criteria. This can add significant and unnecessary cost to infrastructure projects that councils often struggle to afford. We would prefer a system of funding certainty for major projects like those given to Highways England and Network Rail who are able to plan long-term projects in advance.

"What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?"

We are concerned that the current system of cost benefit analysis is not as useful a tool for decision makers as it could be. The Government acknowledges these difficulties in its guidance on WebTAG

"There are some impacts – such as noise, air quality, landscape, social and distributional impacts – where the transport model is unable to directly measure the impact."⁶

When it comes to transport infrastructure, we believe that it would be best if decisions were devolved to highways authorities as far as it is possible. Local authorities will have a better ability to plan strategic decisions around funding that are both cost effective and fit alongside wider policy goals.

4. Transport

"How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?"

It is difficult to anticipate changes in travel patterns. The Chartered Institute of Highways and Transportation looked at the impact of two assumptions for the impact of technology on transport through their report Uncertainty Ahead: Which way forward for transport? They examined how the future cost of energy and the future preference for accessibility might influence transport preferences. Their four scenarios look at how these variables could influence

⁶

⁶https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/427073/webtag-tag-overview.pdf

transport but more importantly how they could influence spatial planning and urban design.

Anticipated changes in these variables could have profound impacts on local councils who have to plan for long term changes in travel behaviour. For instance if more people chose to work remotely it could hasten the demise of traditional high streets with the need for local authorities to make drastic changes to spatial strategy.

There has been much speculation on what impact automated vehicles could have on travel patterns. It seems clear that their impact is difficult to fully predict however there is much work emerging on the questions that would arise from the large scale take up of autonomous vehicles.

According to research conducted by WSP Parsons Brickerhoff more than 50% of land used for parking could be released by a move away from private motoring towards on demand autonomous vehicles. Many suburban streets could release on street parking spaces for greater road capacity or urban realm improvements. Whilst many of the assumptions in their work are highly speculative this gives an indication of the amount of land that could be released by changes in travel patterns in particular away from individual car ownership and the huge changes this could mean for urban planning.

Currently the government have hypothecated Vehicle Excise Duty to pay for road investment. 'Mobility as a service' and autonomous vehicles have the potential to greatly reduce the amount of private motor vehicles. Although the impacts of the technology are unclear, it would seem likely that if this service was widely adopted fewer cars would be used but each car would be used far more. This would significantly reduce VED revenues that are levied on individual vehicles and do not account for the distance a vehicle is driven.

"What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?"

The highest value transport investments are often smaller projects with relatively low costs. However given the cost associated with bidding competitively for funding many small projects can go unfunded as the amount of bureaucracy associated with bidding for them can outweigh their benefits. More devolution of funding for councils to take their own decisions around prioritising smaller schemes as opposed to large national schemes whose cost benefit ratios are much smaller would offer better value-for-money for taxpayers.

Councils currently do not have the power to tackle urban congestion as effectively as they would like. There are a number of immediate measures that could be taken that would allow councils to decrease congestion delivering increased capacity on our infrastructure with no large financial investment. There simply needs to be willingness for central government to get on with giving councils the tools to do the job.

There is a clear case for greater powers to be given to local authorities to tackle urban congestion. We would like the following to be available for all local authorities who wish to make use of them:

- * Stronger powers to manage street works including lane rental
- * The discretion to introduce workplace parking levy
- * Full implementation of Part 6 of the Traffic Management Act 2004

We also believe that the funding streams available for tackling congestion and investing in infrastructure are too complex and involve too much bureaucracy. Currently funding is provided on a competitive basis by a number of different funders in a variety of different funding regimes, causing duplication and waste.

If we were to give councils these powers they could be set at levels that were self-funding meaning that we could better tackle congestion. They could also be targeted at peak times for congestion and have the effect of equalising traffic flow throughout the day. This would mean that existing infrastructure was used more efficiently boosting road capacity without having to resort to large scale capital expenditure.

"What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?"

Many of the observations above apply equally to urban/non-urban environments.

However it is worth considering the role local networks play in facilitating inter urban travel. The Rees Jeffery identified 3,800 miles of local authority-controlled roads providing essential connectivity by filling the gaps in the SRN. These roads account for almost the same amount of traffic as the SRN however their maintenance is delivered by local authorities who have to combine maintenance of these roads with the remaining 96% of the network. More flexibility in the money allocated for the strategic network, allowing it to be used on projects that could improve the SRN even if those projects are not on the SRN, could increase its flexibility and capacity.

"What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?"

Mobility as a service has the ability to make road usage more efficient and a number of areas, such as Transport for the West Midlands, are exploring the potential benefits. Identifying which transport option will be quickest and/or cheapest will incentivise more efficient use of existing transport systems and should release greater capacity out of existing networks.

It could also be used to create a demand management approach with providers potentially adjusting their prices in close to real time in order to encourage passengers to use spare capacity on one mode or route and divert them away from parts of the network that are overcrowded.

It could also increase overall network resilience with the ability for real time adjustments to be made to journeys.

All of these developments would suggest an approach that could lead to an increase in journeys without impacting journey times as more latent capacity is used and overall the network is used more efficiently. If mobility as a service can be effectively introduced and is genuinely multi modal it somewhat undermines the need for road pricing as road pricing is often suggested as means to reflect the impact that peak time car use has on the road network and local communities. To some extent mobility as a service can be considered a carrot compared to the stick of road pricing.

5. Digital Communications

What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

Fixed line connectivity

Over the long term it is widely accepted that only the extension of fibre networks, to the premises where possible, will provide future-proofed digital connectivity. Whilst ubiquitous FTTP coverage is some way off, in the short to medium term, it is important that investment and national policy aims to catalyse its spread, including to rural and remotely rural areas, where fibre backhaul can support hybrid solutions of fibre and wireless to premises too difficult to connect directly.

Encouragingly, the increase in “alt nets” in the market has given local authorities a wider choice when procuring solutions to extending provision to the hardest to reach residents. Solutions must continue to focus on creating a competitive, fair and transparent marketplace that continues to innovate in order to improve the availability of excellent connectivity to UK residents.

Mobile connectivity

Despite reported progress in the extension of national mobile connectivity, country-wide coverage figures have a tendency to mask the deep disparity between coverage in urban and rural areas.

Inevitably better coverage requires the expansion of mobile infrastructure, especially in rural areas. Owing to the sparsity of population and challenges with local topography, such areas are often unviable for suppliers. In these cases, national policy must encourage the sharing of infrastructure between suppliers to decrease cost and seriously consider solutions to how achieve ubiquitous landmass voice and data coverage.

Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

At present significant areas of the country are not serviced with adequate digital connectivity coverage. Public interventions have played their part correcting failures of the market. However, there is still a role for the commercial sector, obligated through regulation, to provide appropriate levels of coverage for residents in both urban and non-metropolitan settings.

Fixed line connectivity

Councils have played a significant role in the extension of digital connectivity to households through the Superfast Broadband Programme. Latest Government figures show that over 90 per cent of UK premises were covered by these speeds or faster with the programme passing over 4.1 million premises.

However, despite the progress of the Superfast Broadband Programme, there are still 1.4 million premises that currently cannot receive a download speed of 10Mbps with 70 per cent of them in rural areas. This increases to 2.6 million if you include those premises that cannot achieve upload speeds of 1Mbps. It is not yet clear the extent to which new roll-out of superfast broadband will provide the remaining sub-10Mbps premises with faster broadband. Inevitably, a portion will be covered by further commercial and publicly-funded roll-out but

some, particularly the most geographically isolated, will not. Ofcom estimates that even taking account of existing public intervention and future commercial roll out plans combined, 600,000 premises will not be able to access speeds of 10Mbps or higher by 2020.

The LGA has consistently made clear that the Universal Service Obligation (USO) will only tackle the country's digital divide by providing a minimum download speed, rising in line with national averages, and guaranteeing a consistent performance of other elements which make for a good quality internet connection, such as upload speed.⁷

As a minimum, the LGA has made clear its support for a highly specified USO which would obligate suppliers to provide the consistent performance of a range of indicators that make for a good connection.

Ofcom has revealed that only BT (and KCOM in the City of Hull), have so far expressed interest in the delivering the USO. This is potentially concerning as a national programme, delivered by a single provider, will not benefit from competitive tenders or be able to provide bespoke technological solutions to local topography and sparsity of premises issues. Ideally, a range of providers would supply connections under the USO. However, if smaller providers show little interest, this preference may prove unviable.

Mobile connectivity

Following councils' deep involvement in the provision of superfast broadband, many are exploring the role they can play in catalysing improvements in local mobile provision. To date, whilst some councils have developed and maintain their own strategic relationships with MNOs, the majority of interactions are via council planning departments regarding the placement of mobile infrastructure.⁸ Such interactions are likely to decrease following Government plans to extend permitted development rights for taller mobile phone masts of up to 50ft to be built or upgraded without planning permission. MNOs need to work with councils and communities rather than bypass them in order to identify and address coverage blackspots together. There is also further work to be done ensuring councils across the country are better placed to have more strategic level conversations with MNOs to fully understand their roll out plans and, where appropriate, help the extension of provision through the use of public infrastructure.

Finally, Ofcom must utilise all the levers at its disposal to encourage mobile operators to provide ubiquitous coverage that equates to improved user experience

6. Flood risk management

What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

⁷ [LGA submission to Ofcom's Call for inputs on the design of the broadband Universal Service Obligation, June 2016](#)

⁸ In an LGA survey conducted last year, less than 50 per cent of councils surveyed had relationships with MNOs, locally. Of the 40 per cent that did not, 75 per cent were keen to develop.

Around 5.4 million properties (about one in six) in England and Wales are at risk from flooding from one or more water sources (rivers, seas and surface water)⁹. Flooding in 2013/14 cost the economy up to £1.5 billion¹⁰ and initial estimates suggests that the economic impact of the December 2015 floods will exceed £5 billion¹¹.

In addition, whilst there are many uncertainties in climate predictions, the Intergovernmental Panel on Climate Change found in its most recent report¹² that over the 21st Century it is very likely that extreme precipitation events will become more intense and frequent in many regions.

On that basis the Government should assess the impact of the current partnership funding approach to flood defences across the country, and specifically how this has impacted on the resilience of communities and businesses to recent extreme weather and future flood events.

What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Capital investment, and subsequent revenue funding, should be devolved to councils working in partnership with Local Enterprise Partnerships to decide on the best direction for this vital programme of investment. This could be trialled through the devolution deal process. The Department for Environment, Food and Rural Affairs (DEFRA) should work with the LGA, councils and other central government departments to develop this.

Councils are ready to take more control of the work that prevents flooding or mitigates damage at a local level, working with local partners, including the Environment Agency. This would enable them to work to make sure future disasters are prevented. Devolution bids calling for additional powers over funding for flood risk management include:

- Cornwall: The agreed deal includes proposals to join together funding for flood defences from a range of partners to provide a joint investment programme to improve coastal defences.
- Greater Lincolnshire: The agreed deal proposes reprioritisation of capital water management investment, to better utilise current levels of national funding, maximise local benefit and attract increased investment. In addition, it proposes developing opportunities to take on more local responsibility for delivering projects in the investment programme, where this would generate efficiencies and private and commercial contributions. Bid offers to use delegated powers and funding to deliver a 30 per cent efficiency in developing projects currently subject to DEFRA's funding controls and approval processes.

⁹https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/381939/F_CRM_Long_term_investment_scenarios.pdf

¹⁰ [The costs and impacts of the winter 2013 to 2014 floods](#)

¹¹ <https://home.kpmg.com/uk/en/home/media/press-releases/2015/12/flooding-economic-impact-will-breach-5bn.html>

¹² IPCC United Nations Intergovernmental Panel on Climate Change 2014 Climate Change 2014 Synthesis Report Summary for policy makers

Proposals to enable affordable, accessible insurance for high flood risk households through Flood Re¹³ are welcome. However, we would also like to see the Government introduce a mechanism to ensure a proportion of the levy (for example any surplus levy at the end of each year) is reinvested on prevention in future flooding.

The Government gave the Somerset Rivers Authority the power to raise a Shadow Precept from April 2016 which will enable the Authority to raise additional funding for flood risk. We would like the Government to allow other areas to use a similar mechanism where there is local agreement to do so.

We would like to see availability of additional resources for catchment wide projects that, for example, could investigate the effects of holding water upstream, catchment sensitive farming techniques and flow diversions, and how this could help mitigate flooding downstream.

7. Solid Waste

Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Councils have indicated that there isn't a clear enough long term strategic commitment from the government to treatment capacity. They therefore find themselves developing localised solutions which don't really benefit from any national plan. For any council the commitment to developing their own treatment capacity is one which is a major financial undertaking which can take years to deliver. Derbyshire County Council developed its own in-vessel composting (IVC) plant which took 10 years to build and millions were spent on the planning process. By the time it was completed the then government announced its backing for the development of anaerobic digestion plants, which meant Derbyshire had invested in technology the government would be moving away from in the future.

In order for the recycling market to grow and be able to process increased tonnages of recyclate, new facilities need to be planned and financed on the basis of a commercial proposition and one that delivers value for the taxpayer. It was on this basis that the Treasury announced Waste Infrastructure Credits back in 2009. Subsequently, DEFRA projections indicated that there would be sufficient residual waste treatment capacity online by 2020 to enable the UK to meet its EU landfill targets. This was the basis for the Government then withdrawing the Waste Infrastructure Credits (formerly PFI credits) from the final three projects it had committed to.

The decision to withdraw this subsidy, which appeared to increase costs, may in the future be seen as having enabled the market to develop infrastructure on a commercial basis creating a more sustainable industry. For the time being the change has left big waste infrastructure, including energy from waste plants, in planning and funding limbo which will see either a hiatus or an end to the delivery of these types of large residual waste treatment facilities beyond those in the pipeline.

English local authorities will continue to drive improvement in collection of waste and recycling, not least because English householders so value the service they

¹³ <http://www.floodre.co.uk/>

receive, on which they report consistently high satisfaction levels. This will continue to involve further evolution of service that reduces landfill and collects more material for reuse and recycling as efficiently as possible. However, increased levels of ambition in recycling performance will become progressively more expensive to achieve above the existing target level, and will be increasingly difficult for tax payers to bear.

There are also practical limitations on what can be realistically achieved. English local authorities have committed many hundreds of millions of pounds to underpin the delivery of waste treatment infrastructure to radically reduce landfill by 2020. This treatment capacity will process a volume of waste that will make meeting a suggested 70 per cent recycling target unachievable.

Local authorities paid approximately £570 million in landfill tax to the Treasury in 2013/14, which will rise to over £600 million in 2015/16, despite reducing landfill by over three quarters per household in a decade. These receipts could provide investment capital that would contribute towards increased recycling levels and help councils to deliver infrastructure that would not otherwise be affordable. This could include the costs of new receptacles, collection vehicles, sorting facilities, reuse storage capacity and organic treatment facilities.

To achieve this we suggest a return to the original principles of redistribution of landfill tax via the Revenue Support Grant. This would allow councils to decide locally how to invest in infrastructure that could be delivered quickly to improve recycling performance by 2020.

Councils in England have doubled their spend on waste and recycling services since 2000 to £3.28 billion. This makes collection and disposal of waste and recycling the third highest cost service for English local authorities. Our estimates show that current spending on waste by English authorities would need to increase significantly to include additional collection services (in particular organic waste) just to meet the existing 50 per cent target. This will be unachievable since councils are under extreme pressures to reduce spending in response to a 40 per cent reduction in government grant to English local authorities since 2010, a level of reduction that is projected to be repeated over the next parliamentary period to 2020.

What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

A circular economy makes best use of waste and resources, which is a high priority for English local authorities as key delivery agents for municipal waste collection, reuse, recycling and disposal services. There are clear benefits from achieving a more circular economy, including greater competitiveness from increasing the value obtained from the existing resources in the economy. A more circular economy would also offer increased employment potential with estimates suggesting that it could help create more than 200,000 additional jobs in the UK by 2030. But this will only be achievable if there is a more equitable contribution by those at the top of the supply chain to supplement the current reliance on those collecting and disposing of material at tax payer expense once it enters the waste stream.

The UK raises the lowest level of contribution from producers amongst all EU member states at less than 20 Euro per tonne of material compared to 200 Euro in Austria and over 150 Euro in France and Spain. To further illustrate this the UK's limited packaging producer compliance scheme generated £111 million of compliance revenue in 2013, only £37 million of which went towards collection.

This compares to the £550 million cost to local authorities for collection and sorting of packaging material. There should be a minimum level of producer contribution based on the costs of collection and subsequent reuse, recycling or disposal of their products. The LGA would welcome further discussion of the implementation of extended producer responsibility schemes with government and industry representatives.

At present a large proportion of material that finds its way into the waste stream cannot be cost effectively reused or recycled. While innovative techniques continue to be developed to disassemble, refurbish, repair and recycle different products it can be challenging to create financially viable markets for secondary resources across all materials and product types. To drive demand for secondary materials and improve the financial viability of recycling collection the Government should consider further product and material specific requirements to use recycled content in product manufacture.

There also needs to be a self-sustaining market for secondary material streams. The current targets require the recycling of particular materials, but make no requirements for the use of recycled material in product manufacture. This gap means, as is currently seen across the EU, that secondary material reprocessors have to compete in a volatile market that is often undermined by lower cost virgin materials.

Compliance with the obligation to set up separate collection systems for paper, metal, plastic and glass is seen as an essential part of the circular economy. However, separate collections come with a direct cost and challenges around the market for secondary material streams. Currently some councils do have contracts where they separate out waste. However, these contracts have an additional cost within them for this service. Expecting all councils to be compliant with this requirement will have a direct financial impact for many councils.

Commission Secretariat
NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London EC3M 8UD

9th Feb 2017

1. Introduction and background to TAG

1.1 Thank you for the opportunity to submit evidence to the National Infrastructure Commission. As a background, we have submitted responses to Government and given evidence to the House of Commons Transport Select Committee (HOCTC) and other House of Commons Select Committees and indeed many other august bodies and inquiries on various Transport, Planning and other Infrastructure issues over many years. This includes giving evidence to the Institution of Civil Engineers on National Infrastructure about this time last year. We attach our statement to the ICE as Appendix 1 and some other supporting Appendices linked to our submission text below.

1.2 TAG as a professional/technical organisation represents a large number of local authorities in the country, these include those with highway and transport responsibilities such as Transport for London, most London boroughs, Metropolitan authorities, Unitary authorities, consultants providing highway and transport services for major local authorities and many of the districts and towns in two tier authorities. While 'second tier' authorities do not have direct responsibility for transport, they do have the major role in looking after significant towns trying to ensure adequate housing is provided and the sensible overall planning of them including providing a reasonable environment protecting them from flooding, through and with other authorities most other infrastructure to support the population and businesses and trying to ensure, through the Highways and Transport Authorities, that the transport system is fit for purpose.

1.3 TAG was first created as a joint officer body to coordinate across the various areas of Local Government and was formed by an amalgamation of the Associations of London Borough Engineers and Surveyors (ALBES), Metropolitan District Engineers (AMDE) and Chief Technical Officers (ACTO) of the districts in two tier areas. One of the major reasons for this combination was so that advice could come from one body. TAG still has a major role in advising the LGA and recent submissions from the LGA on transport issues usually reflect TAG advice.

1.4 Overall we represent over 100 different authorities and for the National Infrastructure Assessment we believe as a body we have much to offer as local authorities have over the years probably had more responsibility and experience than any other organisation in the provision of supporting infrastructure for society as a whole.

The Local Government Technical Advisers Group

1.5 We can confirm that we have consulted our key membership on the content of this submission and it represents the overall views but not necessarily the views of individual members or authorities

2. General and summary.

2.1 In our submission we predominantly consider transport related issues. Nevertheless, we hope that we can adequately address the key issues covering flood risk management and outline views on energy, water etc. For waste TAG does have a waste topic group but our strength in this area is mainly from Northern Ireland. Regarding transport, TAG has and continues to advocate that the Department for Transport (DfT) and Government should formulate a national transport strategy and ensure that decisions are taken on the basis of the best potential national outcome rather than isolated views in relation specific modes of transport or specific parts of the networks. TAG has also raised on a number of occasions concerns regarding the transport scheme appraisal process and the different approach taken on expenditure and value depending on whether such public expenditure could be considered as 'revenue' or 'capital'.

2.2 As mentioned we did submit evidence to the Institution of Civil Engineers and took part in subsequent discussions at Great George St. We do in general support the findings of the Institution in its report – 'National Needs Assessment – a vision for national infrastructure' - in particular we believe that housing and in addition schools, industry, government and local government premises etc. are all part of the National Infrastructure.

2.3 We agree that demand management is essential for much of the infrastructure and particularly national and urban roads. We are concerned that the ICE submission still seems to support adding significant capacity where demand exceeds supply. There is little factual evidence that such a strategy, certainly for the road network, will help our real economy, reduce congestion, help the environment, reduce pollution let alone reduce CO2.

2.4 According to the Eddington study (a link to the documents produced by Eddington can be found on <http://collections.europarchive.org/tna/20100408160254/http://www.dft.gov.uk/about/strategy/transportstrategy/eddingonstudy/>) 89% of congestion is in Urban areas. Unfortunately vast sums are being spent on the interurban network which will tend to exacerbate the problems in the larger urban areas with very little attention being paid to manage the interface. Without effective linking, this 'investment' by Central Government will not help our national competitiveness. It is of note that the House of Commons Transport Select Committee is presently having an Inquiry into Urban congestion. Written (see Appendix 2) and verbal evidence given by TAG on 9th January 2017 may be helpful for the National Infrastructure Commission's work.

2.5 Finally as part of the general issues in TAG's submission to the ICE we also stressed the need to rebalance the economy and reduce the pressure on the south east of England and the importance of ensuring we can (and can afford to) properly maintain our existing infrastructure before adding to the maintenance burden by adding more infrastructure.

3. Answers to the questions raised

3.1 While our overall views on National Infrastructure needs are explained briefly above and in more detail in Appendices 1 and 2 we have endeavoured to answer the Commission's specific questions below:

Cross-cutting issues:

Question 1 - *What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?*

TAG is a national organisation with strengths in different infrastructure needs for different areas. Nevertheless the best returns and most needed infrastructure investments are probably in order:

- rebalancing the economy to bring more employment (and hence people) to the north of England and regions (this should also reduce the need for some infrastructure for water power etc)
- affordable homes
- maintenance and energy conservation in homes constructed before about 1975
- proper maintenance and ensuring the best use of all existing infrastructure
- densification of our cities (including better use of surface car parking and single floor retail stores etc.)
- protection and resilience from hazards of nature (eg coastal or river flooding)
- managing traffic volumes in urban areas and strategic roads
- provision of sustainable transport systems – pedestrian and cycle facilities, comprehensive and affordable bus services and rapid transport systems for our major towns
- integration between strategic roads and urban areas by traffic limitation measures, park and ride, bus lanes etc.
- infrastructure provision specifically targeted at regeneration of our cities and towns to support economic development.
- infrastructure to ensure that waste and resources are appropriately treated and/or disposed of as close to their point of origin as possible. This is particularly pertinent going forward given the importance in the Industrial Strategy on resource efficiency, and the promise that could be realised through better management of resources to stimulate local economic development.

Following Brexit and noting our present severely adverse balance of payments, local infrastructure to serve farming and local industry will become much more important.

Question 2 *How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?*

As the Standing Advisory Committee on Trunk Road assessment (SACTRA) 1999 study showed, care needs to be taken to understand if better infrastructure can help or hinder an area or country's competitiveness. Bridport in the 1850s with a rail connection and Ramsgate this century with improved roads have shown that infrastructure access to ports doesn't necessarily help. In some cases transport may be too easy and cheap for domestic or international competitiveness – an example being potatoes grown in Kent going to Somerset to be packed in brown paper sacks! That said reducing costs for UK located industries should increase our competitiveness but, as we import far more than we export, improving connections to ports could logically reduce our competitiveness.

Helping final access to UK based businesses for staff and inbound and outbound goods should help. For where we have a concentration of exporting industries access to ports and airports would undoubtedly be helpful, this needs to/ could be by both road and rail but is likely to be more local than strategic in nature (e.g. access from Nissan in Sunderland to the port).

The Local Government Technical Advisers Group

We believe greater evidence is needed and probably local needs identified before an automatic assumption is made that port and airport accesses by any mode are desirable.

Agglomeration and sharing of skills should increase Britain's productivity and reduce business overhead. Agglomeration is likely to be best delivered in our big cities and by improving local public transport and improved pedestrian links and environment, or between cities by reduction in vehicle movement and improved electronic communication. However we need to ensure that in delivering agglomeration that the economy becomes increasingly diversified and not focussed on a single aspect.

Question 3 How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

As mentioned above we agree with ICE that housing is an essential and important part of infrastructure. With a rebalancing of the economy there should be less need for housing in south east England. Nevertheless wherever housing is provided a reasonably quiet unpolluted environment is needed with access to all normal facilities including social interactions with people in other housing nearby, by as short a journey as possible and by sustainable means of foot, bus, cycle or even poolcars/car clubs, car share and taxi. We do not believe significant further strategic infrastructure is required now or in the period up to 2050, so hopefully poor environments caused by strategic roads will not cause further damage to places people need to live and work.

Fundamentally, development needs to be properly planned and a more balanced approach needs to be adopted, whereby the government, developers and local planning authorities can be confident that where development takes place infrastructure provision will be adequate. The current approach is resulting in planning consents which are not implemented because of inadequate local infrastructure including provision of bus routes. Similarly, the current approach to housing provision which confuses the issues of ownership and supply is and will continue to be largely ineffective in addressing the shortages. History shows that significant supply can be provided, however housing authorities and associations need to be allowed and resourced to deliver new housing with appropriate infrastructure. Development should be targeted to existing urban areas in order not to exacerbate transport needs and other associated environmental impacts.

Another issue which is frequently overlooked is the necessity to ensure that appropriate waste collection and storage arrangements are in place to ensure that housing is pleasant and easily maintained. Too often, these issues are addressed after the fact. Many European countries ensure that development considers waste collection and storage from the outset so that appropriate, and minimally intrusive, systems are installed to service housing. In most instances, this pre-development stage also ensures that other environmental issues, such as carbon impact, can be mitigated from the outset. Rather than relying on labour and capital intensive approaches such as bins and/or boxes, several European cities and Countries now underground their waste services (for example, Hammarby – see www.envacgroup.com/.../HammarbySjostad_Brochure_ENG.pdf?...)

Question 4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this

www.lgtag.com

The Local Government Technical Advisers Group

could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

If any product or service becomes 'cheaper' to individuals there will be a tendency to use more of that product or service.

For us in TAG we have experienced increase in refuse volume after wheelie bins became commonplace and have noticed that recycling rates and tonnages in some quarters tend to increase if householders know they intend to recycle the items purchased (see <https://hbr.org/2016/10/the-behavioral-economics-of-recycling>). We are also aware when parking controls or congestion restraint are introduced in an area it will reduce terminating traffic and in the centre of big cities but it will result in some growth of 'through' traffic to fill the available space. It is therefore important that a significant part of the benefits, say from a traffic limitation scheme, is used to improve alternative modes such as pedestrians, cycles or buses or improve the general environment.

We are not experts in behaviour change as a result of energy or water conservation measures.

On flooding we do not think change in behaviour is a big issue but property values are likely to increase if areas become less likely to flooding.

For transport schemes we believe there is considerable scope for demand management. London and Nottingham, Oxford St exclusion of general traffic and successful travel plans at various companies and organisations demonstrate effective demand management works. However, as we have highlighted to government on several occasions, in most instances to be successful demand management strategies need to be supported with adequate revenue funding. Generally such revenue funding is not necessarily very large but in the current funding regime imposed on the public sector it is extremely problematic.

Question 5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

If a piece of infrastructure is genuinely redundant or being replaced with a real alternative then maintenance of the previous asset is not required, but any scheme costs for the new infrastructure should include full removal of the old infrastructure and restoring the land to the most appropriate state. Otherwise TAG considers the maintenance of existing assets should take priority over the provision of new infrastructure. Unfortunately new capital funding seems to take too much priority over maintenance (largely revenue spending) at government level.

Recent developments in waste management show that many of the PFI contracts arranged under previous administrations are increasingly under pressure due to the ongoing austerity squeeze being felt by local authorities (for example, GMWDA is seeking to renegotiate their multi-billion pound contract <http://www.letsrecycle.com/news/latest-news/greater-manchester-waste-contract-under-financial-pressure/>). These developments, at a national level, risk causing disruption to the provision and maintenance of appropriate waste treatment and disposal facilities in the UK at a time when alternatives are notably thin on the ground (see Q1 above).

Question 6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Local authorities have been required to seek best value in all construction services of maintenance and provision of new Infrastructure by competitive tendering; unfortunately we www.lgtag.com

The Local Government Technical Advisers Group

have not been able to ensure proper competition and best prices for relocation of statutory undertakers works (please see our submission to the ICE Appendix 1). Local authorities have also considerable recent experience in collaboration between authorities for construction services.

Government has widely promoted competition for funding and the Department of Transport has applied competition to both major scheme and maintenance funding. However, TAG has and remains highly critical of this approach. For maintenance there are both winners and losers; the losers invariably are left under-resourced and the winners often merely receive the funding they initially required. Additionally, there are costs associated with bidding, which can be of the order of £30,000 for a basic competition; so for example the recent DfT competition for sustainable transport funding of £64m attracted 62 bids with a likely cost in excess of £1.8m in total; the sums awarded varied from £680,000 to £7.5m and 37 bids were unsuccessful receiving no funding. This is clearly not an efficient use of scarce revenue resources for public bodies. We fully support the devolution of decision making regarding major transport investment to the regions and wish to see this extended and that the regions are adequately funded.

We do not consider that competition per se has delivered significant benefits to users in the delivery of transport services. We have welcomed the Government's Bus Services Bill, although see no logic in restricting the powers to areas with an elected Mayor. This Bill will allow bus services to be subject to better control where needed, whilst allowing those areas where competition and collaboration are working to remain unaltered. Indeed we believe that the prospect of direct intervention alone may be sufficient to encourage better joint working, overcoming shortfalls in what is a poor regulatory system. We have grave concerns regarding the potential expansion of competition in the operation of rail services as suggested by the Competition Commission fearing that this will ultimately lead to "operator centric" service delivery rather than passenger centric and fail to deliver strategic benefits of a national rail network.

Specifically relating to waste, there are pressures brought to bear in maintaining collaborative working in long-term partnerships arising from planning decisions, delays and changes in the political make-up of local authorities. These are increasingly acute when overlain with the length of time taken to secure appropriate facilities due to, for example, changes in technology, bidding partnership, procurement challenge or dynamic waste streams (a decade is not uncommon). Going forward, it is increasingly apparent that new approaches will be needed to both pay for and deliver waste and resources management in the UK (several reports indicate that policies such as extended producer responsibility will need to be refreshed to provide a greater proportion of the capital and revenue necessary to fund waste and resource management infrastructure, see <https://www.ciwm.co.uk/ciwm/news/2016/ciwm-presidential-report-explores-different-eu-approaches-to-packaging-waste.aspx>).

Many local authorities are working together and collaborating in the delivery of services, however there will clearly be limits to extent to which this will be appropriate, whether it be for reasons of geography or for that matter political differences.

Question 7 What changes in funding policy could improve the efficiency with which infrastructure services are delivered? Note: by "funding", the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

It has been generally accepted that there has been a need for at least 50 years to encourage sustainable transport use over excessive car use. In order to encourage such behaviour we have to work on:

The Local Government Technical Advisers Group

- achieving a culture change,
- providing benefits for those who do change and
- ensuring policies are joined up.

Parking or road user charges, where any net revenue is diverted to improving sustainable transport, obviously provides 'a doubling up' of incentives.

It is notable that an extra driver on the road network does not pay for the extra congestion 'he' causes other road users, let alone the environmental damage 'he' causes. The situation with air travel is not dissimilar. This situation probably also applies to over consumption of energy, water etc.

We mentioned above our support for the devolution of infrastructure decisions and for transport we believe this should extend to all modes of travel and that the regions should be adequately resourced. However, the key issue remains that of revenue funding and in our recent submission to the House of Commons Transport Committee we highlighted how inadequate revenue funding is contributing to increasing road traffic congestion. These restrictions on revenue are also adversely affecting the maintenance of transport infrastructure and particularly highway assets. Generally we have reservations regarding the hypothecation of taxes; however the current arrangements for the distribution of revenue funding to local authorities can only result in the problems being exacerbated.

In terms of waste, policy measures such as extended producer responsibility (see Q6) provide a mechanism whereby waste and resources management costs can be better aligned with producers. This would have the added benefit of affecting the design and products and could be a useful contributor to the development of resource efficiency and the Circular Economy in the UK.

Question 8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets? Note: projects that "can be funded" but "will not be financed" refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

TAG members are generally construction, property or planning professionals in Local Government and we have limited knowledge of all funding and banking mechanisms. We are however very sceptical that there are well functioning markets that properly respond to supply and demand in transport generally and particularly in road transport, the internet, water supply, waste or indeed flood protection.

In order for us to proceed with a project we usually have to go through a complex and costly bidding process for moneys or approval from Central Government. The rules and incentives (please also see our comments on question 12 on cost benefit analysis) set down by government often mean we bid for schemes that we in local government believe are far from the best schemes for our individual areas, but often we consider that something for our individual area is better than nothing.

The process means that we often can't afford to bid for the most desirable schemes for our areas. The failure so far to fund a proper rapid transit system for Leeds is a very pertinent example as described in Appendix 2. We are aware that the government has recently also favoured 'shovel ready schemes' rather than a scheme to try and solve a current problem - we consider that this has further increased the number of less desirable schemes for an area.

More delegation of funding to local areas rather than funding at National level would probably increase the likelihood that worthwhile schemes would be built and our infrastructure be

The Local Government Technical Advisers Group

properly maintained. However it is also recognised that very large scale projects will likely require financial support at a national level.

Question 9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors? Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

As stated above we believe a priority for government is to rebalance the economy between north and south this would substantially increase the resilience of the housing infrastructure market and reduce the demand to move quantities of water, electricity etc. around the country. We also believe that it is essential to rebalance the economy in terms of its' component sectors and that this is interrelated to geographical rebalancing.

Resilience in Transport within the system can best be fostered by using finer networks with less reliance on high capacity strategic roads. Additionally, the extra costs associated with resilience need to be recognised as a benefit rather than elements which can omitted to reduce cost often erroneously labelled as "value engineering". Appendix 3 was a joint response with our County based colleagues ADEPT on a previous inquiry by government into resilience (please note that some compromises were made in this response, for example TAG, on the basis of past evidence (see link references in Appendix 1), do not believe significant large road building programmes would help meet most objectives for the UK)

Question 10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The Local Plan and Local Transport Plan process probably can properly identify housing and transport infrastructure requirements in individual areas especially if the administrative areas were given a greater level of freedom from central government to properly identify the issues and come up with the best local solutions. The process can also identify power, water, waste, flood and energy requirements. What is sadly lacking are national plans based on agreed evidence and objectives for Transport etc. We would stress the importance of doing the right things rather than necessarily speeding up the process.

We believe public involvement with proper information is a major contributor to identifying the right strategies – the Swiss referenda systems seem to work rather better.

It is notable that TAG has previously submitted views on the new 'inquiry' process and classification of schemes of 'National Importance' – please also see Appendix 2.

Question 11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Almost by definition all of us involved in the construction industry cannot be 'protecting and enhancing the natural environment' but we can help reduce the impact of the damage past infrastructure has done on the natural environment and minimise the impact future necessary infrastructure, to support life, does in future. (TAG does recognise the world may be a poorer place for us humans without some of our exceptional pieces of infrastructure.) Our basic themes of rebalancing the economy (including maximum use of brownfield sites), energy conservation, densification of our cities and sustainable transport investment and revenue spending are critical, as is good design, in maintaining and improving the overall environment.

The Local Government Technical Advisers Group

Infrastructure has a critical role to play in providing appropriate services and facilities for society today. A critical element in this is to ensure the principle of systems design from the outset to ensure that these services/facilities are not only fit-for-purpose but are also designed in such a manner as to add positively to the environment. This attitude may be counter to many previous developments which failed to adequately consider the full-life costs and long-term impact of the development, or how it could be maintained, repurposed or dismantled at the end of its life. This emphasis is crucial going forward as, in an increasingly resource-constrained world, more thought is needed at the preliminary/front-end to consider exactly what the value-added benefits are and how these can be maximised.

Question 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent? Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

TAG and many other professional organisations and individuals are very critical of the present system of Cost Benefit Analysis (CBA) when applied to Transport and particularly roads. Appendices 2.1 and 2.2 (as submitted to House of Commons Committees DfT etc) cover TAG’s position on this subject for Transport.

It needs to be remembered that the guiding principle of socio cost benefit analysis is the value society as a whole would ascribe to perceived or calculated benefits whether these are time savings to travellers, improvements to life expectancy from medical treatments, road safety, clean water, flooding etc. Some benefits ascribed to Transport schemes are not benefits that society would value - the best obvious example is the popularity of reducing speed limits to 20 mph in towns which on the basis of CBA calculations according to government advice would be likely to be negative.

The best summary description of TAG’s position on modelling and CBA can be found in a recent peer reviewed technical paper (see page 37-42 of <http://worldtransportjournal.com/wp-content/uploads/2016/02/9th-Feb-final-opt>.

where it is stated:-

‘---there is also substantial evidence that extra road space and higher speeds do not necessarily provide economic benefits. Reference can also be made to the 1999 SACTRA report on roads and the economy which included doubts that the economic benefits could be as high as the calculated time savings. We also know that the ‘economic benefits’ calculated largely on basis of predicted time savings are highly artificial --- in the following terms:

“ --- However linking models (which have been highly calibrated or ‘adjusted’ to try and match a base year situation) to predict behaviour change with an economic assessment introduces potential for a highly distorted view of the potential benefits to real travellers or the economy.

Within the ‘economic assessment process there are the following major issues: -

- The evaluation is largely based on the difference between two enormous sums of time spent on the network with and without a scheme; each of these sums is based on a large number of assumptions, the process is therefore mathematically very unsound.
- For major road schemes most of the ‘benefits’ appear for the peak traffic times (i.e. largely for car commuting – a mode and time that most highway and planning authorities do not want to encourage – it is noted that the very recent increase in the value of time for commuting is likely to further exacerbate this problem) and for the period 30-60 years in the future (where the assumptions taken are even less real).
- The impact of ‘generated’ traffic compared with the so called ‘natural traffic growth’ and its impact outside the proposed scheme is never adequately considered (seldom do the models predict the level of generated traffic caused by the new road fully;also

The Local Government Technical Advisers Group

the extra generated traffic causes minor extra widespread congestion and delays outside the immediate study area, this is usually modelled without the junctions and without other traffic that passes through that area but not through the study area – delays at junctions in urban areas increase very rapidly with small increases in traffic.”

We would wish to clarify that we do consider that modelling travel behaviour is an essential part in the development of most infrastructure but the cost benefit analysis presently carried out gives decision makers a totally flawed value of the likely benefits to society.

We believe greater delegation of funding and decision making to local or regional administrations, proper real information, public involvement, proper planning (see answer to question 10 above) and objective based assessment is likely to improve decision making on infrastructure enormously.

We should add that if the output benefit / cost ratios of schemes were to be taken at face value then road safety schemes, parking management and enforcement, travel planning, traffic signal maintenance, spare drivers for trains, bus lanes etc. would receive much greater funding and most national transport schemes would not pass the tests to obtain funding.

CBA does not align particularly well with Life-Cycle Analysis (LCA) which is better at capturing some of the environmental considerations of projects. CBA tries to ascribe a quantified economic “cost” to every item in the equation, which then limits how this is portrayed and valued. Albeit simplistic, in terms of waste there is a handy guide which can assist (see <http://cri.dk/files/dokumenter/artikler/filea951.pdf>).

Transport:

Question 13 How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

The DfT base most of their strategies on an immutable traffic growth largely assumed on past trends rather than where society may want to be. It is noted that despite large increases in population (and widening of the M25 and other motorways outside London potentially generating traffic increases) traffic levels have been reducing.

It is quite possible and deliverable that traffic reductions could be achieved in the next 30 years for every significant urban area if appropriate policies and strategies were followed. Reductions in traffic in urban areas would probably be reflected in reductions in traffic on the interurban networks.

If such strategies were put in place we would expect an increase in all sustainable travel modes, more needs to be met by providing better access to local shops, jobs, schools, hospitals, recreational facilities etc.; more demand for electronic communications, more home working, and at least a levelling off of air travel demand. Here we also recognise the need for good spatial planning and the appropriate co-location of land uses.

Local van or light goods traffic is presently increasing rapidly for servicing and from home delivery of internet organised goods. Costs of sending a van with very limited ‘payload’ need careful consideration and probably further research before all the appropriate strategies can be put in place for dealing with this issue.

The Local Government Technical Advisers Group

At present we believe it is too early to tell whether self driving vehicles will have any significant effect on the structural elements of road infrastructure provision but we are confident that we should not be relying on such technology alone to solve many of our transport problems.

Question 14. *What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas? Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.*

Our answer to question 1 covers this point best i.e. relatively small schemes improving communication by foot, public transport, bicycle and other means and in urban areas. Reducing traffic volumes and particularly car traffic in and around urban areas will help people travel by sustainable means more reliably and quickly and necessary freight to be able to move on the road network without the need for significant capacity increases. That is not to say that additional junctions and transfer points are needed between the Strategic Road network and local towns. Two examples in Kent are access points urgently needed between the M2 and east Sittingbourne and west Faversham. At a different scale Park and Ride where rail lines cross the M25 and a congestion charge inside the M25 could be very helpful.

We believe that continued electrification of the rail network is an essential element of transport investment which can both improve efficiency and simultaneously contribute to reducing the environmental impacts of travel, furthermore electrification needs to be simultaneously implemented on local and regional networks to ensure greatest efficiency particularly in terms of rolling stock utilisation.

Question 15. *What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area? Note: this includes travel in and between rural areas, as well as between urban areas and international travel.*

Unequivocally demand management to make better use of all existing investment - it is interesting to note that Eddington (see above) stated that road pricing/congestion charging was 'a no brainer'. Also as stated above demand management and better integration of policies between urban and national networks is likely to be very helpful. For freight transshipment from road to rail and sea/coastal freight is probably very helpful nationally and internationally. Loading gauges and the ability of rail to carry more freight needs further investigation. As mentioned above our international competitiveness also depends on final access and this includes links to farms in rural areas.

Nevertheless we also believe that the rail network continues to offer opportunities for further growth with targeted investment. Here the current methodology, largely based upon predict and provide, often understates opportunities for locations either not currently served or not well served.

Question 16. *What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?*

Mobility as a service, for example by taxis, is used by many people to complete journeys to final destinations. Londoners are probably furthest advanced with credit/debit card bus and tube 'tickets' being carried around in pockets and available for use at any time; the taxi, car club and Uber services are also readily available and all have probably been instrumental in reducing car traffic in London. However it is not necessarily the case as more 'empty'

The Local Government Technical Advisers Group

circulating vehicles are not helpful to the environment or traffic. It is probably desirable that no low occupancy vehicles, even if taxis, are given advantages over other vehicles.

We do not see mobility as a service being particularly relevant for the introduction of road user charging – political courage and support combined with an integrated holistic approach to transport and a need to replace present petroleum and vehicle taxation (with an alternative affecting electric vehicles), as the strongest drivers.

Digital communications:

TAG do not consider we are best to comment on the group of questions below except to say home working, conference conversations - instead of long distance national and international travel, management information on network conditions and services and personal advice on services by electronic means are all helpful.

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this? Note: the existing “regime” refers to the current market, competition and planning frameworks. “Digital communications” includes both fixed and mobile connectivity.

Energy:

Again TAG have only limited knowledge of this sector but we do make some observations as below.

Question 19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Rebalancing the economy between the north and south, densification of our cities, energy conservation/insulation, use of roofs for photovoltaic generation, better storage of energy, combined heat and power, microgeneration and more electric vehicles with more available charging facilities could all be beneficial

Question 20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

No comment from TAG

Question 21 What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

We understand that transport is responsible for about 25% of the CO₂ produced in the country and therefore a similar proportion of the energy. We do not believe that air travel can be electrified in the near future however small drones can stay airborne for up to about half an hour – unthinkable with electric motors and batteries 15 years ago; Electric cars now have quite respectable ranges and this is improving rapidly. The result would appear to indicate we will need a significant increase in generation capacity to provide for road transport.-please see our answer to question 19 for where this generation may come from.

Water and wastewater (drainage and sewerage):

Question 22. *What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute? Note: “demand” includes domestic, commercial, power generation and other major sources of demand.*

Question 23. *What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand? Note: this can include, but is not necessarily limited to, governance frameworks across the country.*

Alternatives to traditionally engineered sewerage solutions need to be investigated. These should include real time control, storm water retrofit techniques, education to enable communities to change behaviour, enhancing incentives for communities to reduce surface water flowing to sewers and innovative permitting arrangements across drainage networks and sewerage treatment works. Water and sewerage companies should continue to review and develop other innovative solutions.

For example, where a company may historically have preferred to tackle sewer flooding or combined sewer overflow pollution by increasing its underground drainage to store more rainfall during storms, it might consider other options in future – such as working with customers to manage the rainfall close to source, preventing it from entering the sewer.

Question 24. *How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?*

Flood risk management:

Question 25. *What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?*

Flood and coastal erosion is expected to increase due to climate change and development in areas at risk. It is not possible to prevent all flooding or coastal erosion, but there are actions that can be taken to manage these risks and reduce the impacts on communities.

There are a wide range of approaches available to manage flood and coastal risk. Risks should be managed in a co-ordinated way within catchments and along the coast and balance the needs of communities, the economy and the environment.

Risks of flooding and coastal erosion should be clearly understood, to enable investment in risk management to be prioritised.

Clear consistent risk management plans should be set out so communities and businesses can make informed decisions about the management of the remaining risk.

Emergency plans and responses to flood incidents should be effective and communities should be able to respond effectively to flood forecasts, warnings and advice.

Communities should also be able to recover quickly and effectively after incidents.

Question 26. *What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk? Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and*

The Local Government Technical Advisers Group

resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

Natural flood management (NFM) schemes can provide many benefits such as; reducing flood risk to smaller more prevalent events; multiple environmental benefits, such as improved soil and water quality by managing surface water runoff; schemes are relatively cheap to implement; maintenance can form part of land management practices. NFM schemes are limited by their ability to remain effective during major flood events.

Property level resistance and resilience measures have had a significant effect on allowing property owners the ability to take control of their own flood risk, allowing communities to recover more quickly and effectively after incidents. These measures should however be treated as the last line of defence as they do not address wider community and environmental issues.

Temporary defences can be an effective means in reducing flood risk with the ability to deploy at different locations when required. It is important to consider the amount of setup time and labour needed to prepare the defences in addition to factors like cost and protection. Depending on flood frequency and site conditions, it may be more cost effective in the long-term to install a permanent, in-situ flood barrier.

The above technologies or practices should not be considered as standalone options for reducing flood risk to communities, but instead should be considered alongside more 'traditional' management techniques in order to take a more holistic approach to the management of flood risk.

Solid waste:

Question 27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

The simple answer at this stage is “no”. Currently, local authorities are under considerable pressure to deliver ongoing improvements in terms of their waste collection arrangements, while also delivering improvements and better efficiency regarding waste and resources treatment and disposal. Pressures are coming to bear in terms of the supply chain (increased costs), increases in residual waste arisings, increasing emphasis on health & safety (rightly so) and dynamic waste streams (i.e. newspapers, which used to generate a revenue for local authorities is declining in correlation to the rise of social media). These developments have tended to mean that budgets are squeezed and “*more from less*” becomes the order of the day. This means that publicity and communications budgets have been amongst the first to suffer and has meant that engagement with residents has reduced.

In order to turn the curve and reduce the generation of residual waste, there needs to be a complete recast of the narrative around waste. Several of the answers above (see Q1, Q6) have highlighted that there is a risk of an infrastructural deficit arising in light of Brexit and a lack of funding to develop or maintain the existing facilities. Given the many millions of tonnes of waste generated in the UK each year, this needs to be addressed with urgency as already concerns about increases in waste crime are crystallising (see <http://www.endsreport.com/article/55331/concerns-over-post-eu-illegal-waste-trade-mount>) and without appropriate facilities and an increasing emphasis on the inherent value in the materials being discarded or recycled, the sector will underperform.

This will need specific Government policy to establish the direction of travel and provide certainty for investment and clarity as to expected outcomes.

Question 28. *What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be? Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.*

At present, a lack of clear Government policy and direction and confusion around the CE Package being discussed in Europe, confounded by the Brexit timetable, is hampering support for and investment in the Circular Economy. Much of industry is looking for certainty and simplicity in order to be able to develop appropriate business models (generally on a pan-European basis to streamline production and manufacture and minimise costs) and the UK is failing to provide that at a national level.

This is creating confusion and tension also between the regions where both Scotland and Wales have adopted more ambitious approaches and would seek to be world-leaders in this area. Despite many positive stories in UK manufacturing, the UK is missing out on what is increasingly being called the fourth industrial revolution and a global trade valued in the trillions (see <http://www.mckinsey.com/business-functions/sustainability-and-resource-productivity/our-insights/europes-circular-economy-opportunity>).

4. Concluding comments

4.1 TAG can only advise that in order to tackle the problems associated with existing infrastructure and deliver the required new infrastructure and services over the next 30 years the most appropriate authorities need to be adequately resourced, given, or allowed to use, adequate powers and that revenue funding is fundamental part in providing the right infrastructure. TAG is confident that within local authorities there is adequate understanding and expertise to adequately deal with appropriate planning of our towns and cities, transport, flooding and waste issues.

4.2 Please do not hesitate to contact me through Andy Morris the TAG Secretary or other TAG colleagues if you require further detail information or wish any further discussions on a face to face basis.

Yours sincerely,

The Local Government Technical Advisers Group Evidence to the

Institution of Civil Engineers

National Needs Assessment

1.0 Introduction

1.1 The Local Government Technical Advisers Group (TAG) is a professional association, incorporated in 1995, serving all levels of local government covering the whole range of technical services. Our membership includes authorities with highway and transport responsibilities, including Transport for London, London Boroughs, Metropolitan, Unitary and District Authorities and many with responsibilities for economic development and land use planning. Many of our individual members are Chartered Civil Engineers.

1.2 TAG is particularly active in the areas of transport, flood and coastal management and waste management.

2.0 Summary

2.1 TAG welcomes the opportunity to present its views to the Institution of Civil Engineers and broadly supports the vision and outcomes.

2.2 Regarding transport, TAG has and continues to advocate that the Department for Transport and Government should formulate a national transport strategy and ensure that decisions are taken on the basis of the best potential national outcome rather than isolated views in relation specific modes of transport or specific parts of the networks. TAG has also raised on a number of occasions concerns regarding the transport scheme appraisal process and the different approach taken on expenditure and value depending on whether such public expenditure could be considered as 'revenue' or 'capital'.

2.3 TAG considers that a key issue relating to any decision regarding capacity is the extent to which productivity is enhanced. We also suggest that rebalancing the economy and health impacts are major factors. Additionally, we believe greater clarity is required regarding the meaning of the term "national significance".

2.4 We acknowledge the comprehensive nature of your consultation, however competing demands upon local authority resources has limited our ability to respond to each individual issue and here we will predominantly consider transport related issues. Nevertheless, we hope that we can adequately address the key issues covering flood risk management and outline views on energy water etc. For waste TAG does have a waste topic group but our strength in this area is mainly from Northern Ireland. Relatively recently ICE Northern

Ireland did an infrastructure report to which our colleagues in waste in Northern Ireland contributed. Please see

<https://www.ice.org.uk/getattachment/media-and-policy/policy/state-of-the-nation-2014-northern-ireland/SoN-Infrastructure-2014-Northern-Ireland.pdf.aspx>

3.0 Call for Evidence Questions

3.1 Do you agree with our proposed vision and outcomes? What amendments would you propose?

3.1.2 Broadly yes and we particularly appreciate that any additional investment in infrastructure needs to be done, 'efficiently, affordably and sustainably' and improving 'services' are equally important and may avoid the need in many locations to provide new infrastructure. However we believe that there are two factors that should be added to the considerations: improving productivity and rebalancing of the economy.

3.1.3 Improving productivity is implicit; however it should be an explicit objective. TAG considers that, whereas improving capacity for transport can sometimes contribute to improved efficiency, the current road programme for Strategic Roads is flawed and the appraisal methodology applied to road investment often overstates the benefits. Just over a year ago TAG submitted a document and five appendices to the House of Commons Scrutiny Committee on the Infrastructure Bill – this submission might be particularly helpful in your deliberations - <http://www.lgtag.com/index.php/news/566-tag-evidence-to-hoc-scrutiny-committee-on-infrastructure-bill>

3.1.4 The construction of new or improvement of existing routes contributes to increased travel demand and consequentially the time saving efficiency gain measured in the appraisal process is eroded or fails to materialise. The recent reports regarding the widening of the M25 having resulted in significant increased levels of traffic again illustrates the point and consequentially anticipated time saving benefits will have been reduced on the route. Additionally, the consequential impact of the additional traffic contributes to area wide congestion and further increased delays on the wider network. There is significant evidence to support this view (please also see <http://worldtransportjournal.com/wp-content/uploads/2016/02/9th-Feb-final-opt.pdf> and the listed references).

3.1.5 This issue is exacerbated by the absence of a clear national strategy for transport investment. Consequentially decisions are made on the basis of single mode or sector investments whereas alternative or a combination of investments could deliver greater and better outcomes. Investment in measures that reduce the need for private vehicle travel should be prioritised and we caution against indiscriminate increases in road capacity.

3.1.6 Rebalancing of the economy or at least a contribution to rebalancing the economy should be an objective. Although decisions relating to infrastructure investment will not necessary in themselves rebalance the economy, it is an essential element of any strategy.

3.1.7 Currently the economy is dominated by the financial services (FS) sector, which is also highly concentrated in specific geographical areas, and mainly within the City of London. Invariably, investment decisions based on GDP will therefore favour those projects

that support the FS sector; this is not necessarily wrong. Additionally, the delivery cost of projects increases exponentially with the density of the location, albeit that such costs can be offset by the scale of potential benefits. Consequentially, where the scale of infrastructure investment, and particularly transport investment, has been historically highly constrained an increasing proportion of the national budget has been directed into one specific area and to the detriment of others. Accordingly, a more balanced approach is required if the necessary beneficial change to the economy, including making the British economy more resilient, is to be achieved.

3.1.8 TAG also considers that health impacts should be identified more specifically, rather than as, say, a potential subset of “wider environmental impacts”. Perhaps most prevalent at this time, associated with transport, is the issue of air pollution, which is directly related to traffic volume and therefore capacity and is a particular problem in or near urban areas. The health impact of noise is also increasingly being recognised and is an issue where transport capacity is to be considered. Decisions regarding investment in transport mode also have health implications; broadly, investment in private vehicle transport will have a negative health outcome whereas non-motorised and public transport investment will be broadly positive.

3.1.9 In any case we agree strongly that effective demand management strategies are essential, and if they are not to include road charging on a national scale in the short term, every effort needs to be given to other appropriate measures, such as:

- parking control, limiting available parking; changing the business rating system so that it reflects costs imposed by certain businesses that have many parking spaces and generate much traffic;
- workplace (and shopping) parking charges;
- congestion charging and
- other positive methods such as improving public transport and effective travel planning.

3.2 What will be the main drivers of demand for UK national economic infrastructure over the next 35 years that we should consider in our assessment?

3.2.1 In the transport field Britain and many other countries have spent a lot of effort in an often vain attempt to reduce congestion by adding to road capacity. Unless we educate some of the members of our Institution (ICE), the decision makers and advisers, the pursuit of congestion reduction by road building will unfortunately continue to be a driver. We consider health, pollution, climate change, access to jobs by disadvantaged members of society should be far more significant drivers for capital and revenue investment in Transport.

3.2.2 Security will remain a key issue and the implications for the transport sector will be a major consideration particularly for mass transport systems and international travel. The resulting challenge will relate to the deployment of technologies and adapting our infrastructure to accommodate new and emerging technologies.

3.2.3 Climate change and weather extremes will continue to be a driver together with the need to protect society against severe weather events and the need to cater for an expanded population. Indeed rising ground water levels and tides are also key issues relating to climate change that not only need infrastructure to try and handle but also put up the costs of infrastructure.

3.2.4 This winter has again brought home the need for expanded investment in coastal and river protection, but, like transport investment, proper maintenance and revenue expenditure is essential. However, the lessons relating to previous winters, when snowfall was the major concern, should not be forgotten.

3.2.5 Investment in energy conservation is likely to provide one of the best investments; this will help the UK reduce its contribution to global warming, minimise the need for extra power generation and reduce the need for more capacity in the power networks. However, there is also recognition that investment is essential for the replacement of our increasingly outdated energy generation and distribution systems

3.2.6 Rebalancing the economy and ensuring there is not a continuing southwards drift of population will help reduce the need for extra investment in national water provision or more power networks.

3.3 What will be the main constraints on the UK's ability to provide sufficient UK national economic infrastructure assets and services over the period and what solutions or mitigations of those constraints should the UK adopt?

3.3.1 The main constraints are:

- Political support and commitment, cross party, and the need to take decisions in the longer term and in the wider interests of the country
- Overall economic performance of the UK economy, including the long-term losses on balance of payments
- Public understanding of the issues
- Press and influencers on politicians for short term visible fixes
- Availability of revenue funding, and to a lesser extent capital, and the financial rules favouring certain types or arrangements of funding
- Skills shortages

3.3.2 It is agreed that the diversity of the nature of the potential constraints is such that detailed mitigation strategies need to be developed for each.

3.4 What nationally significant investments in capacity or changes in policy & regulation should we prioritise to deliver these outcomes and deal with these drivers of demand?

3.4.1 A clearer understanding of what constitutes “nationally significant” is required. Many investments required relating to capital or revenue are not of a scale of national significance,

although some are being labelled as such - for example adding extra capacity to Blackwall crossing of the Thames. This is clearly a London scheme and is of similar importance for transport users and delays/congestion as the diagonal pedestrian crossings at Oxford Circus (which is not labelled as a scheme of national importance). However, it is also accepted that local and regional scale projects can make contributions to national productivity.

3.4.2 We strongly believe that, for transport and the economy, the required investments are likely to be local – light rail and tram systems, bus services and priorities, more facilities for pedestrians etc. Nevertheless, where national and local interests coincide there is scope for capital and revenue investments in demand management, park and ride etc.

3.4.3 The situation is broadly similar for the necessary works on flood prevention, power networks etc.

3.5 In what areas can demand management or other forms of behavioural change make a significant impact? What are the blockers and enablers for realising these opportunities?

3.5.1 Traditional economics suggest that all goods and services are price elastic for demand, but there is a lag and probably some hysteresis. However, public opinion, the press and politics are likely to be very strong influencers on what can and can't be used in demand management.

3.5.2 We believe that water metering has not been as effective as expected in reducing demand.

3.5.3 Congestion charging, tolling and parking charges have proved fairly effective over the years in managing traffic volumes, especially if accompanied by carrots of improved public transport. It is interesting to note that cheap (or free to 'pensioners') public transport has similarly increased demand and higher peak rail fares do have some impact on trying to limit peak passenger demand and move some of that demand to other periods. Integrated travel planning was shown to be very effective, however central government does not seem to be giving such measures the priority they deserve commensurate with their potential effectiveness in dealing with excess traffic.

3.5.4 Energy charging again does encourage some reduction in use, but is helped by the carrots of grants for microgeneration, insulation etc.

3.5.6 The scope, on fluvial and coastal protection for demand management to be effective, seems very limited.

3.5.7 For changes to take place in the demand for goods and services, culture is also critical. In the late 1990s there was a bipartisan line on the importance of traffic reductions; some interesting campaigns, effective leadership from politicians and real progress was made, at least on energy and traffic demand management. It seems that much of this has been lost in many areas around the country and by central government.

3.5.8 Effective behavioural change must have leadership, a strong effort at culture change, sticks and carrots and an integrated holistic approach - with no, or as few as possible, mixed messages.

3.6 How can greater cross-sectoral decision making be encouraged?

3.6.1 In large organisations there is a very strong tendency to work in silos, budgets are provided or agreed for specific areas, decisions often made from a narrow point of view. Better multidisciplinary or cross sectoral organisation is necessary. This tends to be achieved with smaller governmental units but it is essential that such units have the necessary understanding or technical support so they are able to make decisions on facts and evidence.

3.6.2 Powerful lobbying or vested interest at local or national level also results in less than optimal decision making on priorities.

3.6.2 Fully open government, with each decision justified and open to scrutiny, will help. Similarly very local responsibility and democratic decisions on infrastructure where the whole range of considerations for such infrastructure can be considered rather than more single discipline organisation that is inevitable with larger bodies.

3.7 What opportunities and challenges are presented by devolution of infrastructure decision making?

3.7.1 If devolved decisions, on the basis of understanding and knowledge, are made (across area boundaries when necessary) and sufficient budgets are delegated to provide a reasonable service, there could be great improvements. Unfortunately recent history shows the reverse has happened; one of the best examples is that about 50% of the roads budget is being spent on 2% of the network and a large part of that on fruitless widening of the strategic road network (see section 3.1 above and other submitted evidence)

3.8 What new and emerging technologies and disruptive trends should we consider in producing this assessment?

3.8.1 Invariably, within the lifetime of the projects identified, technology will impact, however it is difficult to determine the extents of such impacts for future requirements. Often the introduction of such technologies have their own challenges or barriers, which may inhibit or negate any benefits. Care needs to be exercised, therefore, when considering the potential for such impacts.

3.8.2 Current and evolving telecommunication technologies can and will be likely to play a part in reducing travel demand, however the impact to date has been less than initially anticipated. However such developments will likely have a significant impact upon productivity and increase opportunities for social and economic diversity.

3.8.3 The electrification of transport fleets is a further factor that may have only a modest impact in relation to travel demand, but will likely impact upon energy requirements and pollution levels!. Further advances in storage and distribution are essential to improve the

viability of wider-scale delivery, these will no doubt occur, but the timescale is less certain. Additionally, central government's approach and degree of support will have influence. In the case of rail, the financing of the electrification programme and for road, the incentives provided by grants and taxation.

3.8.4 Driverless technology will also be a factor for road transport, however the precise timescale and nature of the impact are more uncertain.

3.9 How can we improve public engagement in infrastructure decision-making?

3.9.1 Fundamentally, good communication will be key. The messages need to be clear, concise and relevant and processes well managed, and where possible early engagement is to be preferred.

3.9.1 The Swiss model of local referenda seems to have some appeal; a piece of research carried out by an Australian academic has compared decision making in the UK, Australia and Switzerland, which may be useful for ICE deliberations –

<http://worldtransportjournal.com/wp-content/uploads/2015/02/wtpp17.3.pdf>

If you require any further information or wish to discuss any issue directly please do not hesitate to contact Martin Sachs the Secretary to TAG Transport Committee or indeed other representatives in TAG who you will find on our contacts page of our website:

[telephone number redacted]

Mrs Louise Ellman MP

Chair House of Commons Transport Select Committee

Dear Chair and Members of The House of Commons Transport Select Committee

INQUIRY INTO URBAN CONGESTION

1. Introduction and background to TAG

1.1 Thank you for the opportunity to submit evidence to the Committee on this most important subject. As a background, we have submitted responses to Government and given evidence to the House of Commons Transport Select Committee (HOCTC) and other House of Commons Select Committees and indeed many other august bodies and inquiries on various Transport Policy Issues over many years. We attach some relevant documents previously submitted to Government and HOCTC as appendices to this submission.

1.2 TAG as a professional/technical organisation represents a large number of local authorities in the country, these include those with highway and transport responsibilities such as Transport for London, most London boroughs, Metropolitan authorities, Unitary authorities, consultants providing highway and transport services for major local authorities and many of the districts and towns in two tier authorities. While 'second tier' authorities do not have direct responsibility for transport, they do have the major role in looking after significant towns and the sensible overall planning of them including providing a reasonable environment and trying to ensure, through the Highways and Transport Authorities, that the transport system is fit for purpose.

1.3 TAG was first created as a joint officer body to coordinate across the various areas of Local Government and was formed by an amalgamation of the Associations of London Borough Engineers and Surveyors (ALBES), Metropolitan District Engineers (AMDE) and Chief Technical Officers (ACTO) of the districts in two tier areas. One of the major reasons for this combination was so that advice could come from one body. TAG still has a major role in advising the LGA and recent submissions from the LGA on transport issues usually reflect TAG advice.

1.4 Overall we represent over 100 different authorities and for this inquiry we believe as a body we have more responsibility and experience than any other organisation to support the Select Committee in its work.

1.5 We can confirm that we have consulted our membership on the content of this submission and it represents the overall views but not necessarily the views of individual members or authorities.

2. Summary

2.1 We note the headings included in the invitation to submit evidence are broadly headed as **Integrated Strategies** including strategies to limit car traffic by road pricing, congestion charging and parking control, improvements to sustainable transport, and technological innovations and **Wider Considerations** including managing construction activities, construction and operating costs, cost benefit analysis, the bus market and safety. TAG members and all Technical officers in Local authorities have to grapple with all these issues. For a detailed understanding of some of the issues, individual local authorities have particular experience and expertise which we have not been able to fully tap into in the time available or do justice to the subject matter in a reasonably concise submission eg Nottingham, Manchester and Sheffield on Tram systems, TfL on congestion charging.

2.2 Nevertheless we will endeavour to provide an overview of most of these issues and their linking. In addition we have also prefaced the consideration of these issues with our

own 'General Issues' section discussing overall urban strategies and interfacing between interurban and urban areas and the nature of congestion.

3. General Issues

3.1 TAG agrees that traffic congestion, including for buses and pedestrians, is wasteful and we support any reasonable measures that can be shown to alleviate congestion. The Eddington Report (a link to the documents produced by Eddington can be found on - <http://collections.europarchive.org/tna/20100408160254/http://www.dft.gov.uk/about/strategy/transportstrategy/eddingtonstudy/>)

) identified that the worst congestion was in urban areas, indeed he identified that 89% of traffic congestion is in urban areas. Furthermore he stated that road pricing/ congestion charging was 'a no brainer' as part of the solution to congestion.

3.2 TAG recognises the political difficulties of road pricing and indeed most traffic limitation strategies but, realistically for any major urban area, efforts have to be directed at measures to reduce the dependence and use of private motor vehicles; this is for congestion, environment and economic reasons.

3.3 TAG believes, with evidence, that enlarging the road network anywhere near major cities will in the relatively short term increase traffic levels, congestion, CO2 and pollution levels and can make all travel worse. (The Committee may want to refer to a recent peer reviewed technical paper on the subject of generated traffic as a result of road enlargements (<http://worldtransportjournal.com/wp-content/uploads/2016/02/9th-Feb-final-opt.pdf> please see pages 37-42); while this particular paper was written as a review of the government policy and strategy on the strategic road network, the analysis applies even more to proper urban, road capacity or design speed, highway 'improvements'. However TAG understands fully that getting this message across is very difficult and indeed it appears that at least some of the people submitting evidence to this inquiry certainly believe the answer to congestion is more road space.

3.4 Much has been written over the years on how to manage the transport system in towns, probably the most useful and perceptive are the 1963 Buchanan report Traffic in Towns and J.M.Thompson's 1977 book Great Cities and their Traffic. Particularly relevant and still very pertinent are some quotes from the Buchanan report:-

"We think it will be necessary for transportation plans to be based on a conscious decision regarding the extent to which demand for the optional use of cars can be met. The plans should contain measures to influence the demand so that it matches the provision that can be made.there appear to be four possibilities:

- (i) A system of permits or licences.....*
- (ii)pricing for the use of road space.*
- (iii) Parking policy.*
- (iv) Subsidising public transport so that it offers considerable financial advantages over the use of cars"*

(Traffic in towns paragraph 451)

"The question of how much parking space should be provided in new buildings needs to be considered.... Developers or owners of a new building should provide sufficient space within

the site to accommodate all the essential traffic generated by the building.... Doubt attaches to the provision of space especially for car-commuters To put it shortly: why should an employer be obliged to provide parking space for all and sundry on his staff who may choose to drive to work primarily for their own convenience?" (T in T Para 454)

"the application of arbitrary parking standards to new buildings may produce an accumulation of parking space which the network cannot deal with..."

"....parking policies need re-examination to ensure that traffic difficulties are not being 'built in' by the provision of too much parking space..." (T in T Para 456)

3.5 Great Cities and Their Traffic complements Buchanan's findings with analyses of the environment, success and liveability of a number of world cities of different sizes. Broadly the main findings are that any city over about 250,000 population will suffer considerable congestion and indeed social disadvantage if it does not promote sustainable transport. It is also worth considering two very different examples of cities for the present day. Central London has a car commuting share of typically about 1 in 20 people driving, yet even in Central London approximately ¼ of all land is used for road transport (and servicing); increasing road space for private motor cars would obviously be fruitless. Austin the capital city of Texas and possibly one of the more pleasant American Cities has a population of about 1 million and occupies the land area of the whole of Greater London yet still suffers considerable congestion.

3.6 TAG has on a number of occasions expressed its concern to your committee and others about the disparity between the policies and strategies being followed on the National Road Network and those required in urban areas - where the vast majority of trips begin and end and which are the main drivers of the economy. If very different strategies are to continue to be employed, much stronger consideration and funding has to be given to appropriate interfaces between the very different policies and strategies.

4. Integrated strategies

4.1 TAG agree wholeheartedly that managing competing demands for urban road space; shifting people from private vehicles to public and active transport modes in urban areas is absolutely essential if there is any desire to reduce urban road traffic congestion, pollution, and environmental damage and to provide healthy cities that are pleasant to live in or economically prosperous. However to deliver such policies requires culture change, leadership, effective design and implementation of 'sticks and carrots' and an integrated holistic approach across the whole planning and funding for urban areas. It is notable on this that recent policies are going against providing the right incentives - rail fares are to rise by 1.9% (above the general inflation rate) while motoring fuel costs have come down over recent years and a further budget freeze on fuel duty doesn't help deliver positive advantages to those willing to use sustainable transport

4.2 If the government has set its sights against national road pricing for the foreseeable future (for understandable political reasons) it needs to provide support and help for all strategies at local and national level to encourage individuals to use sustainable modes -

(e.g. by effective management of public and private parking, park and ride, workplace parking levies, congestion charging, rating changes for premises with plentiful parking, travel planning, planning standards, bus and high occupancy vehicle lanes, cycle provision, wider footpaths etc.).

4.3 TAG firmly believes that to be successful, measures need to be introduced as part of an integrated strategy. Whereas individual elements can be introduced any success is likely to be very localised and limited. Public transport and parking control are considered to be the key elements and the provisions of the Bus Services Bill are particularly welcome and will allow better opportunities for the coordination of public transport and more efficient use of the limited finances currently used for subsidies.

4.4 For our larger urban areas rail commuter services are also an important factor however there is currently only limited opportunity for coordination. Evolving devolution agreements and new franchising arrangements can afford better opportunities for coordination particularly when coupled with the provisions of the Bus Services Bill and are welcomed.

Positive traffic limitation strategies

4.5 Parking control and management have been recognised for nearly 60 years as powerful tools in managing transport and traffic in towns. The policies have been deployed by: development standards for parking provision in new buildings, provision of public car parks, charging for the use of the valuable commodity of a parking space and enforcement to ensure roads are kept clear and spaces are rationed to help essential users and functions. More recently Nottingham has introduced control on workplace parking and some other authorities are exploring possibilities of such controls.

4.6 For Central London positive methods of traffic reduction by parking control precede even Buchanan and his suggestions (see para 3.4 above). A little later In the mid-1970s research by the Greater London Council and Central London Boroughs identified that a 1/3 reduction in traffic volumes was necessary to provide an improved residential environment, facilities for pedestrians or an enhanced bus service. Measures investigated included Supplementary Licensing and Area Control (basically precursors to the present Congestion Charge), Private Non Residential (PNR) parking control – a precursor to workplace parking levies (but which also included privately owned shopping centre car parks) and effective management and enforcement of street parking controls and their extension throughout much larger parts of London (It should be noted that in the late 1970s parking enforcement was so poor that about ½ of all trips ended in an illegal parking act). (Some papers from these studies are still available and one of the authors of this submission can provide copies, if required by the Committee).

4.7 While TfL can provide a great level of detail about the Congestion Charge - in particular it is notable from their studies that there was a very substantial reduction in car commuting and indeed the use of workplace parking after implementation. Many cities have substantial numbers of office car parks in the city centre many dating from before planning standards were changed (1969 in central London and following Planning Policy Guidance note 13 in most other cities – unfortunately PPG13 was removed as part of the NPPF). If there are a lot of terminating as opposed to through movements in a city, workplace parking controls, especially if the charges are passed to employees, can be very effective especially if the revenues can be used to improve public transport at the same time - as happens in Nottingham. While many people involved with urban transport including a previous Minister of Transport (Stephen Norris) may have seen workplace parking charges as a theoretically

better way of limiting traffic in London, the political and practical difficulties of recycling revenues to public transport from several different Central London local authorities would have been very difficult within a political cycle.

4.8 While parking control in all its guises helped hold traffic growth down in London the integrated approach of:

- stopping major new road construction,
- effective parking enforcement,
- extension of controlled parking zones,
- a steady programme of bus lane implementation,
- travel planning type initiatives at workplaces and other land uses,
- improvements to public transport services
- the central London congestion charge
- removal of excess road capacity
- awareness of the effects of CO₂ and a cultural change away from car ownership

all occurring from the mid-1990s have resulted in a fairly dramatic change in traffic levels from a steady growth to a clear traffic reduction throughout London; this is despite the large population increase. This peak car phenomenon has been well researched by David Metz and Phil Goodwin (a quick reference to this change in London can be found on the graphs in this presentation: <http://www.carplus.org.uk/wp-content/uploads/2014/12/D-Metz-University-College-London.pdf>). Incidentally this presentation illustrates another worthwhile contribution to reducing but still allowing car use with 'pool cars'.

4.9 Experiences from Nottingham, which despite having a less benevolent operational framework for bus services than London, indicates significant success in integrating parking management and public transport. Nottingham remains the only city to have introduced a workplace parking levy, which despite some concerns raised by local businesses was introduced and has operated successfully since 2012. Car journeys in Nottingham reduced by 7.9% between 2000 and 2015 whereas other large cities have seen increases and the levy raised £9.3m in 2015/16. The funding raised by the levy has secured improvements to public transport including extension of the city's tram network and appears to represent a more palatable method of traffic constraint than that of road pricing.

Low emission zones

4.10 Low emission zones (LEZ's) represent a valuable tool to control the harmful environmental effects of road transport. A number of LEZ's have been introduced in the UK specifically to address concerns regarding local buses, which is perhaps more of a stinging indictment of the state of public transport. London is the main exception where goods vehicles are also restricted and in common with other major cities, that have introduced such schemes, air quality has improved. However traffic levels are unlikely to reduce following the introduction of an LEZ and therefore it is unlikely to have a significant direct impact on congestion.

Bus priority measures

4.11 Bus priority measures have worked but have not always been popular and for example were removed in Liverpool. London has now had an effective bus lane implementation programme for over 40 years and by and large bus lanes have been accepted and indeed welcomed in many areas. Bus priority can have the effect of reducing the overall capacity of routes for all vehicles and it is therefore essential that where

considered to be introduced the impact on the wider network should be carefully assessed. Nevertheless, relatively low cost bus priority schemes can generate significant benefits, particularly in terms of journey time savings and have the potential to improve journey time reliability. However these benefits are not necessarily readily apparent for users and therefore a commitment to enhancing bus services or least maintaining service levels is essential for on-going public support. Parking management will also be necessary to constrain car trip demand and ensure that benefits are not eroded.

Street running tram and trolley bus systems

4.12 Britain lags substantially behind its neighbours in Europe and the 1985 Transport Act certainly hindered our larger cities except for London in providing effective Public Transport. Nevertheless there is now considerable experience and knowledge from London, Nottingham, Manchester and Sheffield for street running trams. Leeds is still trying to get a workable modern public transport system - recently via trolley buses. The comparison of Leeds not being able to get on with its provision in a city of 800,000 people with a substantial hinterland population, with say Luzern in Switzerland with a population of 50,000 with its own trams, is stark.

4.13 It is certainly clear that the travelling public prefer tram systems over conventional bus services. However the cost of retrofitting the heavy apparatus into existing urban streetscapes is often significant (issues regarding utility costs and cost-benefit calculation are made below). Urban development patterns also present challenges for some cities and the trend towards decentralisation which has weakened many city centres results in a greater geographical distribution of journeys. Nevertheless trams can play a key role in reducing congestion and when coupled with appropriate land use policies can contribute significantly towards the strengthening of city centres as key locations.

Technological innovations

4.14 While TAG is keeping abreast of potential intelligence within cars to avoid collisions and increase capacity on the strategic road system however we do not believe such technological advances will reduce urban traffic congestion markedly in the next 20 years and for our largest cities such technological advance could extract public transport users and cause an increase in congestion.

4.15 Tag is concerned that revenue restrictions and skills shortages are not only reducing the deployment of current technology but also impacting adversely on its' maintenance. Consequently, even a humble set of traffic signals will be maintained such as to operate safely, however replacement of failed detection equipment for example is not prioritised thereby adversely effecting optional efficiency, contributing to congestion and the consequential health and environmental impacts. This we believe has contributed to an increasing tendency to "switch off" or remove installations with the suggested objective of easing traffic flow. Similarly, despite the significant benefits for the management of congestion by the deployment of area wide Urban Traffic Management and Control Systems, revenue funding in particular is challenging and many authorities are unable to commit to further expansion and even retraction to reduce revenue costs. Skills shortages in this area can result in the wrong selection of an appropriate control strategy for junctions or

deployment of the wrong technology in addition to limiting availability of sufficiently qualified maintenance staff.

4.16 Bluetooth and mobile telephone data technologies offer opportunities for real time traffic monitoring which when combined with the control afforded by an Urban Traffic Management and Control System can provide for significantly improved congestion management. However for many authorities the revenue implications are likely to be prohibitive even if the capital can be found for the deployment of the necessary equipment.

4.17 Information technology offers significant benefits for public transport users but uptake and deployment has been slow, particularly in the bus industry. Real time information systems can be readily deployed, however bus operators have not in all areas embraced it and in some areas only partially adopted it, causing a mixture of real and timetable information to be displayed, wholly undermining its' integrity when delays occur. Similarly, wider and more particularly multi-operator network ticketing is not necessarily available. It is to be hoped that the proposals contained in the Bus Services Bill will enable the better and wider deployment of these technologies.

Cycling and walking infrastructure

4.18 Almost all trips for all purposes involve a walking stage and in the centre of our largest cities, and indeed smaller historic cities, walking is fundamental to general travel, the economy and environment. Reducing delays to and improving the environment for pedestrians, even at the expense of slightly increased delay to vehicles, is well worthwhile and particularly space efficient. Such measures will also reduce car traffic volumes - the best example of such an effect was the removal of general traffic from Oxford Street in the 1970s.

4.19 Cycling undoubtedly has significant health benefits, is often the fastest way of travelling in our big cities and is also very space efficient. An holistic approach to cycle facilities and use can be effective to make cycling a significant mode of travel and encourage some people who might have previously used a private motor car. Cambridge, Oxford, York and London provide probably the best examples in the UK, but Holland, Paris and Switzerland (where apparently 14% use cycles for the journey to work in a wet cold hilly country!) can provide useful lessons in improving cycle travel.

4.20 It is notable that the increase in light van use must be contributing to urban congestion. It is likely that many vans are often carrying very little and efforts made to encourage more use of walking (also combined with Public Transport use) and cycles and even mopeds for small loads could have an impact. The recent growth of Deliveroo services is an interesting example

5. Wider Considerations

Managing disruption to local communities and businesses during construction and operation

5.1 Local Authorities feel most acutely the pressure to minimise disruption during construction and other operations of their works, as local council members quickly react to any concerns raised. However this is not the case for other agencies and the majority of complaints arise from utility works. Some improvement in utility company performance has occurred resulting from statutory and regulatory changes, however several authorities have considered it necessary to resort to the introduction of charging schemes whereas others remain reluctant to do so due to the bureaucratic overhead costs associated with the operation of such lane rental schemes.

5.2 The greatest consternation regarding the execution of local authority schemes, particularly major works, remains the performance of the utility of companies and their contractors. Largely, performance is based upon their goodwill with no contractual requirements to perform either to any specific timeline or costs. In many cases where project overruns are encountered, utility companies or their contractor's performance is cited to the major factor.

Construction and operating costs –

5.3 Again one of the likely highest cost elements in a transport project in the urban area will be that of utility diversions. However, it is the uncertainty of performance which raises most concern during the lifetime of a project from its very inception until final completion. Uncertainty of performance brings high risks both directly associated with their costs and also potential indirect costs arising from delays over which neither authorities nor contractors have any control. The utility companies need to be made more accountable; it is worth noting that not all countries fund utility diversion costs resulting from major infrastructure works, which no doubt incentivises better performance.

5.4 For Local Authorities the management of operating costs is a primary concern, however in reality given revenue constraints the relationship between proper management/ maintenance of assets and available funding are diverging. Consequently, in the longer-term overall operating costs will invariably increase or more likely the need for capital replacement. The majority of authorities have adopted or are in the process of adopting best practice in the management of their highway assets, which is to be welcomed, however this process highlights the scale of the value of highway assets and the limited and wholly inadequate funding currently available. An alternative funding mechanism needs to be considered if government wishes to both maintain the asset and stringent financial controls.

5.5 The revenue funding issue mentioned above extends beyond highway maintenance into all aspects of services. Relatively low cost beneficial transport services such as sustainable transport projects including Workplace Travel Planning can demonstrate significant returns but require relatively modest revenue funding which for many authorities is not an option. Limited funding is being made available to some authorities for sustainable transport however this can only be obtained through competition which invariably results in many authorities not receiving any assistance despite very high cost benefit ratios calculated for such schemes.

5.6 Revenue funding for public transport has reduced significantly and consequently many bus services deemed by authorities to be a social necessity are being removed. Additional pressure on public transport budgets arises due to the cost of the operation of the National Concessionary Travel Scheme which is not being met by central government. Consequently many transport authorities are faced with need to reduce concessions for younger people. The current arrangements for Bus Service Operators Service Grant and reimbursement of concessionary fares, outside London, do not make best use of this limited but significant funding.

5.7 Overall the disparity between the treatment and funding for revenue and capital costs, as we have said many times before, is inappropriate and limits the ability to operate our transport assets safely and efficiently. The maintenance of existing infrastructure should be our first priority.

Approaches to cost-benefit calculations

5.8 TAG has at each opportunity voiced concern regarding the way Cost Benefit Analysis (CBA) is being used at present. We have welcomed the devolution by the Department for Transport (DfT) of transport investment decisions but note that the frameworks within which authorities are required to work have been strongly influenced by DfT with significant emphasis placed upon a project's CBA. If it were used rigorously, smaller schemes and even some larger schemes including congestion charging and many smaller public transport projects would likely dominate, not road schemes or grand projects.

5.9 Rather than reiterate previous papers here, a brief summary of issues and concerns relating to CBA and the implications in its use is set out below (Reference can also be made to two appendices attached):- –

- Large Commuter Flows Dominate – for road traffic the result is the potential for continuous road widening,
- Lower Cost Options Dominate – inter-urban construction costs are generally lower than urban resulting in greater values for investment in the Highways England Network,
- Accordingly, we question whether the true costs of projects are being measured and similarly whether benefits are being accurately represented.
- It is appreciated that DfT has sought to improve the approach, however in doing so the models become more complicated and the relationships to real outcomes ever more obtuse.
- Similarly, we question whether the current approach adequately addresses the desired policy outcomes.

Implications for the sustainability of the market for provision of bus services

5.10 TAG has noted the continuing decline of bus services and passenger numbers particularly in large urban areas except London as what must now be considered a long-term trend. This is not necessarily initiated by the 1985 Transport Act but in our view certainly hastened by it. Notwithstanding the introduction of the Act, outside London bus service operations appear to have been overly dependent upon subsidy and with the

major contractions in funding in recent years the levels of service have reduced significantly, together with passenger numbers. The implications on continuing reductions in subsidy appear inevitable under the current model. TAG believes that the Bus Services Bill when enacted will afford authorities an opportunity to intervene where necessary although invariably stability in the funding regime will be necessary to avoid continuing reductions.

5.11 Nevertheless, TAG strongly believes that bus services are an essential element of the public transport system and can contribute greatly to the reduction in congestion in urban areas particularly when operated as part of an integrated transport system.

The safety of road users, particularly cyclists and pedestrians

5.12 TAG contends that the area of road safety has suffered in recent years from complacency due in part to previous success. Consequently insufficient effort or resources are being invested in reducing the occurrence of road traffic accidents in this country. We have benefited in recent years from a trend of reducing accident rates driven by great efforts by road designers, road safety practitioners and significant improvements in vehicle technology. However reductions in revenue funding have resulted in many local authorities dispensing with or at least significantly reducing road safety teams and loss of key staff resources in design teams. Indeed a number of authorities are discontinuing or significantly curtailing their school crossing patrol services due to the limitations of revenue funding.

5.13 TAG strongly recommends that local authorities are provided with adequate financial resources to enable them continue and where necessary reinstate essential road safety services.

The Traffic Management Act – Part 6

5.14 TAG has consistently argued for local authorities to be provided with necessary funding and the tools to carry out their duties. Part 6 of the Traffic Management Act provides for the Civil Enforcement of Traffic Contraventions and is considered by TAG and indeed this Committee to be a key tool for many authorities to better manage highway networks. Despite the introduction of the Act in 2004 key powers have yet to be introduced and successive Secretaries of State have been unable to justify their reluctance to do so even though they exist in London. Although, not all authorities wish to take on all the additional powers - some consider the requirements onerous, for others, particularly our larger conurbations where congestion is a major problem, the powers are considered to offer significant benefits. TAG therefore requests continued support for their introduction.

Skills

5.15 As ever in a time of recession many skilled employees have been lost to the industry and training budgets have been sacrificed. For local authorities budget pressures continue to force reductions in areas which require revenue funding, such as traffic

management and road safety, consequently there is little prospect of skills development and skills shortages are inevitable.

6. Concluding comments

6.1 TAG can only advise that in order to tackle the problems associated with congestion and to deliver an effective transport network, authorities need to be adequately resourced, given or allowed to use adequate powers and that revenue funding is key. TAG is confident that within local authorities there is adequate understanding and expertise to adequately control congestion in the areas where congestion for pedestrians, public transport, goods and private cars is worst.

6.2 Please do not hesitate to contact me or other TAG colleagues if you require us to appear before the committee (which we would welcome) or if you require further information, explanation or copies of other documents.

Yours sincerely,

Dear [name redacted]

Transport Investment and Economic Performance

5. Introduction

1.1 As you may be aware TAG represents a large number of local authorities in the country, these include those with highway and transport responsibilities; such as Transport for London, most London boroughs, Metropolitan authorities, Unitary authorities, consultants providing highway and transport services for major local authorities and many of the districts and towns in two tier authorities. While 'second tier' authorities do not have direct responsibility for transport, they do have a major role in looking after significant towns including their economic health and the sensible overall planning of them including providing a reasonable environment and trying to ensure, through the Highways and Transport Authorities, that the transport system is fit for purpose. Overall we represent over 100 different authorities. Thus for any technical or professional group likely to respond to your Call for Evidence, we believe we are the most effective representative organisation likely to have a technical as well as public view on any policy issues.

1.2 TAG was first created as a joint officer body to coordinate across the various areas of Local Government and was formed by an amalgamation of the Associations of London Borough Engineers (ALBES), Metropolitan District Engineers (AMDE), Chief Technical Officers (ACTO) of the districts in two tier areas; One of the major reasons for this combination was so that advice to the new combined Local Government Organisation could come from one body. TAG still have a major role in advising the LGA and recent submissions from the LGA on transport issues usually reflect TAG advice.

1.3 As we were not aware until recently about your call for evidence we have not been able to consult our full membership (but have consulted our executive) on the form of this response before submission. It will up on our web site imminently and if we receive any other views or further important information we will relay it to you.

1.4 TAG have expressed concerns and made a number of suggestions to Government over the years on;

- the types of schemes most likely to help the economy,
- delivering transport and communication systems to serve the customers - the people, visitors and businesses of the UK
- the assessment and funding methods for infrastructure.

1.5 We do not intend to repeat our previous submissions to the DfT on these issues but if you are not able to find them please contact us. Nevertheless we do attach our recent response on the NN NPS for context, We summarise our fundamental points on

assessment, illustrate particular issues from our experience from a number of authorities and attach our response on the NATA refresh consultation of February 2008 - we believe this now slightly old response is still highly relevant.

6. Background on Assessments

2.1 We note in the document Understanding and Valuing the Impacts of Transport Investment from October 2013 that the 'Transport Business Case' assessment

considers the investment decision from five perspectives – the strategic case, economic case, commercial case, financial case and the management case. We are concerned that these seem divorced from the public service aspects of meeting peoples and businesses transport needs unlike the NATA Appraisal Criteria:

- “Integration – ensuring that all decisions are taken in the context of our integrated transport policy;
- Safety – to improve safety for all road users;
- Economy – supporting sustainable economic activity in appropriate locations and getting good value for money;
- Environmental Impact – protecting the built and natural environment;
- Accessibility – improving access to every day facilities for those without a car and reducing community severance.”

2.2 We note the government’s vision for Transport in the NN NPS and have suggested relatively minor changes that would make the vision a useful test to ensure that any scheme works to such a shared vision. Any scheme which does not meet such a shared vision should be rejected without any further assessment analysis. The suggested vision as included in our response to NN NPS is as follows:

“The Government will deliver with its partners national networks that meet the country’s long-term needs; supporting a prosperous and competitive economy and improving overall quality of life, as part of a wider transport system. This means:

- *Networks with the capacity and connectivity to support national and local economic activity and facilitate growth and create long term jobs (note - not jobs just during construction)*
- *Management of networks to support and improve journey quality, reliability and safety*
- *Networks which support the quality of the national and local environment and the move to a low carbon economy*
- *Networks which provide reasonable access for our communities to services and jobs and link to other communities and facilities.”*

2.3 Within our submission on NN NPS we summarised our overall views on assessment as follows:

- Schemes should not even be considered, let alone need to get to an assessment process, unless they meet reasonable national and local transport objectives; we would hold for the reasons above (*explained in detail in our response on NN NPS attached*) that there will be very few occasions when trunk road schemes are likely to meet such reasonable objectives.
- The present methodology is too complex, opaque and not adequately useful for the real politician decision maker.
- The seeming importance of a flawed cost benefit analysis method seems to carry a disproportionate weight in the overall assessment.
- Within the 'economic assessment' process there are the following major issues:
 - The evaluation is largely based on the difference between two enormous sums of time spent on the network with and without a scheme; each of these sums is based on a large number of assumptions, the process is therefore mathematically very unsound.
 - For major road schemes most of the 'benefits' appear for the peak traffic times (ie largely for car commuting – a mode and time that most highway and planning authorities do not want to encourage) and for the period 30-60 years in the future (where the assumptions taken have even less accuracy).
 - The impact of 'generated' traffic compared with so called 'natural traffic growth' and their impact outside the proposed scheme is never adequately considered.

2.3 TAG accepts that Transport Models are necessary to help predict how people and industry would react to any Transport System change. However linking models (which have been highly calibrated or adjusted to try and match a base year situation) to predict behaviour change with economic assessment introduces potential for a highly distorted view of the potential benefits to real travellers. TAG also recognises that there are some useful principles in the assessment methods but there is much work to be done before the methods are really useful. The recently published Post-Opening Project Evaluations completed for the Highway's Agency, highlight concerns relating to the forecasting of scheme benefits which are fundamental to the 'economic' assessment of a project.

2.4 While we have pointed out a number of other problems in our 2008 NATA refresh submission there are some other assessment issues we would wish to address specifically.

- On the infrastructure costs side of any assessment, some past infrastructure certainly has 'value' after 60 years however the 'vehicles' on the infrastructure are not always included properly – there are real costs to individuals in the UK economy in providing cars to 'fill up' the new roads which last typically 12 years; these need to be compared in any assessment with tram or train carriages which typically last 40
- It is notable that in some cases transport is artificially cheap at the point of use eg it does not really add value to the economy that low value added work like packing Kent potatoes is being done in Somerset

7. Socio-economic time savings assessment and real economic benefits

3.1 As mentioned in our 2008 NATA Refresh submission (attached) the present 'economic assessments', especially for road schemes, have potential for enormous errors.

Our members generally report that the schemes they try and implement are for economic regeneration or improving the environment. Congestion reduction does figure, however for major road schemes in urban areas evidence shows they are likely to be counterproductive but travel planning and public transport schemes work. Furthermore, if we are calculating socio economic returns in the traditional DfT/ Treasury way, road safety, other small schemes, travel planning and (smaller) public transport schemes have the highest returns. Thus, if the economic calculations are to be believed, the government should transfer a very large part of the funding away from national projects to much more local projects of these kinds.

3.2 While LAs normally promote schemes for regeneration or environment, to get 'through the hoops' and obtain funding we have to spend large sums on consultants who know how best to create a model and assessment system to 'show' an economic return.

It is relatively easy for consultants to identify various assumptions to tweak to produce the required result. One of the authors of this submission personally recalls from earlier in his career changing a vehicle speed assumption on the minor residential road network by 2 mph in both do nothing and future and it changed the economic assessment fundamentally. Similarly forecasts of growth, study areas etc can be readily changed.

3.3 Turning to real benefits to the economy, the 1999 SACTRA study probably investigated this more thoroughly than other efforts. As we recall they did come up with a theoretical argument that the savings to the economy could be the time savings however they could also be less than those or possibly greater. TAG would agree that there are agglomeration benefits to the real economy from some transport interventions. However such benefits are likely to occur most with improving accessibility and densification of cities. This is likely to occur most with local walking, public transport and other sustainable transport measures and trunk road enlargements are likely to work against these.

3.4 Generally we are of the view that a node or centre of an area will be stronger than a peripheral area and links to the peripheral area will often weaken that area to the benefit of the node (an exception is possibly a 'nice' area that can be an attractive commuter centre for better off people). Also a good environment is usually the factor that is most important to improve the economy; this is hardly ever delivered by building roads. It is poignant to note that Professor Peter Hills (ex Buchanan study and Newcastle University) remarked that if a Martian arrived in England and did a correlation between roads and economic prosperity they would find that roads did the reverse of helping the economy – this can be seen almost everywhere eg Hampstead versus Cricklewood, York versus Doncaster etc.

Concluding comments

4.1 TAG recognises that your staff try very hard to constantly refine and develop the appraisal techniques and *academically* we would agree that the UK system has possibly the most advanced assessment techniques in the world. However the result appears that we invest in infrastructure which often does not help the environment, the economy or reduce traffic congestion. It also adds a substantial on-cost to implementing schemes to help the UK economy and does not really provide the help needed for local or national politicians to make the decisions that are or should be theirs to make.

4.2 TAG would be pleased to contribute to any new studies of assessment or modelling techniques and would also be more than willing to explain in more detail our reservations on the present system.

4.3 Please do not hesitate to contact me or other TAG colleagues if you require further information, explanations, meetings etc.

Yours sincerely,

Dear [name redacted]

NATA Refresh Consultation

Following telephone conversations in the Autumn, information on your programme for “Refresh of the New Approach to Appraisal”, and receipt of the consultation documentation, the Technical Advisors Group (TAG), wish to make the comments as described in this note. If you need to follow up any of these please contact me on [telephone number redacted] or by e-mail.

As you know TAG represents a large number of local authorities in the country, these include those with highway and transport responsibilities; such as Transport for London, most London boroughs, Metropolitan authorities, Unitary authorities and also many of the districts and towns in two tier authorities - where the county is responsible for Transport Issues. While these ‘second tier’ authorities do not have direct responsibility for transport, they do have a major role in looking after significant towns and the sensible overall planning of them including providing a reasonable environment. Thus of any group you are consulting on this programme we believe we are the most effective representative organisation likely to have a technical as well as public view on any proposals.

Our response is now structured under 3 general headings:

- Overall Comments
- Response to specific issues raised in DfT’s aims of NATA refresh
- Response to formal consultation questions on NATA

Overall Comments

Summary

We welcome the principle of a review but have very grave reservations on the form and direction of the review and overall we would like to see:-

- A significantly simplified process.
- Much less reliance should be put on old style transport economic principles.
- Time savings should not be given anywhere near the effective weight they are at present - reducing congestion/journey time should not be the key issue – certainly when it cannot be achieved with additional infrastructure because of induced traffic.
- Any ‘benefit’ that is contrary to policy should not be included or perhaps entered as a negative.
- Health and community benefits particularly for urban areas need to be brought about by applying appropriate transport policies including more walking and cycling and if this is not reflected in the assessment, the methodology could be said to be flawed.
- Present assessment methods seem to be directed to approving schemes to encourage mass movement between urban areas which we do not believe should be promoted by government for sustainability and environmental reasons.
- Similarly high speed standards are promoted by the existing methods which certainly should not be promoted in urban areas.
- Even if the present approach were reasonable for rural parts of the country the implications on the urban areas are seldom properly considered in a joined up

fashion and also the importance given to potential inter city or regional infrastructure could squeeze out the smaller/urban schemes.

Funding decisions

Before attempting to answer the detail questions in your consultation document we believe it would be helpful to give an overall view on the systems used to appraise schemes and assign funding. These general views have been expressed by TAG previously in terms of the LTP process and for other consultations by the DfT, House of Commons Transport Committee and studies such as the Lyons review.

Furthermore and also in this context we have concerns about the approval process for schemes. We understand that it is planned for a greater level of responsibility for scheme approval to be given to regional authorities. If this is to be a genuine delegation of authority for the final approval of which scheme gets given the go-ahead then a review of the cost benefit balance by the DfT centrally would seem to devalue such delegation.

Bureaucracy and complexity

From the Highway / Transport Authority point of view we have been concerned for a number of years over the level of bureaucracy that we have to deal with to justify schemes, sometimes on relatively small schemes. We are fully aware that the present LTP and LIP system (for TfL) produces vastly more paperwork and results in substantial extra staff and consultant costs over previous systems. Each district highway authority is now producing LTPs or LIPs with a volume of paperwork and analysis that dwarfs the content of TPPs for the largest local authority of just over 20 years ago. Our members confirm that up to 1/3rd of their staff time on developing major schemes is now involved with producing planning documents such as LTPs and assessments. This excludes consultant resources which often need to be called in to deal with the complications which often only they know how to deal with to best advantage.

While we recognise the cost of such studies and paperwork production is normally less than major road or public transport infrastructure schemes, we are getting nothing for this investment to help the public. We believe there is an urgent need to get back to a very much simpler system that ensures public money is spent on useful capital and even more importantly revenue schemes rather than studies and policy documents.

Policy and objectives of Transport assessment

Overall policy whether for local or central government now appears to be:-

- reduce traffic especially during peak periods,
- increase use of sustainable modes,
- reduce traffic congestion,
- improve the environment,
- reduce carbon footprint,
- improve safety,
- support economic development.

When the NATA process was first introduced in 1998 in the Integrated Transport Policy – A New Deal for Transport, there were the five simple investment criteria as follows:–

“Decisions on when and where to invest in network improvements, including measures to manage traffic, will be taken in the light of the new approach to appraisal based on the criteria:

- Integration – ensuring that all decisions are taken in the context of our integrated transport policy;
- Safety – to improve safety for all road users;
- Economy – supporting sustainable economic activity in appropriate locations and getting good value for money;
- Environmental Impact – protecting the built and natural environment;
- Accessibility – improving access to every day facilities for those without a car and reducing community severance.”

These criteria were well supported by most professionals including TAG members. The interpretation of these in the NATA web-tag based guidance in 2003 appeared to be a step backwards. It is noted particularly that in bullet point three above “and getting good value for money” in respect of economy was a very minor point amongst the total investment criteria. However as has happened in the past the “socio-economic cost benefit analysis” has again been raised to a very high level of importance in the assessment process. This is not only in weighting of the schemes for investment but also in the amount of analysis required just to deal with what seems to be a minor point. Some of the factors which help to improve the cost benefit ratio are clearly contrary to the overall thrust of the present transport policies at a national or local level.

We should make it clear that Value for Money in terms of achievement of all five elements included in the Integrated Transport Policy is of fundamental importance. However this requires a level of judgement, on all aspects included in the appraisal, by decision makers and not the consideration of one single fairly arbitrary figure. Furthermore as stated above (Funding Decisions section) we believe such assessment should be much more locally based.

The true role of many transport schemes in supporting economic development and especially sustainable economic has sometimes been used in rather a suspect way. This was extensively studied by SACTRA in the late 1990s. Generally economic development is fostered by local access and a good environment rather than large scale schemes. We recognise agglomeration (and density) benefits and these are discussed in our response to your consultation document (question 6 below).

Overall problems with the ‘cost-benefit analysis’ process

Before going into the elements in the cost benefit analysis we would first like to address the intrinsic unreliability of the mathematics in the analysis. The essence of the calculation is to add up all the (largely time) costs for vehicles using the proposed whole network subtract the ‘costs’ for the vehicles using the old whole network and divide by the capital costs of the scheme. Both the (time) cost totals are very large figures (which are developed using a number of assumptions) for which minor changes in either or both could change the cost benefit ratio dramatically. Curtailing the study network to concentrate around the proposed

scheme may produce an increase in mathematical predictability (by having a larger time cost difference relative to the capital cost) it totally under-represents any extra time costs from extra congestion (often caused in TAG towns and cities) by induced traffic from the new road scheme.

The values output from the analysis have also been changed dramatically in recent years by increasing the investment cycle to consider benefits over 60 years and to reduce substantially the discount rate. These changes do not always reflect reality, for example many roads justified on economic analyses have been replaced before 20 years let alone 60 years with “by-passes of by-passes” in many locations. If this happens for a proposal presently being considered the discount rate and amortisation period would clearly give a highly inflated artificial benefit.

Turning to more detailed considerations in the economic assessment, a number of items within it are counted towards a good cost benefit ratio where they are clearly contrary to policy. Anything increasing tax revenue for the exchequer by burning more fuel and collecting more tax must be a dis-benefit of a scheme rather than a benefit. It is absolutely illogical to consider this as a benefit of the scheme even if it could be explained in the pure financial / economic terms. Similarly any scheme adding to **urban** road congestion or just increasing car commuting in almost all urban areas is counter to central and local government policy. Thus for a road scheme which generates any extra peak hour traffic or even just saves car commuting time such benefits should be viewed at least as zero if not as a negative benefit. Showing such economic factors as benefits, we believe, provides misleading information to our decision makers.

In a similar vein it seems illogical and counter to policy that time savings in less prosperous areas are valued less and similarly pedestrian or bus passenger time versus car driver time. This is clearly counter to policy of helping more depressed areas and encouraging more sustainable modes.

Often in the actual calculation of cost-benefit the travel time savings in peak times are a very large contributor to the cost-benefit ratio and so distort the approval process for such schemes.

Also at a more detailed level most appraisal processes for new schemes are reasonably tightly constrained around the scheme itself. A small increase in traffic, even if a long way away from the scheme will generate disproportionate delays to traffic in an urban area which cumulatively could substantially reduce the economic benefits. While we would not support ever finer modelling to show this for each scheme it clearly paints a picture that any ‘economic’ benefits at congested times could be substantially reduced by a road scheme that induces any significant traffic - a clear finding from the SACTRA Review of 1993 and demonstrated since to be even more significant.

Response to specific issues raised in DfT’s aims of NATA refresh

We note the aims of NATA refresh and would have the following comments on the programme document ‘Refresh of the New Approach to Appraisal’:-

1) Make guidance more multi-modal. We welcome this but efforts should be made not to complicate any further.

2) Easier to use for small scale schemes and on infrastructure based decisions. Again we would welcome this and would stress a common line from Local Authorities that most of our transport problems are more revenue related rather than capital - involving support for public transport, smart choices work, maintaining existing roads etc, rather than providing new infra-structure.

3) More aligned with DfT objectives. We are concerned that these objectives should not just be DfT's they should be the whole Government including planning issues, all local government and indeed meeting the public's objectives.

4) Improved consistency with other advice such as Highway Agency's Design manual for roads and bridges. The Highways Agency are concerned primarily with inter-urban roads not for urban roads, their advice is related strongly to a "trunk road" approach for long distance traffic. It is very important that urban issues are properly considered and priority is given to the most important modes for access such as walk, bus and cycle.

Furthermore within the other road advice we have noted there is clear inconsistency with, for example, capacity design standards. The DMRB indicates design standards in excess of 2000 vehicles per hour per traffic lane on a high standard road. This standard is clearly at odds with road safety advice to keep a minimum of two seconds gap between vehicles on dry roads. This two second gap, if cars were infinitely short and absolutely evenly distributed, would mean a maximum capacity of 1800 vehicles per hour. We accept that if we do design roads to a realistic safe capacity, the capacity of the network through much of the country would be seriously overloaded now. Nevertheless an artificial capacity that is unsafe should not be included in the design standard. A design standard should now be more an issue of reducing traffic levels to a level the network can handle rather than thresholds for improving roads.

5) Ensure guidance provides coherent transparent expert advice. On the face of it we would thoroughly agree with this sentiment.

6) Update the price base for which costs and benefits need to be expressed. We would be concerned about any update of a price base on its own without consideration of policy issues, for example, as a matter of policy people walking or using public transport should be considered before the saving of in-vehicle car-travellers time especially in peak times. We understand that the present system values car driver (time) more highly than say walk or bus passengers which appears very perverse in policy terms. Any update of price basis should reflect such policy issues. We are also concerned at the evaluation of many issues in fixed economic/financial values hides a multitude of value judgements on items that cannot be realistically measured and compared with different impacts.

7) Reflecting Stern, develop strategy for making progress on valuing environmental impact. We would strongly support this and developments since Stern. We are aware that Stern has suggested that any carbon intensive infrastructure which may be out dated in the next few years should be viewed with extreme caution; this would apply to most major roads and airports.

8) Review summary information presented to decision makers including comparability of BCRs across modes. As mentioned above we are very concerned about the present methodology of calculating BCRs, however providing that any BCRs “benefit” which is contrary to policy is taken out of the equation, we would support presenting such modified BCR information as a sub criteria amongst the five NATA criteria.

9) Improve appraisal guidance at early stages in scheme developments. While we note there is guidance within the web-tag pages for simplified analysis we think this could be simplified much further, perhaps by using a simple policy sieve rather than the full weight of the Web-tag’s pages.

Response to formal consultation on NATA

Turning to the October 2007 document ‘The NATA Refresh: Reviewing the New Approach to Appraisal’ we have the following comments to the various questions raised:-

Chapter 2: Analytical Framework

1. The need to ensure proportionality of appraisal effort is noted in NATA, but users suggest that in practice the burden appears to be on the excessive side. How might we support promoters and analysts so that appraisal is proportionate?

Response: As described under the Bureaucracy and complexity heading above, we fully concur with the view that the burden is very much on the excessive side

2. If there were a light touch appraisal, how should sufficient robustness be maintained?

Response: There should be much greater reliance on policy filters or perhaps using other techniques such as Multi Criteria Analysis. Furthermore as also mentioned above a greater delegation to Regional and local authorities of their total budgets and priorities should reduce the central bureaucracy and improve decision making. It is notable that such an approach is in line with the Lyons report.

3. The Department and other bodies involved in strategic planning should consider wider dissemination of strategic analysis to provide the context for later stages in decision making. How should strategic appraisal tools be developed, balancing the right options being generated without unnecessarily analysing those that are unsuitable?

Response: Unlike the approach local authorities have been required to adopt for many years, the Department does not seem to consider transport planning for a whole area as an integrated whole before coming up with a proposal (and sometimes variations on the proposal) covering just one link. Without the proper context of a Strategic analysis of the problems throughout an area and a holistic approach to all solutions we will continue to get schemes being put forward that do not effectively deliver Central Government, Local Government or the public’s objectives and needs. When looking at schemes it is far better to assess a wide range of options using simpler appraisal tools but in an even handed way,

than to put most of the available resources into doing one option at a very high level of detail. Given limited resources inclusiveness should be the priority. This is more in accord with the Green Book guidance and Webtag.

4. In the future, option generation is likely to be more complex, integrating for example small-scale and better use options. The range of alternatives considered, including some possibly rejected at an earlier stage, may be informative to decision making. How might this information be presented?

Response: Small scale schemes and better use are part of the proper strategy development for the whole area. It is important that the Strategy is developed to meet the overall objectives for an area before assessing the 'value for money' of an individual scheme.

5. The analytical framework should continue to improve the linkage with the value-for-money assessment. As analysis widens its scope, the evaluation of schemes should also correspondingly broaden. Further, the framework should allow an assessment of the impacts of regulatory or other non-infrastructure options so that it is neutral over each option.

Response: The test should be – “ does the strategy meet the objectives and is it affordable” not a detailed cost benefit analysis of specific schemes. It is of fundamental importance that revenue based schemes are put on at least an equal footing to capital. This has been suggested many times over the decades including by the original ACTRA committee. We would particularly stress our earlier general comments that it is important to reduce bureaucracy and complexity in the analysis. Ever more complication increases the overhead reduces the effectiveness of public expenditure especially when such work can only effectively be delivered by the use of very complex models and external consultants.

Chapter 3: Economy, accessibility and safety

6. Over the Refresh, the extent to which the evidence for strategic decisions can be consistent with local or scheme specific evidence should be explored. How might the provision of more detail about the strategic analyses of economic, safety and accessibility impacts of Transport policies be made helpful to project appraisal?

Response: We fully concur that many aspects of life including health needs to be considered in the assessment of Strategic options or plans for an area. We also recognise the economic benefits of agglomeration but this is now an aspect that may be reducing with more remote working. Agglomeration appears to be a new aspect in assessment which could be readily linked with the idea of reducing the need to travel. This is critical to transport policy but also to the real agglomeration benefits. For example, it is the close proximity of businesses, minimising travel, which can produce three benefits: synergy, competition, and capacity. In many cases, particularly the service sector, this will be related to the density of development and the concentration of activity within short travel distances often by walking. It will be important not to confuse the extension of potential commuting distances (potential employees within a certain drive time) with agglomeration. Thus land

use planning, including zoning, relationship to relevant non-commuter transport networks, and density, are the key factors. Modelling the impact or valuing it would be confusing and probably counter productive.

Chapter 4: Environmental appraisal and assessing housing impacts

7. In providing decision makers with the evidence on environmental impacts there is always going to be a balance between taking appropriate account of the environmental impacts of transport interventions and the need to summarise evidence for decision makers alongside other impacts. Is the current balance between detailed assessment and summary appraisal information appropriate?

Response: The proper completion of the AST or similar should provide the best summary. However the standard and impartiality to which the AST is prepared needs enhancing. We would also suggest that there needs to be a rationalisation of the different methodologies between the current NATA and planning requirements for environmental assessment. As a thread running throughout our response the weight given to the calculated 'economic benefit' over all other aspects needs to be substantially reduced.

8. What are the priority areas for extending the use of the monetary valuation of environmental impacts?

Response: The monetary valuation of environmental impacts is not satisfactory at present and no extension should be contemplated until the current problems are addressed. Accurate measurement is supported, but the attached valuations are flawed conceptually (see overall comments) and depend on surveys of what people might be willing to pay. The overall point is that basing "hard" numbers like a BCR on a mixture of real world estimates, such as buying a bus or building a road, with derived values which are far more speculative, is not prudent.

Chapter 5: Assumptions and scenarios

Although there is no formal question from this chapter we agree that the Department should release and update regularly all assumptions and should make them known and readily available to decision makers. For example if all decision makers were to realise that the economic speed assumptions do not properly reflect what happens in real congested situations, the treatment of traffic growth and induced traffic between the do-minimum and do something options or that increased fuel usage actually helps justify a road scheme we are sure they would have a more pragmatic approach to approving schemes.

Chapter 6: Evidence from appraisal

9. Given there are a range of decision makers and the mass of evidence underlying appraisal is large and increasing, does the AST remain a useful format? How should the

AST be augmented to be a more effective way of conveying the information to decision makers?

Response: The AST was one the most potentially useful elements of NATA but has been poorly implemented on the ground. It needs to be altered to be consistent with the objectives in the latest Sustainable Transport document (for example including health).

10. How do we summarise the results of strategic analysis?

Response: As a first filter we believe all alternative area strategies should be checked for policy delivery or through multi criteria analysis or goals achievement methods before getting on to the detail of ASTs. At the AST stage, the ASTs for the alternative approaches considered should be presented, with the addition of a set of implications for local schemes. For example, the achievement of standards for street noise, of public transport accessibility, numbers of walk trips, and of GHG emission reductions should be cascaded down. Schemes would have to contribute or be given a negative rating in the local AST. Packages would tend to fare better than isolated schemes rather than the opposite, as present. This is another area where Government policy (towards integration) would be better supported by refreshing but, more importantly, implementation.

We are even more concerned about further text in this chapter which states '*The Department is committed to further work to provide a detailed specification of the BCR, as PSA Delivery Agreement 5 will use this ratio as an indicator of the Department's success in seeing better value for money from its investment over time.*' We do not think the present BCR estimation methods deliver sensible results let alone be given such fundamental importance - as explained elsewhere in this submission.

Chapter 7: Building analytical capability

11. From the range of techniques available to better communicate the appraisal advice, what should the Department consider?

Response: Notwithstanding our more fundamental comments, advice on appraisal, including the strong common sense element in documents such as the early Traffic Appraisal Manual (TAM), has often been provided but insufficiently read or followed. Now that the internet is available, webtag offers some improvement but the Department could consider using the web more actively, for example through debates, video, and particularly disseminating problems, solutions and assumptions that have been generated by practitioners. There is a problem in relation to the adversarial nature of major scheme Inquiries, but this should also be addressed not least by simplifying the process.

12. Do you have any suggestions about the consultative change process we envisage to ensure that you can participate as we develop changes to the guidance?

Response: The commitment to produce more material and hold further discussions is entirely appropriate for such a wide ranging and complex subject. It should be run in close co-operation with the debates around the Sustainable Transport process. It is important in such discussions to broaden the discussion and make it relevant and understandable to people not carrying out the detail assessments including particularly the decision makers.

13. The document identifies some issues and we would appreciate your views

on the priority – a ranking if appropriate – the Department should attach in

progressing these. We recognise that all the areas will need some consideration, but what are your views on their importance?

Response: We have already made our position clear that the whole assessment process needs to be simplified, reflect real policy priorities of all the authorities with an input to transport. We do not think that this can be achieved by addressing those issues listed in the questions. However for completeness within the priorities we have endeavoured to answer the detailed questions.

a. The Department should consider how best to support the continued interest

in the reliability and wider economic benefits of transport improvements. The

nature of these issues suggests the support would be wide, looking at data,

modelling issues in the context of innovative transport solutions. The need to

reconcile wider economic benefits and regeneration benefits is a particular area for guidance.

The importance of reliability in transport systems is very important for business and particularly future planning of depots etc. However this is better achieved on rail or with fine road networks; present strategies of high speed high capacity roads are intrinsically unreliable. The 'economic assessment is the area we have least confidence in as it does not reflect policy (e.g. a benefit is actually derived from extra peak hour car traffic as discussed above) and it still has an overwhelming role in the justification of schemes. In addition there is little sound evidence for the economic regeneration benefits claimed from more high speed roads.

b. The importance of journey time savings in the overall benefits of a scheme

suggest some further information about their composition would be informative. Whether this is possible should be explored.

Recognising the dominance of time savings in current appraisal and the need to understand their treatment across modes and who is gaining or losing and at what time (calculated travel time savings from cars at peak times has very limited value especially when such time savings encourage further car commuting) is important.

c. The Department will seek, engaging with the industry, to improve data and

methods regarding freight time savings.

Freight is very important, but predictability and reliability of journey times are probably much more critical to industry. Also leaving freight out of considerations of induced traffic leads to distortions.

d. The Department should consider how accessibility measures should be used in the NATA framework. In particular, should the information on the accessibility impacts in relation to local targets be presented, or should a more national approach be used? How should the accessibility impact be presented alongside the other impacts of interventions?

Accessibility is probably the main issue in identifying the need for any transport investment rather than the present approach of maximising mobility. Again for urban areas to deliver the required outcomes for the citizens and to deliver policy, accessibility by foot and public transport are the prime requirements. Walking line of sight mapping is now well developed, as are public transport accessibility and travel time contours. These are both informative and easy to understand.

e. The Department should consider how best to determine value for money within the transport appraisal framework using cost effectiveness analysis, in order to take account of economy-wide carbon and other environmental limits .

On the face of it this sounds to be an excellent objective however we are concerned if the outcome from analysis will leave more variables entering into the traditional monetary cost benefit analysis reducing the transparency still further for the decision makers.

f. The Department should develop desk-based analysis of the spatial aspects of environmental impacts. This can be used to facilitate strategic analysis, especially using GIS evidence, and support analysis of smaller schemes.

Some of this is quite well done already. Consistency and good practice would be useful.

g. The Department should investigate the extent to which transport's wider economic benefits can be associated with housing growth. The considerable change in land value due to the use of land for housing may – in part – reflect some benefits of transport enabling housing growth.

This is a complex area where double counting is likely to be a problem. While academic research is supported, it is a higher priority to get other elements in the appraisal right.

h. While work to join up freight, rail and aviation forecasting of trip generation is continuing, the Department should in the short-term consider how to ensure that the modal interactions are adequately represented in some specific areas. This is needed at a strategic level, to incorporate into the trip generation common assumptions, such as TEMPRO.

As stated above a strategic plan for the area under study is essential including, if required, models that allow for full changes in behaviour. We fully accept that part of that strategic plan must be future forecasts. However if the future forecasts are not in line with policy the options being put forward should not be followed and an alternative to change the expected

future should be implemented. Historical predict and provide have resulted in strategies that have failed to deliver the required policies e.g. the DfT or Highways Agency have promoted Trunk roads which have generated enormous problems for Urban authorities in delivering the needs of such areas.

i. The Department should consider defining common modelling scenarios to be used by those involved in strategic modelling and scheme level appraisal. These would recognise that some scenarios are policy determined. The evidence from alternative scenarios will need parallel tools to analyse uncertainty around scheme impacts.

As stated we believe that policy should determine appropriate strategies for an area. The “Do Minimum” option as presented frequently is not a viable option but alternative revenue based rather than capital based strategies could often better meet the needs of an area. This would require the preparation of some alternatives. General guidelines on these can be produced, for example a Smart Growth land use approach with Smarter Choices policies.

j. The Department’s guidance should continue to be developed on scheme costs. Such work should make decision makers aware about the risks around costs and how estimates become more firm with time. Risks may be mitigated through the financing of schemes. The overlap between cost appraisal and finance issues should be considered.

The use of optimism bias has caused some thought to be applied to this issue already and what is needed is some review of how this worked in practice, leading to further refinement of the guidance. Blanket application needs to be avoided. Revenue based schemes will always have lower and identified risks. After studies of the costs of all schemes would be helpful. At a more general level in consideration of funding regimes, financing of schemes to pass on risks to the private sector often prove very expensive especially especially when the risks are more in the control of the public sector.

k. The Department should look at the evidence emerging from Congestion TIF and other evidence on assessing packages and then consider how this approach can be widened beyond city and regional networks.

As for ‘j’ above evidence of performance of all investments needs to be critically assessed to see the long term effects. We would welcome closer working with the Department in the Congestion TIF areas as elsewhere.

l. The Department should continue to develop distributional analysis. In which types of interventions or transport problems should the priorities for this be?

If more freedom is given to the regions on what they believe they should be spending money to help their areas, this issue becomes less of a problem. Please see our earlier comments.

m. The Department’s support for determining whether a transport model is fit-for-purpose may supplement the standards by recognising the staged nature of designing solutions to complex transport problems. Should this be part of a

more general look at model validation?

Validation is important but there is an urgent need for greater understanding of the nature and limitations of models (across all modes). In particular the current models are very poor in relation to changing behaviour, since most of them are calibrated to existing behavioural responses. This issue should be addressed as a far higher priority. In any changes to the requirements for modelling we would again stress the need to minimise bureaucracy and overheads and also the fundamental limitations of such models if they are to be used for any 'cost benefit analysis'.

n. Developments to the Department's guidance should be issued with appropriate support. Appraisal tools assessing reliability and productivity impacts are demanding analytically and the Department should consider using workshops, training and the provision of data to enable analysis in these areas.

Far more progress can be made at the strategy level to improving reliability rather than analysing it for an individual proposal. For example regulated speeds have been shown to generate less accidents - a cause of much unreliability on the trunk road system. Similarly anything to reduce the peak loading on road links by demand management, Smarter Choices and simply finer networks are more robust for failure than coarser networks.

p. The Department is considering the scope to which a range of social research techniques may provide useful data involving the participation of the public at different stages in the appraisal process and to assess the social impacts of schemes, starting in the areas of option generation and in issues around public acceptability of proposals.

This is a very difficult area, involving different people's willingness to be involved, how articulate they are, how well supported they may be and what their personal agenda may be. Guidance on producing a range of alternatives, use of mediation techniques instead of adversarial inquiries, and trying to create the working atmosphere of the best EIPs should be prioritised.

We trust these comments will be useful in hopefully a more fundamental review of the appraisal processes. We would be pleased to take part in discussions with relevant people in the DfT and/or with other groups on our submission.

We confirm these comments have been circulated amongst the membership of TAG and reflect the technical views of the organisation, tempered by our public sector experience and public accountability.

Yours sincerely,

Resilience Review Expert Panel 9nd May 2014
Department for Transport
resilience.review@dft.gsi.gov.uk

Dear *[name redacted]* and Panel
Review of the Resilience of the Transport Network

1. Introduction

1.1 Thank you for the opportunity to submit comments/evidence to the Review Panel. As you may be aware ADEPT represents Directors of Environment, Economy, Planning and Transport. The Local Government Technical Advisers Group (TAG) represents similar professionals mainly in London Boroughs, Metropolitan Authorities and Districts in two tier areas. We have come together in this submission to produce a single agreed response and have consulted members of our respective organisations before finalising this document.

1.2 As combined bodies representing authorities around the country, instead of answering the specific questions raised by the call for evidence, we are submitting a statement covering the key issues. However this does not take away from individual TAG or ADEPT member authority responses on specific examples. Indeed in this response we have tried to concentrate on generalities under various topic headings (listed as below) illustrated by a limited number of specific examples.

1.3 The severe weather experienced in parts of the country during last winter was caused mainly by rain and wind, with occasional frost. This resulted in high river levels and overtopping, exceptionally high waves and storms in coastal areas, and high ground water levels, all leading to prolonged flooding in many areas. Numerous properties suffered internal flooding, sewer and drainage systems were overwhelmed and many roads had emergency closures for safety reasons for up to several months, leaving communities and businesses often using long diversionary routes to conduct normal daily duties. Some diversionary routes suffered severe congestion.

1.4 The damage caused to the transport links were due to standing and flowing water, structural damage in coastal areas and fallen trees. In flooded areas this caused extensive damage to the fabric of the roads. The damage to the lower classes of road (C and unclassified) with an already large maintenance backlog could be foreseen. However it was alarming to see the speed of deterioration in A and B class roads which were previously in good condition. Despite Local Authorities diverting substantial levels of resource to deal with potholes and defects, there remains a large part of the network which is yet to be tackled. The true cost of the damage will only be known when asset condition data has been updated for the whole network.

2. Discussion topics

2.1 Reliability - Resilience continuum in transport strategy

2.1.1 Whereas the extreme weather this winter of winds and rain have caused problems particularly in southern England, recent years have tested winter preparedness for snow in many other parts of the Country. We attach a TAG response on a previous winter preparedness consultation as an appendix (*Please note available but not attached*). Furthermore various one off incidences can cause real problems of access over several hours or days and these often do not appear newsworthy nationally (e.g. the sink hole in the M2 that made access from East Kent very difficult for several days this winter).

2.1.2 Industry, commerce and the public need reliability and predictability from the networks more than speed. Recovery from an accident or incident or avoidance from random congestion from overloaded networks need much higher prioritisation in transport policy. This can best be achieved by ensuring we manage demand to a level that can satisfactorily be coped with by the transport system or if this is not politically acceptable we need to tell business and the public clearly that there is not a solution to congestion (or weather) problems. If we cannot reasonably ensure provision of services or flood prevention to an area this must also be made clear so that people and businesses can plan accordingly. It is inevitable that disruptions to the transport links during floods will have social and economic consequences. Yet communities appear unprepared for these consequences and often expectation is that disruptions can be avoided. Better communication at both national and local level may go some way to manage expectations and prepare transport users for the disruption.

2.1.3 Redundancy and availability of alternative routes are also critical to avoid reliability or severe weather incidences (the rail line to the West Country in Dawlish is the best recent example). A finer network of reasonably balanced road or rail routes is required not necessarily the widening of already very high capacity links (like the M25 or M1). There are examples of resilient transport in other countries with frequent severe weather conditions which can be adapted (It is notable that road networks in France away from the toll roads is very robust to provide diversionary routes to the Routes Nationales).

2.1.4 A good example to understand the impact of closure of routes was in Salisbury where closure due to flooding of a pedestrian underpass under A36 used by many students going to a secondary school caused major risks due to lack of safe alternatives. In this case the pedestrian link may not have ranked high amongst many priorities that the Highways Agency had to deal with during the floods, but the impact on the local community especially in terms of safety was significant.

2.1.5 One of the important aspects of recent floods was reliance on forecasts from Met Office and Environment Agency for weather conditions, river and ground water levels, and coastal storms. There is no doubt that there have been significant advances in methods to better predict these elements, however there is still some way to go before transport operators can accurately predict and plan in advance for all weather events, based on the predictions received from the responsible agencies. There is also room for improvements and investment in use of smart technologies (sensors, etc.) by transport operators for obtaining advance warning at locations on the network known to be vulnerable to disruption during severe weather.

2.2 End to end journey and communications

2.2.1 We do not believe that resilience of networks should be considered on the basis of ownership/management responsibility for the networks but how best to ensure that end to end of journey access for people or goods can be maintained. A very large part of the rail network is under a single management organisation albeit all rail journeys need buses,

walking, taxis, delivery vehicles etc. to complete. For roads only 2% of the road network is under the management of the DfT; almost all journeys must begin and end on the 98% of the network that is the responsibility of ADEPT or TAG member authorities. The changes planned for the Highways Agency provide the opportunity to consider the end to end resilience for parts of a number of journeys via the strategic route network. Journeys via local highways need to be seen in the same context.

2.3 Maintenance versus new infrastructure (revenue versus capital)

2.3.1 TAG and ADEPT have expressed concern over the years at the imbalance between the funding available for new and especially large national infrastructure at the expense of looking after our existing infrastructure. As a nation we should look after our existing infrastructure in terms of coastal defences, dredging or clearing minor or major waterways or just proper maintenance of our roads and railways, in conjunction with investment to develop and extend existing networks. In the recent past it has been easier to raise capital funding for schemes than improve transport resilience. At the same time revenue funding to maintain drainage and flood mitigation systems remains under severe pressure, and although lack of maintenance may not be noticed during normal weather conditions, it can lead to disruption or failure of the network during severe weather, often at the time that the link is needed most. A ring-fenced fund specifically allocated to improve resilience of transport networks should be considered.

2.3.2 For improved resilience in strategic transport infrastructure of regional and national importance, alternative funding sources may have to be explored if central government funding is not available. The assessment of benefits of major schemes ought to give more weighting to transport resilience than it currently does compared to economic and environmental outcomes. Examples include:

- The major road (M4/M5) and rail links to the south west peninsula have proved vulnerable during severe weather events in the recent years. Investment to upgrade A303 which suffered closure at two locations in recent floods and has a poor record in providing journey time reliability would provide a good alternative transport link to the region.
- In the south east, extreme weather disrupts the Channel ports and the M20 motorway. There is a need to mitigate this with the provision of an “offline” solution in the form of a lorry park; and closures of the Queen Elizabeth II Bridge at the Dartford Crossing during times of high wind, which through provision of a new Lower Thames Crossing, physically separated from the existing crossing, i.e. to the east of Gravesend, and in tunnel, would provide much needed transport resilience.

2.3.3 Recent floods disrupted normal operation of many businesses ranging from small (e.g. restaurants and shops in riverside and coastal areas) to large employment centres (e.g. business and industrial areas) as well as freight movements and deliveries. With the current focus on growth and employment and creation of Local Growth Fund, consideration should be given to investing in improvements to resilience of the transport links serving these businesses to secure economic resilience during future weather events.

2.3.4 Furthermore the decision making in how to deal with flooding in an area often rests with several agencies. Whereas LLFAs have lead flood management and highways management responsibilities in many areas, decisions by Environment Agency, utility companies and emergency services often has a significant impact on how the risk of flooding is managed. Improvement to resilience of transport therefore requires a multi-agency approach in many instances.

2.4 Design and review of access arrangements to and within settlements

2.4.1 Many road closures during recent floods occurred on the main roads through villages, as well as some of the side roads branching away, typically where houses exist on both sides. For historic settlements we need to:

- Maintain access as far as possible to settlements by reasonable maintenance of existing waterways coastal defences roads and railways (as in 2.3 above)
- Advise businesses and residents of settlements properly and fully where it will not be possible to maintain access in all weather conditions
- Review areas that will regularly suffer from adverse weather and really need to be abandoned to find locations where the activities could be maintained (if this is agriculture we need to ensure that we do not build on 'green land' before all 'brownfields' have been exhausted – ref. ADEPT, TAG and POS comments on NPPF etc.)

2.4.2 For new developments on low lying brownfield (see comment immediately above) sites it may be worthwhile looking again at design guides and recognise that the immediate local road network could be used for water storage and then boat access in flooding conditions to ensure housing remains habitable.

2.5 Future adaptation and resilience

2.5.1 Prolonged rainfall causing flooding will lead to road and rail delays and rail cancellations in the 2020s and 2050s which may have a severe impact if no adaptation occurs. Adaptive actions include improving drainage management plans and improvement of the standard and capacity of drainage systems. Adaptive capabilities are likely to be lower in the 2020s reflecting their long-term nature of infrastructure assets. There is greater certainty in benefits of adaptation for rail; substantial uncertainty on the benefits of adaptation exist for roads.

2.5.2 The Local Adaptation Advisory Panel for England (LAAP) has been set up to provide advice to central government from a local perspective, enhancing the capacity of local leadership to help build resilience. It will develop strong links with other important national partners and networks to remove barriers to adaptation and help shape a fully supportive framework for local adaptation. Many Council's already have their own plans to adapt to a changing climate. LAAP's role is to support local ambition, identify and share best practice and be an influential voice to government to ensure there is the right level of support to local needs. They will provide advice on how this work benefits business, residents and supports economic prosperity.

2.5.3 The National Adaptation programme is a useful tool in helping industry sectors, tiers of government and business deal with the uncertainty of climate change. The time-scales over which climate change is expected to occur and the extent to which it will impact on society are not clear, although impacts of a changing climate were strongly felt last winter. There is also uncertainty about expected weather conditions as a result of changes in climate. Uncertainty can magnify barriers to adaptation and attract government intervention that leads to a crowding out effect.

2.5.4 Climate models indicate that many parts of the UK are likely to experience rising average temperatures, more heavy rainfall (leading to flooding), rising sea levels and faster coastal erosion, more heatwaves, droughts and extreme weather events as this century progresses. The current Climate Change Risk Assessment (CCRA) shows that projected climate change presents a set of opportunities and threats for the UK economy. The latest Intergovernmental panel on climate change reports highlight further evidence of impacts and the importance of adaptation. In supporting the Review team's important work, TAG and ADEPT would be very pleased to meet the team to discuss any of the points raised in this response or any other issues arising from the review.

London City Airport response to the National Infrastructure Commission's Call for Evidence 10th February 2017

Introduction

1. London City Airport is one of the UK's fastest growing airports with a record 4.5 million passengers in 2016. LCY serves nearly 50 European and domestic destinations, as well as a daily service to New York JFK.
2. London City Airport makes a vital contribution to the UK's airport capacity and connectivity. In July 2016, the Government granted LCY with planning permission for the City Airport Development Programme (CADP) which will improve the airport infrastructure. CADP includes plans for 7 new aircraft stands, a parallel taxiway to maximise runway capacity, and a terminal extension to accommodate increasing passenger numbers.
3. The aviation sector and the connectivity it provides is a main driver behind facilitating trade in goods and services, business investment and tourism. LCY alone supports over £11bn of UK trade exports to key European markets each year. London City Airport (LCY) welcomes the opportunity to respond to the National Infrastructure Commission's Call for Evidence to provide input into the development of its National Infrastructure Assessment.

Airport capacity

4. According to DfT statistics, passenger numbers at UK airports are set to increase from 219 million passengers in 2011 to 315 million in 2030 and 445 million by 2050¹. This is an increase of 225 million passengers over the next 40 years compared to an increase of 185 million since 1970. It is obvious that the demand for air capacity is acute and will continue to increase. Such increased passenger demand makes it pertinent to include the aviation capacity debate in the analysis of the major infrastructure needs facing the UK over a 30-year period. The airport welcomes the DfT's current consultation on "Reforming policy on the design and use of UK airspace". Enabling the South East airport system to add more capacity through increased efficiency and connectivity between airports should be a top priority in the long-term needs-based infrastructure assessment.
5. Despite the Government's approval for expanding Heathrow, a third runway is still years ahead. In the meantime the passenger growth forecast clearly demonstrates that the demand for air travel will continue to rise and will not be addressed in the near future. This has created an opportunity for the National Infrastructure Commission to consider providing the Government with a recommendation on aviation capacity across the UK.
6. LCY welcomes the fact that the Government is going to consult on a new Aviation Strategy with the aim of finalising it by the end of 2018. It is however important to recognise that the UK needs a strategic assessment and direction for the further development of air travel in

¹ DfT: UK Aviation Forecasts

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/223839/aviation-forecasts.pdf

the short, medium and long term. This is even more relevant in the context of Brexit, when the UK would rely on strengthened connections with Europe and the rest of the world and therefore airports infrastructure should be part of the country's strategic Infrastructure Assessment. Based on the passenger growth forecast and in cooperation with airports, the National Infrastructure Commission should provide an overview of anticipated future demand and a recommendation on how the sector can respond -outlining areas of strategic opportunity for the future. The National Infrastructure Commission should recommend examining airport passenger figures on a yearly basis. This will allow the DfT to understand demand and infrastructure provision.

7. In July 2016 the Government granted LCY planning permission for the City Airport Development Programme (CADP). CADP will allow the airport to build seven new aircraft parking stands, an extended terminal building and a parallel taxiway.
8. LCY is expected to start construction in 2017 delivering much needed aviation capacity into the London system at least a decade before a new runway is built. With expansion LCY can add 30,000 additional flights per year to the London airports system and 2 million additional passengers by 2023. Our plan for expansion is in line with LCY's 2006 Master Plan which envisages LCY handling 6 million passengers by 2025. The Master Plan's ultimate vision for further future growth at LCY is for 170, 000 flight movements by 2030.
9. Granting permission for LCY to expand was clear indicator that the Government understands the need to enable travel and trade. The airport believes that it would be better to develop a strategy to respond to the passenger demand over the coming decades. The National Infrastructure Assessment should play a role in advising the government on a strategic direction for the development of air travel in the UK up to 2030.
10. LCY is located in London's Royal Docks which has been established as a Local Enterprise Zone and is currently undergoing substantial investment and development. To realise its full potential the area should be supported by significant investment in its infrastructure. An upgrade to the DLR, improved broadband and digital infrastructure could transform the Royal Docks into London's next global business hub. Improved surface access in the area—including more river crossings, an upgrade to crucial road capacity and Crossrail –can in turn have a wider economic impact on East London.

Improved surface access needed to create an integrated airport system

11. Airport growth is dependent on improved surface access which can allow airports to deliver their full potential and better respond to the increased demand. In the current constrained aviation environment it is important that improved surface access is seen as a crucial part of a transport strategy for an integrated airport system. The Infrastructure Commission's call for evidence provides an opportunity to assess the current infrastructure connecting airports and in this way identify the existing gaps to a wider integrated network of airports.
12. London City Airport has very good transport connections with the DLR having a stop at the terminal building. LCY currently has the highest percentage of passengers arriving by public transport in the UK. Crossrail will be transformative for east-west travel in London and once it opens its Custom House station it will offer a 40-minute journey time from LCY to Heathrow. Additionally, LCY has ambitions for a new Silvertown Crossrail Station which will act as a regeneration stimulus for Silvertown due to the greater connectivity the station would provide to the local area. It will ensure that LCY is even better connected to the

London's transport network – a direct connection to Heathrow and to Gatwick and Luton via Farringdon.

13. In the context of an increased demand and constrained capacity, a better connected wider network of airports can create an opportunity for passenger transfers. LCY can relieve pressure on other capacity constrained airports by taking some of their short-haul traffic and freeing up valuable slots for much needed long-haul traffic.

The planning system should ensure that infrastructure is delivered as efficiently as possible

14. Infrastructure development should be better accommodated by the UK planning system. LCY submitted its planning application in 2013 and received planning permission from the London Borough of Newham in February 2015. In March 2015, however, the Mayor of London, going against the recommendations of his planning team, directed Newham to refuse permission for CADP. LCY appealed this decision and our planning appeal and CPO process eventually led to approval in July 2016. Due to the protracted planning process and caused delays in LCY's ability to add much-needed new capacity in the South East.

For further information, please contact LCY's Policy and Public Affairs Executive

▶ London Councils' response

▶ National Infrastructure Assessment: Call for Evidence

London Councils represents London's 32 borough councils and the City of London. It is a cross-party organisation that works on behalf of all of its member authorities regardless of political persuasion.

Introduction

London Councils welcomes the extensive consultation activities undertaken by the National Infrastructure Commission on the National Infrastructure Assessment. We would welcome an ongoing conversation with the Commission, given that new evidence, policies and strategies continue to emerge. The text below represents London Councils views at this point in time.

Cross-cutting issues

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region? *Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.*

London has a growing population and not only needs infrastructure to support this growth but also to improve connectivity to other parts of the UK.

On transport, London Councils supports the following schemes:

- Crossrail 2, connecting Hertfordshire, London and Surrey, and providing regional benefits across the south east;
- Brighton Mainline Upgrade, removing the bottlenecks at East Croydon station and improving reliability between London, Gatwick Airport and Brighton;
- Crossrail 1 extension from Abbey Wood to Ebbsfleet for connections to High Speed 1;
- River crossings in East London and the lower Thames;
- Improved orbital bus, rail and road links in outer London;
- Financial incentives and a positive regulatory framework for uptake in electric vehicles, including commercial light-vans.
- Southern access to Heathrow Airport and improvements to the South West mainline;
- East-West rail and road links between Oxford and Cambridge;
- North Downs rail link between Gatwick and Reading;

- Road and rail corridor Dover-Southampton (A27/M27/A259);
- Great Eastern mainline (connecting London, Ipswich and Norwich);
- East London rail connections to the Thames Gateway;
- Western access to Heathrow Airport from London and Reading;
- Midlands and West Coast mainline (connecting London, Luton, Bedford and Milton Keynes);
- New link from Felixstowe to Nuneaton and the East Midlands.

On digital, London Councils wants to see:

- UK adoption of the standardised wayleave produced by the City of London to speed up fibre connections;
- Preparatory work to secure the rollout of 5G.

On energy, London Councils wants to see:

- A decentralised energy system based on cleaner energy technology;
- Incentives for individuals and organisations to install cleaner energy technologies on their buildings;
- More emphasis on demand management, including energy efficiency measures for current buildings and planning standards for new builds;

On water and wastewater, London Councils wants to see:

- Strategic adoption of SUDS across new and retrofitted buildings;
- Changes to regulation that remove the automatic right to connect to a sewer, requiring developers to maximise their site capacity for managing its own wastewater and rainwater;

On flood risk management, London Councils wants to see:

- Changes to the financing of capital schemes that allow consideration to be given of funding flood defence works to protect commercial property and strategic assets.
- A continuation of the local prioritisation of projects for funding by Regional Flood and Coastal Committees, giving local politicians oversight over flood risk in their areas.

On solid waste London Councils wants to see:

- Greater policy and regulatory focus on waste minimisation, with increasing recycling rates as a secondary priority.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Infrastructure needs to enable businesses in the UK to thrive; be that through fast broadband connections, proximity to national, regional or international transport gateways, or because they can get their goods quickly to market. The physical infrastructure of transport and digital is inevitably backed up by waste and energy infrastructure and the need to 'green' and decarbonise our activities. Infrastructure should be an enabler of business, rather than an inhibitor (for example, sending staff home because upload speeds are faster there than in the office).

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

There is some infrastructure that is integral to building sustainable communities, such as public transport provision, digital infrastructure, localised energy generation, water supply and some waste facilities. There is other infrastructure relevant to the NIC's remit, which could potentially be located anywhere, providing important jobs for that locality, but also providing nationally significant infrastructure, such as certain waste and energy facilities that due to their nature could not be close to all the communities they serve.

Infrastructure needs to be designed in at the beginning of new developments, to make sure that places where people live 'work' for them and the lifestyles they are expected to lead. For example, a no-car development needs to have good public transport links; if a bus route cannot be secured into the development, the development becomes not only undesirable, but potentially very difficult to live in.

Infrastructure can be used to unlock sites, and often needs to be built ahead of housing in order to secure it. Masterplanning a site needs to understand these interdependencies and funding mechanisms need to be in place to enable this to happen. Business cases for strategic infrastructure, such as new railway lines, new energy and waste facilities should include the real value they are adding in accommodating existing and future demand.

However, we need to be realistic that a lot of infrastructure is needed in places already well-established and heavily built-up. Design and delivery solutions here need to identify whether new infrastructure is simply about improving what already exists or reshaping a place. It is worth stating that making the most of existing assets should always be the first consideration.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

We acknowledge the challenges around demand management and believe there is a lot more we need to understand about it. Demand management, however, is a valuable tool in helping shape infrastructure and investment decisions albeit its limitations. We do believe that more emphasis is needed on demand management measures, such as energy and water efficiency and should also be applied more strongly in waste management (reducing the amount of waste produced).

We think demand management can be best used where there are several positive outcomes available; for example in London the Hopper fare reduces the cost of bus travel, meaning more people take the bus. This in turn contributes to reducing the number of people using a car and therefore helps to improve congestion. The negative outcome however is more overcrowded buses. Demand management can then be used again to understand when increasing the frequency of the route is appropriate, before people switch back to car use.

We support demand management such as metering as it offers more holistic solutions, for example addressing the costs of utility bills for lower income households. We acknowledge this can in turn increase the amount of energy used, but if this energy is from a renewable source, the negative outcomes are reduced. As such we believe a 'whole system' look at demand management is necessary.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

We know that communities want to see existing assets maintained to an adequate standard. Allowing assets to decay to a position where they no longer provide the expected standard is damaging for public confidence, especially where assets are relied upon to protect communities, which is especially the case for flood defences. London Councils commissioned polling of Londoners on infrastructure in summer 2015 and on flood defences, 87 per cent of respondents living in inner London, compared to 58 per cent of respondents living in outer London, prioritised maintaining existing defences rather than building new ones. We know London Boroughs are equally concerned that there is sufficient ongoing funding for the maintenance of existing and new assets, as for installing new schemes.

We suggest a better understanding of assets at a national level, and levels of risk with regards to maintenance regimes. This would enable a prioritisation of maintenance of existing assets alongside construction of new assets. It is important to bring both schedules together rather than viewing them as separate.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

We believe that packaging of schemes and/or aspects of work within those schemes could be used to a far greater extent at all levels of infrastructure, national and local. We note that the Environment Agency actively packages schemes for flood defence works in order to achieve efficiencies, and we suggest a similar approach is taken in other infrastructure sectors where it is not already. Determining whether to use consultants or train internal staff is another factor in competition and collaboration, as well as in skills.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered? Note: by "funding", the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

Regardless of who pays for infrastructure, the process by which funding decisions are made needs to be drastically accelerated. We believe there is a bigger role for greater standardisation of agreement between government and local parties. For example, it took the Mayor of London and the London Borough of Croydon four years to agree a business rates retention deal to secure regeneration and infrastructure upgrades in Croydon. The next local authority who wishes to negotiate such a deal will take equally long. There needs to be a single, standardised agreement and process, with due diligence, rather than bespoke negotiations for each funding agreement.

Greater use of 'user pays' principles can only be achieved with fiscal devolution from government, which in turn ensures that not only can an infrastructure asset be paid for, but its long-term maintenance secured as well.

London Councils supports the recommendations of the London Finance Commission for the Government to work with the GLA, TfL and the London boroughs to develop a consultation paper on the objectives, principles and design options of a land value capture charge¹. Mechanisms for extracting value uplift on property brought about by infrastructure investments should also be considered. Infrastructure investment, usually paid for through fares and taxes, results in property price rises and new development. Evidence from TfL shows existing mechanisms only extract a small fraction of land value gains from transport investment (for example extension of the Jubilee Line). Further modelling predicts future transport schemes in London are also likely to produce large land uplifts.

A sample of eight prospective TfL projects that cost around £36 billion (including Crossrail 2, the Bakerloo Line Extension and the DLR extension to Thamesmead) could produce land value uplifts of about £91 billion. Under existing arrangements, local transport schemes capture less than five per cent of this uplift in value.

- 8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?** *Note: projects that "can be funded" but "will not be financed" refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.*

London Councils takes the view that this is a major factor in slowing infrastructure investment in the UK. For example, one funding source for Crossrail 2 is from the payback gained in house prices, which the Treasury will see through increased stamp duty receipts. Due to the risk appetite of government, this is delaying the project's progress.

- 9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?** *Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.*

London Councils believes resilience to flood risk and climate change is a major consideration in interdependencies. This requires that infrastructure takes account of future projections, for example of sea level rise, flood risk zones and changing land use; and appropriate solutions for the future are developed in the present. Flood risk and climate change is relevant not only in the siting of physical infrastructure such as roads and bridges, but also for the UK's energy and water supply requirements in future generations. Consideration should also be given of the interrelated aspects of digital and transport infrastructure. Transport is a sector where digital solutions have not yet made a significant impact on transport patterns, nor seen a marked increase in working from home or flexible solutions. However, this could change in the future, and so needs to be considered when determining the transport infrastructure investment the UK needs in the longer-term.

¹ https://www.london.gov.uk/sites/default/files/devolution_-_a_capital_idea_lfc_2017.pdf

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

London Councils cautions against any attempts to reduce the amount of public consultation or opportunity for the public to better understand proposals. That said, we have noted already that greater standardisation in the way that funding is negotiated with government would speed up the timescales for infrastructure projects. Local and regional projects that have funding secured should not get caught up in national government interest or bureaucracy, when the project is not of national significance.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

We want to see greater adoption of green infrastructure and sustainable drainage measures to ensure that new infrastructure does not worsen flood risk and contribute to create greener, more pleasant and biodiverse environments that do not exacerbate the effects of urban heat islands. Use of green energy sources should always be considered, along with more of the environmental practices already commonplace; for example reusing aggregate, tree planting and building materials that reduce the impacts of noise. The concept of Circular Economy should be at the heart of decision making, particularly regarding waste management but also in other areas, such as construction. When ageing infrastructure comes up for renewal, options for improving the environmental impacts of its replacement should always be considered. This could include a change of location if appropriate and should look at the wider impacts, such as transport, biodiversity, amenity, social and economic.

Transport

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies? Note: "travel patterns" include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

We are concerned about the projected increase in vans in London, as regardless of whether these vehicles are low emission vehicles, they will contribute to congestion. Driverless vehicles present a set of challenges that need further investigations; currently London Councils remains concerned the impact this technology may have for London in terms of congestion.

We envisage a continued increase in cycle couriers and the transition of the entire taxi fleet to low emission vehicles. Climate change and the impacts of the urban heat island effect may hamper efforts to encourage people to walk and cycle more, if conditions to do so are unpleasant. We have yet to see any great impact of technology on the way people work and an increase in working from home. By 2050, this may be more prevalent, and we want to see this supported by better part time and off peak ticketing. London's population is projected to increase at almost twice the rate of the rest of England, and public transport investment needs to keep pace with this demand, otherwise congestion will worsen.

- 14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?** *Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.*

London Councils supports the progress boroughs are making in establishing freight consolidation centres to reduce the impact of 'final mile' deliveries. We believe freight consolidation, along with greater use of the river in London, can contribute significantly to improving the relationship between freight and the city. Restricting car use and encouraging people to reduce car use will be important going forward.

- 15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?** *Note: this includes travel in and between rural areas, as well as between urban areas and international travel.*

In London, we need fast, through routes connecting people in London to other places; for example as the Thameslink line already achieves, and as the Elizabeth line will do as well. Better connectivity as well as faster journey times are vital to ensure the UK's competitiveness. As discussed above, tackling congestion is very important, and London is due to receive new airport capacity before 2050.

- 16. What opportunities does 'mobility as a service' create for road user charging? How would this affect road usage?**

Road user charging extends the principle already part of public transport and taxi trips to private cars. Car clubs play a role in this, alongside road user charging as mechanisms for encouraging people to stop owning their own car and instead hire one as necessary. Any proposals for 'mobility as a service' need to take into account the impacts on the lowest paid as they travel to work or school, and the impacts high travel costs have on social isolation and loneliness.

Digital communications

- 17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?**

We feel government's role is not to second-guess the market but to focus on bringing those left behind by existing improvements up to speed and quickly. We want government to identify how it can incentivise or regulate providers to address the need of the 'final mile' hard to reach and often unprofitable areas. We note the government's recent work in this area to bring a digital connection in line with other utility connections, but believe there is still more to do in this area. Areas of London continue to suffer from poor broadband speeds, and so access to good, reliable broadband is not an issue reserved only for rural areas. Whilst we welcome efforts to ensure the UK is well-placed to adopt 5G quickly, this should not be at the expense of providing everyone with a reliable, fast connection. We note the City of London's recent work in developing a standardised wayleave that can be used across the UK to speed up the process of agreeing new internet connections between providers, tenants and building owners; and that the GLA is currently producing a standardised wayleave for mobile connections.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing "regime" refers to the current market, competition and planning frameworks. "Digital communications" includes both fixed and mobile connectivity.

We are not convinced that making digital connectivity the 'fourth utility' will resolve all the problems associated with rollout. We want to see government introduce a planning requirement for fibre-ready connections to be installed within new buildings, and for the wayleave toolkit to be adopted as best practice by government.

Energy

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

More support and strategic planning is needed by government to assess the most effective methods. Energy efficiency remains important as this reduces demand for heat regardless of fuel source and therefore should take high priority. Further research into carbon capture and storage needs to be undertaken.

The Committee on Climate Change notes that the continued roll-out of low-carbon heat networks through the 2020s will require a supportive planning policy framework and a financing framework. The government will need to establish a process for determining the direction of travel for heat decarbonisation post-2030. This includes identifying stakeholders and their roles, and which decisions need to be made during the 2020s.²

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.

London Councils wants to see a range of solutions: increased energy efficiency of buildings; increased use of low carbon gas; increased electrification of heat; increased decentralised (district/local/community) energy systems (as efficiency is lost through transmission); and increased use of "fringe technologies" such as solar thermal, geothermal and heat pumps. To achieve this, the government needs to set out a long-term plan, and provide investment (see comments above).

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

We note that one scenario used by the Committee on Climate Change is for electric uptake in the UK to increase significantly to 13.6m electric vehicles on the road by 2030. This would have an impact on energy infrastructure; storage will be important alongside the decarbonisation of the power system. Innovative solutions around demand side response and vehicle to grid technology would assist with this.

² <https://www.theccc.org.uk/wp-content/uploads/2016/10/Next-steps-for-UK-heat-policy-Committee-on-Climate-Change-October-2016.pdf>

Water and wastewater (drainage and sewerage)

- 22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?**
Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

London Councils supports the rollout of metering and we want to see greater uptake of strategic sustainable drainage systems (SUDS) across London and the UK. Water stress needs to be given much greater consideration when development sites are identified, particularly as this is a pressure that needs to be considered from the beginning, as solutions are difficult to add once buildings and layouts are designed.

- 23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?** *Note: this can include, but is not necessarily limited to, governance frameworks across the country.*

We want to see stronger requirements on developers to introduce SUDS and greater retrofitting of existing buildings. The right to connect to a sewer needs to be discontinued, to force developers to give much greater consideration to the water that can be managed on site. We see a continued role for local authorities and water companies working together on ensuring developers include adequate sustainable drainage in their development. Not having an automatic right to connect to a sewer (and especially a surface water drain if this is nearest) would help improve this approach.

London is already building the Thames Tideway Tunnel to better manage demand, but we note that Thames Water still predicts severe capacity constraints in some parts of London, regardless of this new infrastructure.

- 24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?**

London's local authorities are part of the Thames Regional Flood and Coastal Committee which is funding 'slow the flow' land use management pilots in the upper part of the Thames catchments. At a very local level, there needs to be greater public awareness of the implications of paving driveways, perhaps for neighbours several streets away. Local authorities could play a greater role here if planning permission were required for such changes. In London the Greater London Authority is mapping where there are opportunities for effective installation of SUDS measures.

Flood risk management

- 25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?**

London Councils believes that flood resilience should focus on protecting homes and significant economic assets to the UK. We need to be mindful of a changing climate and locating developments in flood plains and this includes in cities like London. As a country we need to improve the way we determine which areas will flood, and we need to do this in cities as well by making space for water and for water to drain.

- 26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?** *Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.*

The Thames Regional Flood and Coastal Committee is looking at piloting schemes in the upper Thames catchment. These are valuable, as they help protect green assets, but we also know that they do not protect against the worst floods. A number of boroughs install property level protection for homes at risk of flooding where a large scheme is not viable. We need increased use of construction materials that repel water, and to ensure householders are educated in the benefits of these materials. We welcome the innovative approaches in flood risk, and note that there is a much more limited approach in the drought and overheating aspect of water management.

Solid waste

- 27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?**

We are concerned that the focus on increasing recycling rates is misplaced when the focus should be on waste minimisation. As such we want to see changes to regulation that require greater action from business to reduce their packaging, and of what remains, ensure it can be firstly reused and secondly recycled. We hear mixed views on whether London and the UK have enough infrastructure to meet its waste needs – a robust and comprehensive review would be welcomed. The transition to a circular economy should reduce requirements for landfill, which should be an ambition of the UK anyway.

- 28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?** *Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.*

London Councils is supportive of achieving a more circular economy as a key principle to move to better waste management to reduce waste and become zero carbon. Planning and leadership would generate long term certainty which will enable the correct infrastructure to be delivered so we would like stronger government commitment to circular economy principles across all department including BEIS, DEFRA and DCLG.

New targets for reuse and recycling place a financial burden on local authorities as capture rates for traditional materials will need to be increased and new materials added to collection and disposal services. At the moment local authorities bear all the costs of waste management but have no control over materials entering the waste stream so see none of the benefits. This makes a strong case for extended producer responsibility to incentivise the circular economy approach as far upstream as possible. Once circular economy principles are implemented it makes no sense to continue to measure recycling by weight as materials move out of the traditional waste stream to new uses. We support targets and measures which encourage the best environmental or economic outcome.

It is expected that further investment in waste processing infrastructure would be required to ensure the appropriate capacity is available. There is currently a lack of investment in recycle processing infrastructure so confidence needs to be renewed which could be provided by government. An additional barrier to the circular economy is space for new industries and storage especially in urban areas.

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support longterm sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

The greatest need is to provide for existing communities poorly served as a result of chronic overcrowding. Schemes which promote longer distance commuting represent poor value for money. Modal shift of freight to rail is essential if we are to achieve long term sustainable growth.

2. How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

We need to create a network suitable for piggy-back freight. Use of existing lines with action to overcome the bottlenecks, diverting around them, is likely to be more cost effective than building a new line.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The housing is crucial. It must be close to places of work which may mean that infrastructure is geared to relocating offices more than housing.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Your note partly answers the question, but there is clearly scope for more demand management, notably road pricing.

5. How should the maintenance and repair of existing assets be most effectively

balanced with the construction of new assets?

A priority should be to ensure that there is a network of secondary routes that minimises delays when the primary route is being repaired, e.g. an alternative rail route when the Cornish coastal link is flooded, alternative road routes for buses when a road is blocked, particularly by flooding which takes several days to repair, or alternative provision of step-free access when a lift is taken out of service.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Proposals should be drawn up by people with no vested interest in their delivery. We get schemes that are best value for those constructing it, we need best value for passengers and freight users.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Greater decentralisation would result in more lower cost higher value schemes. A Land Value Tax would ensure contributions from those in receipt of windfall benefits and compensation to those unexpectedly disadvantaged.

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

Transport should be treated as a means to development, the same as water and electricity. It exists to facilitate economic activity, not to make a profit itself.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

No observations.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as

possible and on time?

Planning should be recognised as an asset to sustainable growth. It should be properly funded, and planning briefs should be drawn up by planning authorities not would-be developers.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

This needs a robust and balanced planning regime.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

Analysis should be undertaken by disinterested parties. Those with a vested interest can always find a technique that generates data which advances their own cause

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

Optimistic: more walking, cycling and shift from air and private car to rail and bus.

Pessimistic: people travelling further to achieve the same end, and the problem of an ageing population resolved by worsening air quality.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: “high value transport investments” in this context include those that enable ‘agglomeration economies’ – the increase in productivity in firms locating close to one another.

Planning to support greater contra-flow commuting would achieve the greatest efficiency. Measures that streamline interchange, or that iron out bottle-necks, would be the most cost effective expenditure on transport infrastructure.

15. What are the highest value transport investments that can be used to connect

people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

Bus services regulated to ensure that buses complement trains where the volume of traffic does not justify a rail link.

16. What opportunities does 'mobility as a service' create for road user charging?

How would this affect road usage?

We believe road charging has the potential to regulate usage to the general good.

National Infrastructure Assessment call for evidence 10 February 2017

Via email : NIAEvidence@nic.gsi.gov.uk

London TravelWatch is the statutory body representing all transport users in London and rail users within the wider London Rail Area which includes London's airports

London TravelWatch welcomes the opportunity to respond to the commissions' consultation, as it touches on areas of significant concern to users of London's transport networks, and which London TravelWatch as a passenger representative body has carried out significant research in recent years. Our previous response to the previous consultation relating to London is set out in Appendix A.

London TravelWatch has produced a series of transport user priorities for the 2016-20 Mayoral term based on our research and our passenger contacts. This response reflects these priorities:

1. Sustained investment to meet London's ever-growing transport needs
2. A road network that makes the best use of scarce capacity
3. As many of London's rail services as possible coordinated by the Mayor
4. Reliable bus services that keep up with the pace of change
5. Simpler fares, better value for money and a fairer deal when things go wrong
6. A co-ordinated approach to transport interchanges
7. Transport networks accessible to all
8. Reliable, accessible and timely information
9. Everyone able to travel without fear of crime or anti-social behaviour
10. Disruption effectively managed

Consultation questions

Cross cutting issues:

- 1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?**

These would be ones that make the best use of existing infrastructure, but where disruption to existing users is kept to a minimum. Appropriate mitigation should be put in place before major works are commenced to give users or passengers alternative means of completing their journeys or doing their business, particularly if the infrastructure project is on a 'live' part of an existing network used by large numbers of people while the project is taking place. An example of this would be the Thameslink upgrade project.

New infrastructure projects should be fully integrated into the maintenance programmes for existing infrastructure – the Thameslink upgrade has had many instances where failure to do this has resulted in much more extensive and costly disruption from a failure to do this.

There should be no fixation on the size of infrastructure investments, although London TravelWatch fully supports projects such as Crossrail 2, Western and Southern rail accesses to Heathrow Airport, HS2, upgrading the rail route to Stansted Airport.. Highest value can often be achieved from smaller scale projects. This might be new platforms on rail lines adjacent to existing rail stations. London TravelWatch has long advocated ¹the construction of additional platforms on the Chiltern line at West Hampstead, the South London line at Brixton and on the Lewisham – Victoria route at Brockley are examples of where considerable connectivity and productivity benefits could be achieved for a relatively modest outlay, making better use of the existing adjacent London Underground, London Overground, Thameslink, Southeastern and Southern services and stations. An example of where such benefits have already been achieved is the linkage between Hackney Downs and Hackney Central stations by a new pedestrian walkway. This has freed up extra capacity into Liverpool Street station, but also reduced journey times for many passengers and opened up new job opportunities across north east London that would otherwise have not been possible, but for a very modest outlay.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Airports, rail stations and other interchanges are the 'shop windows' of the UK that give the first and last impressions of the UK to overseas travellers, and therefore ensuring that these are of top quality is therefore really important. London TravelWatch has developed an assessment tool² for determining how well these interchanges perform, and what operators and authorities can do to bring in improvements. An inefficient and unpleasant experience at such a location will reduce the attractiveness of the UK as a whole and therefore reduce its international competitiveness. For airports serving London we have recommended a series of improvements to road, rail, bus, taxi and private hire car services that would substantially improve the user experience and by extension the UK's overall competitiveness.³

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Infrastructure and housing should be considered as part of a whole land use planning environment, whereby the need to transport or transmit people, goods and energy is minimised, and where priority is given to the most efficient modes. This would include prioritising walking, cycling and public transport in housing schemes.

¹ http://www.londontravelwatch.org.uk/documents/get_lob?id=4254&field=file

² http://www.londontravelwatch.org.uk/documents/get_lob?id=4040&field=file

³ http://www.londontravelwatch.org.uk/documents/get_lob?id=3894&field=file

Creation of 'hubs' of retailing and services around public transport interchanges would also reduce trip rates and congestion on the road network. Examples of this might be rail stations with adjacent food superstores where commuters are able to link their shopping trip to before or after their rail journey to and from work, rather than make a separate trip to a food superstore. In the case of energy, for sustainability production should be closest to the place of use e.g. the use of solar panels on buildings or alongside rail routes that use electricity.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Circumstances for this will vary, but ultimately there is not necessarily a maximum for demand management in any sphere of public life.

5. How should the maintenance and repair of existing assets be more effectively balanced with the construction of new assets?

Evaluation of how many users or passengers affected by a maintenance regime on existing assets and how many would benefit from a new asset, and how much disruption both options would cause.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

This depends on whether there is competition for the market (franchise concessions, competitive tendering etc) or competition in the market (parallel routes and competitive pricing for individual users). Infrastructure usually requires competition for the market rather than competition in it. Competition for the market has the potential to drive quality and provide equality of universal access. An example of this might be tendering of road maintenance for an existing road network and the addition of new roads.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

On the road network a change from Vehicle Excise Duty and taxation of fuel to a roads pricing model based on congestion and vehicle utilisation would be a major incentive to make more efficient use of the road network and public transport.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well functioning markets?

Yes there will be occasions where private finance will not be available because of the risks involved are too great or unknown. In which case direct government payment will be the only appropriate means.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Localisation of responsibility for service delivery and production would make our infrastructure system more resilient and more able to respond to changes in demand or service disruption. The transport sector and information provision are increasingly dependant on electricity supply and radio based communications and therefore resilience in these sectors is very important. However, infrastructure itself presents numerous opportunities to address this such as solar and wind power electricity generation on station buildings, highway embankments etc. or the use of rainwater collection systems for reuse of water where a drinking water standard is not required. Other examples might be permeable car park surfaces to absorb rainwater or the use of small scale hydroelectric power from streams and rivers passing beneath railways or roads. Encouraging this kind of sustainable investment in these sectors should be integral to all industry plans and thinking.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

London TravelWatch has no view on this question.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

In the first instance it should be through making best use of existing infrastructure through demand management, and concentration of development to minimise the impact on the environment. In transport, this would mean providing more and better interchanges that would encourage modal shift towards more sustainable modes, but at the same time increasing and improving consumer choice.

The natural environment can also be used to protect infrastructure and make it more resilient if understanding of methods and capabilities is applied correctly. For example, use grass and selected tree planting to protect road and rail embankments and cuttings from collapse or flooding.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Modelling of cost benefits and operation of infrastructure is using data from the past to predict future usage and revenues. However, the past is not always an accurate predictor of the future and so an element of judgement needs to be applied when making decisions based on cost benefit analysis. Some infrastructure schemes may not necessarily 'stack up' according to conventional cost benefit analysis but may well be worthwhile to do if there are other credible reasons for pursuing a scheme, such as making better use of another piece of infrastructure.

Transport

13. How will travel patterns change between now and 2050? What will be the impact of the adoptions of new technologies?

New technology will always have an impact on travel patterns. Some trips will be reduced, but others introduced. However, experience of the recent century would suggest that overall trip rates will increase regardless of the adoption of new technologies. International travel and movement of goods however will be subject to political and social pressures associated with globalisation, and any change to the attitude and practise towards globalised trade will have an impact on traffic levels to and from ports and airports. This will mean that predictions of traffic growth are likely to be less accurate, and more unpredictable in future.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Making best use of existing transport networks is likely to produce the highest value in relation to urban areas. For the London area London TravelWatch has produced a report⁴ listing and exploring potential schemes that would do this. Doubtless in other urban areas there are also projects that could deliver similar benefits. Improvements to public transport, cycling and walking can also deliver significant benefits to freight and private transport in terms of reduced congestion and reduced journey times. Likewise investment in freight infrastructure can have major benefits for public transport, cycling and walking. Examples of this might be upgrading and electrifying the rail route between Felixstowe and Harwich ports to the West Midlands via Ely, would free up capacity on rail routes between East Anglia and London, within London on the North London Line of London Overground and on the West Coast Main Line between London and the West Midlands: or a smaller scheme such as changing the junction arrangements for the Angerstein Wharf branch railway in South East London would bring significant reliability and capacity gains for passenger railways throughout that area. Similarly, investment in cycling, walking and bus priority schemes will also make better use of existing roads in and around urban areas.

15. What are the highest value investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Similarly to urban areas, making best use of existing transport networks is likely to produce the highest value of investment outside of urban areas. In particular making public transport financially sustainable by growing usage, and designing bus route networks such that rural areas are served by services that link major urban areas should be regarded as important goals to pursue.

⁴ http://www.londontravelwatch.org.uk/documents/get_lob?id=4254&field=file

16. What opportunities does 'mobility as a service' create for road user charging? How should this affect road usage?

Road user charging represents a significant opportunity to change the way in which road space is allocated, paid for and managed, and to incentivise the use of sustainable and healthier means of transport. London TravelWatch supports the concept of road user charging, but it will require extensive consultation on the detail to ensure that any schemes brought forward are effective but fair.

Questions on digital communications, energy, water and wastewater (drainage and sewerage), flood risk management and solid waste are not part of the remit of London TravelWatch and so we do not feel able to give answers to these. However, we would make a number of observations on these subjects where they have an impact on transport users.

All of these sectors affect transport through their use of the road network, and the installation, repair and maintenance of power lines, telecoms, sewers and water supply because of the resultant road works has a big impact on road congestion, journey times and buses. This requires careful management of roadworks and we would urge the use of licensing schemes for these to reduce the impact of such works on transport users.

In relation to flood risk, this also a big impact on passengers and users of both road and rail networks. Flood risk can arise from natural disasters and human mismanagement (e.g. water main burst). For both road and rail the first mitigation of this risk is basic maintenance of both the water infrastructure and keeping the road and rail infrastructure clear of rubbish and litter. An example of this was the flooding of Clerkenwell tunnel in January 2015⁵ where a burst water main at road level led to flooding of the railway tunnel below. However, failure by Network Rail to clear litter and rubbish in this tunnel from at least 2007 onwards led to the tunnel drains being blocked and this then caused the flooding, and massive disruption to train services across London and the South East region. Similar examples have occurred elsewhere with culverts, embankments, cuttings etc. These failures cause massive disruption to passengers' journeys and are very costly to correct. Network Rail and highway authorities must be incentivised to prioritise this basic maintenance.

Other mitigations should include provision for flood and rainwater to soak away. In urban areas this might require a planning block on additional hard surfaces or a policy of replacement of hard surfaces with permeable ones. A further mitigation, but also one which would improve resilience of water supply would be to mandate the use of rainwater harvesting systems in new developments or the encouragement of water butts at domestic properties.

⁵ <https://waterstink.com/2015/01/31/thames-water-network-rail-argue-over-farringdon-flooding/>

Culverts, streams and rivers flowing underneath road or railway lines could also be converted to provide hydro-electric power to the grid. Such schemes would also have the effect of protecting the road and rail assets from the effects of flooding. Network Rail and highway authorities should be incentivised to invest in such schemes.

Appendix A

National Infrastructure Commission call for evidence, 8 January 2015

Via email: londonevidence@Infrastructure-Commission.gsi.gov.uk

London TravelWatch is the statutory body representing all transport users in London and rail users within the wider London Rail Area which includes London's airports

London TravelWatch welcomes the opportunity to respond to the commissions' consultation, as it touches on areas of significant concern to users of London's transport networks, and which London TravelWatch as a passenger representative body has carried out significant research in recent years.

London TravelWatch has produced a series of transport user priorities for the 2016-20 Mayoral term based on our research and our passenger contacts. This response reflects these priorities:

1. Sustained investment to meet London's ever-growing transport needs
2. A road network that makes the best use of scarce capacity
3. As many of London's rail services as possible coordinated by the Mayor
4. Reliable bus services that keep up with the pace of change
5. Simpler fares, better value for money and a fairer deal when things go wrong
6. A co-ordinated approach to transport interchanges
7. Transport networks accessible to all
8. Reliable, accessible and timely information
9. Everyone able to travel without fear of crime or anti-social behaviour
10. Disruption effectively managed

Consultation questions

1. What are the major economic and social challenges facing London and its commuter hinterland over the next two to three decades?

Transport is a derived demand. It therefore follows that it needs to respond to the economic and social challenges of population growth, job creation and distribution, the supply of housing, the affordability of fares and regional connectivity. Provision of transport can open up opportunities for education, employment, and the provision of services that would otherwise be difficult to access; it can allow development of housing that is both desirable and affordable: and develop regional economies through the benefits of aggregation, knowledge sharing and sociability. Equally,

congestion, crowding, a poor living environment and the lack of effective and reliable transport services can hold back the development of new housing, the creation of new jobs and educational opportunities. The challenge is to improve accessibility in a way that is affordable to both the fare payer and taxpayer, and which meets the aspirations for service standards for both.

The capacity constraints that create congestion and crowding issues are in our view the most important issues that the infrastructure commission should focus on, and where investment is most needed. Creating additional capacity can be done in a number of ways, and will range from large projects such as Crossrail 2 to modest small scale investments e.g. improving walking routes within interchanges or additional entrances to existing stations. These smaller schemes can add considerable value compared to their modest costs in creating new capacity, relieving crowding and congestion that exists already, improve connectivity and reduce journey times.

The need for this continued and enhanced investment in capacity is reflected in the views of passengers. During focus groups for our recent affordability research⁶, it was apparent that even amongst low earners, there was a clear desire for investment aimed at reducing journey times, crowding and congestion, even if this meant more expensive ticket prices, although there was an overall resignation to the high cost of travel. Behind this was a recognition that better transport connectivity gives better access to a wider range of job and educational opportunities, allowing for career progression and increasing income, and housing that would better suit their circumstances and aspirations.

In a complex city such as London, where the most journeys are made using a variety of modes this suggests that improving the number and quality of public transport interchanges⁷ is the most cost effective way of delivering additional capacity on the transport network, delivering economic growth and sustaining population growth. London TravelWatch argues that the investment in London's transport in recent years has been the catalyst that has allowed London's economy and population to grow.

This growth has in part been sustained by the continuous income stream that fares on the public transport network and the Congestion Charge on roads, and it would be important that this is protected to allow investment to continue, and in the case of roads there is an argument that pricing should play a greater role. Nevertheless passengers tell us through our research⁸ that their primary concerns are the

affordability of the transport network, its' reliability and the travelling environment that they experience.

Affordability

London TravelWatch with its partners Trust for London and London Councils recently conducted research on transport affordability in London⁹. This found that:-

- Most people living in London are resigned to the high cost of travel; they need to get to work and have no choice but to put up with the costs involved because they lack viable alternatives.
- 64% of all Londoners who commute to zone 1, which equates to around 1 million people tend to choose the quickest or best journey available to them to get to work, including many people on a lower income. 36%, or a projected 500,000 commuters, are not using the quickest or best journey option available to them.
- However, travel cost is one of the main factors in the route chosen by one in four, or a projected 180,000 people, commuting to Zone 1 from outer London and the equivalent of around 145,000 workers living in outer London choose the cheapest route to work rather than the shortest or most convenient.
- 9%, or a projected 70,000, outer London residents who commute to zone 1 could get to work faster if they spent more.
- Over one in five, or a projected 156,000, commuters who commute from outer London¹⁰ to zone 1 have to cut other spending to pay for travel to work.
- London residents earning more than £600 per month have to work approximately 20 minutes every day they work to pay for that day's commuting costs. This increases sharply to 54 minutes for those earning £200 to £599 and 1 hour 56 minutes for those earning less than £200.
- Travel to work accounts for almost one tenth of a manual worker's average earnings.
- Lower earners are more likely to use the bus and some choose this method to reduce their travel expenditure.
- Everyone is concerned about rising travel costs but people on low incomes are worried that further increases could affect their ability to earn a higher salary by working in Zone 1.

⁹ http://www.londontravelwatch.org.uk/documents/get_lob?id=4100&age=&field=file Living on the edge: the impact of travel costs on low paid workers in Outer London.

¹⁰ For this report, outer London is the 14 boroughs situated around the edge of the Greater London Authority area plus the boroughs of Brent, Ealing, Haringey, Barking & Dagenham and Merton.

This concern with cost is a challenge, as there will need to be a balance between securing funds for investment and the need to restrain cost increases for transport users.

London's passengers, through the fares they pay, cover a significantly greater proportion of operating costs of their transport system than other areas of the UK and comparable cities in Europe. This has the benefit in that this allows a much greater certainty of investment return and long term sustainability of the system.

However, rail passengers tell us that their number one priority for improvement is better value for money for the price they pay for their tickets¹¹.

Reliability

Bus passengers in London (who account for over half of all public transport users in London and over half of all bus users in Great Britain) tell us that they want their services to be more reliable, and have consistent journey times. This is especially true of younger people in education or entering the employment market, who are unable to afford faster modes of public transport or more expensive private transport.

Rail passengers also want their trains to operate more reliably, consistently and have sufficient capacity for them to travel in comfort. This will require upgrades to capacity of the network in terms of train frequency and length. The National Rail network in London needs to be provided with services that are of a 'turn up and go' nature i.e. at least every 15 minutes throughout the operational day.

Travelling environment

When we asked passengers about their travelling environment they told us of many concerns. Most importantly is their concern for their personal security, not just being a victim of crime, but just as importantly having to deal with anti-social behaviour.

Passengers also regard overcrowding, particularly at peak travelling times, as an important issue for them which exacerbates other discomforts such as noise. Finally, though not at the top of passengers concerns they do want stations, trains and buses to be clean and clear of litter and graffiti which they associate with anti-social behaviour.

2. What are the strategic options for future investment in large – scale transport infrastructure improvements – on road, rail and underground – including, but not limited to Crossrail 2?

¹¹ Transport Focus research <http://www.transportfocus.org.uk/research/publications/rail-passengers-priorities-for-improvements-october-2014> , London TravelWatch research . http://www.londontravelwatch.org.uk/documents/get_lob?id=3734&field=file and http://www.londontravelwatch.org.uk/documents/get_lob?id=3896&field=file

- How should they be prioritised, taking account of their response to London's strategic transport challenges, reliability, journey times and connectivity to jobs?
- What might their potential impact be on employment, productivity and housing supply in London and the South East?

As noted above the priorities for improvement in the transport network need to be focused on improving affordability (including passenger value for money and the ability to access a wide range of jobs and services), reliability, capacity (including reducing crowding and congestion), connectivity (including reducing journey times) and improving the overall travelling environment.

Therefore any transport schemes that are brought forward need to meet a number of tests that cover these elements :-

- Does it increase the accessibility of jobs and services?
- Does it improve the reliability of the existing network?
- Does it provide sufficient additional capacity where it is most needed?
- Does it reduce the incidence of crowding and congestion?
- Does it improve the overall connectivity of the London and South East region?
- Does it reduce overall journey times?
- Does it improve the overall travelling environment?

London TravelWatch has previously recommended¹² a number of infrastructure projects that would meet these tests, address the issues that have been identified above and increase the opportunities for employment growth and housing provision. These include:-

Rail

- Developing the Chiltern rail route within Greater London, with improved frequencies and a diversion of longer distance services to serve Old Oak Common (for the development corporation area and interchange with Crossrail and other rail routes).
- A bigger interchange at West Hampstead with platforms on the Chiltern and Metropolitan lines, reducing journey times and increasing accessibility of jobs and services
- Resignalling London's national rail routes to enable higher frequency services to be run
- Linking the Great Northern City branch (Finsbury Park to Moorgate) to rail routes in South London e.g. the London Bridge – Tulse Hill corridor, relieving

¹² http://www.londontravelwatch.org.uk/documents/get_lob?id=3916&field=file Potential future transport projects for London – June 2014

congestion in the City, but enabling development of areas such as that around South Bermondsey station for new housing

- Improving rail access to Heathrow Airport with western and southern rail routes, including the opportunity to develop housing and improve access to job opportunities.
- An electrified Reading – Gatwick Airport rail route – outside of London but of strategic importance to it, because of its ability to give an alternative to travel via London or by car via the M25.
- A reinstated and electrified Southall – Brentford rail link and an electrified West Ealing – Greenford rail route to improve access to jobs and open up new opportunities for housing, and to remove the need for non-standard diesel operation.
- New capacity at central London rail and underground stations through new entrances and link tunnels e.g. Covent Garden to Temple, new entrance to Waterloo East, City Thameslink to St. Pauls. Camden Town to Camden Road, Regents Park to Great Portland Street and linking the two Edgware Road stations.
- A new station at Maiden Lane serving the Kings Cross developments, but from the catchment area of the North London Line, improving access to employment and new areas of housing.
- Improving connectivity in South London by building a bigger interchange at Brixton with platforms on the London Overground and Victoria – Dartford routes, and an interchange at Brockley with platforms on the Victoria – Dartford route. These would open up access to employment and housing across a very wide area.
- Extending the Bakerloo line to Lewisham, Bromley North, Hayes and West Croydon, with significant opportunities to improve access to employment and encourage housing development.
- An ‘outer circle’ rail route linking London’s outer boroughs, to improve access to housing and employment.
- Upgrading the Felixstowe – Ely – Nuneaton rail freight route to allow diversion of freight services away from the Great Eastern, North London and West Coast Main Line routes to free up capacity for passenger services.

Light Rail

It is of concern that the role that light rail in London could play is being overlooked. Passenger loadings along some existing corridors and potential growth corridors will be such that light rail would be the appropriate mode. We have previously supported the proposed extensions to Croydon Tramlink, West London Tram and the Cross River Tram proposals. Like these latter two, there are many other corridors where high levels of bus passenger numbers would imply that light rail may be an appropriate mode. The potential of further light rail schemes in London should be investigated.

Roads

Unlike passenger transport schemes where the demand can, to some extent, be managed by price, additional road capacity in an urban transport environment will be self-defeating because of the latent demand for road travel. Similarly measures to encourage modal shift will have the effect of releasing latent demand.

London TravelWatch supports a wider, more sophisticated system of roads pricing in order that demand can be managed properly on London's road network and the need for additional road infrastructure can be assessed. This would enable more reliable essential motor vehicle journeys and have the additional benefit of releasing funds for investment in transportation schemes.

That said London TravelWatch has supported the mayor's east London river crossings subject to various caveat regarding tolls, the provision of public transport and assurances that the wider road network does not become more congested.

One of the key infrastructure investments in London is the continued programme of bus priority. London TravelWatch believes that buses should have priority on all bus routes and that there is much to do to achieve this.

Cycling and walking

London TravelWatch supports continued investment in safer cycling and walking to allow and encourage increased use of these modes of travel, especially for shorter journeys, thereby freeing up additional capacity on the public transport and road networks thereby improving journey time reliability, crowding and congestion.

In particular, reusing redundant railway infrastructure for cycling and walking schemes e.g. Finsbury Park to East Finchley and Alexandra Palace, to reduce traffic congestion on major arterial roads by offering alternative routes and modes of transport, and on improving the public realm generally. Other potential ideas could include a pedestrian and cycle link between Canada Water and Canary Wharf.

Interchange

Londoners, make more multi-modal journeys than elsewhere, typically using two or three different modes to get around. This means that interchanges play a significant role in the experience of London's travellers. Research by London TravelWatch shows what passengers think good interchange looks like¹³.

Good interchange is often overlooked, but is as important as the services from the interchange. Increasing the usefulness of existing routes and interchanges; adding new ones to existing networks where this would steer growth towards the areas and routes that have the capacity to absorb this, and to relieve existing congestion and crowding. Examples of this would be the extension of the Bakerloo line into South

¹³ http://www.londontravelwatch.org.uk/documents/get_lob?id=4040&field=file Interchange matters: passenger priorities for improvement.

East London¹⁴ and developing a Chiltern Metro, including additional platforms at West Hampstead.

3. What opportunities are there to increase the benefits and reduce the costs of the proposed Crossrail 2 scheme?

Co-ordination of HS2 at Euston with a future Network Rail scheme at their station. We have received assurances that any Crossrail 2 scheme would be built having regard to a future Network Rail scheme it would seem poor value for money if the Crossrail 2 proposals were developed in isolation. We strongly recommend that Euston is developed as a single scheme.

Interchange is really important to passengers who regard interchange as necessary, but not desirable. Crossrail would be an opportunity to develop first class interchanges at the stations served. We would expect Crossrail 2 to do as Crossrail 1 has and develop proposals for not only the stations, but also the public realm around them and the routes to nearby transport objectives such as the local town centre. Unlike Crossrail 1 any additional public realm works should be funded.

The stations served by Crossrail 2 should act as catalyst for promoting development and regeneration at, above or nearby.

Consideration should be given to the extension of Chessington branch of Crossrail 2 beyond the London boundary to Leatherhead to form a through line, and open up area around Malden Rushett for housing development.

4. What are the options for the funding, financing and delivery of large-scale transport infrastructure improvement in London, including Crossrail 2?

- What is an appropriate local and regional contribution – given the potential distribution of benefits to business, residents and transport users and the wider economy – and how could this be achieved?
- What innovative funding mechanisms could be considered to support delivery of key schemes?

As stated above the affordability of the public transportation system is very important both in terms of the proportion of an individual's income, but also as a tool of transport policy. The latter is often forgotten, but if the cost of public transport is too high we know it will be used less. Some of the demand will translate into private motor vehicle use which will exacerbate London's problems of congestion.

In order to secure the maximum social, economic and environmental benefits that a good public transportation system can contribute to then public investment is required. In addition to passenger fares, a mixture of funding from general taxation,

¹⁴ http://www.londontravelwatch.org.uk/documents/get_lob?id=3940&age=&field=file Bakerloo line extension consultation response.

roads pricing and land / property value uplift should be used. Additionally it is vital that all passengers pay their way and that this is assured through high levels of enforcement.

5. How have major metropolitan areas in other countries responded to similar challenges and priorities? Are there any lessons to be learned and applied to London?

London TravelWatch's limited resources do not allow us to give direct comparisons with other areas, however, we note that in dense urban areas such as Hong Kong, development has been successfully tied to the implementation of transport schemes. This approach has been done in London in the past e.g. the Metropolitan Railway constructed Chiltern Court above a reconstructed Baker Street station: In the 1980's British Rail redeveloped the former Holborn Viaduct station to include the low level City Thameslink station and office development above. This could be repeated in the future, but with careful consideration of the needs of existing passengers and users during and after the construction period.

Submission to The National Infrastructure Assessment: Call for Evidence

The Critical Role of Carbon Capture and Storage (CCS) in the Lowest Cost Decarbonisation of the UK Economy.

Submitted by [name redacted]

This submission

During 2016 at the request of the Secretary of State for Energy and Climate Change (now Business, Energy and Industrial Strategy) Lord Oxburgh chaired the Parliamentary Advisory Group on Carbon Capture and Storage. This group brought together parliamentarians from all major parties with figures from industry and finance to provide the government with independent advice on the potential contribution of CCS to cost-effective UK decarbonisation. Ian Temperton was a member of the group and acted as its secretary.

The primary purpose of this submission is to draw the National Infrastructure Commission's attention to this report and its conclusions and recommendations. The report was published in September 2016 and is entitled "Lowest Cost Decarbonisation for the UK: The Critical Role of CCS".

The Parliamentary Advisory Group, having completed its work, is now disbanded and so we provide this submission as individuals rather than on behalf of the group. We do however believe that this submission is fully consistent with the report of that group.

The report is 46 pages long excluding Appendices and hence while this exceeds your limit for submissions we hope you will consider the report in its entirety. We append the full report and ask you to consider the "Summary", "Recommendations" and "Milestones for Lowest cost decarbonisation using CCS" of the report to be a formal part of this submission to the Call for Evidence (these sections comprise seven pages). We have also included the six recommendations in this submission.

This rest of this short submission is in two sections: firstly we briefly highlight the key conclusions of our report, and secondly we specifically answer the questions in the Call for Evidence as they relate to CCS. We address the Cross cutting issues (Qs 1-12 – excluding 3 & 4) and the Energy questions (Qs 19-21).

We are available to discuss this submission and the Parliamentary Advisory Group report at your convenience should you wish to do so.

The Critical Role of CCS in the Lowest Cost Decarbonisation of the UK Economy.

CCS is critical to lowest cost decarbonisation

Our report concluded that CCS has a critical role to play if the UK is to meet its decarbonisation goals at the lowest cost. Despite the many setbacks in the development of CCS over the last two decades we critically assessed and then concurred with the analysis put forward by the Committee on Climate Change, the Energy Technologies Institute and others that the savings from using CCS as part of the decarbonisation programme run to several billion pounds per year. It is actually unclear, with the alternative technologies that exist today or are likely to exist in the necessary time-frame, that our decarbonisation goals can be achieved at all without a meaningful programme of CCS deployment.

The application of CCS across sectors makes it a national infrastructure priority

Underpinning this conclusion and similarly underpinning the importance of CCS as a part of the national infrastructure programme is its application across sectors in energy and industry. CCS can be applied in electricity, industry, heat and transport.

For heavy industry there are few if any viable cost effective solutions to mitigating its emissions other than CCS.

In heat CCS is essential for a pathway to decarbonisation. This is true whether hydrogen is chosen as the energy vector or electricity. Neither choice is possible without CCS, in the latter case to manage emissions from the enormous increase in winter generating capacity, of which at least part would need to come from fossil fuels.

The use of hydrogen appears to us to be a leading contender for the most cost effective decarbonisation of the UK's heating system. However this hydrogen will certainly be supplied most cost effectively, for some considerable time, from the processing of hydrocarbons and the associated disposal of their CO₂ via CCS. Hence without CCS at scale there is no hydrogen heating option. Given the timescales for a decision on the right approach for heat (early to mid 2020s in our view), development of CCS at scale is now time critical if the infrastructure is to be in place to make hydrogen for heating a viable option.

If a hydrogen supply infrastructure is developed based on CCS then it has the potential to form a critical part of the decarbonisation of transportation. While there is a clear focus on electrification for cars and light vehicles, hydrogen has potential applications in heavy goods transport and other difficult sub-sectors for decarbonisation in transportation.

CCS hubs as a national infrastructure priority

Our report highlights the need for the development of CCS infrastructure at key industrial hubs around the UK. Adding CCS infrastructure to existing industrial and energy intensive regions of the UK provides the lowest cost route to decarbonisation of the industry in those regions, while leveraging access to existing infrastructure for energy supply and transportation at those hubs.

The report recommends the development of 3-6 strategic national hubs for CCS around the UK.

Financing CCS in the UK

Our report makes two crucial recommendations on the financing of this CCS infrastructure which perhaps present the greatest policy challenge.

Firstly, CCS development in the power sector is absolutely critical. Only power stations provide the scale and creditworthiness needed to underpin the development of CCS infrastructure at reasonable cost. We believe that new stations with CCS could generate electricity at less than £85/MWh (on a Contract for Difference (CfD) equivalent basis) which is less than the cost of the Hinkley Point nuclear power station and considerably less than any offshore wind farm awarded a CfD in the UK to date. It is also at the level of the cap on CfD prices for offshore wind in the early 2020s. This can be achieved with existing technology deployed in a suitable commercial environment.

Our report recommends a programme of development of 3-6GW of CCS power stations at 3-6 strategic UK hubs providing 24-48TWh/year of electricity supply by 2030. This will sequester 15-30m tonnes of CO₂ from that power generation and make available the transport and storage infrastructure for 2-3 times that volume of CO₂ from other sectors.

Secondly, the state must play a significant role in the initial financing and development of those CCS power stations and their associated transport and storage infrastructure. Our work showed that there is no cost effective private sector financing approach for CCS and that costs will be minimised if a newly formed state-owned company takes this role. Key to this conclusion is the difficulty of placing the risk of “full-chain development”, that is end-to-end capture, transport and storage, and the risk of long-term storage in the private sector. We strongly believe that once initial projects are developed then this initially state-owned development company will be able to be privatised.

Hence we are proposing a financing approach which is not unusual in any way for other infrastructure sectors such as transport (for example HS1, HS2, Crossrail 1&2). It is however unusual for the power sector.

The government in its new CCS Strategy, and the National Infrastructure Commission in its infrastructure assessment, must recognise the essential role for CCS power stations in a future decarbonised energy system. It must also recognise that the development of this critical national low-carbon infrastructure requires a business and financing model which is more akin to that used in transportation infrastructure. This point will be critical to the success or failure of that new strategy, in our view.

We believe that the National Infrastructure Commission is uniquely placed to recognise both the crucial role of CCS as infrastructure for use across a number of sectors of the economy, along with the need to apply business and financing approaches from other infrastructure sectors to its successful development.

The six recommendations of the Parliamentary Advisory Group in CCS

Below are the six recommendations of the report.

1. Establish a CCS Delivery Company (“CCSDC”)

A newly formed and initially state-owned company tasked with delivering full-chain CCS for power at strategic hubs around the UK at or below £85/MWh on a baseload CfD equivalent basis. Formed of two linked but separately regulated companies: “PowerCo” to deliver the power stations and “T&SCo” to deliver the transport and storage infrastructure, the CCSDC will need c.£200-300m of funding over the coming 4-5 years.

2. Establish a system of economic regulation for CCS in the UK

The government will establish a system of economic regulation for CCS in the UK which is based on a regulated return approach. This will draw heavily on existing regulatory structures in the energy system and hence include: a CCS Power Contract based on the existing CfD or capacity contract to incentivise CCS for power; the regulation of T&SCo as other energy network operators; the introduction of an Industrial Capture Contract (see below); and the continued regulation of the energy network industry.

3. Incentivise industrial CCS through Industrial Capture Contracts

The Industrial Capture Contract, will be funded by the UK government and will remunerate industry for capture and storage of their CO₂. It will be a regulated contract which will have a higher price in the early period in order to deliver capital repayment in a timescale consistent with industry horizons. Industry will have access to transport and storage through short-term contracts. Early projects will use existing infrastructure and pure streams of CO₂.

4. Establish a Heat Transformation Group (“HTG”)

The Heat Transformation Group will assess the least cost route to the decarbonisation of heat in the UK (comparing electricity and hydrogen) and complete the work needed to assess the chosen approach in detail. The HTG has a likely funding need of £70-90m.

5. Establish a CCS Certificate System

Government will implement a CCS Certificate System for the certification of captured and stored CO₂.

6. Establish a CCS Obligation System

Government will also implement a CCS Obligation from the late 2020s as a means of giving a long-term trajectory to the fossil fuel and CCS industries. This will put an obligation on fossil fuel suppliers to the UK to sequester a growing percentage of the CO₂ associated with that supply. Proof of storage and hence fulfilment of the obligation being via presentation of CCS Certificates.

Answers to Questions in the Call for Evidence

Relevant cross-cutting issues

Q1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

CCS is widely recognised by bodies such as the Committee on Climate Change, the Energy Technologies Institute, the UK Energy Research Centre and others as the most critical and hence highest value energy and industrial infrastructure in a low carbon context. Our report fully backs the analysis that decarbonisation will be materially more expensive in the absence of the cost-effective deployment of CCS.

For the major industrial regions of the UK where there is existing energy infrastructure and industrial production, CCS is essential to both sustaining the existing level of economic activity in a decarbonising world and to providing new opportunities for growth and its associated employment and economic development.

Q2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

CCS infrastructure plays a critical role in maintaining the cost effectiveness and competitiveness of UK heavy industry and energy supply in a decarbonising world.

The UK clearly has regions which are critical gateways for energy import, export, production, transmission and consumption and these require access to CCS infrastructure at scale and at the lowest possible cost.

Q3 & 4 – not relevant to CCS

Q5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The development of CCS at critical UK hubs will enhance the value and extend the life of existing energy and industrial infrastructure at those hubs.

Furthermore there are opportunities to re-use existing infrastructure such as pipelines and power generation facilities which might otherwise be decommissioned.

Most importantly of all there is a substantial, but time-limited, opportunity for the UK to use its existing hydrocarbon fields as stores for CO₂. This has the potential to save the UK exchequer the costs of decommissioning those facilities.

The choice between re-use and new-build should be based solely on the need for the most cost-effective long-term solution, in our view.

Q6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Our report came in response to the second (some might say third) successive failure of a CCS Competition in the UK. Our view is that the government has designed inappropriate and unrealistic competitions to procure CCS developments from the private sector and this has led to project failure, unnecessarily high costs, and ironically a reduction in the opportunity for industrial collaboration and supply from existing component providers.

Our clear conclusion was that the high costs often associated with CCS developments and reportedly revealed by those competitions were a function of the design of the competitions rather than the fundamental costs of CCS.

Perhaps paradoxically, we believe that having a leading initial role for the state in the development of CCS going forward will increase the opportunity for involvement by an array of existing product and service providers while maximising competition and hence reducing overall cost.

An initially state-owned overall sponsor of CCS development will also facilitate the types of technical and industrial collaboration needed to overcome the challenges of developing the first UK CCS projects.

As we have noted above and in our report, a re-think on the business and financing model for CCS is needed which draws in lessons from other infrastructure sectors and we believe the National Infrastructure Commission is excellently placed to help the government to understand that.

Q7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The system of economic regulation which is proposed in the report draws heavily on the existing mechanisms used in UK energy. See below on financing.

Q8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

There is no private sector company willing and able to finance CCS projects while taking “full-chain” and long-term storage risks at the scale required and keeping costs to acceptable levels. Hence a fundamental re-think is needed of the way in which CCS projects are financed.

Therefore, the report recommends that an initially government-owned entity is responsible for the development of CCS power stations at strategic hubs around the UK. This entity will subsequently be privatised.

Far from distorting well-functioning markets this approach will enhance competition and allow the markets for product and service providers to operate more efficiently. This is because while there is

no viable market for full-chain CCS developers, there are very well-established markets for all the components of a CCS project. Hence addressing the component markets, as we recommend, rather than the non-existent, full-chain developer market, as the government has to date, will broaden the scope of economic opportunity, enhance competition and reduce cost.

Q9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

As noted above, the cross sector application of CCS is of critical importance to the UK.

Developing CCS infrastructure at multiple hubs and having multiple sources and sinks for CO₂ will also add much-needed resilience to the CCS system over time.

Q10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

CCS developments can sit within the existing planning regimes quite easily.

Our report does recommend the development of a new system of economic regulation for CCS in the UK. Even this however, draws very heavily on existing mechanisms, market infrastructure, regulation and regulators.

Q11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

CCS facilities are industrial plants which will not be beautiful. They will however be positioned at industrial hubs among other similar industrial facilities and so will not have any material additional impact on the natural environment

Q12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

The majority of reputable cost benefit analysis of the decarbonisation of the UK show a critical role for CCS. What is clear is that the decisions that should be made based on that robust long-term analysis are often affected by short-term considerations which while appearing to save money today, impose significant additional costs on future generations.

We would encourage the National Infrastructure Commission to pay attention to how such cost-benefit analysis is used in actual decision making.

Energy specific questions

Q19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

The report recommends the formation of a Heat Transformation Group which is tasked with the technical and economic work of determining the right solution for the decarbonisation of heating in the UK. For the urban and suburban environments this appears to be a choice between electrification with heat pumps and hydrogen as a replacement for natural gas. There is much work to do to determine the final answer and even more work required to plan the associated implementation.

This work needs to be properly funded and have a broad cross-industry representation. The report recommends a budget of £70-90m for the Heat Transformation Group to be spent over several years.

Generally it is considered that a decision will be needed in the mid 2020s ready for large-scale implementation from c.2030 onwards. While this may seem a long way off, there is much work to be done and most importantly if decisions are to fit within the existing regulatory framework of the energy network companies then early decisions and allowance for preparatory and planning work are needed in time for the next regulatory settlements in the very early 2020s.

The report sets this out in more detail and includes a Milestone chart for decisions which are needed (page 10 of the report).

It is very important to note that there simply is no hydrogen route without CCS and it seems inconceivable to us that any government would make a decision to go the hydrogen route without ever seeing a CCS project successfully developed in another sector. Hence the urgency for the first power CCS projects.

Q20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

The Parliamentary group did not directly address this question and the report focuses exclusively on delivering decarbonisation at the lowest possible cost. As a result what follows is solely the view of the authors of this submission

The largest uncertainty for the power sector over the next three decades actually centres on the decarbonisation of heat.

If electrification is chosen as the route for heat the seasonal winter power demand will be between three and six times the present winter maximum. The lower end of the range would require major improvements in the energy performance of buildings, wide deployment of heat pumps, strengthening of the grid and, conceivably but improbably, development of cost-effective inter-seasonal electricity storage.

Sufficient energy must be available on demand for the winter heating peak. The low-carbon dispatchable sources of this energy will be nuclear, some imported hydro, any stored renewable

energy and efficient thermal generation with CCS for fossil fuels. Biogas and biomass in thermal plants will also play a limited role.

It is very likely that the storage of fossil fuels, or the storage of hydrogen, each utilising CCS in some way, will prove more cost effective in providing this on-demand energy than the storage of renewable energy for this purpose.

If the hydrogen route is taken for heat, a range of possibilities opens up. Hydrogen initially generated from fossil fuels and sequestering the associated CO₂, could be progressively replaced by hydrogen generated efficiently from other low carbon sources such as nuclear, or eventually renewables. A hydrogen grid could also allow clean power generation in thermal plants and widen the opportunity for fuel cell vehicles particularly in heavy transport..

The key question is therefore whether we have electricity as our sole energy vector or whether we introduce hydrogen to make a system that might be both less expensive and more resilient. The information needed to make this choice objectively is not currently available. Whatever decision is made over the future of power generation, if it is to be robust it has to be made in the context of the decarbonisation of the energy system as a whole.

Because of its unique application across sectors of the energy market and its unique financing challenges, CCS will need to play a part in power sector decarbonisation between now and 2050 and it will also need to draw on the characteristics of the power sector to underpin the financing of the CCS infrastructure. There are very good economy wide reasons for CCS to play a special role in the power sector in this period.

Many models of UK decarbonisation have CCS serving other sectors of the economy but not necessarily power come 2050. This means that while power is crucial to the financing of a low cost CCS infrastructure, by the middle of the century the use of that infrastructure by the power sector may well be in decline.

Q21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

As noted above, if a hydrogen supply infrastructure is developed based on CCS for disposal of the associated emissions then this opens up viable zero-carbon hydrogen-based options particularly for heavy goods transport which is known to be a hard-to-decarbonise sub-sector of transportation.

10th February 2017

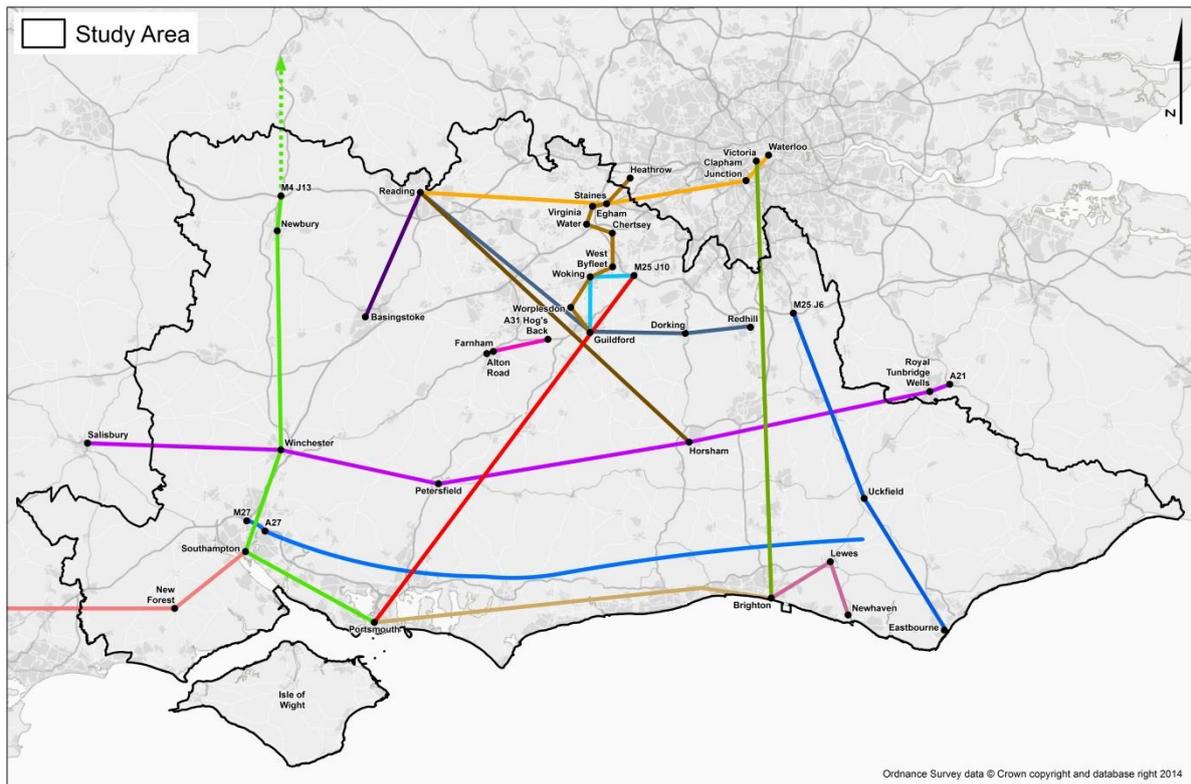

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London
EC3M 8UD

Dear Sir/Madam,

**NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE
Response from Enterprise M3 Local Enterprise Partnership**

Cross-cutting issues:

- 1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?**
 - High value infrastructure is key to economic growth across the transport, energy and smart cities agenda. It is important that Digital strategies within all sectors are considered at a national level within the context of every major investment to ensure consistency.
 - We have worked with our neighbouring LEPs and local authorities on a key study 'Influencing Strategic Transport in the South East' to quantify the economic case for improving connectivity along 17 major strategic movement corridors across South East England, A copy of the study is attached and the corridors are identified on the plan below.. The report estimates that the benefit to the economy would exceed £19.5 billion per annum, with more than 100,000 new jobs created. This additional economic activity would see the Government gain additional revenue of £1.2 billion a year from personal income taxation and just under £1 billion a year from corporation taxation. Conversely a failure to invest in congested transport links could seriously hamper economic growth.

- Enterprise M3 LEP has also identified a number of strategic transport asks, which supported our latest Local Growth Fund submission in July 2016,

- Guildford A3 Strategic Corridor Improvements
- M3 Junction 9 Improvements
- A3/M25 Junction to Wisley Interchange
- A31 Ringwood Junction with A338
- Southern Rail Access to Heathrow
- Electrification of North Downs Railway Line
- Woking Junction Rail Flyover – grade Separation
- Existing and New Guildford Railway Stations
- South West Main Line Capacity Improvements (inc Crossrail 2)
- A3 Strategic Package - NE Guildford
- River Thames Scheme - Datchet to Teddington
- A33 Basingstoke – Reading Corridor Upgrade
- A34 Corridor Upgrade
- A320 Corridor Upgrade
- A31 Upgrade

- These primarily sub-national schemes are essential to support local investment and provide the infrastructure capacity on transport networks to deliver economic growth, housing, jobs and increased productivity underpinned by our Strategic Economic Plan.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

- The Enterprise M3 economic area is a national asset which sits at the heart of the UK's digital industrial strategy and is unique in its scientific, technical and innovative capability. Success here does not only benefit our region; it resonates across the UK. Hundreds of international corporations, including BMW, BP, IBM, McLaren and QinetiQ, choose to base their headquarters here and go on to locate offices, staff and generate company offshoots throughout the UK and overseas. Enterprise M3 is an area which reaches out across the globe. It has the highest number of foreign owned companies of all LEPs outside London and it attracts many high-tech smaller companies as well as a world-class cluster of gaming businesses, who generate on average 45% of their turnover from exporting, with the top three target markets being the USA, China and Japan.
- Key International Gateways for businesses in the Enterprise M3 LEP area are Heathrow and Gatwick airports and the ports of Southampton and Portsmouth. To ensure they continue to function as an excellent, globally competitive location, the following key infrastructure schemes are needed:

- | |
|--|
| <ul style="list-style-type: none">• Western Rail Access to Heathrow• Southern Rail Access to Heathrow• Upgrade to the North Downs Line (combined with the above to link Heathrow and Gatwick)• Major improvement to Junction 9, M3 as the access to the ports of Southampton and Portsmouth |
|--|

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

- Housing development is often contested due to either a perception or a reality that adequate infrastructure does not follow. Infrastructure and housing have to be considered together if we are to seriously address the issue of the housing deficit. We hope to see this as a key of the Housing White Paper.
- A coordinated and integrated approach to infrastructure is needed to unlock and regenerate key sites by supporting developers and local authorities to accelerate housing delivery. There needs to be a focus on accelerating housing growth through upfront infrastructure, championing skills provision and creating a digital approach.
- Early engagement with strategic infrastructure providers is key. Siloed thinking and the way funding is allocated fails to capture the potential of these benefits of joint delivery across all infrastructure providers.
- Enterprise M3 LEP has developed cross working relationships with Network Rail and Highways England as providers of strategic transport

infrastructure and also works closely with local authorities, bus and rail operators. The emerging Sub-National Transport Body, Transport for the South East, will also cement partnership working and start to prioritise strategic infrastructure asks across the whole of the South East.

- In digital we are working to bring together leading academic expertise and key industry partners in a shared vision, the 5GIC will help to define and develop the 5G infrastructure that will underpin the way we communicate, work and live our everyday lives in the future.
- It is also important to develop and deliver a place based approach. Enterprise M3 has identified a series of Growth and Step Up Towns and developed cross-cutting delivery packages for each of these places, to help to ensure that this joined up approach will deliver the greatest economic benefit.
- We fully support the approach to infrastructure outlined in the Industrial Strategy and would echo the need to improve standards of performance on digital, energy, transport, water and flood defence infrastructure, and better align central government infrastructure investment with local growth priorities. We will ensure this will be reflected in the revised Enterprise M3 Strategic Economic Plan that will be published later this year will focus on how this is essential to raising productivity and living standards.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

- The focus will increasingly be on flexibility and on maximising the use of existing capacity rather than the provision of new capacity. It is difficult to overstate the potential impact of new technologies in offering new forms or alternatives to travel. There are many examples such as autonomous vehicles and digital rail, which have the potential to maximise use of existing networks. Digital systems can provide a vital platform for integrating and enabling this. Autonomous Driving will change the perception and experience of cars as they become less objects that have to be driven and more as a means of moving between two locations during which time can be used for other tasks such as work, rest, etc.
- 5G capabilities will deliver transport improvements including reduction in congestion as transport networks become far better co-ordinated.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

- Within Enterprise M3 Area, the types of initiatives that will help to ensure high value in our key centres are the Basingstoke Rapid Transport Network and Guildford Sustainable Movement Corridors, complemented by investment on strategic corridors, such as the Woking Rail Flyover and improvements to the A3 around Guildford.

- High value doesn't always mean large. Highest value will often be demonstrated by relatively small local schemes, such as sustainable transport. There is a need to ensure financial support for local investment is maintained and a reasonable balance is struck in terms of strategic and local infrastructure.

Digital communications:

17. **What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?**

- It is important to build on the world leading 5G Innovation Centre (5GIC) flagship project with existing test beds in Growth Towns of Guildford and Basingstoke and deepen links with our multi-site digitally focussed business. Enterprise M3 has invested in delivering the world's first 5G testbed in Guildford, connecting SMEs to the leading facilities of the 5GIC. Another is being rolled out in Basingstoke allowing businesses, especially SMEs, to investigate the commercial potential and market opportunities of 5G.
- The commercial potential of Surrey's 5GIC is being explored in Sunderland and Newcastle too, as the 5GIC begins a working collaboration with the North East LEP and the Digital Catapult Hub in Sunderland, including NE business parks, the Automotive Cluster and the Connected Health Cities Initiative.
- Another key area is that of big data and cyber security. To support 5G development and business in cyber security and big data Enterprise M3 is housing a number of specialist activities and providing a base for early stage start-ups and spin outs. The regional centre will be built to MoD requirements and based at the Former Proctor & Gamble site in Egham, adjacent to Royal Holloway University. It will also link to the Enterprise Zone at Longcross. This innovation centre will put the region in a strong position to enable training of the nation's next generation of coders within business and the community at all levels.
- In terms of access to and exploitation of cutting edge broadband access and the digital technologies that are enabled by it, the rural environment lags behind the urban and suburban areas. 5G will be able to address the digital divide and overcome difficulties in providing broadband connectivity in more rural areas where current fixed networks struggle to provide adequate service. Businesses in the Enterprise M3 Area frequently highlight the need for improved business park broadband connectivity. This can sometime be a real issue and sometimes one of perception and can impact upon productivity. Focus should be on business clusters in rural and urban areas and coupled with advice to get businesses adopting new technologies more quickly to increase their competitiveness and safeguarding and/or creating jobs. This also needs to be links to digital skills apprenticeship programmes which will address skills shortages in the sector and help support increased growth.

- In order to ensure the benefits from investment in 5G and digital technology are realised there is a need to set out how local authorities will enable the deployment of mobile networks and maximise the opportunities and benefits to residents and businesses. There is a need for this to be as a priority in local planning policy, to empower and encourage local authorities to coordinate the role that public buildings and infrastructure, such as lighting columns can be used to facilitate the deployment of mobile telecoms infrastructure.
- One of the challenges for our area is that we struggle to attract the younger, digitally-skilled workforce required for these businesses due to the high cost of housing and comparatively poor/patchy public transport network (as these employees are less likely to own a car). Particularly as we are so close to London this sort of workforce tends to just go there instead and is a limiting factor in where digital clusters are located.

Yours sincerely

**Manchester Airports Group response to National Infrastructure
Assessment call for evidence. [No redactions].**

National Infrastructure Commission – Call for Evidence

Submission by Manchester Airports Group

10 February 2017

Summary

1. Infrastructure – from transport to housing, energy and broadband – provides the essential foundations needed to deliver jobs, growth and prosperity for all. **The National Infrastructure Assessment (NIA) is a significant positive step towards understanding the UK's infrastructure needs over the next 30 years.**
2. In setting out its 'Vision and Priorities' **the National Infrastructure Commission (NIC) should commit to an ambitious plan for growth**, taking the opportunity to explore not just where problems exist with today's infrastructure but also how an integrated programme of investment can transform the UK economy, balance growth across the country and shape our future as a competitive global trading nation.
3. **The NIC needs to become the driving force behind a more integrated approach to infrastructure development.** In the past, a fragmented approach to infrastructure development, focusing in turn on the needs of individual sectors, has cost the UK both financially and in terms of missed opportunities. With the negotiation of Britain's exit from the European Union about to get under way and with a new Industrial Strategy set to underpin the Government's economic vision, the NIA should focus on identifying the programme of infrastructure investment needed to deliver that vision. The NIC, taking a supra-departmental view, can add huge value to providing integrated planning across (and within) sectors to secure the long term interests of the economy.
4. **Aviation will be a cornerstone of the Britain's global competitiveness, providing the world-class connectivity that the UK's main economic 'engines' need to access global markets.** Connecting cities to each other and to international markets will increase productivity by allowing businesses to draw on a larger pool of skills and talents, establish larger markets and supply chains, and stimulate knowledge spill over. Infrastructure enables higher regional productivity to be unlocked, with the potential to add £208 billion to the UK economy over the next decade.¹
5. **The NIA needs to strike the right balance between addressing today's infrastructure problems and investing in opportunities to re-shape the UK economy.** For example, the rail industry has focussed too much on tackling pressure points with today's infrastructure, and too little on projects with benefits that, while harder to quantify, may have far greater societal value to the UK overall. The NIC should identify the appropriate tools and techniques for understanding the wider economic value of infrastructure investment, and build the confidence of decision makers in the value of such projects.
6. In our submission we identify **three key areas that the Commission should incorporate into the forthcoming NIA:**
 - **Transformation of east-west connectivity in the North through Northern Powerhouse Rail, connecting Northern cities with Manchester Airport.** The NIC has already assessed the value of this and developing this network beyond better links between Manchester and Leeds must be a key project for the NIA;
 - **Rail improvements to Stansted – developing an incremental, integrated plan for infrastructure investment along the West Anglia Main Line.** Repeated calls for investment since the Airports Commission's recommendation for urgent action in 2013 have highlighted the strategic benefits of journey time improvements to the airport.

¹ 'Unlocking Regional Growth', Confederation of British Industry, December 2016

Delivered in advance of four-tracking and Crossrail 2, these improvements would better connect the airport to its catchment across the region, supporting regeneration in the Upper Lea Valley, housing, jobs and economic growth.

- **A need for the NIC to consider the long term needs of the UK's strategic airport network**, including support for development of airports like Manchester and Stansted to reach full utilisation of their runway capacity. The NIA should outline how the need for additional capacity to 2050 should be considered. While recognising that the NIC is unlikely to offer a definitive judgement at this stage, the potential timing of the need for additional capacity must be addressed in the NIA and considered in detail in due course.
7. We also **highlight the strategic role of East Midlands Airport in providing vital air freight capacity**, which if supported would enable the airport to play an even greater role in development of hi-tech and advanced manufacturing clusters in the Midlands as part of the Government's Industrial and Midland Engine strategies.
 8. Central to the rationale for the priorities we have outlined is the need for the NIC to consider the value of a small number of strategic airports and how they can be supported through infrastructure investment to play an even more significant role in meeting UK's global access needs over the period to 2030. **Focussing on these strategic assets will deliver the strong economy envisioned in the Government's Industrial Strategy and achieve its goal of a truly global Britain.**

Introduction

1. We welcome the opportunity to make a submission to the National Infrastructure Commission's Call for Evidence and would like to see further direct engagement with the NIC over the coming months.
2. Manchester Airports Group (MAG) owns and operates four airports in the UK (Manchester, London Stansted, East Midlands and Bournemouth), handling around 56 million passengers per annum across multiple regions within the UK (North West and North Wales, South East and East, Midlands and South respectively).
3. Our airports are nationally significant infrastructure assets, providing essential connectivity both for the regions they serve and the wider UK economy, contributing £6.2 billion in GVA each year.
4. Following the vote to leave the European Union, the Government has renewed its focus on both improving trade relationships across the globe ("a truly global Britain") and supporting infrastructure improvements across the whole of the UK. This in turn comes under the broad umbrella policy of helping to stimulate growth across the whole of the United Kingdom or "a country that works for everyone".
5. In this submission we highlight the role that airports and international connectivity play within the wide body of national infrastructure, their supporting role in the economy, and the need to ensure that as the NIC plans for investments through to 2050 it considers how best to integrate international and national infrastructure networks to support the economy.

The role of the National Infrastructure Assessment

6. The NIC's proposed National Infrastructure Assessment (NIA) has the potential to make a significant contribution to the way the UK plans and delivers future infrastructure needs.
7. In setting out its 'Vision and Priorities' the NIC must commit to an ambitious plan for growth, taking the opportunity to explore not just where problems exist with today's infrastructure but how an integrated programme of investment can transform the UK economy, balance growth across the country and shape our future as a competitive global trading nation.
8. With the negotiation of Britain's exit from the European Union about to get under way and with a new draft Industrial Strategy set to underpin the Government's vision for the UK economy, the NIA should be focused on identifying the infrastructure needed to deliver that vision. Our sector, aviation, will be a cornerstone of the UK's global competitiveness, providing world-class connectivity to and between the engines of the UK economy.
9. While much attention has been paid to the Airports Commission process that has shaped the Government's policy support for Heathrow, its assessment of need and recommendations were explicitly limited to a 2030 time horizon. The Airports Commission made clear that another body should assess the need for further new capacity in the period to 2050 at some future point in time. The National Infrastructure Commission is the logical and appropriate body to take on that responsibility.

10. The Airports Commission also set out a number of short-to-medium term recommendations for Government, which were intended to make 'best use' of existing aviation capacity at other airports. The NIC should further consider the progress that has been made in delivering those measures and incorporate these into the immediate priorities in the NIA where appropriate, particularly as Heathrow's new runway is unlikely to be operational much before 2030.
11. We welcome the opportunity to make further submissions to the NIC and urge the Commission to engage more extensively with MAG and the aviation sector as its work on the NIA moves forward. In the following submission we have focused on those questions that are of greatest relevance to our business.

Highest value infrastructure investments (Q1)

12. Airports are some of the highest value infrastructure assets within the UK, providing access to global markets and acting as economic multipliers. Air connectivity is crucial to supporting UK businesses and the wider economy, facilitating trade in services and goods, enabling the movement of workers and tourists, and drives business innovation and investment. The Government's decision to take forward the Airports Commission's recommendation for a new runway at Heathrow accepts the fundamental principle that improving global connectivity will drive growth in the UK economy.
13. The UK benefits from having a number of well-developed international networks from other airports, including at Gatwick and Stansted in London, Manchester and Birmingham in the North and Midlands and Edinburgh and Glasgow in Scotland, for example. These airports are more than simply 'regional airports'. They form a network of strategic assets on which the UK's global connectivity will rely and which Government (and the NIC) should seek actively to support. With the right investment they can drive ever greater choice and value for consumers and act as drivers for regional economies.
14. The Government's draft Industrial Strategy is clear that airports are *"major local employers in their own right"*, but more than that, *stronger networks of international connections will "also help to promote trade and create jobs."*² To give an example, MAG analysis shows that the addition of two direct routes to China from Manchester Airport will be worth at least £500 million in economic benefits to the UK over the next decade.³ Two-thirds of this will be felt directly in the Northern economy in terms of increased jobs, economic activity and tourism.
15. Furthermore, analysis by York Aviation for MAG concluded that growth at Manchester Airport to its maximum capacity of 55mppa would generate benefits for the economy of a discounted GVA value of £76 billion in the North West, £94 billion in the North and £131 billion across the UK over the next 60 years.⁴ Crucially, this value begins to accrue in the short term because Manchester (as at other major airports) has the capacity to grow now.
16. In fact, for most of the sector there is sufficient runway capacity to meet demand for the next 10-20 years. While airport owners are investing in their infrastructure to meet passenger growth over that period, investment in the supporting road and rail

² <https://www.gov.uk/government/policies/industrial-strategy>

³ Since December 2015, Cathay Pacific fly four direct flights a week to Hong Kong. Since June 2016, Hainan Airways fly four direct flights a week to Beijing. Tourism spend only (based on projected 20,000 Chinese visitors per year), not including inward investment, jobs or infrastructure.

⁴ The economic impact of Manchester Airport, York Aviation, December 2016

infrastructure is needed to fully utilise this spare capacity and to maximise the value of a competitive network of airports across the country.

17. Sustaining a wider network of direct services from our airports will in large part continue to be driven by the quality of UK surface transport connectivity. An airport's penetration into a catchment of people wishing to travel is a key factor in airline investment decisions, so while we will continue to invest in airport infrastructure, it is government's commitment to long term strategic investment in road and rail to airports that will have a significant impact on the future 'size and shape' of the UK airport sector.
18. An important part of the NIC's remit is to "*contribute to sustainable economic growth across the UK*".⁵ As part of this, the NIA should identify and assess schemes that will maximise the value of capacity that is already available at airports like Manchester and Stansted. These airports will be responsible for meeting growth in air travel demand in both the medium and the long term, and the NIC should examine what rail and road improvements are needed to ensure that the benefits of global connectivity from major UK airports are more accessible for the greatest number of people.
19. The following key infrastructure investments would most effectively drive economic growth across the regions that our airports serve:

The North and north Wales:

HS2 & Northern Powerhouse Rail (NPR)

20. The Government recently announced the inclusion of a Manchester Airport terminus as part of the HS2 Crewe to Manchester western leg⁶, recognising the scope for significant wider benefits in jobs and productivity across the region. MAG supports the inclusion of a station at the airport because of the long term strategic value of linking HS2 into an east-west rail service (Northern Powerhouse Rail) that connects Liverpool, Sheffield, Leeds, Hull and Newcastle more effectively into the global connectivity provided by Manchester Airport.
21. In 2016, around four million return business-related air trips were made to/from this region, of which around 60% were by UK residents. The concentration of this demand for business travel is primarily around the core cities but as Figure 1 below shows, the propensity to travel for business is more than five times higher in Greater Manchester than Hull and Humber and twice that of Sheffield, a city less than 40 miles away.

Source: Independent International Connectivity Commission Report, February 2016 – data based on CAA Passenger Statistics (2016)

22. Given the relative scale of the population and economic base across the North, this suggests that there is a significant disparity between the different regions in terms of their attractiveness to business and there is an opportunity to improve access to global markets by better connections to the available air connectivity. Transport for the North estimate that the true number of passengers travelling to/from the region should be around four million per annum higher than the 39.6mppa today (an increase of 10%).
23. Investment in the Northern Powerhouse Rail network, as outlined by Transport for the North, would reduce journey times between the North's core cities and Manchester Airport to between 30 and 60 minutes. Such a transformation in travel times could, based on analysis of CAA passenger data, increase the catchment area for Manchester Airport by more than 300%⁷. This would serve to extend the benefits of its global network across the North, bringing around 10 million people within a two hour public transport journey time, compared to just over three million today.
24. With the capacity to more than double the 25 million passengers currently served by Manchester Airport each year, the value of utilising this full capacity of the airport would be transformational. As described above, analysis by York Aviation, concluded that the cumulative benefits to the economy would have a discounted GVA value of around £76 billion in the North West, £94 billion in the North and £131 billion across the UK.⁸
25. We therefore agree with the NIC's own recommendation in High Speed North, that the design of the northern phase of HS2 should ensure latter phases of HS2 are planned and delivered *"so as to facilitate the development of the HS3 (NPR) network, enhancing connectivity between Leeds – Sheffield, Liverpool – Manchester (and its airport), and between Sheffield – Newcastle, as well as to onward destinations."*⁹

⁷ Steer Davis Gleeve, 2014

⁸ The economic impact of Manchester Airport, York Aviation, December 2016

⁹ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/507791/High_Speed_North.pdf

26. It is clear that such an investment would deliver transformational change to the quality of public transport and international connectivity available in the region, driving significant benefit through investment, productivity gains and economic growth. The NIC is in a strong position to ensure just this kind of integrated strategic planning – linking the NPR directly into Manchester Airport would deliver local, regional and global connectivity to the region. Supporting the development of Manchester Airport to its maximum potential in this way would deliver on the Government’s commitment to ‘making best use of existing aviation capacity’ while delivering large economic gains for the region.
27. The NIA should recommend urgent priority be given to the development of a full Northern Powerhouse Rail network and for the Government to release capital in Network Rail’s next Control Period (CP6) to undertake this development work.

Recommendation

The NIA should prioritise the integrated planning of surface access and global air connectivity. It should specifically recommend the development of a full Northern Powerhouse Rail network, connected directly through Manchester Airport, and the release of capital by Government to undertake the next phase of development, either as part of Network Rail’s next Control Period (CP6) or separately by Transport for the North.

South East/East of England

28. Almost four years ago, the Airports Commission recognised “*the strategic importance of Stansted Airport to the wider London airport system*”¹⁰ and identified an urgent need for investment in the West Anglia Main Line serving the airport. Since then there has been repeated calls to improve the infrastructure and deliver quicker journey times, better reliability and more aligned timetables. On 25 October, the Secretary of State for Transport acknowledged these calls for action, stating his desire “to see everything done as soon as we practically can to make sure the links to Stansted are as good as they are to London’s other airports”.
29. As the Commission identified, London Stansted is the only major airport in the London system with capacity to meet demand in the coming decade. In fact, Stansted will account for more than half of all passenger growth in London over that period. Sitting at the heart of the productive London-Cambridge corridor, serving an area whose outputs have grown by 65% more than the national average, and now has a total annual output of £121 billion¹¹, Stansted handles more than 24 million passengers each year (with a maximum runway capacity of around 43 million passengers). It is also the third largest air freight hub in the country after Heathrow and East Midlands Airports.
30. However, since the Airports Commission first recommendation, no infrastructure investment has been committed to improving journey times or reliability on this route. Furthermore, the Anglia rail franchise was let to Abellio in 2016 for a further nine years (to 2025) without specifying any timetable or infrastructure improvements for Stansted, despite requests to do so as part of the franchising process. The Transport Select Committee’s recent Report on Rail Franchising was particularly critical of this failure to prioritise Stansted services¹².

¹⁰ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/440316/airports-commission-final-report.pdf

¹¹ https://www.london.gov.uk/sites/default/files/taskforce_brochure_a4_24ppv11.pdf

¹² <https://www.parliament.uk/business/committees/committees-a-z/commons-select/transport-committee/inquiries/parliament-2015/rail-franchising-15-16/>

31. Most recently, recommendations for upgrades to the rail infrastructure on the route were made by the West Anglia Taskforce¹³, which was set up by the then Chancellor and Mayor of London to take forward such plans. In October 2016, the Taskforce report demanded investment to secure 'Stansted in 40' - an incremental improvement to journey times as part of a programme of infrastructure upgrades projected to add £15 billion to the regional economy.
32. Incremental improvements, including changes to the timetable and minor infrastructure enhancements ahead of a larger programme for four-tracking as part of Crossrail 2, would be deliverable and highly effective in sustaining massive investment in housing and regeneration along the Upper Lea Valley (up to 100,000 homes), creating around 45,000 jobs and driving sustainable growth of the airport.¹⁴ In the longer term, these investments, including Crossrail 2, will further support development and growth in London Stansted's capacity; failure to invest in infrastructure improvements for a further 10-15 years would severely restrict the growth of one of London's major aviation assets.

Recommendation

The NIA should, in its Vision and Priorities document, identify the need for investment in Network Rail's next control period (CP6) to deliver urgent incremental infrastructure improvements on the West Anglia Main Line in the short term; with a commitment to four-tracking and Crossrail 2 in the long term.

East Midlands Airport (EMA)

33. East Midlands Airport is the largest pure freight hub in the UK and over the coming decades our vision is to double passenger numbers (10mppa), triple cargo tonnage (one million tonnes) and double employment (14,000) at the airport. As such, EMA performs an important function both for the national and regional economy, supporting the sustained growth of technology, aerospace and advanced manufacturing clusters, key sectors in the Government's Industrial Strategy.
34. Ongoing investment by DHL at the airport will make EMA its second largest cargo hub in the world, underlining the strategic importance of the airport's pure freight operation and role for the government's aspirations for a truly global Britain.
35. In the long term, to support the region and the airport's growth aspirations, surface infrastructure surrounding the airport will need to be expanded to provide the capacity to deal with such growth. In the absence of this, roads will become increasingly congested with freight traffic, slowing down aircraft operations which must run to time to meet international deadlines. The rail services and timetable to East Midlands Parkway is inadequate for the needs to most airport passengers (reflected in relatively low mode share) and is not supported by onward connections to the airport itself.
36. Working with Midlands Connect and the Midlands Engine, we are looking to secure improvements to rail provision and connections to East Midlands Parkway station through the upcoming franchise process – specifically to increase to four trains per hour. However, in the long term we believe the most effective solution to meeting demand and increasing capacity at the airport is likely to be a fixed light rail link that connects Parkway to the

¹³ https://www.london.gov.uk/sites/default/files/west_anglia_taskforce_tors.pdf

¹⁴ https://www.london.gov.uk/sites/default/files/taskforce_brochure_a4_24ppv11.pdf

airport terminal, Roxhill (a new rail freight hub), businesses at the nearby Pegasus Business Park and key freight businesses at the airport (such as DHL and UPS).

37. The arrival of HS2 to nearby Toton, while not a direct link, should include provision for significantly improved services to Parkway station, which will further drive the case for a fixed link to the airport. The NIA should consider how to effectively co-ordinate and sequence a programme of potential investments to facilitate expected growth at EMA and to crystallise the economic contribution made by both cargo and passenger operations at the airport.

The UK's international competitiveness and the role of international gateways (Q2)

38. Transport infrastructure is an essential component of productive economies and airports are the principal 'international gateways' for the UK – 73% of all visitors to the UK and 40% of freight by value arrives by air each year – facilitating trade, tourism and foreign direct investment. While air connectivity is undoubtedly key to unlocking a country's economic growth potential failure to invest in world-class connections to our international gateways effectively and efficiently via surface transport risks undermining the UK's competitive position.¹⁵
39. The UK's international competitiveness depends on, amongst other things, the agglomerated effect of efficient and well-connected cities and regions. Reducing the distance between population centres creates a more integrated labour market, more social cohesion and more productive regional economies. Connecting these linked economies to international markets via a strong network of strategic airports allows people, goods and capital to flow into and out of the country more effectively, enabling companies to get their goods and services to key international markets in a secure and timely manner, as well as facilitate the movement of workers to the most suitable jobs.
40. In the north of England for example, poor road and rail infrastructure means that access to global connectivity is not as good as it should be. As the recent Independent International Connectivity Commission Report sets out clearly, enhancing global connectivity starts on the ground, which means investing in the key 'landside enablers' for ports and airports. For many cities in the north, getting to Manchester Airport is too difficult or takes too long and therefore limits its effective catchment area. In turn, this affects airlines' ability to develop further their route networks even though demand for travel in the North is high.
41. In making this case for the Northern economy, the report concludes that *"improved global connections can only be achieved by making it easier and quicker for passengers to travel to and from the North. By increasing the proportion of trips which can connect globally direct from the region's airports and ports, as well as improving surface access to these key hubs, we can ensure that the potential of the North's airports is exploited for the benefit of the wider economy"*.¹⁶
42. An integrated rail network with HS2 and Northern Powerhouse Rail connecting the Airport with the North's core cities would have the effect of both dramatically improving access to the airport for passengers wishing to travel and supporting a broader, more frequent network of services.

¹⁵ <http://www.pwc.co.uk/industries/capital-projects-infrastructure/insights/connectivity-and-growth.html>

¹⁶ http://www.transportforthenorth.com/wp-content/uploads/International-Connectivity-Report_websafe.pdf

43. Furthermore, evidence suggests that connecting airports to their surrounding catchment areas will drive investment in skills and increase employment rates. This is a critical factor in delivering the Government's Industrial Strategy and particularly key to the growth of the northern economy. The Airports Commission noted the important role airports can plan in increasing national and regional productivity, concluding, "there is strong evidence that good transport links, and especially aviation connectivity, make an important contribution to enhancing productivity".¹⁷
44. Reducing the 'friction' of poor connectivity it is easy to envisage a virtuous circle where an increasingly highly-skilled, well-connected labour market attracts inwards investment and trade, which in turn supports better and more frequent international connections.¹⁸ The NIC should seek to prioritise the integration of surface access investment to airports to ensure road and rail services to the UK's major airports match projections of demand over the coming decades.

Recommendation

The NIC should undertake a specific analysis of surface transport requirements for UK airports, identifying investment priorities that will most effectively deliver integrated domestic (road/rail) and global (aviation) connectivity.

Airport Capacity to 2050

45. Considering the role of international gateways further into the future, it is also worth recognising that the Airports Commission's consideration of aviation capacity looked only at demand in London and the South East over the period to 2030. In its final report in 2015, the Commission was explicit that further consideration would be required of how to support demand in the longer term, recognising that, "continuing growth in demand for aviation will see the existing constraints in the UK's air transport system, and particularly the London airport sector, exacerbated".¹⁹
46. Consistent with that report, we urge the NIC to keep the issue of aviation capacity under review and to lead this next phase of assessment. Further, the NIC should ensure that full consideration is given to all options for expansion.²⁰ This must include full evaluation of airports across the country and their potential to play a different and larger role in meeting demand than they do today.
47. The potential of HS2 and Northern Powerhouse Rail, for example, would be to dramatically increase the share of demand that Manchester Airport would be able to meet, reducing pressure on the South East airports in the long term. The business case for NPR is enhanced by the integration of surface and air transport, and investment in the project would serve to deliver on the Government's wider policies to rebalance the economy, support a Northern Powerhouse and maximise the value of the UK's strategic airport network.
48. In the short and medium term, passenger growth at London Stansted Airport is likely to represent around half of all growth in the London aviation system and on current projections will be at maximum capacity by 2030. With respect to future runway capacity,

¹⁷ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/440316/airports-commission-final-report.pdf

¹⁸ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/505705/northern-transport-strategy-spring-2016.pdf

¹⁹ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/440316/airports-commission-final-report.pdf – 7.3, p135

²⁰ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/440316/airports-commission-final-report.pdf

we do not seek to set out here the case for additional capacity or where it might be needed at this stage. However, we believe it is important that the NIA sets out a preliminary view on when that consideration of further capacity might be required, the process that might be followed for that work and a view on how a network of strategic UK airports could be developed over the next 10-20 years.

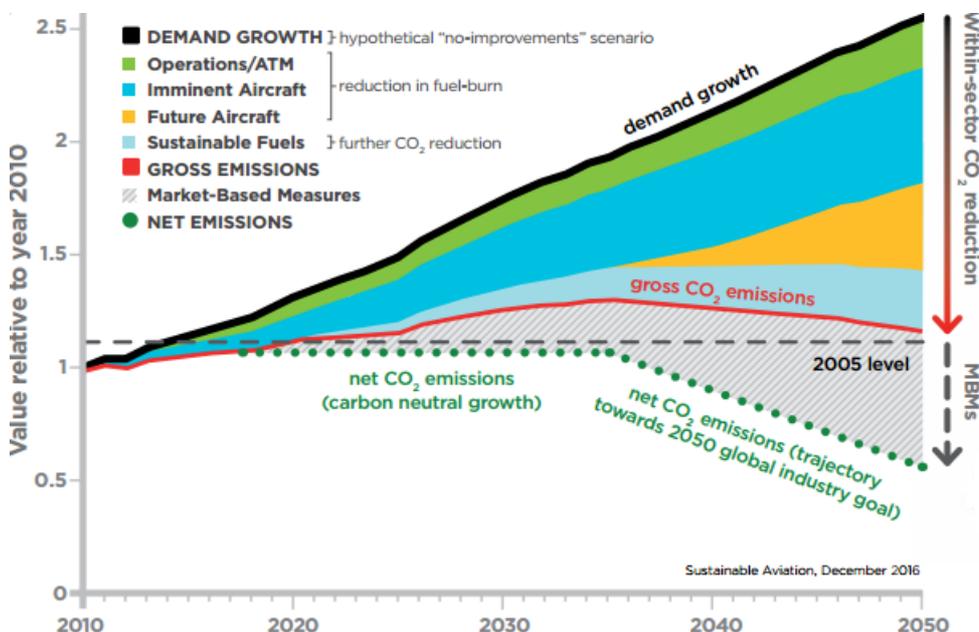

Recommendation

The NIC should keep the issue of future airport capacity needs in the UK to 2050 under review, and set out in the NIA its preliminary view on when further capacity might be required and the process for assessing the potential options.

Maximum potential for demand management (Q4)

49. In the case of transport, particularly in the aviation sector, the NIC must first consider the extent to which demand management or regulation is actually required. A large proportion of known demand for air travel in the UK (passengers and freight) can be met with existing capacity. Increasingly, the impact of aviation on the environment has been reduced, such that increases in activity (in terms of the number of movements) can be accommodated without increasing the impacts on air quality and noise, for example.
50. Sustainable Aviation²¹, an industry group which works to support the sustainability of the sector, has recently published the most up-to-date report on projected CO₂ emissions vs demand growth. It demonstrates a number of mitigation measures expected between now and 2050, demonstrating how CO₂ emissions should be broadly in line with the 2005 levels while at the same time accommodating significant sector growth.

Figure 2

Source: Sustainable Aviation Carbon Road Map 2016

²¹ Sustainable Aviation sets out the collective approach of UK aviation to tackling the challenge of ensuring a sustainable future for our industry. Launched in 2005, it is a world's first organisation of its kind, bringing together major UK airlines, airports, manufacturers and air navigation service providers.

51. Noise levels per aircraft movement too are expected to decrease, with the introduction of quieter aircraft types such as the Airbus A380 and the Boeing 787 able to offer significant noise reductions compared to their predecessors. Further design improvements such as blended wing body and engine shielding by fuselage and tail plane offer the potential to reduce perceived noise from aircraft by 65% by 2050.²²
52. In this sense, the NIC should not set off to 'manage' or reduce demand but to identify whether mitigation of the impacts of an activity are sufficient and assess whether the scale of impacts associated with an increase of supply can be similarly managed. As aviation consists of competing businesses in the private sector, the NIC should consider carefully the implications of seeking to intervene in the effective functioning of the market.

Competition and/or collaboration in the supply of infrastructure services (Q6)

53. The break-up of BAA has shown the benefits of encouraging competition between airports.²³ Airports are a competitive sector, both in terms of competition in the services they provide, and the infrastructure they build. The NIC's approach should recognise the role for competition between airports (and other potentially competitive sectors) and allow this to drive delivery of new infrastructure as far as possible. A stronger network of competing airports will also generate significant economic benefits by promoting direct connectivity from all parts of the UK.
54. This can be further strengthened by advising government to undertake fuller, more coherent integration of transport planning. This should recognise the essential linkages between rail/road investment and the wider airport catchment areas which support international connectivity, ensuring the value of access to airports is understood as part of any business case(s) development.
55. To take an example, an important part of the business case for Northern Powerhouse Rail, is the improvements in direct international connectivity that it will support by increasing the catchment area of Manchester Airport to the wider North of England. These rail improvements will allow the airport to build on its existing international network and create the critical mass required to support faster route creation, with benefits falling in the North. The point is supported by Transport for the North, which recently published recommendations from its independent International Connectivity Commission²⁴, suggesting a key aim for government should be to strengthen Manchester Airport's international network by improving surface connectivity.
56. If achieved, a larger network of direct international connections will feed back to the economy, supporting inward investment and productivity gains. This too has been referenced by the Government's own draft Industrial Strategy, citing the £500m benefit to the northern economy derived from direct links to China from Manchester Airport.²⁵
57. In terms of collaboration, the Transport Committee's recent report on rail franchising highlighted the Government's failure to deliver improvements to rail services to airports through the franchise process.²⁶ The consequence of this has been to shift the burden of financing onto Government funded infrastructure improvements further down the line, with

²² <http://www.sustainableaviation.co.uk/wp-content/uploads/2015/09/A4-Tri-fold-SA-Noise-Road-Map-Leaflet-Final-Version-230413.pdf>

²³ <https://www.gov.uk/government/news/cma-report-shows-benefits-of-baa-break-up>

²⁶ <https://www.publications.parliament.uk/pa/cm201617/cmselect/cmtrans/66/66.pdf>

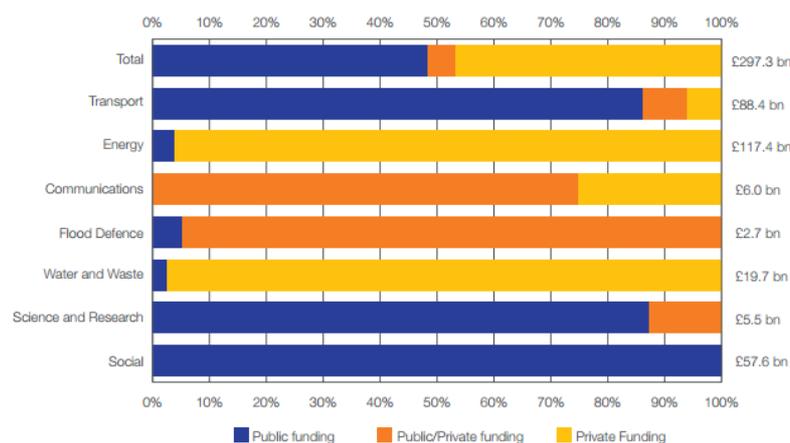

the opportunity for cheaper and more efficient operational improvements by the franchisee missed.

58. This points towards a lack of collaboration and integration between stated Government priorities, tendering and capital expenditure processes, as well as between rail, road and aviation departments. This conclusion is supported by the Committee's report: *"This outcome demonstrates to us another failure from the Government in taking to take a clear lead on integrated transport planning which is, as we concluded, the major obstacle to better surface access to the UK's airports"*.²⁷
59. Alongside the need to recommend infrastructure investments, the NIC must also ensure that it improves the processes behind future infrastructure decisions. A siloed approach to infrastructure development, with a focus on a particular sector alone, has the potential to cost future Governments both financially and in missed opportunity. The issues outlined above on the West Anglia Main Line should not be repeated, and a key role for the NIC is to be the driving force behind a more integrated approach to infrastructure development in the future.

Changes in funding policy to improve the delivery of infrastructure (Q7)

60. The UK has an ambitious target for improving its infrastructure. In March 2016 the Government committed itself to a £483 billion project pipeline, with the 2016 Autumn Statement releasing an additional £23 billion in order to support the UK's modern infrastructure needs.²⁸ This is, of course, welcome public Government spending but it is clear too that private investment is a vital part of the infrastructure spending mix.
61. While it has always been part of the UK financial framework, with mechanisms ranging from private finance initiatives through to Government guarantees, there is widespread variation in the ratio of private/public spending across different areas of infrastructure investment. Compared to other areas of infrastructure investment, transport infrastructure is often largely paid for by the Government, which demonstrates the complexity of securing third-party financing in the sector.

Figure 3

Source: National Infrastructure Delivery Plan, 2016-2021

²⁷ <https://www.publications.parliament.uk/pa/cm201617/cmselect/cmtrans/66/66.pdf>

²⁸ hansard.parliament.uk/commons/2016-11-23/debates/4F39F2C9-583D-407B-A529-3956F6A927F1/AutumnStatement [Column 902]

-
62. Our recent experience with Government and its agencies, including Network Rail, is that there is a growing expectation that we, as a private company, should pay the full cost of any improvement we wish to see prioritised – in this case, for the rail improvements to Stansted. This, however, ignores a number of factors, namely the wider benefits and strategic importance of the investment and the range of beneficiaries. It also ignores the significant contribution that airport passengers make to the rail farebox and franchise premium payments to help fund infrastructure improvements.
63. Once these contributions are taken into account, we support the principle of making appropriate contributions to UK infrastructure that promotes growth at our airports, particularly where the benefits are clear and well-defined for our business, customers and surrounding communities. Any further financing for infrastructure projects, however, requires a suitable framework that sets out clear risk and revenue sharing opportunities. As Baroness Jo Valentine, former CEO of London First, recently commented, *"policy-makers need to create the value before they capture it"*.²⁹
64. The incremental benefits to the airport, in this case, are modest compared to the increased farebox revenue and wider economic and social benefits. While it would be entirely feasible to make a contribution to funding a programme of improvements, there would be no commercial justification for MAG to pay the full capital requirement given the farebox premiums these will generate to Government over the life of the asset. We understand that this approach will be followed in connection with the Southern and Western Rail Access schemes developed (to support Heathrow's third runway) and the same principles should apply elsewhere where investment is being considered. Contributions must always be proportionate to the benefit that users derive from the scheme(s) or a mechanism must be found to return increased farebox revenue to third party investors.
65. Given the parlous state of Network Rail's capital programme, it is clear that the rail sector is a key part of the UK's transport infrastructure that could benefit from a new mechanism to attract private funding. In addition, the ability of the existing franchise system to deliver against wider Government aims has rightly been called into question by the Transport Select Committee and should be re-examined to ensure it has sufficient flexibility to incentivise third party investment.
66. Such mechanisms do not yet exist within the rail industry for outside investors, where, for example, the franchise system locks in ticketing revenue for the train operator and Department for Transport. This limits the likely participation of private companies to support investment in rail across the UK. It is worth considering that investment in rail services is likely to drive an incremental increase in passenger numbers and fare revenue.
67. Analysis from Steer Davies Gleeve demonstrated that the increase in farebox revenue alone would be enough to finance the proposed programme of improvements to the West Anglia Main Line. The possibility of using these incremental revenues to support and return investment to investors should be examined more closely as a potential new mechanism to access wider finance for rail projects.
68. The need to examine new mechanisms to invest in rail infrastructure is supported by Nicola Shaw's report in 2016, which recommends the Government *"explore new ways of paying for the growth in passengers and freight on the railway. Further options for involving private sector finance – for example, from letting a concession, or involving suppliers in technological investment – should be explored to release government capital, encourage innovation, and speed up delivery of improvements for passengers. Routes should also be required and empowered to find local sources of funding and financing, including from*

²⁹ Speaking at the London Infrastructure Summit, April 2016

*those (such as local businesses or housing developers, for example) who stand to benefit from new or additional rail capacity.*⁸⁰

Recommendation

To accelerate the delivery of investment in railway services and infrastructure, the Commission should encourage the Government to work with stakeholders to develop a clear and easily understood template for investing in infrastructure enhancements, including mechanisms for both risk and revenue sharing. Such a template has the potential to unlock significant third-party investment in the rail network, accelerating the delivery of enhancements that will be of substantial long term benefit both to rail users and the wider economy.

Projects that can be funded but not financed (Q8)

69. As outlined above, we believe the delivery of investment in railway services and infrastructure could be accelerated with the right framework, identifying opportunities for investment in infrastructure enhancements that include mechanisms for both risk and revenue sharing. Such a template has the potential to unlock significant third-party investment in the rail network, accelerating the delivery of enhancements that will be of substantial long term benefit both to rail users and the wider economy.
70. Our analysis of potential infrastructure improvements on the West Anglia Main Line via London Stansted Airport, for example, indicates that these kinds of project should be financeable by third party investors, were it not for the current structure of the rail industry. Changes to Network Rail's status mean that it is no longer possible for it to use its Regulatory Asset Base to deliver third-party rail enhancements. For example, the approach that was taken to financing improvements as part of the long term Chiltern franchise, known as Evergreen, would no longer be possible under the current framework. This previously provided a mechanism for third parties to secure infrastructure improvements on commercial terms, using incremental farebox revenue to remunerate the investment.
71. A range of new approaches need to be developed to enable other projects to be delivered in a similar way. We are confident that new structures could be developed that would have the potential to unlock significant third-party investment in the rail network, accelerating the delivery of enhancements that will be of substantial long term benefit both to rail users and the wider economy.
72. The Shaw Review into Network Rail funding and financing considered the role of third-party funding in delivering rail infrastructure and we would support further consideration by the NIC of these options for delivering infrastructure enhancements, and particularly future structures for Network Rail that will facilitate this type of third-party investment.

Improvements to the planning system and infrastructure governance arrangements (Q10)

73. While the 2013 Aviation Policy Framework set out broad support for the sector, it effectively deferred consideration of all policy until the end of the Airports Commission process. It is essential for UK airports' future planning needs that there is a clear national statement of policy support. We are concerned that the Government has chosen to use the Airports National Policy Statement (NPS) to facilitate only the delivery of a new runway at Heathrow without reference to the wider strategic policy and planning needs of the sector.

⁸⁰ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/510179/shaw-report-the-future-shape-and-financing-of-network-rail.pdf

74. The National Policy Statement for Ports (2012), for example, provided for all new port development across the whole of the UK, and took into consideration, wherever relevant, “associated developments, such as road and rail links”.³¹
75. The Government's preferred vehicle – an Aviation Strategy – will take two years of consultation to complete. We would urge the NIC to consider the speed at which both policy and then planning processes take place so that the sector can plan and deliver sustainable growth that supports the UK economy. Further, the NIC should set out clear expectations that the Government will use the Aviation Strategy to outline clearly the development it supports (in policy and investment terms) as well as the conditions attached to growth.

Cost-benefit analysis techniques (Q12)

76. The Government's approach to cost benefit analysis on transport infrastructure is clearly varied. To take two prominent examples, the HS2 project and Airports Commission process as examples, the methods used for the former to calculate both economic value to the UK as well as productivity gains have received much criticism, summarised in the House of Lord Economic Affairs Committee paper, *The Economics of High Speed 2*.³² The methods for the latter, primarily those used for calculating and capturing productivity gains, too have been unreliable, a situation demonstrated by the differing benefit figures offered by the Government and Airports Commission (£61bn³³ and £147bn respectively³⁴).
77. The weaknesses and lack of confidence in the economic methods that are used to assess wider economy benefits are likely to be distorting public investment towards projects that have more easily quantified costs and benefits. In particular, this may lead to over-investment in projects that address capacity constraints (such as Crossrail and Thameslink), and under-investment in projects where the business case depends on unlocking long term development opportunities (such as Crossrail 2 and NPR). There would be significant benefit in the NIC developing new tools and techniques to build decision makers' confidence to invest in the latter category of projects.

Travel patterns between now and 2050 and the impact of new technologies (Q13)

78. The aviation sector demonstrates a clear upward trend in both the number of air transport movements and the number of passengers travelling through UK airports. Projections of growth have consistently underestimated the pace of growth but demand forecasts consistently show all the major UK airports reaching capacity between 2040 and 2050.

³¹ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/3931/national-policy-statement-ports.pdf

³⁴ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/440316/airports-commission-final-report.pdf

Figure 4

Source: Transport Statistics Great Britain, 2016

79. There are a number of factors that make it difficult to predict long term sector trends – population growth and age, the economy, society and technology to name but a few. In recent decades, technological and political change has had the largest impact on the aviation sector with the emergence of low cost airlines and ever more efficient aircraft challenging industry norms and driving significant growth.
80. To overcome some of these challenges, the Airports Commission developed a range of five alternative scenarios for future development of the aviation sector, aiming to reflect the kinds of risks and uncertainties that cannot be easily (or quantitatively) predicted from past events (such as the future development of airline business models). Each scenario then showed different implications for the respective market shares of hub-and-spoke and point-to-point networks and for the inclusion of UK airports in global route networks.³⁵
81. The Commission did conclude, however, that *“aviation is in a dynamic and constant state of evolution as airlines find new ways of adapting their businesses to respond to these changes, with two main paths of development being seen over the past two decades – one of consolidation, partnership and network integration; the other one of new entrants and expanding point-to-point travel.”*³⁶
82. Like the Airports Commission before it, the NIC cannot realistically attempt to predict and provide entirely for future trends. It is clear, however, that to meet demand in the long term and to ensure that growth is balanced across the country, further runway expansion will be needed beyond that proposed at Heathrow. At a global level, aircraft technology which allows airlines to fly smaller numbers greater distances at a reduced cost, making point to point travel more profitable and reducing a reliance on hubs for certain routes over time.
83. This increase in point-to-point travel, driven by significant advances in aircraft technology, ever more financially viable. Consultants ICF noted: *“[technology] will continue to drive new nonstop services, taking advantage of longer ranges and better fuel efficiency than*

³⁵ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/439173/strategic-fit-review-of-airports-commissions-forecasts-and-scenarios.pdf

³⁶ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/440316/airports-commission-final-report.pdf

historical long-haul aircraft. The trend towards new international services from hubs to non-hubs and even long-haul point-to-point will continue to grow, bringing new players and opening new markets at an unprecedented rate".³⁷ These increases in demand, combined with better access to airports and a reduced cost of aviation too are likely to spur the profitability of long haul routes away from 'hub' airports. We are already seeing evidence of this at Manchester Airport, with the opening of a range of new routes to China, America and Asia.

84. The benefits of direct aviation connections are well known³⁸ so the NIC should seek to set out a clear vision for infrastructure investment that supports a network of competing airports – including road and rail programmes that shape the choices available to passengers and businesses in the future. It is reasonable to expect that investment in Northern Powerhouse Rail, for example, would transform the travel choices for millions of people across the North, supported by a growing network of connections from Manchester Airport in particular.
85. Of course, to sustain projected passenger growth airports must ensure their own infrastructure is fit to meet demand. At Manchester and London Stansted Airports, we have plans in place to develop and replace terminal and airfield infrastructure to cope with projected demand, including terminal redevelopment and train station upgrades, but this work on site must be matched by supporting outside infrastructure too in order to make use of these national aviation assets.
86. Equally, the NIC must take into consideration what mode of transport is best for the country as a whole, looking at environmental impacts, costs to customers and so on. How the Government invests in infrastructure to support aviation growth will determine travel patterns. For example, airports which serve London, with high comprehensive public transport networks, have universally higher percentages of public transport than airports such as East Midlands, which do not.
87. Finally, as outlined above, the NIC must undertake to consider the long term capacity needs for UK airports beyond 2030, as recommended by the Airports Commission in 2015.³⁹

Lord Adonis, Chairman
National Infrastructure Commission
1 Horse Guards Road
London
SW1A 2HQ

8 February 2017

Dear Andrew

NATIONAL INFRASTRUCTURE COMMISSION CALL FOR EVIDENCE

I am writing in response to the National Infrastructure Commission's Call for Evidence to inform the development of a National Infrastructure Assessment.

Firstly, I would like to welcome the establishment of the National Infrastructure Commission: if we are to drive growth across the country as a whole, and increase the opportunity for all to benefit from that growth we must take a strategic approach to identifying the UK's long-term infrastructure requirements and examine how those requirements can best be met.

Infrastructure plays a critical role in creating the conditions for growth, supporting agglomeration economies, widening catchment areas so that companies have access to the supply chains and human capital they need to expand, diversify and compete on a global scale. It provides our people with better access to the opportunities that growth will bring, and to health care and other essential services. And it helps to create places that are an attractive environment in which to live, work and invest. We welcome the development of a National Infrastructure Assessment that will take a holistic view of infrastructure requirements - transport, digital, energy, water and waste water, flood risk and solid waste – over a 30 year time horizon.

If that Assessment is to underpin the National Infrastructure Commission's long-term approach to the major infrastructure investment decisions facing the country it is critical that it is underpinned by a robust evidence base. We therefore further welcome the opportunity to provide input into the development of that assessment.

The Greater Manchester Combined Authority and Local Enterprise Partnership have submitted a response to the Commission's Call for Evidence, which Manchester City Council wholeheartedly supports. However, I wanted to highlight a number of specific issues in relation to the Commission's thematic discussion paper "**The impact of population change and demography on future infrastructure demand.**" Given that the Commission's Assessment of population growth and demographic change will be based on ONS Mid Year Estimates, which have historically underestimated population growth in Manchester, it is particularly important to ensure that this aspect of the Assessment adequately reflects potential population and demographic change.

In addition, the growth potential of Greater Manchester and wider Northern Powerhouse ambitions mean that it is also important to ensure that the Assessment accurately reflects the likely spatial distribution of population growth.

The Commission is proposing to use the following population projections as inputs into scenario development, with a view to spanning “the range of plausible outcomes”:

- The ONS central population projection;
- The ONS low migration population variant;
- The ONS high fertility population variant;
- A projection based on the aggregate population in the ONS central population, but with sub-national populations less skewed towards London, with the shift in population distribution motivated by trends in house building.

Whilst using a range of projections to support the development of different scenarios seems sensible and is to be welcomed, it is debateable whether the proposed variants do, in fact, span the range of plausible outcomes.

Migration

It is concerning that the proposed methodology does not include a variant for continued high migration. ONS MYE in 2012 and 2013 significantly underestimated population growth in Manchester as a result of assumptions that forecast a reduction in international immigrants and an increase in internal emigrants. These assumptions ran counter to the high levels of international migration recorded through school registrations and National Insurance registrations in Manchester but were carried forward by ONS into the methodology used for 2012 and 2014 sub-national population projections. As a result, current ONS projections forecast a loss of 1,000 people each year due to fewer people arriving in the city from abroad and more people leaving to live elsewhere in the UK.

In contrast, Manchester City Council’s own forecasting model, which uses administrative data (such as geo-demographic profiling and data on students, child benefit, state pensions and the electorate, along with NHS, pre-school and National Insurance data) to quality assure and adjust ONS figures from 2001 and 2014 and sets net migration at an average growth rate of 6,000 per annum.

Whilst it is recognised that the Council’s own forecasting model cannot be used to underpin the national projections required to inform the NIA, they do demonstrate that the NIC should consider including a “high migration population variant” within the modelling to be undertaken.

This is ruled out in the discussion paper, because ONS higher migration, higher fertility and higher life expectancy variants have similar rates of implied population growth (on average at 0.64%, 0.6% and 0.57% respectively) so the view of the Commission is that the inclusion of a high fertility variant adequately reflects a higher growth scenario. But for cities such as Manchester that have a higher than average fertility rate and high levels of migration, this variant is unlikely to adequately reflect expected levels of population growth. Whilst Britain’s exit from the European Union may lead to restrictions on the free movement of people, the discussion paper acknowledges that it is not yet possible to estimate what the impact of those restrictions may be on migration levels. Britain’s post-Brexit immigration policy remains to be negotiated and the discussion paper acknowledges that other advanced economies that are not members of the EU, such as Canada, Australia and New Zealand have significantly higher levels of migration than currently seen in the UK. A “high migration population variant” should therefore be considered as scenarios are developed.

Rebalancing the country

A further issue with the proposed methodology is that it does not adequately reflect stated Government policy to rebalance the country, through increased investment in the North of England. Whilst the inclusion of a variant to reflect lower growth in London and higher growth elsewhere in the country is welcome, this variant is essentially 'policy off'. According to 'Zipf's Law' – a statistical relationship between city size and rank – there is a pattern in the relative size of cities across time and between countries. The second largest city is usually half the size of the largest city, with the third city half the size of the second. Based on this analysis England's major cities are smaller than would be expected, implying that London's growth therefore may not be sustained over the coming decades.

The scenario is therefore based on an assumption that some rebalancing would occur without active intervention by the Government and therefore doesn't reflect the Government's Northern Powerhouse Strategy and existing Government commitments to that Strategy. That strategy will both drive a requirement for additional infrastructure provision, and be driven by that additional infrastructure provision.

The discussion paper acknowledges that "the direction of causation between population and infrastructure demand is not necessarily one-way" and identifies the interaction between infrastructure and housing as most significant. "Ultimately, people can only live where there is housing. Housing, in turn, requires infrastructure." The NIC should consider a "policy on" scenario that reflects sustained investment by the Government and Northern cities, not only in infrastructure, but in key sector strengths and assets, in increased international trade and investment to drive growth and productivity across the North of England, in the skills of the population, and in the housing offer required to attract and retain that skilled population.

We are at a pivotal time in the UK's history: the Government's emerging Industrial Strategy, and the huge potential of the Northern Powerhouse that could underpin that strategy, provides a real opportunity to forge a bold, new positive role in the world following our withdrawal from the European Union, with strengthened trading relationships and more productive businesses driving growth across the country and increasing opportunity for all. If we are to capitalise on this opportunity the National Infrastructure Plan must respond to the different drivers of growth in different parts of the UK.

We look forward to working with you in future and actively engaging with the Commission in the future.

National Infrastructure Assessment Call for Evidence

Response from Manchester Digital

Manchester Digital

Manchester Digital is the largest network of digital and technology businesses in the North of England. Founded in 2001, it has over 500 paying member businesses, from start-ups to global e-commerce brands, covering the full digital, creative and technology footprint.

The organisation plays a significant role in the growth and development of the industry across Manchester city region, taking a lead on skills and talent development, infrastructure and the development of the ecosystem. As well as providing leadership for its members the organisation runs several highly regarded events such as the pioneering Digital Skills Festival, which brings together businesses, education and students, and the Big Chip Awards, covering the North of England and now in their 19th year. The organisation has also recently launched a software development apprenticeship, using a brand new delivery model, successfully placing apprentices in digital businesses, small and large.

Manchester city region has both the potential and the ambition to figure among the world's digital centres and was recognised in the recent Tech Nation report as the second centre for digital, tech and creative business in the UK.

Basis of our response

The basis of our response is who we are. Manchester Digital is a creation of digital and technology businesses. It is governed by an elected council of 12 people drawn from across the sector. It is therefore in a unique position to speak for the sector.

Summary of our response

We are responding solely on the questions concerning digital infrastructure. Together with skills this policy issue has considerable impact on our members.

We conclude:

- That investment in new dark fibre is the highest value digital infrastructure, needed to support digital tech growth and 5G.
- That decisions should be made now without delay.
- That the structure of the markets is holding back growth and innovation in the digital-tech sector and that:
 - Government should take steps to open up the market in dark fibre;

- Government should take steps to ensure that the 5G infrastructure (rather than services) is open, shared and accessible for SMEs to add value.

Question 17

What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

We concur with the current view coming from Government that the digital infrastructure that the UK will need to compete should support ever-increasing demands for speed, data volume, low latency, symmetry, reliability and QoS. This is vital for the development of the digital and technology sectors, where there is pent-up demand. It is also vital for the economy more generally.

These are the demands that users place on services. Our infrastructure must also support opportunities for economic development in how it is built, maintained and operated. We cover this in our response to Question 18.

To support these service demands requires a combination of direct fibre connectivity ('full-fibre') and 5G. Only these technologies have the capacity to meet the changing demand:

- Fibre, particularly dark fibre, offers almost unlimited capacity to those that are prepared to innovate.
- 5G, because it offers an integrated approach to wireless connectivity, offers the chance to stretch the capacity limits set by spectrum availability.

We agree with the current view that 5G and 'full-fibre' are effectively two aspects of the same integrated network infrastructure that the UK needs. Supporting the suite of technologies represented by 5G will require dense fibre penetration, particularly in cities.

Fibre is expensive to deploy. The UK lags behind other nations in its deployment of fibre.

Putting fibre in the ground is without doubt the highest value infrastructure investment required.

We believe that to maximise the value of new fibre, new, neutral aggregation points¹ are needed and that there is a role for Government in ensuring that these neutral spaces exist. However these are not as costly as fibre.

The pent-up demand for fast, affordable, reliable connectivity among digital and technology businesses in Greater Manchester is already putting a brake on growth and innovation.

Decisions need to be made now to ensure rapid deployment of fibre. This has been true for some years. It only becomes more urgent with time.

¹ For example the Digital Exchange model pioneered in Brighton

Question 18

Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing “regime” refers to the current market, competition and planning frameworks. “Digital communications” includes both fixed and mobile connectivity.

In our response to Question 17 we pointed to the pent-up demand for speed, data volume, low latency, symmetry, reliability and QoS among digital and technology businesses. These are service demands rather than infrastructure demands.

It is our view that Government policy has been overly focused on these ‘service demands’ in the past. They are important, but we believe the solution to them should emerge from the digital and technology sector - from our members. The role of Government is not to ensure the delivery of services to meet a specification, but to ensure that the infrastructure supports a functioning market that permits innovation and competition.

As the question implies, the role of Government therefore is to promote digital infrastructure as utility, able to support a rich value chain. This can be viewed as a ‘value grid’:

LAYER	FIXED	WIRELESS	HOSTING
Application (content)	social, websites, mobile apps, SaaS/cloud apps		
Application (network)	www, mail, voice, video, backup		
Service	Internet access (“layer 3”)		Virtual servers, cloud
Active	Point to point (“layer 2”)		Servers
Passive/base	Fibre	Antennae	Racks, power, cooling
Physical/property	Ducts and poles	Masts	Data rooms

The innovation in our sector is not confined to the top layer: our sector is about more than apps and content. Our members occupy all parts of the grid, adding value across layers and moving between technologies.

The opportunities to add value and cross vertical and horizontal boundaries in this grid are vital to the development of the digital and technology sector and for the wider business and consumer market for services. That is because these are the opportunities that allow:

- Smaller and startup players to grow;
- Innovation with service specifications and wraps;
- Differentiation.

However these opportunities are severely limited because of the market structure:

The dark fibre market is broken

Most of the value in the grid is above the active layer. Most of the investment is below the active layer. Most dark fibre is in the hands of a small group of carriers that are vertically integrated businesses. They can earn more by adding value themselves.

A consequence is that SMEs find it hard to access dark fibre. Prices are not transparent. There is not an open market. This has been recognised by Ofcom and other regulators².

We therefore believe that Government should take steps to ensure the existence of an open market in dark fibre, accessible by SMEs.

There are many ways to do this:

- Regulatory - for example through mandatory infrastructure sharing³
- Leadership - for example by encouraging public sector demand-asset aggregation⁴
- Legislative - for example with a 'dig-once' bill⁵

The cellular wireless market discourages innovation

The (cellular) wireless column in the grid has the same basic value/investment characteristics as the fixed column: most of the value is added above the active layer, most of the investment cost is below the active layer. Consequently the market acts to prevent smaller and innovating entrants from accessing the value chain. Also, in common with fixed line, an exacerbating factor is the lack of a mechanism for infrastructure sharing - whether market-based or regulatory.

SMEs that want to include cellular in their service wraps are limited to MVNO agreements, reselling services over which they have no control.

If the UK is to lead in 5G, then it is vital that this closed market is not replicated and that SMEs get access to a shared infrastructure.

We therefore believe that Government should take steps to ensure that new 5G infrastructure is shared, open at lower layers, and accessible by SMEs.

There are various ways to do this:

- Regulatory - for example through mandatory infrastructure sharing, perhaps linked to spectrum allocation.
- Leadership - for example through Government investment in 5G standards development.

Response to National Infrastructure Assessment call for evidence:

Written evidence submitted by Frank Rogers, Lead officer for Transport for the Liverpool City Region Combined Authority

Merseytravel, on behalf of the Liverpool City Region (LCR), greatly welcomes this important opportunity to make a submission to the National Infrastructure Commission's call for evidence on the National Infrastructure Assessment looking at requirements over a 30 year time horizon to 2050. We welcome the ambition and foresight proposed by this. Our submission focuses upon infrastructure requirements relating to Merseytravel's perspective particularly around the cross cutting issues and transport. We will leave other partners to comment on the other themes.

The LCR welcomed the opportunity to discuss this work on the 15 December 2016 through the round table session that the National Infrastructure Commission held in the Liverpool City Region. We would welcome further opportunities to be of further assistance to the National Infrastructure Commission with this work.

CROSS CUTTING ISSUES:

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

Our unique history, our cultural and environmental assets and architectural distinctiveness have already made Liverpool City Region a globally renowned destination. Built up around a port city with a rich, cosmopolitan maritime history, bringing together diverse cultures, communities and assets the City Region is a unique place. Liverpool City Region is built on a rich history of international maritime trade and world-leading innovation and achievement in science, culture and civic life. It is internationally renowned with an outstanding physical environment, more listed buildings of architectural distinction than any other UK city outside London, and an iconic waterfront recognised by UNESCO as a World Heritage Site. With a beach-lined coastline and easy access to mountainous national parks including Snowdonia and the Lake District, the LCR is seen as one of Britain's most liveable places.

The Liverpool City Region is one of the fastest-growing economies in the UK, and has the highest productivity of any of the 6 core Northern city regions. For all that, it has some obstacles to overcome in creating long-term sustainable growth, including reducing levels of unemployment, increasing graduate retention levels and reducing public sector reliance. None of this is unique to Liverpool, and we would highlight the Northern Powerhouse Independent Economic Review (NPIER) for providing evidence for transformative long term growth of the whole North of England.

Transformative long-term growth is based around recognising that there are specific 'capabilities' (as opposed to industry sectors) where the North has a strength and/or competitive advantage. The Liverpool City Region is well placed to capitalise on this, having substantial levels of activity in the NPIER capabilities. However, as the report

identifies, there are infrastructure investments that are prerequisites to enabling this growth:

“Transformational improvements to the North’s transport connectivity are also critical, both between and within cities. Enhanced pan-Northern city-centre to city-centre rail links, east-west and north-south are needed to facilitate the bigger labour markets that support the success of knowledge-based firms – and, to be effective, they must be integrated with city-region local public transport networks, which are joined-up with wider networks, involving frequent rail services, light rail and bus, all supported by smart, multi-modal ticketing. Global connectivity, for people and for goods, is also essential if the North’s Smart Specialisation opportunities are to be realised fully.”

NPIER 2016, Executive Summary, p16.

Already the City Region is exerting a step-change, with the recent opening of the Liverpool 2 container terminal that more than doubles the port’s capacity, funded by private sector investment. “Logistics” is one of the NPIER’s identified capabilities of the North, and greater use of the port-centric logistics can generate substantial benefits across the country through fewer freight miles.

In addition to this, the Liverpool City Region also has a trend of strong long-term growth in its visitor economy (the city itself being the 6th most visited city in the UK by overseas visitors), including in expanding high-value conference, cruise and sports markets. The Visitor Economy in Liverpool City Region is a success story not just for Liverpool and wider city region, but for the entire UK. The growth experienced over recent years has helped create a sector which, according to the latest STEAM 2015¹ figures released in July 2016, contributes over £4.1 billion in GVA to the local economy and supports 51,000 jobs. Liverpool City Region attracts over 61.49 million visitors per annum. As a result it is one of the most significant and successful industry sectors in the city region.

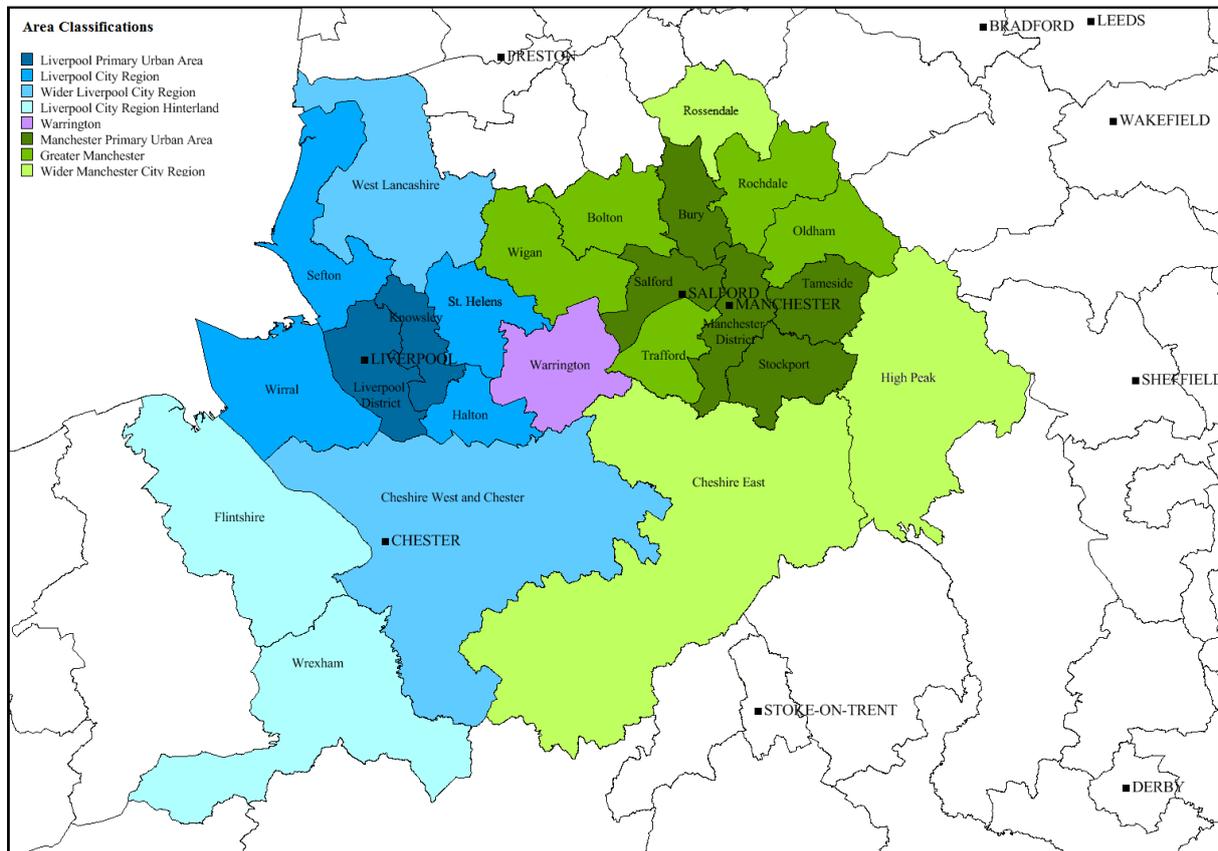

The city region has inherent strengths in high value industry sectors, including:

- Advanced manufacturing
- Food manufacturing and processing
- Life sciences
- Low carbon & renewable energy
- Financial & professional services
- Digital & creative
- Maritime & logistics

There are four Enterprise Zones located in or near the Liverpool City Region including Mersey Waters, Sci-Tech Daresbury, Deeside, and Cheshire Science Corridor. The city region economy includes notable names such as Peel, Jaguar Land Rover, Unilever, Cammell Laird, Alstom, Dong Energy, Ineos, Typhoo Tea, etc.

¹ STEAM is the Scarborough Tourism Economic Impact Monitor provided by Global Tourism Solutions. It is an industry standard model used across the UK by local authorities and Destination Management Organisations

Often a mistake has been made in different studies when evaluating the size of the Liverpool City Region; for example, by just using the ‘primary urban area’ (which is just Liverpool and Knowsley), or 6 districts which make up our LEP and Combined Authority area (Liverpool, Knowsley, St.Helens, Halton, Sefton and Wirral). However, our analysis shows that the functional Liverpool City Region extends beyond the LEP and CA boundaries, drawing in West Lancashire, Cheshire West & Cheshire and Warrington, thus representing a much larger population and economic base.

It should be noted that our functional LCR geography – whether in terms of commuting populations, business activity or transport networks – reaches further (see map), covering West Lancashire, Warrington, Chester & West Cheshire and adjacent parts of North Wales; many of these areas are already partly served by the Merseyrail network, with all areas mentioned seeing strong plans for growth enshrined in the City Region’s Long Term Rail Strategy. West Lancashire and Warrington are in fact already associate members of the Combined Authority, with the natural overlap with North East Wales represented in part by the ‘Mersey Dee Alliance’ and the North Wales Mersey Dee Rail Taskforce.

There are fundamental linkages between North Wales and North West England in terms of jobs, retail, tourism, education & healthcare. However, because economic data is collected independently on both sides of the border, the combined strength is not fully recognized. Strategic planning of rail infrastructure in the Mersey Dee and North Wales Region needs to form part of an integrated multi modal approach, recognizing the importance of the North Wales cross border corridors serving Ireland, North Wales, and Northern England and beyond, with the existing enterprise

and labour market of this shared economy providing significant potential to help deliver the objectives of the Northern Powerhouse.

The Growth Track 360 Rail Prospectus, published in July 2016 by the North Wales and Mersey Dee Rail Task Force (a cross-border alliance of business, political and public sector leaders), outlines aspirations for the future in terms of rail services and infrastructure improvements needed. The prospectus calls for substantial and transformational rail investment to enable growth in the cross border economy of the North Wales & Mersey Dee region. Transport investment will act as a key enabler to help the region to act as a gateway to the Northern Powerhouse and European TEN-T routes and play a key role in this wider economy.

However, the prospectus has not fully considered the available rail capacity east of Chester, especially in the Manchester area, and the many conflicting demands for that capacity. Significant investment will be necessary in North West England if the aspirations of North Wales are to be delivered in full.

The portfolio of city region strategies aim to protect and enhance our distinctive quality of place, to improve quality of life for our residents and attract and retain those investors, skilled workers and visitors who will contribute to future economic growth. There are a number of infrastructure constraints for the city region including:

- Liverpool Lime Street Station
- Access to the Port of Liverpool
- Trans-Pennine Capacity and Journey Times
- Liverpool Central Station
- Merseyrail Network
- West Coast Main Line Capacity
- Surface access to Liverpool John Lennon Airport
- Connectivity to Wales

For the Liverpool City Region, in line with the findings of the NPIER and to respond to these infrastructure constraints for people and goods, the following are the critical high-value investments that would enable transformative growth:

- **A new twin-track high speed rail line between Liverpool City Centre and the High Speed 2 mainline**
 - Providing improvements to the proposed HS2 service offer and enabling Northern Powerhouse Rail (NPR)
 - This is vital to free up capacity on both the current East-West and North-South rail lines serving Liverpool, where even with enhancements there will not be sufficient paths for the growing freight traffic out of the Port of Liverpool and other freight terminals.
 - It is also important in terms of enabling Liverpool to maintain a competitive level of connectivity to London and the South East, with similar journey time reduction to other key Northern cities.
- **A new multi modal terminal station in Liverpool City Centre for HS2 and NPR**
 - Linked to existing transport nodes and improving the travel experience in the City Region

- Lime Street may not be able to accommodate high speed rail services so new station better option to take forward.
- **Further roll out of high speed rail to other parts of the UK.** This would further improve the customer offer on the rail network by expanding high speed rail into a national network and help provide new capacity.
- **Merseyrail Modernisation Programme**
 - Stage 1 – New Rolling Stock fleet (and associated infrastructure upgrades) now ordered from Stadler
 - Stage 2 – Liverpool Central Capacity Enhancement
 - Later stages – network expansion, new stations, stations devolution
- **Improved connectivity to other parts of the UK**
 - Key ‘missing’ markets for Liverpool City Region include North Wales, the West Country, South Coast and Scotland
 - Service and infrastructure enhancements required
- **More Rolling Stock and Longer Trains** – increasingly the rail network is enjoying substantial growth and there is a shortage of rolling stock leading to many services becoming overcrowded thereby compromising the customer journey experience. Consequently there is a need for longer trains to be used on many routes including long distance intercity routes where Cross Country is a particular issue with only 4-5 car trains. Ideally all train services on long distance intercity and cross country routes should be 8-12 car.
- **Rail Electrification** including key routes such as Transpennine, CLC, Hope Valley, Calder Valley, Borderlands Line, North Wales Coast Main Line, etc. as a rolling programme in line with the conclusions of the Northern Sparks Report (March 2015) by the Northern Electrification Task Force.
- **Higher Priority given to Rail Freight investment nationally**
 - Liverpool 2 Container Terminal is now in place
 - Routes need capacity and capability to handle larger, faster and more frequent freight services
- **Development of an East-West ‘freight super corridor’ across Northern England that is gauge cleared to W10.** This would link the major ports (Mersey, Humber, Tees and Tyne) to a series of multimodal logistics hubs and help make the North a linchpin of a global trade corridor for the movement of freight from North America to/ from Europe. There are opportunities for the development of a chain of multi-modal logistics parks adding value to the distribution chain. In this way, connectivity for freight will be leveraged to add significant value to the Northern economy.
- **Increase use of inland waterways and coastal shipping for freight.** While our road and rail networks have constrained capacity, the coastal waters around the UK are an untapped resource that can help relieve things.
- **Improvements to Port of Liverpool access.** The recent private sector investment in Liverpool 2 which will more than double the container capacity of the port is part of the LEPs ‘Superport’ growth sector (covering ports, airport, logistics operators and support services); an area which substantial growth is expected over the following years, in line with the NPIER. However, there are capacity issues on the road and rail networks serving the area. Although (at a highly localised level) improvements to the port and other terminals are a matter for the operator, other crunch points exist on both local and national networks. For example, capacity for freight on both the Chat Moss line and CLC is limited, and there are crunch points on the WCML both

North and South as well as on trans-pennine rail routes. This makes a full NPR network as well as a direct HS2 link (above) important. The recent opening of the 'Liverpool 2' deep water berth has resulted in a doubling of capacity at the Port, from 750,000 TEU p.a to 1.5m TEU p.a. Such a significant increase in potential throughput can only be accommodated with the implementation of a comprehensive multi-modal approach to traffic movement to and from the Port estate, incorporating rail, short sea shipping, inland movement along the Manchester Ship Canal as well as road. There are capacity issues on the A5036 linking the port to the motorway network and currently Highways England is consulting on two potential options. We must find a way of getting goods from the port, to their ultimate destination in as quick, efficient, and sustainable form as possible, and whilst causing as little disturbance to those living along the way. To do that we will work closely with Highways England, Network Rail, the port authority and the local authority to ensure that as much cargo as possible leaves the site by rail and on water. But planning timescales are long, some goods cannot be transported by anything other than by road, and so in the meantime we must look to develop a road scheme that seeks to balance the needs of those living close to the affected areas whilst also standing the tests of time and provides the capacity for the port to expand in the decades to come.

- **Improved surface access to Liverpool John Lennon Airport (LJLA).** LJLA is a growing regional airport, with currently c.5.0 m passengers per annum. It already contributes an estimated £440m GVA per annum to the Northern Powerhouse, with the capability for this to increase to £1bn. The key gateway airport for the Northern Powerhouse will always be Manchester Airport, but LJLA has its own distinct strengths, with its market covering not just the Liverpool City Region but stretching to North Wales, the Midlands, Yorkshire and even Scotland. Improving surface access to enable seamless journeys will help make LJLA yet more attractive to new routes and drive upwards its economic contribution to the area, not least in increasing levels of inbound tourists.

Our independent economic assessment has shown that with an improved HS2 offer and delivery of the NPR Conditional Outputs, the benefits for the Liverpool City Region that could be realised include £15 billion boost to the Liverpool City Region economy, 20,000 new jobs, 10,000 new homes, and 2.9 million more visitors.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

International gateways serve two distinct passenger markets; inbound (overseas visitors) and outbound (domestic travellers going abroad). For both, maximising improvements to surface access is important (though noting from CAA data that inbound visitors tend to be more likely to use public transport at UK airports than outbound visitors). The improvements needed and their justifications for delivery will do the following to improve the UK competitiveness on the global stage:

- Improved surface access increases the airport's catchment; this gives operators considering establishing new routes to/from the UK a wide

choice of options – and may mean that inbound travellers are more likely to be able to locate a flight closer to their end destination in the UK.

- Increased aviation connectivity can be an important factor in attracting inward international investment to the UK. There may be little to improve in terms of new routes when considering the London area and Manchester, for example, but improving aviation connectivity to LJLA, Doncaster and Leeds/Bradford is likely to represent more of a step change for these areas.
- Improved surface access can make it easier for the UK to grow its inbound visitor economy, through making the journey between the airport and the visitor's destination as seamless as possible; there are some sizeable growth markets identified by Visit Britain. This should mean considering not just surface access between an airport and its nearest city but (where reasonable) how to improve surface access from that airport to all key cities. For example: flights from South America only serve London, meaning that if visitors and investors from these areas are to have their spend/investment dispersed to the regions, this wider surface access must be considered.

In terms of freight, there are some substantial competitive gains to be made through focussing on port-centric logistics, looking to ensure that imports and exports are able to use the port in closest proximity to their market / source respectively. For example, increased use of Northern ports offers the user reduced distribution time and costs for their goods, whilst also offering the UK net national savings through reduced lorry miles on congested infrastructure around London and the Southeast whilst contributing to reducing air quality levels. It can also help rebalance the UK economy and ease pressure on the congested London and South East.

Note that some 'gateways' which though technically 'domestic', are in fact international. By this, we urge consideration to the links to Northern Ireland (and to a lesser extent the Isle of Man). From a transport operation perspective there is little difference between the links to Northern Ireland and those to elsewhere in Europe, besides differing taxation levels at each end of the operation. Further, when it comes to the links to/from Northern Ireland, many users may in truth be international passengers, having a destination in the Irish republic. This should be remembered in any work. The recent TfN report on International Connectivity (Feb 2017) may also be relevant in this context. http://www.transportforthenorth.com/wp-content/uploads/International-Connectivity-Report_websafe.pdf

Liverpool City Region has three important international gateways which are Liverpool John Lennon Airport, Port of Liverpool and the Liverpool Cruise Terminal.

Liverpool John Lennon Airport:

Liverpool John Lennon Airport mainly has a passenger role with limited freight traffic at the moment. Liverpool Airport is one of the fastest growing airports in the UK. In 2016 it generates £250m GVA per annum for the LCR (with the capability for this to increase to £625 million), £440m GVA per annum to the Northern Powerhouse (with the capability for this to increase to £1billion), supports 6,000 full time equivalent jobs

in the LCR (with potential for this to increase to 12,280 full time equivalent jobs), supports 11,900 full time equivalent jobs in the Northern Powerhouse (with potential for this to increase to 22,860 full time equivalent jobs), handles nearly 5 million passengers per annum, supports 700,000 visitor arrivals per annum, and offers flights to destinations across Europe. Main airlines serving Liverpool include EasyJet, Ryanair, Flybe, WizzAir and Blue Air for example.

Port of Liverpool:

The Port of Liverpool is an important maritime gateway and is one of the UK's top five container ports alongside Felixstowe, Southampton, Tilbury, and London Gateway. The largest volume and density of large warehousing (over 97k sq ft / 9k sq m) of any UK region is located within a 70 mile radius around Liverpool. It is likely that the Port of Liverpool will increasingly be seen as a preferred option as cargo owners discover the benefits of delivering their products and goods much nearer to their end destination. Liverpool's location at the heart of the UK offers a distinct advantage, with over 65% of the population of the UK and Ireland living within a 150 mile radius of the city. They have 15 shipping services providing deep-sea and short-sea connections to the USA, Canada, Spain, Italy, Portugal, Cyprus, Israel and Turkey. Port forecasts have indicated that rail traffic from the port has the potential to grow to around 38 trains per day per direction.

Peel Ports has invested £400 million over the past three years constructing Liverpool2, to expand the UK's largest transatlantic port and create one of Europe's most advanced container terminals. As one of the most operationally efficient and modern terminals in Northern Europe, it is capable of accommodating the world's largest container vessels, future-proofing the facility to allow global shippers 'ship-to-door' access to major import and centres at the heart of the UK. Together with their Cargo200 initiative to cut road and rail miles from freight logistics, Peel Ports is leading the way in helping businesses to reduce costs, congestion and carbon emissions in their supply chains.

The Mersey Ports have a strategic importance in petrochemicals dominated by the oil industry, through the Tranmere Oil Terminal connected by pipeline with the refinery at Stanlow and the Eastham Refinery via The Manchester Ship Canal. The Liverpool City Region has a strategic national importance in the petrochemicals industry with major assets such as Stanlow, Eastham and Runcorn located in the area involving major companies including Essar Energy, Shell and INEOS.

Additionally the Port is a major short sea shipping hub for the Irish Sea area with ro-ro ferry services to the Isle of Man, Dublin and Belfast (key operators including Stena Line, Seatruck Ferries, P&O Ferries and Isle of Man Steam Packet) and container feeder services to Dublin, Belfast and Glasgow and from English Channel Ports (including Southampton, Rotterdam, Antwerp and Le Havre) for example. These feeder services to the English Channel Ports connect Liverpool to deep sea container services to the Far East, India, Africa and South America.

As well as rail and road, another inland transport link from the Port of Liverpool is the Manchester Ship Canal. The Manchester Ship Canal is a 36-mile long seaway linking Liverpool and Manchester. It's a unique, innovative, 'green highway' into the

heart of the UK, carrying around 8 million tonnes of cargo a year, removing freight from overcrowded roads and rail. The Manchester Ship Canal is the UK's largest inland seaway. Peel Ports currently operate an innovative container ship shuttle service from the Port of Liverpool to Manchester along the Ship Canal. This shuttle service is the most environmentally-friendly bulk logistics solution on offer in the UK, and already serves major retailers. The shuttle service makes an important contribution to the UK's carbon footprint reduction targets by delivering waterborne goods right to the heart of the country.

Liverpool Cruise Terminal:

Alongside the port, the Liverpool Cruise Terminal at Pier Head also plays an important role in the visitor economy. <http://www.cruise-liverpool.com/> In 2016 Liverpool's cruise industry brought in around £7 million to the local economy as the city welcomed 63 cruise ships with, in total, 114,676 passengers and crew. In 2017, the Liverpool Cruise Terminal will celebrate its 10th anniversary and play host to 63 ships bringing in more than 111,000 passengers and crew. Now, building upon this success, city region partners are developing plans to construct a larger improved cruise terminal facility able to handle turnaround cruises with up to 3,600 passengers. This improved cruise facility will help handle future growth in the Liverpool cruise market, continue its customer service excellence and position it to handle the next generation of super cruise liners.

The LCR is a must see tourism destination and delivers world class, ground breaking events including the Liverpool International Music Festival, International Mersey River Festival, Liverpool Sound City Festival, Liverpool Biennial, Royal de Luxe Giants, etc. To have the iconic three Cunard Queens (Queen Mary 2, Queen Victoria and Queen Elizabeth) gather together on the River Mersey in their company's spiritual homeport and birthplace in 2015 for Cunard Line's 175th anniversary celebrations was a spectacular sight and nothing short of majestic and showed a global audience that the city region is a world class destination.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

There are some obvious gains to be made in terms of:

- Reducing generalised journey times between housing and work
- Offering options that mean low carbon options are attractive.

Both of the above options offer substantial economic benefits, whether through user benefits such as reduced travel times and lower emissions, or health benefits (as recognised by the HEAT tool) through increased active travel.

Going forward, we cannot be sure what the digital future looks like, but ensuring digital capacity to support increased homeworking would seem to be critical.

We would also urge careful consideration of infrastructure, to ensure that it aids economic growth, and recognise the economic risks that may exist in some schemes induced traffic is a potential outcome.

We need to place greater emphasis on facilitating low carbon, electric and low emission vehicles and the promotion of active travel, especially walking and cycling.

We need to ensure the coordination of transport and land use planning so that denser urban development can be served by mass transit systems. Densification enables more efficient, interconnected mobility solutions which could alleviate congestion and improve air quality.

Spatial Planning shapes the places where people live and work and the country we live in. Good planning ensures that we get the right development, in the right place and at the right time. It makes a positive difference to people's lives and helps to deliver homes, jobs and better opportunities for all, whilst protecting and enhancing the natural and historic environment and conserving the countryside and open spaces that are vital resources for everyone. But poor planning can result in a legacy for current and future generations of run-down town centres, unsafe and dilapidated housing, crime and disorder, retrofitting of sustainable transport solutions and the loss of our finest countryside and green spaces to development.

Housing provision needs to reflect the economic ambition put forward in City Region Growth Strategy and the Government's Industrial Strategy.

Housing is just one element of many that go towards creating sustainable communities; it is not the only or most important element. All the various elements are of equal importance e.g. health, education, shops, community facilities, etc. Delivering just houses and not communities will just create dormitory suburbs and towns and so lead to greater commuting and long distance commuting; this will then have significant implications for the transport infrastructure. Currently there is a major shortage of affordable housing and housing to meet the diversity of everyone's needs. In some areas such as London and other major cities the predominance of global wealth and use of housing as an investment vehicle is risking driving out affordable housing for locals. Therefore a comprehensive package of bold and transformative actions needs to be urgently delivered to address this housing crisis. If not people will be forced to live further and further away from their place of work and this will lead to greater commuting adding to the transport challenges. Also not tackling the housing crisis adequately will compromise our nation's economic ambitions.

Sustainable housing does not just mean an energy efficient build, but it must also encompass housing design and how the resident will live in the house and access the necessary services. Good building design, location and build quality are all very important in creating housing that can create long term sustainable communities.

- Foster a balanced, integrated and sustainable approach to development in order to deliver homes (in a variety of sizes and tenures to meet all needs including affordable housing), jobs and better opportunities for all, whilst protecting and enhancing the natural and historic environment, key social

assets and public amenities as well conserving the countryside and open spaces and ensuring high quality design for development.

- Tackle climate change, decentralise energy infrastructure, promote energy efficiency & renewable energy and move towards zero carbon development.
- Ensure that development is based around the need for access by all forms of transport, management of parking in new development and expectation that developers should contribute to cost of public transport access in areas that are not well served by existing public transport services.

There is a very urgent need to address concerns over air quality. There is clear evidence that NO₂ emissions have negative health effects, including respiratory symptoms, asthma prevalence and incidence, cancer incidence, adverse birth outcomes and mortality. This will require a bold package of measures including Clean Air Zones and electrification and decarbonisation of transport including buses, trains, cars, freight, etc. Clean air and carbon reduction are critical elements of infrastructure that serves the needs of future generations. By 2050, zero carbon emissions should be the norm, as should zero NO_x and PM emissions.

4. What is the maximum potential for demand management, recognising behavioral constraints and rebound effects?

Rising demand places significant strain on our transport systems in terms of capacity which then can struggle to keep pace. For example on the railways there has been very substantial growth in demand which is causing track capacity constraints and on-train capacity constraints. Track capacity constraints need to be overcome in order to run more frequent services. On-train capacity constraints need to be overcome by operating longer trains rather than the 2-3 car trains that are typical at present. There is a significant rolling stock shortage across the rail network. Long distance intercity routes like Cross Country are a particular issue with only 4-5 car trains. Ideally all long distance intercity and cross country routes should be 8-12 car. Likewise local commuter rail networks need to have longer and more frequent trains.

On road networks, ever growing car use creates traffic congestion hindering public transport and freight movements. Therefore there may be a need to introduce some form of demand management or road user charging on a national basis. This revenue then could be reinvested to help maintain and upgrade the road network. Rise of autonomous and driverless vehicles may not help the situation either and could just increase car use and thereby contribute further to traffic congestion.

As our major cities become 24/7 economies, customer expectations of public transport increase with more expectation for 24/7 services. London increasingly is moving in this direction with its night tube and night bus networks. But over the timescale of the National Infrastructure Assessment it is likely that most major cities will have to move in a similar direction for their local transport. It is vital that the role of walking and cycling for short trips and huge modal shift potential to walking and cycling seen in most exemplar, prosperous European cities is transferred and embraced here in the UK. Planning for a huge increase in trips made by foot and cycle should heavily influence the commission's thinking.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The analysis behind investment needs to be carefully constructed to be consistent, but here we would urge for attention to be paid around metrics such as “Jobs/GVA maintained” in addition to “Jobs/GVA created”. This should recognise in the ‘do minimum’ any disbenefits through not maintaining and repairing existing assets.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Infrastructure requirements must be set within the context of the economic ambition set at the national level through the Government’s Industrial Strategy. There is a need for this to link with a spatial dimension through National Policy Statements and ideally a National Spatial Plan which currently is lacking. Relationship with housing policy, research & development and education / skills training policies is also vital.

There also needs to be place based delivery below national level through devolved bodies such as devolved administrations, sub-national bodies (Transport for the North etc), and county and city region authorities. It is vital that devolution is accompanied by appropriate devolution of both powers and resources. Again there needs to be synergy at these levels with economic ambitions set out in Growth Strategies and a spatial dimension through city region spatial plans and local plans.

Lastly economic ambition and infrastructure requirements need to be supported by education and skills training to provide the talent to realise these needs and ambitions. Without the skilled people delivery will be compromised.

Infrastructure decision making systems need to be efficient but robust to ensure adequate scrutiny of impacts in regard to economic, social and environmental issues.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

As above, one key step here is identifying those investments where a substantial risk is that of generating induced traffic demand (with associated negative impacts on the environment). Here we would recommend part of the options assessment should be to explore other (potentially multi-modal) solutions.

Transitioning everything including transport to a low carbon economy is essential. If we don't reduce carbon, transport, energy emissions etc there will be dire consequences for future generations by 2050 if not earlier. Plus the fossil fuel era is ending globally. Low carbon infrastructure, supporting zero transport emissions must be the guiding principle for future infrastructure planning.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Current recommendations around WebTAG (including making use of LUTI models where it is proportionate to do so and using local data as a sensitivity test against the core economic case) represent a step forward in improving cost-benefit techniques and are to be commended. However the Government still is far too preoccupied with narrow economic benefits rather than the full life costs and impacts of infrastructure – how they support quality of life, happiness, health and well-being, tourism etc.

There are still weaknesses with WebTAG which can result in BCRs both overestimating and underestimating scheme impacts. These include:

- A lack of recognition of additionality, which seems to be based on flawed economic theory. For example, a scheme which encourages inward international investment is going to have substantial economic impacts. We suggest this is a priority for research to help schemes.
- The NTEM dataset associated with WebTAG is often out of synchronisation with other official datasets (for example, the subnational population projections). We would argue that, although WebTAG recommendations allow for other data to be used alongside NTEM, either NTEM should be refreshed once new official data is available or users should be encouraged to use these datasets in lieu.
- Further, when it comes to looking at trips forecast within NTEM, this element of the package does not seem to work logically, suggesting an ongoing growth of car drivers but relative stagnation of rail trips. This does not match up with either recent trends or most other forecasts. Suggest the model is looked at anew in this regards, possibly in the light of some of Network Rail's work in this area.
- WebTAG overall (and its data sources) are not set up to deal with schemes that provide a step change in an area's economy; this needs recognition.

Geographic coverage of the analysis used is not always appropriate or accurate. We would recommend that in terms of schemes the analysis should cover the widest geography possible, to ensure all benefits and disbenefits are captured. Example: an investment in improving rail access to the Port of Hull should measure not just the change in mode around Yorkshire but also allow for the fact that less traffic may be

using southern ports. When it comes to analytical units used for areas, we would also urge that these be relevant, transparent and consistent; specific examples of geographic units that are demonstrably inappropriate for analysis include:

- LEPs – Local Enterprise Partnership boundaries represent political areas and may not necessarily represent functional economic areas.
- PUAs – Primary Urban Areas are drawn from a theoretical construct that fails to employ any ground-truthing as to whether they represent a cohesive area.
- ONS TTWA – ONS’s work in estimating travel to work catchments is valid from a certain perspective, but fails to understand the overlapping nature of travel catchments, with cities naturally having greater primacy than towns. Hence, Shrewsbury’s catchment in practice encompass Ludlow, rather than the two being separate.

TRANSPORT:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

The drive towards smarter zero carbon and zero emission transport systems will lead to more efficient and sustainable urban centres. Increases in computer and processing power will enable this shift and will lead to more effective, real-time use of big data. Big data and the Internet of Things will enable communication between different modes and with the wider environment, leading to truly integrated and inter-modal transport solutions that maximise efficiency gains. Augmented reality technology could transform the onboard journey experience, ticketing and customer information. Cloud-based services will become more widespread driven by the uptake of smarter mobile devices and faster connectivity.

In order to provide sufficient transport capacity for the growing volumes of goods and people, intelligent and integrated transport solutions will become essential. In addition to growing demand, people’s expectations of seamless and integrated mobility are increasing and their transport needs are evolving.

Smart communications technology will become one of the key infrastructures of future cities, helping to improve the efficiency and coordination of systems. However as transport becomes more reliant on technology the importance of improving telecommunications infrastructure such as fibre-optic superfast broadband, wi-fi and 4G and 5G will increase. At the moment in many areas this infrastructure is woefully inadequate. Improving connectivity and smarter devices will enable cloud-based services to become widespread and more user-friendly. Smart technology will enable real-time information for travellers and more integrated services. Interoperable tickets, valid for trains, buses, car-sharing schemes and bicycles, could encourage intermodal travel by providing seamless connections to other modes.

Integrated ticketing and payment systems, such as the use of smartcards, phones or bank cards as a single device to pay for journeys, linked to personalised real-time travel information, further simplify inter-modality and improve customer experience.

Greater use of Intelligent Transport Systems (ITS), will enable better traffic flows, more accurate road pricing, and enhanced capacity and safety. ITS encompasses a range of technologies used to manage transport – from sensors and surveillance to ticketing and payment systems – that are used to monitor and manage travel conditions. ITS equipment continuously generates new data about the transport network, and enables operators to make real-time interventions to manage traffic and travel.

The growing reliance on smart technologies and systems, however, can give rise to issues of safety and security, especially in the form of cyber-attacks. In addition, use of data gives rise to concerns around privacy and the secure handling of data, including personal and financial details. One of the greatest risks to transport organisations is the combination of both physical and cyber-attacks on their infrastructure. The increased risk is the result of the surge of social media applications, online technologies and self-service user terminals, and increasing threats of terrorist attacks.

In a new report published in Nov 2016 entitled “Cyber Security and Intelligent Mobility”, supported by IBM, The Institute of Engineering Technology (IET), the Intelligent Mobility Partnership (IMPART) and the Digital Catapult, the Transport Systems Catapult cites numerous trends in the realms of technology, cyber security, mobility, and society are all converging to make it a much more complex environment in which to deliver safe, secure, and reliable mobility services and infrastructure. https://s3-eu-west-1.amazonaws.com/media.ts.catapult/wp-content/uploads/2016/11/24133246/3416_Cyber-Security_Report_Final-1.pdf

While fossil fuels have dominated the ground transport sector for the last century, it is expected that electricity and alternative fuels will play an increasingly important role in both private and public transport in the future. It is likely that most vehicles will be electrified or run on alternative fuels to some extent, and well-developed networks of chargers to support battery electric vehicles will be vital. Wireless charging infrastructure could also be embedded in the road, providing induction charging for electric vehicles on the go. Alongside low emission and low carbon transport there is likely to be more importance given to walking and cycling especially for shorter, local journeys as well as public transport. If healthy living is not encouraged then this will store up health issues for the future and only add to the challenges faced by the NHS, mental health and social care. Technology will increasingly help reduce the need to travel through things such as video conferencing, etc.

The Internet of Things will enable the rise of technologies such as intelligent vehicles that can measure the latest traffic, road and weather conditions. These vehicles will be able to communicate with each other and the wider environment, transmitting their speed and direction and warning other vehicles about traffic and safety hazards. Wireless sensor networks combined with ultra-low power sensors and drones will make it possible to monitor the condition of a wide range of structures like bridges or tunnels, alerting authorities to weaknesses or disrepair.

Autonomous vehicles, enabled through increased connectivity, could fundamentally change urban mobility and have a number of implications for governments, including rethinking transport policies and existing regulatory frameworks, the role of urban

infrastructure, auto licensing and traffic enforcement, parking and taxi provision. Already you can see the impact of technology with Driver Only Operated trains and in some areas such as Docklands Light Railway even driverless trains. Connected or driverless vehicles could become mainstream transport with major impacts on buses, taxis, private car, etc. Private cars are likely to focus more on prestige luxury brands and for the pleasure of the driving experience and collector value, while mainstream day-to-day vehicles may become driverless pods replacing cars, taxis, buses, etc.

Fully automated vehicles will open up new markets for automotive companies to sell to older people, or those with physical or mental impairments. Driverless vehicles will likely cause changes to the infrastructure of cities, as roads could be made narrower and roadside signage could be reduced. As driverless cars will travel safely in closer proximity to other vehicles, the capacity of existing infrastructure could be improved.

Vehicle convoys can reduce congestion and cut fuel consumption. A complete uptake of driverless vehicles will depend on the development of comprehensive regulatory frameworks as well as public trust around security and safety issues. Resilience to weather issues, terrorism and cyber-attacks will also be important to consider in this context. An incremental uptake of autonomous vehicle technologies is more likely. This includes steps to automation within vehicles but also the use of autonomous vehicles within a confined area. Applications could include parking assistance and taxis / buses operating on pre-set routes or within a defined location.

The UK Technology Strategy published by the UK Transport Systems Catapult in 2016 <http://tsctechstrategy.co.uk> and gives a good overview of the challenges we will face as we move towards uptake of new technologies in mobility.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

As an island nation the UK's economic success has always been founded on maritime trade. While history has seen individual ports flourish and decline, their central role in facilitating commerce, migration and exploration has remained constant. Today, the UK relies on its ports and their supporting road and rail freight infrastructure to connect its producers and consumers to the global economy. Therefore freight and logistics plays a vital role in the economy of the Liverpool City Region with the SuperPort Liverpool initiative and the Northern Powerhouse.

Global trends in supply and demand are driving larger shipping sizes and freight volumes, and the rise and fall of commodities and industries require the ports and logistics sectors to be responsive and adaptive to changing patterns of trade. These pressures have had cascading effects on national and regional infrastructure, with the road and rail networks already proving insufficient to meet the demand for higher capacity, efficient freight corridors. These changes also impact on skills needs.

Key infrastructure needs from a freight perspective include:

- **Higher Priority given to Rail Freight investment nationally**
 - Liverpool 2 Container Terminal is now in place

- Routes need capacity and capability to handle larger, faster and more frequent freight services
- **Development of an East-West ‘freight super corridor’ across Northern England that is gauge cleared to W10.** This would link the major ports (Mersey, Humber, Tees and Tyne) to a series of multimodal logistics hubs and help make the North a linchpin of a global trade corridor for the movement of freight from North America to/ from Europe. There are opportunities for the development of a chain of multi-modal logistics parks adding value to the distribution chain. In this way, connectivity for freight will be leveraged to add significant value to the Northern economy.
- **Increase use of inland waterways and coastal shipping for freight.** While our road and rail networks have constrained capacity, the coastal waters around the UK are an untapped resource that can help relieve things.
- **Improvements to Port of Liverpool access.** The recent private sector investment in Liverpool 2 which will more than double the container capacity of the port is part of the LEPs ‘Superport’ growth sector (covering ports, airport, logistics operators and support services); an area which substantial growth is expected over the following years, in line with the NPIER. However, there are capacity issues on the road and rail networks serving the area. Although (at a highly localised level) improvements to the port and other terminals are a matter for the operator, other crunch points exist on both local and national networks. For example, capacity for freight on both the Chat Moss line and CLC is limited, and there are crunch points on the WCML both North and South as well as on trans-pennine rail routes. This makes a full NPR network as well as a direct HS2 link (above) important. The recent opening of the ‘Liverpool 2’ deep water berth has resulted in a doubling of capacity at the Port, from 750,000 TEU p.a to 1.5m TEU p.a. Such a significant increase in potential throughput can only be accommodated with the implementation of a comprehensive multi-modal approach to traffic movement to and from the Port estate, incorporating rail, short sea shipping, inland movement along the Manchester Ship Canal as well as road. There are capacity issues on the A5036 linking the port to the motorway network and currently Highways England is consulting on two potential options. We must find a way of getting goods from the port, to their ultimate destination in as quick, efficient, and sustainable form as possible, and whilst causing as little disturbance to those living along the way. To do that we will work closely with Highways England, Network Rail, the port authority and the local authority to ensure that as much cargo as possible leaves the site by rail and on water. But planning timescales are long, some goods cannot be transported by anything other than by road, and so in the meantime we must look to develop a road scheme that seeks to balance the needs of those living close to the affected areas whilst also standing the tests of time and provides the capacity for the port to expand in the decades to come.

Urban logistics systems form the backbone of a functioning city and economy providing the goods and materials needed to successfully operate a city. The way goods and services are delivered has wide ranging implications for urban life, including congestion, safety, noise and air quality considerations.

Congestion and environmental pressures are leading to the development of alternative and more efficient logistics systems to reduce freight in city centres. Some of these last mile logistics solutions include electric cargo bikes, underground freight pipelines, delivery lockers at stations, and 'closed loop' systems where vehicles making inbound deliveries into the city pick up outbound recyclable waste for disposal and returns from retailers. Other reduction measures, such as consolidation centres, also aim to lessen the impact of freight movement in cities.

Furthermore, manufacturing might increasingly return to cities; 3D printing, or additive manufacturing, is a revolutionary technology that could lead to reduced transport of certain goods, which could be printed on site or closer to consumers. It is expected to transform the supply chain, reducing the need for mass-produced manufacturing, transport and storage. Increasing automation within warehousing will impact jobs. Urban areas need to ensure that their planning policies seek to ensure that all major new distribution parks are rail (or water) connected and seek to ensure that 'last mile' deliveries are completed by low/zero emission modes where possible.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Key infrastructure needs include:

- **A new twin-track high speed rail line between Liverpool City Centre and the High Speed 2 mainline**
 - Providing improvements to the proposed HS2 service offer and enabling Northern Powerhouse Rail (NPR)
 - This is vital to free up capacity on both the current East-West and North-South rail lines serving Liverpool, where even with enhancements there will not be sufficient paths for the growing freight traffic out of the Port of Liverpool and other freight terminals.
 - It is also important in terms of enabling Liverpool to maintain a competitive level of connectivity to London and the Southeast, with similar journey time reduction to other key Northern cities.
- **A new multi modal terminal station in Liverpool City Centre for HS2 and NPR**
 - Linked to existing transport nodes and improving the travel experience in the City Region
 - Lime Street may not be able to accommodate high speed rail services so new station better option to take forward.
- **Further roll out of high speed rail to other parts of the UK.** This would further improve the customer offer on the rail network by expanding high speed rail into a national network and help provide new capacity.
- **Improved connectivity to other parts of the UK**
 - Key 'missing' markets for Liverpool City Region include North Wales, the West Country, South Coast and Scotland
 - Service and infrastructure enhancements required
- **More Rolling Stock and Longer Trains** – increasingly the rail network is enjoying substantial growth and there is a shortage of rolling stock leading to many services becoming overcrowded thereby compromising the customer

journey experience. Consequently there is a need for longer trains to be used on many routes including long distance intercity routes where Cross Country is a particular issue with only 4-5 car trains. Ideally all train services on long distance intercity and cross country routes should be 8-12 car.

- **Rail Electrification** including key routes such as Transpennine, CLC, Hope Valley, Calder Valley, Borderlands Line, North Wales Coast Main Line, etc. as a rolling programme in line with the conclusions of the Northern Sparks Report (March 2015) by the Northern Electrification Task Force.

16. What opportunities does “mobility as a service” create for road user charging? How would this affect road usage?

Mobility as a service should be coordinated by public sector otherwise could lead to dominance of the car and corporate monopolies.

Traditional models of ownership are changing, especially within younger generations. For example, the trend towards a shared economy of service provision rather than product ownership means that consumers are increasingly likely to purchase access to a car rather than buy their own car. Services like Uber, Gett, Hailo and Lyft are evidence of the shift from providing mobility as a product to providing mobility as a service. Mobility services could help counter growing car ownership and improve affordability and efficiency.

Access to cars, car sharing and taxis are likely to become part of a wider trend towards the retailing of packages of mobility. So people can use smart devices to access information and make payments for the transport that meets their particular needs and budget. This could include access to car hire, taxis, public transport and bike hire.

The retailing of mobility packages could also become increasingly detached from the operation of those services with a race between increasingly large corporate entities to be the ‘Amazon of mobility’ in a global market of enormous value.

A wide range of players are likely to enter this space – including large automobile, energy, telecoms companies, the internet giants alongside existing public and private sector public transport providers.

However this risks the creation of corporate monopolies and dominance of car based forms of transport rather than public sector led integrated transport across all modes coordinated on a city region basis for example.

There are also scenarios where the public sector could lead by adding taxi, car share and car hire options to a core public transport offer – perhaps through strategic alliances with the automotive industry. This appears to be the objective for many urban areas in countries like Germany and Austria.

A recent report in July 2016 by the Transport Systems Catapult (TSC) suggests we are at the beginning of a Mobility as a Service (MaaS) revolution that will change the way many people travel and may see a move away from traditional car ownership. The report highlights what the future of MaaS could look like and how policy makers

and the transport sector can innovate to meet the changing expectations of consumers. The TSC is calling on policy makers and the private sector to work toward a shared vision for how to make MaaS a success. Several trends identified in the report support future growth of MaaS concepts, with consumers increasingly expecting their transport to be delivered as a 'service'. Adoption of MaaS would also incentivize technological advances around improving journey experiences.

https://ts.catapult.org.uk/wp-content/uploads/2016/07/Mobility-as-a-Service_Exploring-the-Opportunity-for-MaaS-in-the-UK-Web.pdf

CONCLUSION

Over the period covered by the National Infrastructure Assessment, it will be vital to transition to smarter, low carbon and low emission forms of transport. We should embrace the opportunity of changing technology to better integrate all modes of transport, improve the customer experience, enable more efficient operations and enable seamless journeys. Infrastructure also needs a spatial dimension as integration with spatial and land use planning is essential to realise these ambitions.

Also transport infrastructure has interdependencies that need to be taken into account with other infrastructure sectors such as telecommunications, energy, housing, education and skills, research & development, natural resources etc. Resilience to weather issues, power outage, terrorism and cyber-attack is essential.

A comprehensive package of bold and transformative actions needs to be urgently delivered to address the current housing crisis. If not people will be forced to live further and further away from their place of work and this will lead to greater commuting adding to the transport challenges. Also not tackling the housing crisis adequately with bold action will compromise our nation's economic ambitions.

Likewise there needs to be a strong focus on encouraging sustainable transport, healthy living, walking and cycling. If this is not done there is a risk of storing up health issues for the future and compounding the challenges facing the NHS, mental health and social care which in turn will compromise our nation's economic ambitions.

In the short to medium term for the Liverpool City Region, our infrastructure priorities from a transport perspective focus on:

- High Speed Rail
- Rail Electrification
- Merseyrail Upgrade
- Ensuring that transport networks have the necessary capacity to meet demand and changing customer expectations.
- Move to a smarter, low carbon and low emission transport system
- Support and enable the economic ambition of the Liverpool City Region including its major gateways and assets such as Port of Liverpool and Liverpool John Lennon Airport for the movement of people and goods.

We welcome the ambition and foresight of the proposed National Infrastructure Assessment and look forward to working with the Commission as it develops. While

it is hard to predict what the world will look like in 2050 it is clear that our economic ambition as a nation must be underpinned by infrastructure, R&D and education / skills in order to remain competitive on a global scale and must adapt to global trends such as technological change, demographic change and climate change.

Response to National Infrastructure Commission Call

In addition to investment in rail, local roads and the motorways my constituency has an urgent need for two larger schemes: the Botley Bypass and the Chickenhall Link Road. Both schemes are supported by local partners and authorities.

Botley Bypass – Summary

Botley Bypass has been proposed for many years and a route is formally safeguarded in both the Eastleigh Borough and the Winchester City Local Plans. Botley experiences a significant amount of traffic travelling along the A334 Botley High Street, particularly during peak periods, causing noise and air quality issues and difficulties for pedestrians and shoppers wishing to cross the High Street. The High Street has been identified by Eastleigh Borough Council as an Air Quality Management Area, where improvements are needed. Congestion along the route causes journey time delays with stop-start conditions during peak periods. Survey work has identified that whilst approximately 20% of traffic on the A334 Botley High Street is local traffic, over 80% is through-traffic which has origins and destinations outside of Botley Village. The through-traffic is largely associated with vehicles travelling between the Fareham/eastern Hampshire areas and the North Hedge End area/Winchester in the north. This includes traffic diverting from the congested M3 and M27 motorways at peak times. Forecast levels of new development in the wider Botley area over the next 20 years combined with traffic growth is likely to compound existing traffic issues. For these reasons the justification for a bypass for Botley is now much greater than in previous years. A new bypass could bring significant benefits to the High Street in terms of reduced traffic volumes, improved pedestrian accessibility, improved air quality, reduced noise pollution and enhanced quality of place

Chickenhall Lane Link Road - Summary

A new link road between the A335 Wide Lane (adjacent to Southampton Airport Parkway rail station) and Chickenhall Lane, including improvements to Chickenhall Lane.

Scheme involves:

- New bridge over A335 and Southampton-Eastleigh railway lines
- New bridge over the Eastleigh-Hedge End railway line
- Road passes to the north of the Airport Runway.

The current cost estimate is £100 million. This is because there are a lot of ground works required to raise or lower the level of the proposed route to contend with gas mains, railway lines and flight paths of aircraft. Drivers currently have to join the M27 eastbound from junction five near Southampton airport, whereas they can join both the M3 northbound and southbound at Leigh Road, which also leads to the M27 westbound towards Southampton and Bournemouth.

Local Need:

- Eastleigh Borough Council has recently reaffirmed its longstanding commitment to the scheme (25 years support).
- Solent LEP is supportive of the scheme.
- Hampshire County Council believe that this scheme can and should be funded including partnerships and the Department for Transport.
- Traffic congestion in the Borough is extremely high. This new road will provide another route out of Eastleigh.

- Projected new housing in the Borough will exacerbate the already dire infrastructure need.
- Junction 5 redevelopment design was originally planned to link into the Chickenhall Link designs
- Growth in passenger numbers at Southampton Airport and link road is vital for surface access to Airport

Benefits:

- Large amount of land unlocked for housing in the Bishopstoke area.
- Strengthen potential future bid for Enterprise Zone in the area which has received support from the Business, Innovation and Skills Minister.
- Network rail land freed up for development.
- Improve poor air pollution and congestion by reducing standing traffic.
- Unlock area for Southampton University sponsored Science Park.
- Delivers jobs, improves local economy and increases productivity.

Development of this link road will also have an impact on the Eastleigh Cord.

- The current estimate for the Eastleigh Cord is £180 million.
- An attractive alternative to the car for access to the Airport from the east. Will enable commuter journeys into Southampton city centre and Eastleigh Riverside from the Hedge End and Botley area to be made by rail without the need to change trains at Eastleigh.
- This would help to relieve congestion on the strategic highway network.

Strategic Issues

Eastleigh constituency is positioned in an ideal place for strong economic growth once infrastructure issues have been addressed.

Southampton Airport is based in the constituency and is poised for expansion. Nearly 2 million passengers passed through the airport this year. A reduction in journey times on the train from London would allow for this success to increase. Journey times to the Solent Area need to be reduced to less than an hour and I support the Solent in 60 scheme.

Southampton Port, the best cruise port in the world, is nearby and acts as a hub for car distribution in the South to Europe and beyond. This therefore requires significant investment in the Solent and Eastleigh infrastructure] networks in order to expedite rapid transit. There are also plans to increase the capacity of the port which signal further demand for investment in neighbouring infrastructure in particular the strategic road network.

Eastleigh is located very close to the strategic road network however throughout the constituency I receive complaints about excessive ramp times and severe delays on the M27. I have been working with Highways England on a new Junction 6 which would reduce congestion for my constituents. This is urgently needed and would contribute to economic output. Additional pressure on the network is present at Junction 5 where substantial new development is not sustainable with the severe ramp times.

Conclusion

My constituency currently suffers from dire traffic and an acute infrastructure deficit. These two schemes would go some way to alleviate the situation and would unlock significant economic

output. Additional investment is required to provision a Junction 6 and to ensure that the currently congested strategic road network in the area is sustainable for future growth.

Dear Sir/Madam

NATIONAL INFRASTRUCTURE ASSESSMENT - CALL FOR EVIDENCE

The Mineral Products Association (MPA) is the trade association for the aggregates, asphalt, cement, concrete, dimension stone, lime, mortar and silica sand industries. With the recent addition of British Precast and the British Association of Reinforcement (BAR), it has a growing membership of over 480 companies and is the sectoral voice for mineral products. MPA membership is made up of the vast majority of independent SME quarrying companies throughout the UK, as well as the 9-major international and global companies. It covers 100% of GB cement production, 90% of aggregates production, 95% of asphalt and over 70% of ready-mixed concrete and precast concrete production. Each year the industry supplies £20 billion worth of materials and services to the Economy and is the largest supplier to the construction industry, which has annual output valued at £144 billion. Industry production represents the largest materials flow in the UK economy and is also one of the largest manufacturing sectors.

Further to the consultation on the above document, we note that this is a call for all interested parties to submit *“evidence, ideas and solutions”*. We were largely supportive of the aspirations of the initial consultation; however, our comments appear to have gone awry and been overlooked in the NIC’s initial assessment of consultation responses. Our initial comments have therefore been attached below as Appendix 1.

In response to the current consultation, the UK infrastructure aspirations have the potential to have significant implications for the UK mineral products sector and mineral planning system.

As we move towards Brexit it is imperative that development in the UK, supports UK industry. The recent Hendry Review on the Role of Tidal Lagoons, which ran in parallel to the initial NIA consultation, recognised that *“the National Policy Statement process should also include an assessment of the sustainability of the main construction elements for a longer-term tidal lagoon programme”*. Further, Hendry also concluded that *“tidal lagoons would help deliver security of supply; they would assist in delivering our decarbonisation commitments; and they would bring real and substantial opportunities for the UK supply chain”*. (our underlining)

Tidal Lagoons would undoubtedly be considered as National Infrastructure Projects and the opportunities for UK supply chain for the wider scope of projects identified in the consultation document, are significant.

The Mineral Products Association is the trade association for the aggregates, asphalt, cement, concrete, dimension stone, lime, mortar and silica sand industries

Registered in England as Mineral Products Association Limited No. 1634996
Registered at the above address

It is therefore important that National Infrastructure Projects are not considered in their own 'bubble', as appears to be the case at present. Currently, there appears to be a fundamental dislocation between infrastructure policy and the supporting policies for those activities (such as minerals and construction products) needed to support and enable the delivery of projects. To ensure that National Infrastructure Projects can be delivered effectively, the supporting activities required to ensure delivery have to

The Cardiff Bay Barrage is a good example of this, with the original £200m cost for the infrastructure leveraging a further £2.3 billion of public/private investment to redevelop and regenerate the Cardiff Bay area in following years. Scaled up (to say one of the larger Tidal Lagoons in the Bristol Channel), the demands on resources and skills could be considerable. However, these opportunities to unlock and compound the growth potential realised by national infrastructure will only be realised if they are fully accounted for in the wider policy and planning processes.

In order to realise the potential for indigenous supply, these essential supporting assets need to be factored in to the planning for the entire lifecycle of National Infrastructure Projects, so the needs and opportunities pre- and post- construction are fully considered. This will allow opportunities to improve the role of competition or collaboration in different areas of the supply of infrastructure services.

Such projects overlap with the nature of the projects identified in the current National Infrastructure consultation. Whether public or private infrastructure proposals are being considered, the Government's approach to steel is equally as applicable to the mineral products sector for National Infrastructure Projects and other major developments, to ensure the UK minerals industry can compete on a level playing field. The measures applied in this PPN 11/16 and the associated guidance are designed to ensure that government applies a more strategic and transparent approach to the sourcing of steel in major projects. Procurement decisions should always be made on a quality/cost/risk basis and whilst procurement will ultimately occur during the construction phase, the procurement strategy should be outlined at the earliest opportunity and considered during the permitting process. This would lead to better value for money, while helping to address any barriers that prevent UK suppliers from competing effectively and ultimately contributing to the UK's international competitiveness.

- Infrastructure - such as rail and roads
- Construction - such as the building of and or refurbishment of prisons, hospitals, universities, housing, community centres, bridges and schools
- Flood defences
- Defence related projects (ensuring consistency with the Defence and Security Public Contracts Regulations 2011 as appropriate)
- Medical equipment
- Energy related projects - e.g. new nuclear technology

The UK Government Procurement Policy Note: *Procuring Steel in Major Projects - Revised Guidance Action Note: PPN 11/16*, (13 December 2016), is a practical guide on how contracting authorities in both central government and the wider public sector can design their major projects (involving steel) to ensure best value for money by recognising relevant wider social and environmental benefits. The PPN applies to any major procurement project where steel is a critical component. There is no set value as to what constitutes a major procurement project, as this will differ between contracting authorities. However, the PPN states that major procurement projects are likely to include, but are not be limited to the following:-

be identified. These activities then need to be given proper consideration so that the potential needs and opportunities can be considered in advance, along with any risks or gaps that may have to be addressed.

At present the unwritten assumption appears to be that if you create the demand for construction materials this demand will be met. While the UK undoubtedly has a rich and varied resource of indigenous construction minerals, in order for these to be realised in practice both the mineral products industry and the wider mineral planning system require greater visibility around what scale of demand is likely to be required by infrastructure projects to allow suitable provisions to be made alongside the existing base demands in the market. This forward planning should allow the most cost-effective and sustainable solutions to be put in place to support the delivery of infrastructure projects. Needless to say, this takes time and therefore needs to be planned in advance of, or at least in parallel to, the National Infrastructure Projects themselves.

It is important to recognise that mineral product resources are not evenly distributed around the country and that a considerable amount of inter-regional trade in materials already occurs to meet the base load demand for construction aggregates in the market. Consequently, it is likely that many areas of primary mineral supply will be required to support the demands from multiple National Infrastructure Projects. The timings of prospective individual infrastructure projects therefore need to be understood, so that both the anticipated total cumulative and annual peak demands can be determined in order for sufficient production capacity and associated transport/delivery infrastructure to be put in place. This will ensure the demand management can be fully considered.

The National Infrastructure process must be aligned with the mineral planning system and vice versa. The full and proper consideration of resource requirements for National Infrastructure Projects should form an inherent part of Mineral Local Plans and the Local Aggregates Assessment to ensure the timely delivery of the raw materials necessary. This will allow the aspiration for infrastructure to be designed, planned and delivered to create better places to live and work, to be fully considered from a spatial and time perspective at the earliest opportunity. It will also ensure that the planning system and infrastructure governance arrangements can be dovetailed to ensure infrastructure is delivered as efficiently as possible and on time. It is widely recognised that quarries offer significant opportunities for biodiversity net gain. This would allow infrastructure projects to effectively contribute to enhancing the natural environment. Quarry restoration schemes may also present opportunities for water storage and flood management allowing integration for certain National Infrastructure Projects identified within the consultation document.

We would welcome the opportunity to discuss the above matters with you further and look forward to hearing from you in due course.

Yours faithfully

[job title redacted]

historically. There is an implication of major infrastructure projects into this process has proved problematic. National Planning Policy Framework, but factoring in the potential development of minerals for construction work and other applications, in accordance with the authorities (generally Counties in England) aims to ensure adequate materials supply. The mineral planning system, managed by other construction work and the impacts on key elements of the infrastructure developments does not appear to take account of the interaction with (skills) and natural (minerals and raw materials). Currently the process of considering to the management and sustainable utilisation of indigenous resources both human aspirations are accountability and achievable. Consideration must therefore be given in putting society's needs at the heart of Government Policy, it is important that the and regular review built in to statute.

paragraph 4. However, this programme must be a rolling programme with a formal Government to consider infrastructure planning for the 30 year period identified in responsible for local planning for periods for 15 years, it is not unreasonable for Central Government to the development plan process where local authorities are planned approach to the delivery of national infrastructure, even more so in a post Brexit climate. Akin to the development plan process where local authorities are We strongly support the aspirations of the document in seeking a long term and works to this objective?

What issues do you think are particularly important to consider as the Commission

- improve the UK's international competitiveness
- improve the quality of life for those living in the UK
- foster long-term and sustainable economic growth across all regions of the UK

Q1. The Government has given the National Infrastructure Commission objectives

(For more information, visit: www.mineralproducts.org)

The Mineral Products Association (MPA) is the trade association for the aggregates, asphalt, cement, concrete, dimension stone, lime, mortar and silica sand industries. With the recent addition of British Precast and the British Association of Reinforcement (BAR), it has a growing membership of 480 companies and is the sectoral voice for mineral products. MPA membership is made up of the vast majority of independent SME quarrying companies throughout the UK, as well as the 9 major international and global companies. It covers 100% of GB cement production, 90% of aggregates production, 95% of asphalt and over 70% of ready-mixed concrete and precast concrete production. Each year the industry supplies £20 billion worth of materials and services to the Economy and is the largest supplier to the construction industry, which has annual output valued at £144 billion. Industry production represents the largest materials flow in the UK economy and is also one of the largest manufacturing sectors.

essential materials
sustainable solutions

Appendix 1

arising from major projects - they will be met. While this has been the case it cannot be guaranteed unless the demand implications of infrastructure projects are better factored into mineral planning and regulatory systems. As such there is a key requirement for early engagement between developers of infrastructure schemes, materials suppliers and the planning and regulatory authorities with regards to sustainable materials supply.

Q2. Do you agree that, in undertaking the NIA, the Commission should be:

- **Open, transparent and consultative**
- **Independent, objective and rigorous**
- **Forward looking, challenging established thinking**
- **Comprehensive, taking a whole system approach, understanding and studying interdependencies and feedbacks?**

Are there any principles that should inform the way that the Commission produces the NIA that are missing?

Yes, we agree that in undertaking the NIA, the Commission should meet the criteria identified above. In addition, the NIA must be accountable, particularly where decisions on infrastructure challenge or conflict with the local political agenda, in the interests of a wider society. A key aspect of the interdependence between infrastructure and other construction projects and the supply of mineral products and associated materials is set out in our response to Question 7 - Cross Cutting Issues.

Q3. Do you agree that the NIA should cover these sectors in the way in which they are each described?

Yes. However, as is all too often the case, the provision of raw materials has been overlooked. Each and every sector referred to is wholly reliant upon the provision of the minerals products derived from extracted raw materials. All built development, such as major energy proposals; transport infrastructure; and flood defences, is reliant upon the aggregate minerals extracted from the ground or dredged within UK waters. Further, the added value minerals products associated with water purification; agricultural land improvement; energy deliverability and digital technology must not be underestimated.

Individual projects need to give appropriate consideration to the resources required and collectively this should be considered in the NIA, in terms realising the potential for utilising indigenous resources. In addition, however, the NIA should not underestimate existing commitments of the minerals sector, any limitations in production capacity; inherent delays in the planning and regulatory regimes; and the surety to allow companies to invest in resource security and sustainable supply; increases in production capacity and ability to deliver to major projects. Moving forward as major infrastructure projects are delivered, these will inevitably trigger further growth and investment, which again influence the demand for raw materials.

Q4. Are there particular aspects of infrastructure provision in these sectors which you think the NIA should focus on?

Yes. As detailed above, the provision of indigenous raw materials and mineral products

Q5. The NIA will seek to pull together infrastructure needs across sectors, recognising interdependencies. Are there are particular areas where you think such interdependencies are likely to be important?

Yes. All projects will have an influence on raw material supply patterns, be this through the provision of borrow pits specific to individual developments such as transport infrastructure, or the consequences of importing raw materials from

distance, by a road or rail network which may already be at capacity, or where there is insufficient loading or discharge capacity through wharves or rail sidings which are put under ever increasing pressure through non compatible development and encroachment. Further, major projects may give rise to a windfall of resources and the minerals products industry is appropriately placed to ensure a managed flow of resources in to the market.

Q6. Do you agree that the NIA should focus on these cross-cutting issues?
Yes.

Q7. Are there any other cross-cutting issues that you think are particularly important?

Yes. UK infrastructure ambitions have huge implications for the UK mineral products sector - with national resources being used to support national infrastructure. However, in order to realise this potential, these essential supporting assets need to be factored in to the planning for the entire lifecycle of projects, so the needs and opportunities pre- and post- construction are fully considered.

Cardiff Bay Barrage is a good example of this, with the original £200m cost for the infrastructure leveraging a further £2.3 billion of public/private investment to redevelop and regenerate the Cardiff Bay area in following years. Scaled up (to say one of the larger Tidal Lagoons in the Bristol Channel), the demands on resources and skills could be considerable. However, these opportunities to unlock and compound the growth potential realised by national infrastructure will only be realised if they are fully accounted for in the wider policy and planning processes and managed appropriately.

It is therefore important that national infrastructure projects are not considered in their own 'bubble', as appears to be the case at present. Currently, there appears to be a fundamental dislocation between infrastructure policy and the supporting policies for those activities (such as minerals and construction products) needed to support and enable the delivery of projects. To ensure that infrastructure projects can be delivered effectively, the supporting activities required to support delivery have to be identified. These activities then need to be given proper and timely consideration so that the potential needs and opportunities can be considered in advance, along with any risks or gaps that may have to be addressed.

At present the unwritten assumption appears to be that if you create the demand for construction materials this demand will be met. While the UK undoubtedly has a rich and varied resource of indigenous construction minerals, in order for these to be realised in practice both the mineral products industry and the wider mineral planning system require greater visibility around what scale of demand is likely to be required by infrastructure projects to allow suitable provisions to be made alongside the existing base demands in the market. This forward planning should ensure the most cost-effective and sustainable solutions can be put in place to support the delivery of infrastructure projects. Needless to say, this takes time and therefore needs to be planned in advance of, or at least in parallel to, the infrastructure projects themselves and considered during the consenting process.

It is important to recognise that mineral product resources are not evenly distributed around the country and that a considerable amount of inter-regional trade in materials already occurs to meet the base load demand for construction aggregates in the market. Consequently, it is likely that many areas of primary mineral supply will be required to support the demands from multiple infrastructure projects. The timings of prospective individual infrastructure projects therefore need to be understood, so that both the anticipated total cumulative and annual peak demands can be determined in order for sufficient production capacity and associated transport/delivery infrastructure to be put in place.

Q8. Do you agree with this methodological approach to determine the needs and priorities?

We agree with the general methodological approach but would raise one related issue. The consultation (paragraph 6.4) refers to the need to “appraise the quality and condition of the UK’s existing infrastructure assets” but it is not clear how the NIC could or should deal with infrastructure condition issues which are more related to revenue spending than capital budgets. For example, there is evidence that the condition of probably our most extensive infrastructure asset, the road network, is in poor condition in many parts of the UK. While the condition of the national road network in England is managed by one organisation, Highways England, and there is a specific regulatory regime operated by the Office for Road and Rail, there is no overview of the 95% plus of the network operated by numerous local highway authorities. Given that the quality of local road conditions is an issue of significance to virtually the entire population of the UK and has economic, social and environmental implications, it would seem appropriate for the NIC to have a role in assessing and, where necessary, improving the condition of the local road network. It does not seem to be a rational approach to invest in new and improved road capacity without a complementary focus on the quality of the existing network.

Q9. Do you have examples of successful models which are particularly good at looking at long-term, complex strategic prioritisation in uncertain environments?

No

Q10. Do you believe the Commission has identified the most important infrastructure drivers (set out below)? Are there further areas the Commission should seek to examine within each of these drivers?

These four drivers listed are very significant. However as indicated earlier there also needs to be a focus on supply chain issues including materials supply and capacity, the impact of land use and mineral planning and regulatory and permitting issues; and the effects these may have on the deliverability of any infrastructure project.

Q11. The NIA will aim to set out a portfolio of investments that best meets the demands of the UK in the future. Do you have a view on the most appropriate methodology to determine that portfolio?

No

Q12. In your view, are there any relevant factors that have not been addressed by the Commission in its methodological approach?

None other than comments made in this response.

Q13. How best do you believe the Commission can engage with different parts of society to help build its evidence base and test its conclusions?

Engagement with society on major developments has well established principles through the planning process and the development management procedures.

General Comments

In addition to the questions specific comments, we raise the following additional points for consideration.

- 1
- Para 4 - Whilst it is appreciated that long-term planning requires detailed consideration, the timescales identified are less than ambitious in light of some of the critical decisions which need to be made on matters such as energy supply.
- Para 18 - Again the timetable is far from ambitious. Further, it is imperative that the HM Treasury response takes full account of social and sustainability issues.
- Paras 23 - It can equally be stated that politicians do not always take the long term view and simply focus on the life of parliament. This applies to both local and central government.
- Parag 30 - It is imperative that the legislation has a statutory periodic review mechanism and appropriate safeguards to ensure projects are deliverable and accountable.
- Para 38 - The absence of an ambitious timetable, i.e. by 2018 for the report to be published, will be compounded by the additional 12 months for Government to respond to the NIC, i.e. by 2019. There will be an election in 2020 and as such it is unlikely that much will be pursued within the life of this parliament.
- Para 63 - We support the strategic thinking behind the NIA process.
- Para 65 - We are pleased to see that interaction will be a fundamental part of the process.
- Para 79 - We trust the Minerals Products Association will be consulted during the "call for Evidence" in Autumn 2016.
- Para 80 - It is imperative that the Minerals Products Association is given the opportunity to be present at the roundtable meetings.
- Para 82 - We trust the expert panel will consider raw material supply issues and the Mineral Products Association will have the opportunity to contribute to this work.

Response to the National Infrastructure Commission's Call for Evidence from the Mineral Wool Insulation Manufacturers' Association (MIMA)

1. Introduction:

The Mineral Wool Insulation Manufacturers' Association (MIMA) is a trade body providing an authoritative source of independent information and advice on glass and stone wool insulation. MIMA actively promotes the benefits of mineral wool insulation and the contribution it makes to the energy efficiency of buildings and the comfort of their occupants.

We represent four of the leading insulation companies in the UK - Isover Saint-Gobain, Knauf Insulation, Rockwool and Superglass.

MIMA welcomes the opportunity to feed into the National Infrastructure Commission's (NIC) Call for Evidence. The results of the exercise are intended to inform the Vision and Priorities document, due to be published in summer 2017, as well as the first National Infrastructure Assessment itself in 2018.

Key message:

Investment in the quality and energy efficiency of buildings in the UK is an urgent, infrastructure priority. Energy efficiency is an integral part of a well-functioning energy system which is fit for the future.

Improving our building stock – a physical asset – delivers a wealth of infrastructure “services” ranging from economic growth, improved consumer health and well-being, greater national energy security and significant carbon emissions reductions.

The NIC has confirmed that **building energy efficiency is within the scope of the NIA**, and so we hope the information from MIMA, and from others in the energy efficiency sector, serves as a spring board for further detailed analysis, where needed, by the Commission and its collaborators.

Through our role providing the secretariat to the Energy Efficiency Infrastructure Group (EEIG)¹, MIMA has been in regular contact with officials at the NIC, and so our submission to this Call for Evidence reiterates and consolidates certain information already provided, but also references a number of new and relevant projects which reported recently or are due to be published this year.

We also note that the NIC plans to continue to seek expert advice and challenge by establishing panels and hosting roundtables along with regional roundtables, sectoral seminars and social research. **MIMA and its members look forward to being activity involved** in these sessions.

¹ The EEIG is an informal group of 20+ influential organisations who have expertise in the functioning of the energy efficiency sector and an interest in seeing its links to growth and well-being realised.

The International Energy Agency in their Energy Efficiency Market Report 2016² made the statement: *“As the world transitions to clean energy, efficiency can make the transition cheaper, faster and more beneficial across all sectors of our economies. Indeed, there is no realistic, or affordable, energy development strategy that is not led by energy efficiency. For the IEA, it is the first fuel... And yet energy efficiency is far from fulfilling its potential. Globally, two-thirds of the economic potential remains untapped. An entire 70% of the world’s energy use takes place outside of any efficiency performance requirements.”*

The same is true for the UK, and particularly for the existing building stock. In 2016, the Committee on Climate Change stressed that *“energy efficiency should be improved across the existing building stock. This can reduce emissions and energy bills, improve competitiveness and asset values for business, improve health and wellbeing, help tackle fuel poverty and make buildings more suitable for low-carbon heating in future.”*³

Therefore, MIMA welcomes the NIC’s acknowledgment of the importance of looking at the future of heating and the shift to low carbon solutions in the context of the UK’s carbon targets, and the important role that increasing energy efficiency will play.

Buildings are one of the largest energy using sectors, and therefore any robust long-term infrastructure plan for the future energy system must include investment in energy efficiency to reduce energy demand and increase energy security.

2. Why energy efficiency upgrades to buildings are a priority/long-term infrastructure need

Energy efficiency is a highly cost-effective way of meeting Government economic, energy and climate change goals and improving consumer health and well-being.

➤ **Energy security and energy system objectives**

Driving energy efficiency across the board – to balance demand and supply of **both electricity and gas** – is a wise choice. Around 80% of heat demand is currently still met with natural gas.⁴ No matter what our future energy mix, it will always make sense to invest in the fabric and energy efficiency of buildings.

Not only does demand management and energy efficiency help to de-risk national supply strategies, which could easily be thrown off track by changes in the global market, it is also one of the most effective ways of protecting consumers from the full force of energy price rises and volatility in energy markets.

² Energy Efficiency Market Report, IEA, 2016,

<http://www.iea.org/publications/freepublications/publication/mediumtermenergyefficiency2016.pdf>

³ Next Steps for UK Heat Policy, CCC, 2016 <https://www.theccc.org.uk/publication/next-steps-for-uk-heat-policy/>

⁴ Department of Energy and Climate Change (DECC): *The Future Of Heating: Meeting The Challenge*, March 2013 https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/190149/16_04-DECC-The_Future_of_Heating_Accessible-10.pdf

By way of example, analysis by the UK-GBC⁵ in 2014 highlighted that the UK could **reduce its reliance on imported gas by 19% by making UK homes more energy efficient**, saving £2 billion in gas imports every year. BEIS's (then DECC) 2012 Energy Efficiency Strategy also found that energy saving measures cost less on average per unit of power than large-scale power generation, and through cost-effective investment in all forms of energy efficiency, **the UK could be saving 196 TWh of energy in 2020** - equivalent to 22 power stations.⁶ Furthermore, a report by Verco and Cambridge Econometrics in 2014⁷ found that energy security could be significantly enhanced if all homes were to achieve an EPC rating of C by 2030. In that scenario the country could see a **reduction of gas imports of 26%**, worth £2.7bn per year by 2030.

In terms of electricity, it is also vital to make solid progress on energy efficiency as we work towards decarbonising the electricity grid and a greater proportion of homes become electrically heated. Electricity is currently a more expensive and carbon intensive form of heating compared to gas, and even as this begins to change, we must not waste this clean heat.

Failing to insulate homes properly would mean consumers paying for low carbon energy which is needlessly wasted.

Investing in the fabric of the building stock reduces the amount of energy needed to achieve the same levels of comfort in the home. Energy capacity is then freed up, potentially reducing the need for further investment in new infrastructure in other areas of the energy system. In doing so, energy efficiency helps to **de-risk security of energy supply strategies**.

Again, the IEA has noted in their Energy Efficiency Market Report 2016, that internationally, *“Reducing infrastructure investment requirements in the electricity system is another important benefit of energy efficiency. Energy efficiency improvements since 2000 saved an estimated 1,600 terawatt-hours of electricity consumption in 2015 equal to 15% of total electricity generation in the IEA. Servicing this hypothetical additional demand would have required new power supply. To estimate the additional generation capacity and investment required, the Energy Technology Perspectives energy supply model was used to run a scenario in which electricity consumption is 15% higher in 2015...The modelling results show that energy efficiency avoided 578 gigawatts of new generation capacity and USD 1.2 trillion in investment across IEA countries.”*

Fabric measures can also help to flatten morning and evening peak loads. While only 2-3 million homes rely solely on electric heating, this still constitutes a significant part of peak UK winter energy demand. Large numbers of gas homes are also meeting this peak demand

⁵ A Housing Stock Fit of the Future, UK-GBC, 2014 <http://www.ukgbc.org/resources/publication/housing-stock-fit-future-making-home-energy-efficiency-national-infrastructure>

⁶ The Energy Efficiency Strategy: The Energy Efficiency Opportunity in the UK, DECC, 2012 https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/65602/6927-energy-efficiency-strategy--the-energy-efficiency.pdf

⁷ Building the Future: The Economic and Fiscal Impacts of Making Homes Energy Efficient, Verco and Cambridge Econometrics, 2014 <http://www.energybillrevolution.org/wp-content/uploads/2014/10/Building-the-Future-The-Economic-and-Fiscal-impacts-of-making-homes-energy-efficient.pdf>

with plug-in electric heaters providing top-up heat which again likely coincides with peak times of the day.

Replacing inefficient appliances with the most efficient appliances is part of the answer, but making homes more energy efficient would also reduce some of demand for electricity, such as for secondary heating, in the first place. 4.2 million English households currently have **secondary electric heating**.⁸

Similarly, when **smart meters** are rolled out, they could soon be followed by “time of use tariffs” which will aim to shave peak demand by setting higher peak prices. Without careful management, this could have a potentially regressive effect on poorer households, pushing them away from peak use, whether it’s no longer cooking dinner at dinner time or heating their homes first thing in the morning. Ensuring fabric renovation options are available will allow such homes to retain heat, meaning homeowners can comfortably move away from the winter peaks but still stay warm.

Looking ahead, the country anticipates increasing taking up **microgeneration technologies** for heat and power such as Solar PV, Solar Thermal and Heat Pumps. Again, it is of fundamental importance to ensure that we simultaneously upgrade and insulate the fabric of buildings to minimum levels, otherwise risking the waste of renewable energy generation, and in the case of heat pumps, reduced performance of the systems. The “fabric first” principle is a key tenet of energy policy and was reiterated in BEIS’s recent response to the Feed in Tariffs consultation.

The move towards **smart homes** with technology which enables people to control their heating, hot water and appliances should also be matched with a quality building. Being able to precisely control when your heating comes on, in order to be comfortable and save energy, has much greater value and impact in a building which is not simultaneously leaking heat.

From an energy security perspective, the most secure energy system we can create is one which invests in demand management and energy efficiency, alongside decarbonisation and security of supply.

➤ **Carbon emission reduction objectives**

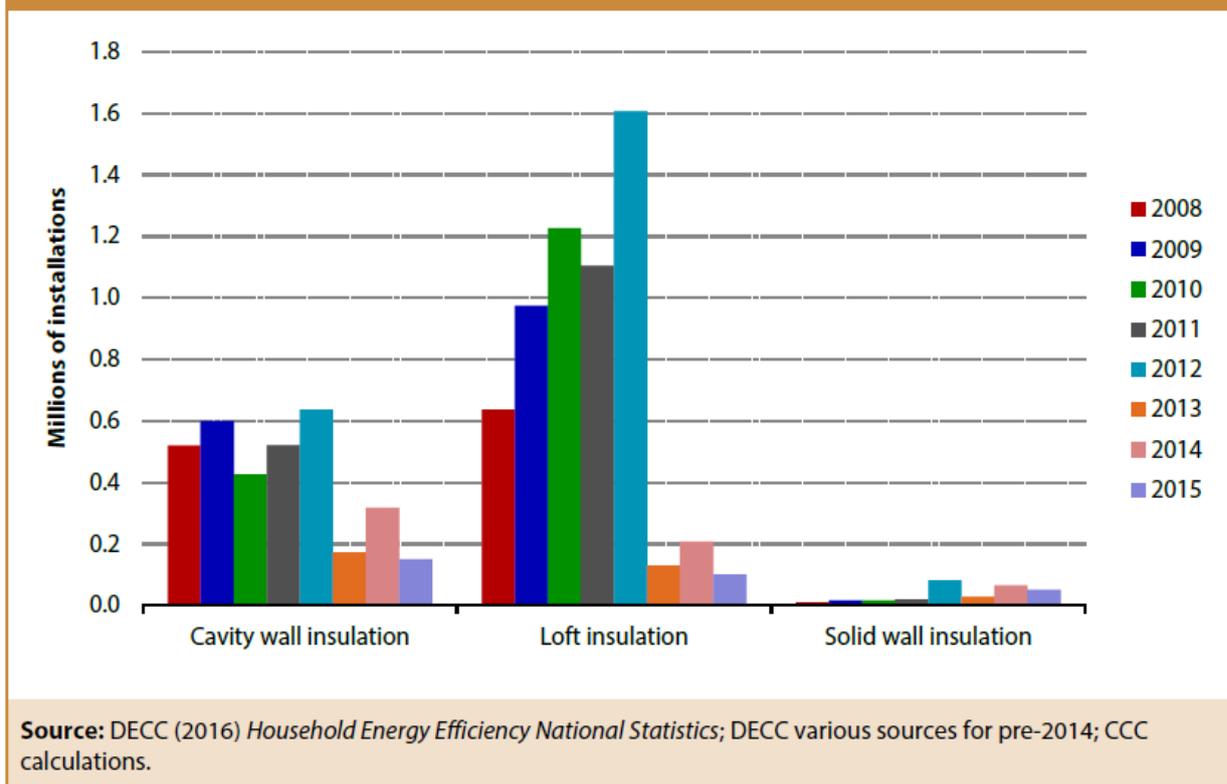

In terms of our climate change commitments and targets, failure to deliver an ambitious energy efficiency programme is likely to make it more difficult and costly to meet carbon budgets.

At present **more than a third of all energy used in the UK goes towards heating either water or air in buildings**. If demand side measures – particularly those improving the fabric of UK buildings – are not fully considered as part of wider infrastructure choices, the UK risks being locked into a high carbon energy system.

⁸ Cambridge Architectural Research Ltd et al, Further Analysis of the Household Electricity Survey 2013.
https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/275483/early_findings_revised.pdf

The Committee on Climate Change has recently raised strong concerns about the lack of progress in the energy efficiency sector. Their 2016 Progress Report to Parliament⁹ found that: “The total number of energy efficiency measures installed under government schemes in 2015 was down 49% on 2014 and 87% on 2012 across cavity wall, loft and solid wall insulation. This was due to the reduction in installation under the Energy Company Obligation (ECO) during 2015, which was already delivering far less than previous policies in place to 2012. This lack of progress reflects the **weakening of energy efficiency policy during this period.**”

Figure 3.4. Annual insulation installation rates (2008-2015)

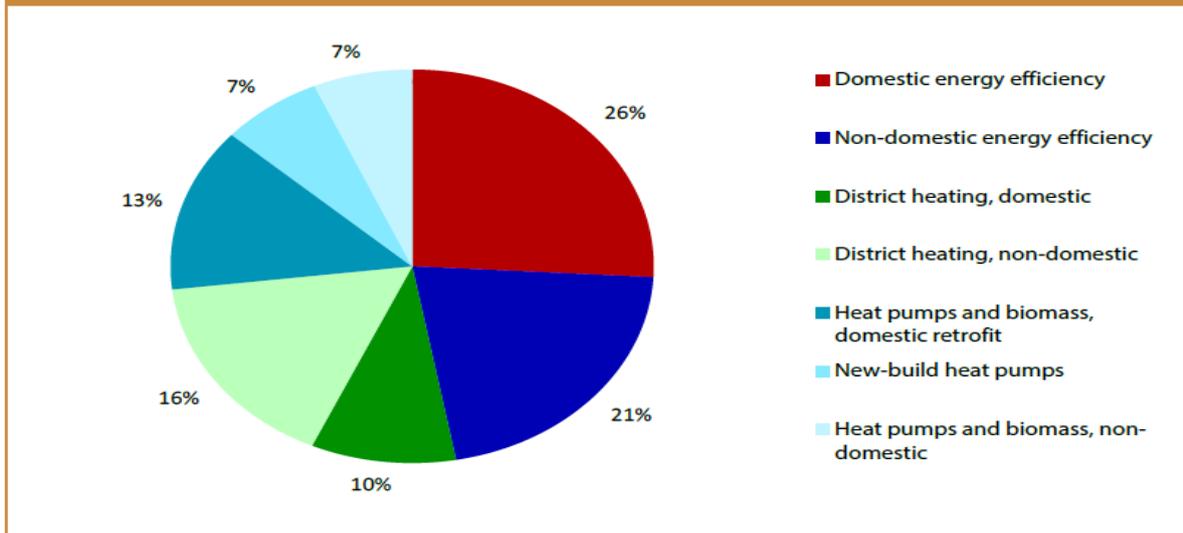

The CCC made the firm recommendation that a stronger policy framework to drive residential energy efficiency improvement is needed - addressing gaps and strengthening existing policies, including for the able-to-pay, increased funding for fuel poor households, and providing an effective approach to the private-rented sector. They also noted that Scotland, Wales and Northern Ireland have allocated tax-payer funds to support uptake of energy efficiency measures in buildings and work with local authorities on area-based delivery. **Scotland has also made energy efficiency a national infrastructure priority.**

Such policies are vital for meeting carbon budgets. The CCC assumes that **26% of direct abatement in buildings comes from residential energy efficiency**, and that emissions savings from residential energy efficiency are mainly fabric efficiency, with cavity wall insulation contributing the most.

⁹ Meeting Carbon Budgets – 2016 Progress Report to Parliament, Committee on Climate Change <https://www.theccc.org.uk/publication/meeting-carbon-budgets-2016-progress-report-to-parliament/>

Figure B3.1. Direct abatement in 2030 in buildings, central scenario

Source: CCC analysis.

Source: CCC (2015) Sectoral Scenarios for the Fifth Carbon Budget.

In summary, the CCC is concerned that current policies will not deliver the level of energy savings needed to meet policy targets. A new policy or package of measures to encourage energy efficiency in able-to-pay households is also essential to achieve the necessary emission reductions from buildings. The CCC says “A new scheme will have to be simple, provide a stable and long-term framework, develop trusted intermediaries, help households to overcome financial barriers and the range of nonfinancial barriers (e.g. information, perceived risk, hassle, and social norms) and have effective delivery and communication.”

➤ **Fuel poverty and health objectives**

There are a growing number of examples of consumers wishing to make their homes more energy efficient, but being unable to access the remaining support, because government-driven delivery is now almost solely in the hands of energy suppliers, since other programmes and schemes were cut.

This has far reaching implications. For the average consumer, energy bills may be up to £300 per year more than they could be. For the 2.3 million households in fuel poverty, the decision to under-heat their home to save energy and money is sometimes the only option. Cold homes can put people’s health at risk, especially vulnerable groups such as the elderly or very young.

Living in cold conditions is linked to a number of negative physical and mental health impacts. For example, the Hills Fuel Poverty Review found that low-temperatures in homes can create conditions which increase the likelihood of cardiovascular events, some of which may result in death, exacerbate the risk of respiratory disease and cause physical discomfort, which can contribute to mental health issues.

The ONS provisionally estimated there were over **24,000 cold-related winter deaths** in England and Wales in 2015/2016.¹⁰ The cost impacts of cold homes and fuel poverty on the NHS is an estimated £1.3bn per year.

In the future, as the population ages, more people will fall into vulnerable categories, struggling to pay needlessly high energy bills or suffering the effects of living in a cold home. Energy efficiency is one of the most cost-effective ways to protect vulnerable groups for the long-term.

BEIS cites modelling done prior to their 2012 Energy Efficiency Strategy to value the health benefits associated with some energy efficiency investments. The findings show that these can be significant. For loft insulation, these benefits alone outweigh the costs of installing the measures, even before energy savings are taken into account.

There is now wide-spread concern that the new version of Energy Efficiency Obligation¹¹, which will mainly focus on improving energy efficiency in fuel-poor households, is not ambitious enough. The CCC in their 2016 Progress report estimated that **annual funding of at least £1.2 billion** a year would be needed to meet the government's target of an Energy Performance Certificate (EPC) rating of C by 2030 for fuel-poor households in England. *“The announced [level of] funding from ECO and the income redistribution of the Warm Homes Discount will be inadequate for this objective.”* Furthermore, BEIS’s current target is to improve the energy efficiency of 1 million homes, is less than half of the actual number in fuel poverty.

➤ **Economic and employment objectives**

The Government’s stated objective in the 2017 Industrial Strategy¹² is to *“improve living standards and economic growth by increasing productivity and driving growth across the whole country.”*

Energy efficiency is acknowledged as making a significant contribution to economic growth in the Strategy, and, as a result, the Government plans to commission a review of the opportunities to reduce the cost of achieving decarbonisation goals in the power and industrial sectors. The review will cover how best to support greater energy efficiency, amongst other policies.

Although the focus of the Industrial Strategy is on the non-domestic sector, reducing domestic energy bills means an increase in the disposable income of households, which in turn leads to higher consumption and economic growth.

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/586626/building-our-industrial-strategy-green-paper.pdf

For instance, authoritative research by Frontier Economics in 2015¹³ showed that a national programme of investment in the energy efficiency of the building stock in Britain, over a period of ten years, is capable of delivering major economic and social benefits – in the order of **£8.7 billion**. This net benefit is comparable to other major infrastructure road and rail projects, including HS2 (Phase 1).

The report concluded that there is a **strong case for Government to make home energy efficiency an infrastructure investment priority** and to develop an infrastructure programme to deliver it. This finding holds, even without quantifying many of the social benefits of energy efficiency measures, for example health and wellbeing improvements.

Figure 1. Summary of infrastructure scheme assessments

Source: Frontier Economics, based on sources detailed Box 1 on page 17. The NPV is the present value of the difference between the stream of costs and benefits of each scheme. The BCRs represent the ratio of societal benefits to Government costs (In line with Webtag guidance). The NPV figures do not include wider economic benefits. The base year for the present values varies between 2010 and 2013.

In addition, macroeconomic modelling by Cambridge Econometrics and Verco in 2014¹⁴ suggests that a major energy efficiency programme would have a significant positive impact on economic growth. It also demonstrated that **for every £1 invested in energy efficiency, £3.20 is returned to economy**.

In particular, energy efficiency measures in homes:

¹³ Frontier Economics, Energy Efficiency: An Infrastructure Priority, 2015.

<http://www.frontier-economics.com/documents/2015/09/energy-efficiency-infrastructure-priority.pdf>

¹⁴ Building the Future: The Economic and Fiscal Impacts of Making Homes Energy Efficient, Verco and Cambridge Econometrics, 2014 <http://www.energybillrevolution.org/wp-content/uploads/2014/10/Building-the-Future-The-Economic-and-Fiscal-impacts-of-making-homes-energy-efficient.pdf>

- bolster employment and output in the construction sector
- reduce consumer expenditure on energy
- increase expenditure on consumer goods and services

This has a net impact of creating jobs and output. Furthermore, a large proportion of the jobs created will be closely linked to the locations where the measures are put into homes, supporting local economies, and potentially assisting with the Government's stated aim of spatial rebalancing of the economy.

In 2014, the energy efficiency market accounted for over 136,000 jobs in the construction and manufacturing industries. The modelling estimates an increase of **91,000 additional jobs by 2020** as a result of a major energy efficiency programme.¹⁵

It's also not hard to see why consumer spending power increases when the energy efficiency of homes is improved. For example, the Government estimates that energy efficiency measures to be delivered under the ECO's Affordable Warmth obligation alone will result in **£2.76 billion lifetime energy bill savings**. In terms of savings per household, for those treated under ECO, the policy could deliver a net saving on their annual dual fuel bill of up to £300.

Despite these significant economic benefits, the Treasury has not allocated any public capital funds to support home energy efficiency programmes even though it plans to spend over £100 billion of public capital funds on infrastructure projects by 2020. Instead, the Government has largely relied upon the Energy Company Obligation, which uses a levy on energy bills to generate investment in home energy efficiency. Political pressure to reduce energy bills in the short term for consumers has led to a reduction in the levy which has **reduced building energy efficiency investment by a third since 2012**.

3. Why the improvement of building energy efficiency is an infrastructure programme

It has long been recognised that investment in infrastructure has a positive effect on economic growth by increasing productivity and attracting investment, as well as boosting employment in the construction and other industries.

Visible, major construction projects, such as power stations and roads are most commonly thought of as infrastructure. Increasingly communications, connectivity and networks on a smaller scale and within local communities play just as big a role in ensuring our economy has the solid base needed to continue to grow. The inclusion of Smart Meters, which will be installed in individual properties, in the list of priority projects in the National Infrastructure Plan demonstrates our increasingly modern view of what constitutes infrastructure, and therefore what can drive economic growth.

- ***The UK's building stock is also part of our national infrastructure***

¹⁵ Building the Future: The Economic and Fiscal Impacts of Making Homes Energy Efficient, Verco and Cambridge Econometrics, 2014 <http://www.energybillrevolution.org/wp-content/uploads/2014/10/Building-the-Future-The-Economic-and-Fiscal-impacts-of-making-homes-energy-efficient.pdf>

A nationally coordinated programme of investment in the quality and functionality of our building stock - including in the 27 million existing homes – will drive growth and employment, just like other infrastructure projects.

The analysis by Frontier Economics in 2015 explains in more detail why domestic energy efficiency investments constitute infrastructure. In brief, reductions in energy demand, delivered through an energy efficiency programme would **increase available energy sector capacity** just as effectively as delivering new large capital investments, such as new generation plant, networks or gas storage. While domestic energy efficiency investments are not in themselves large monopoly assets, investing in them can have the equivalent impact on the economy as investing directly in such assets. This equivalence is recognised in supplementary guidance to HM Treasury’s Green Book, which states that **investment in energy efficiency reduces the need for investment in other energy system infrastructure**.

ResPublica built on these findings in 2015¹⁶ by recommending that, in addition to classifying energy efficiency as a national infrastructure priority, there is a case to **devolve infrastructure spending** to the city or local level, which MIMA also supports:

“As the Energy Bill Revolution and others have proposed, we advocate that energy efficiency should be made a national infrastructure priority: included in the top 40 priority infrastructure investments. But in keeping with our support to devolve powers and fiscal responsibilities to the lowest appropriate level, we also argue that Government should devolve infrastructure spending, where appropriate, to city regions.”

The inclusion of energy efficiency in the NIA was also recommended by Parliament’s Energy and Climate Change (ECC) Committee in 2016 following their inquiry into energy efficiency and demand reduction (Recommendation 7):“...the National Infrastructure Commission must consider the infrastructure requirements of meeting the UK’s carbon budgets and long-term legally binding carbon reduction targets. **Energy efficiency will be a crucial part of the mix.** The Government and the National Infrastructure Commission should assess the potential benefits of designating energy efficiency as a national infrastructure priority.”

The Government responded to the ECC Committee’s report on 11 July 2016, stating “DECC will continue to work with the Commission as it prepares its National Infrastructure Assessment. As per the Commission’s consultation document, this will examine the future of heating and **important role that increasing energy efficiency could potentially play.**”

4. Demand reduction potential

The quote below from the IEA’s Energy Efficiency Market Review 2016 gives a sense of what is possible, even at relatively low levels of investment in energy efficiency.

“Energy efficiency levels in IEA member countries improved, on average, by 14% between 2000 and 2015. This generated energy savings of 450 million tonnes of oil equivalent (Mtoe)

¹⁶ After the Green Deal, ResPublica, 2015 <http://www.respublica.org.uk/our-work/publications/after-the-green-deal/>

in 2015, enough to power Japan for a full year. These savings also reduced total energy expenditure by 540 billion United States Dollars (USD) in 2015, mostly in buildings and industry. While GDP grew by 2% in IEA countries, efficiency gains led to the flattening of growth in primary energy demand.”

Importantly, the IEA highlighted that **energy demand growth slowed, while global GDP grew.**

In the UK, domestic energy consumption reductions in the past have been even more pronounced, driven to a large extent by energy efficiency measures (and partly by austerity). Under previous policies, between 2005 and 2015 UK homes saw a huge 23% drop in (weather adjusted) median gas consumption.¹⁷ At today’s prices this means that approximately £4 billion less per year will be spent on gas alone across the UK’s 27 million homes than if consumption had remained at pre-2005 levels.

DECC’s (now BEIS) Energy Efficiency Strategy 2012 also references modelling by the Building Research Establishment modelling which suggests that, if no energy efficiency gains had been made since 1970, energy use would be almost double the current levels, adding about £1,000 to the average annual energy bill.¹⁸ Energy consumption, per household, is now at its lowest point since pre-1970 levels.¹⁹ **This is a great UK success story meaning we are already far more energy secure than we otherwise might have been.**

However, the job of retrofitting the UK’s housing stock is only half done. The UK’s housing stock still remains amongst the “leakiest” in Western Europe.²⁰ Over 20 million out of the 27 million homes in the UK are still below EPC Band C – the rating considered to represent a reasonable level of energy efficiency.²¹ The reasons for this become clear when examining the remaining energy efficiency technical potential. For example, the latest Impact Assessment for the ECO shows that in Great Britain there are still:

- 7.8 million of the 8 million solid walls to be insulated;
- 5.4 million cavity walls to be filled;
- 5.8 million lofts to be fully insulated; and
- around 5 million party walls to be insulated. The estimated fuel bill cost to consumers from heat loss through party walls alone is around £465 million a year.

¹⁷ Energy Consumption in the UK, BEIS, July 2016 - Table 3.01 <https://www.gov.uk/government/statistics/energy-consumption-in-the-uk>

¹⁸ The Energy Efficiency Strategy: The Energy Efficiency Opportunity in the UK. DECC, 2012 https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/65602/6927-energy-efficiency-strategy--the-energy-efficiency.pdf

¹⁹ Energy Consumption in the UK, BEIS, July 2016

²⁰ A Housing Stock Fit of the Future, UK-GBC, 2014 <http://www.ukgbc.org/resources/publication/housing-stock-fit-future-making-home-energy-efficiency-national-infrastructure>

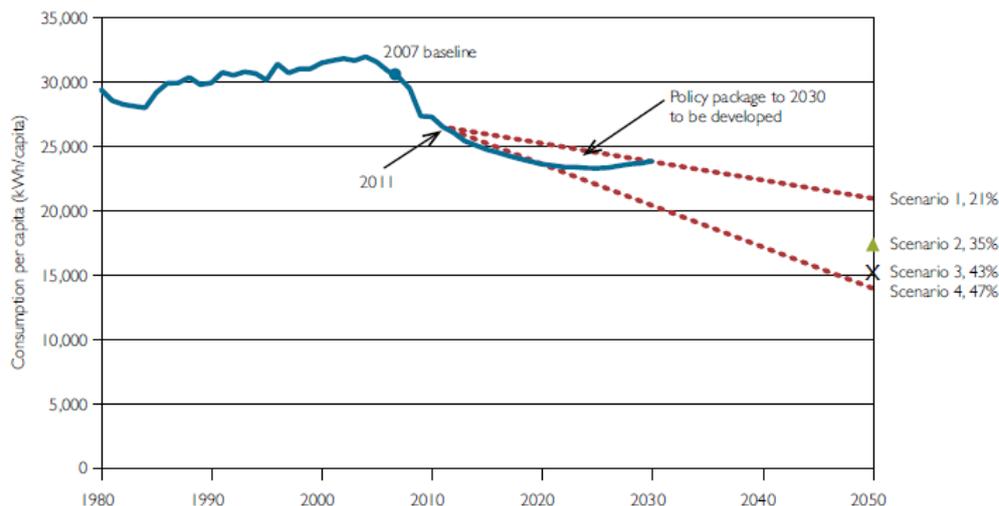

²¹ Live Tables on Energy Performance of Buildings Certificates <https://www.gov.uk/government/statistical-data-sets/live-tables-on-energy-performance-of-buildings-certificates>

Analyses of the future cost-effective demand reduction potential differs depending on the assumptions used. Many scenarios, such as those produced by the National Grid, make choices about whether levels of energy efficiency are low or high, for example, and then estimate the corresponding energy consumption levels in the future.

In light of this variation, we recommend the NIC works with the sector, and with modelling experts to produce a definitive and up-to-date estimate of the technical and cost-effective level of demand reduction possible, for use in the NIA.

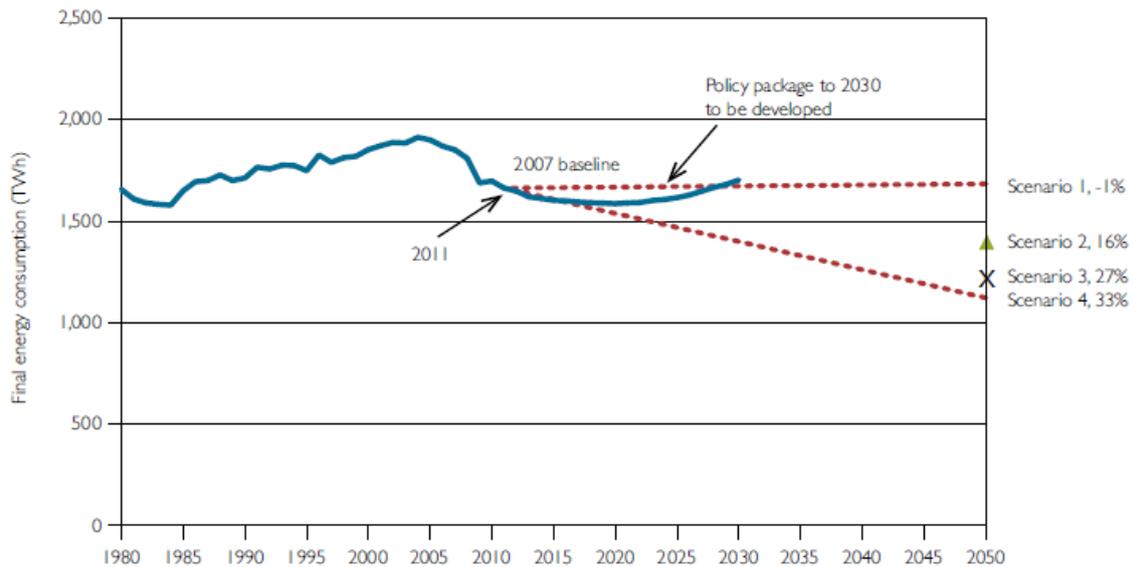

This analysis should draw on existing estimates, such as BEIS’s 2012 estimates based on the 2011 Carbon Plan 2050 scenarios. These said energy efficiency would need to “contribute a reduction in final energy consumption per capita between 2007 and 2050 of 31-54%.” Figure 3 shows that, after moving to a 2011 baseline, the Carbon Plan Scenarios would require **per capita savings of between 21% and 47% between 2011 and 2050.**

Figure 3: UK final energy consumption per capita compared against carbon plan scenarios: 1980-2050²³

In terms of final energy consumption, the Carbon Plan scenarios translate to a range from a 1% increase in absolute final energy consumption from 2011 to a 33% decrease.

Figure 4: UK final energy consumption compared against carbon plan scenarios: 1980-2050

The policy package was thought to be on track at the time (though this will no longer be the case), but even then BEIS stressed that additional action would be needed to maintain progress on energy efficiency after 2020.

Currently, overall energy demand is roughly stable. However, it is expected to rise after 2025 as the impact of historic energy efficiency policies declines. In the absence of a major policy intervention, current levels of energy efficiency and the impact of fossil fuel prices are likely to be insufficient to offset the impact of economic and population growth.

➤ **The rebound effect**

It is often asserted that improving the energy efficiency of the homes of low income households, in particular, has reduced carbon benefits. It is assumed that these households are likely to take back much of the potential energy savings as extra warmth and hence the carbon savings are less than in the homes of warmer, better-off households.

Whilst it is true that poorer households sometimes forgo some of the potential energy savings in favour of a warmer internal climate:

- Even within the coldest homes, there are cost effective carbon and monetary savings because the fuel poor want the extra money to pay for other essentials, as well as the extra warmth
- The rebound in cold homes tends to only happen with the first energy efficiency improvements. Once the home has reached a higher level of warmth, there will be less rebound. Therefore, any “discount” should be applied at a lower level for example when homes are improved to EPC Band C or better.

- The rebound effect is less likely to be found in relation to electricity, for instance from more efficient lights and appliances. There is also less of a rebound, if any, with hot water use, but this has not been properly researched.

We are aware that The Centre on Innovation and Energy Demand (CIED) is currently investigating the source, nature and magnitude of rebound effects in a number of UK sectors. Led by the Centre for Energy Policy at the University of Strathclyde, this new project is investigating the impact of energy efficiency improvements throughout the UK economy and along international supply chains, as well as using sophisticated multi-sector macroeconomic models to capture a much wider range of economic effects.

However, it is clear that most reliable economic modelling already accounts for rebound effects. The Cambridge Econometrics analysis referenced above, for example, assumes a large comfort/rebound factor of 40% for fuel poor homes.

5. Delivery vision

We now need to make investment in the quality and efficiency of our building stock, and particularly dwellings, an urgent infrastructure priority.

While some energy efficiency improvements are already financially attractive, many measures need public sector support to lever in further private investment. Consumers generally only take up these options when sufficiently incentivised to do so, and businesses will only invest and innovate in supplying the market if they are confident that incentives will remain in place.

The reasons policies so far have not succeeded in delivering the technical potential (or even the cost-effective potential) are varied and complicated. But we would argue, it comes down to a failure to deliberately and concertedly drive demand for energy efficiency across the board towards an agreed target or goal.

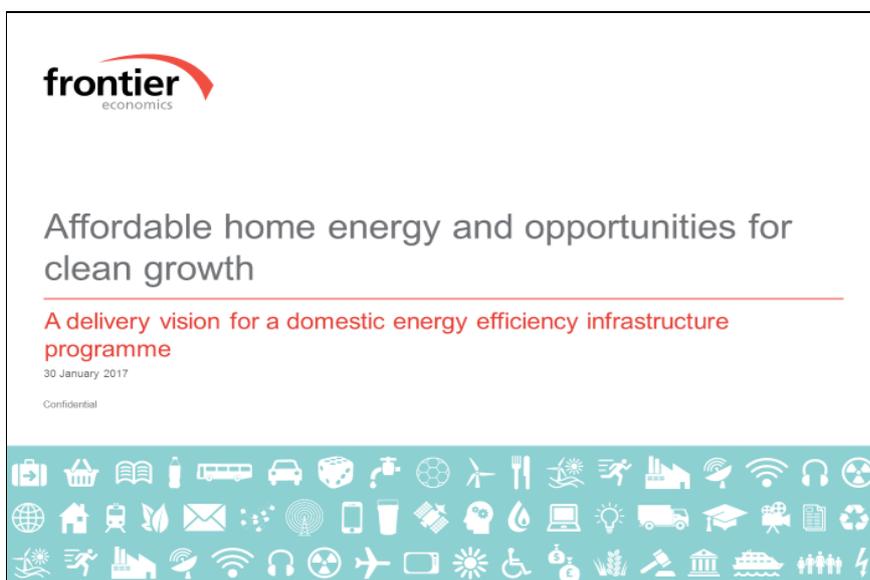

The UK instead focused on piece-meal policies, often designed to remove barriers to uptake, such as the upfront cost in the case of the Green Deal. Such policies are more likely to be successful only in cases where consumers were already persuaded on the benefits of energy efficiency in the first place. Where there is latent demand.

The ECO has proved to be more successful than the Green Deal, demonstrating that creating fixed targets e.g. to save a specified amount of carbon and making organisations responsible for driving sufficient demand to meet the target, works in terms of driving numbers – but in some cases, this has been at the expense of quality.

There is now a clear opportunity for the NIC and the Government to put in place the plan for improving the UK's existing housing stock through the infrastructure “architecture” to fully insulate our buildings. We need to integrate energy efficiency into national infrastructure planning.

With energy efficient buildings classed an infrastructure priority, and an appropriate long-term vision outlined, delivery can be implemented through a set of coordinated policies designed to drive the uptake of measures, including support for zero or low interest loans, cost neutral stamp duty reform which rewards home owners with energy efficiency homes, and a programme of targeted capital investment. Only through a commitment to improving our building stock at a national level can we – the sector and government – attract sufficient investment and achieve efficient coordination and delivery of national energy efficiency objectives.

The NIC is aware that the EEIG is working with Frontier Economics to create a Delivery Vision. Good progress is being made, and this should be finalised in Spring 2017.

Lastly, making building energy efficiency a public infrastructure priority has widespread support, including from other leading UK business associations and businesses, including the CBI. And in Scotland, the five main parties, including the Scottish Conservatives, have already committed to improving home energy efficiency through a “national infrastructure project”. More than 200 businesses, charities and consumer groups are now calling for energy efficiency to be an infrastructure priority including Age-UK, Kingfisher plc., Co-operative Energy, the Energy Saving Trust, Keepmoat, Willmott Dixon and Worcester Bosch.

10 February 2017

National Infrastructure Commission: Call for Evidence

Response from Mobile UK

February 2017

About Mobile UK

1. Mobile UK is the trade association for the UK's mobile network operators - EE, Telefonica UK (O2), Three and Vodafone. Our goal is to realise the power of mobile to improve the lives of our customers and the prosperity of the UK as a whole.
2. As mobile increasingly becomes the device of choice for running daily life both at home and at work, customers, quite rightly want better coverage, more capacity and greater capabilities. Our role is to identify the barriers to progress, and work with all relevant parties to bring about change, be they Government, regulators, industry, consumers or citizens more generally.

Introduction

3. Mobile UK welcomes the opportunity to respond to the National Infrastructure Commission's *National Infrastructure Assessment*.
4. Mobile UK welcomes the creation of the National Infrastructure Commission (NIC). We also agree with the statement in the recent *Connected Future* report that mobile connectivity is critical to the growth of our economy and that the Government must play an active role as a digital champion.
5. Mobile network operators are committed to meeting the rising demand from customers for more capacity and coverage throughout the UK. However, it is dependent on many factors and stakeholders across national government, local authorities and the devolved nations to ensure that the environment for mobile infrastructure is built to allow rapid deployment and limits barriers.
6. Mobile UK has previously submitted evidence to the NIC and stands ready to assist further to expand on points made in this submission.
7. This submission sets out Mobile UK's priorities for the National Infrastructure Assessment (NIA) and, in addition to the set questions of the Call for Evidence, we have outlined our key priorities.

National Infrastructure Assessment

8. Mobile UK supports the ambition set out by the National Infrastructure Commission to produce an NIA once in every Parliament, setting out a comprehensive assessment of the UK's long-term infrastructure needs on a 30-year time horizon.
9. Mobile UK also strongly supports the NIC's assertion that the NIA should span across national and devolved governments, as well as regulators.

Administration Office: Gore End, Newbury, RG20 0BD: Registered Office: 1 Carnegie Road, Newbury, RG14 5DJ

10. Mobile UK welcomes the NIC's inclusion of digital communications as an individual sector of focus.

Mobile Communication – Critical Infrastructure

11. Mobile communication is part of the UK's critical infrastructure and is integral to people's lives. At the end of December 2015, there were 85.3m mobile connections (79.7m active mobile handsets and 5.6m active mobile broadband connections)¹. 95% of the adult population has a mobile phone.
12. The increase in coverage, capability and capacity of mobile networks has led to an explosion in demand for mobile data. 4G is driving greater volumes of data usage. A total of 106 petabytes was sent over all mobile networks in June 2016, a 44% increase over the previous year. The average volume of data consumed per subscriber now stands at 1.3 gigabytes per month up from 0.9 gigabytes in 2015.²
13. Improved 4G services, and the rollout of 5G has the potential to increase this demand further. It is expected that 5G will form the critical backbone of many of the UK's key services such as e-health, the internet of things and autonomous vehicles.
14. Mobile network operators have played a central role in driving this progress by continually investing in their networks, value added services, and subscriber acquisition. In the current cycle the mobile network operators are investing around £2 billion per annum in new coverage, capacity and capability. In turn, business and consumer customers have shown extraordinary ingenuity in harnessing the power of mobile, to be more creative and productive, to offer new services, and to improve lives.

Communications Infrastructure

15. It is our experience that the best results are achieved if Government, mobile network operators and other stakeholders work cooperatively. Changes across a broad range of policy need to be considered
 - a. Reform to planning regulations for telecommunications apparatus, enhancements to Permitted Development Rights
 - b. Reform to planning regulations for housing and other construction, requiring developers to make greater provision for electronic communications
 - c. Other improvements within local authority planning (LPA): updating planning guidance, better training and more resources for planning officers, so that LPAs do not become a bottleneck
 - d. The business rates regime: make marginal investment more viable with business rates exemptions in selected areas (for example National Parks)
 - e. Access to public assets and other landowners: encourage Government to make it easier for mobile network operators to access suitable locations on which to place their apparatus
 - f. Develop partnership schemes for the parts of the country where there is no commercial business case but where additional societal gains can accrue from wider coverage (for example, in the efficient delivery of public services)
 - g. Coordination across Government: all measures will be much more effective if there is

¹ Ofcom – Communications Market Update, Q4 2015

² Ofcom – Connected Nations, 2016

good coordination between government departments and between the Westminster Government and the devolved governments.

16. When looked at from an international perspective the UK's average mast height is low bearing in mind that the ability to cover a wider area depends on how high a mast can be built. In the UK, the average mast height is 17m. In France, the comparable figure is 30m, in Sweden it is over 70m. It is also disproportionately expensive to build mobile infrastructure in the UK.³
17. In addition to masts it should also be noted that small cell antennae form a significant and growing part of the infrastructure required to deliver mobile connectivity and coverage. In cities, to maintain bandwidth and capacity an extraordinarily dense network of small cells is required in addition to existing mobile infrastructure. As demand increases as more and more devices come online this will be exacerbated. In London alone it is estimated that as many as 500,000 small cells will be needed to support 5G services, a number far greater than the UK's entire existing stock of 37,000 mobile masts. To ensure bandwidth and capacity keep up with current and future demand further reform is required in the legislation that underpins digital communications infrastructure. This is vitally important if the UK is to match its goals and remain a leader in this field.
18. It should be noted that Mobile UK welcomes recent reforms to planning in England, and consultations in Northern Ireland and Scotland on similar reforms, alongside the Welsh Government's announcement of a Mobile Action Plan for Wales, but these changes only provide additional height and rights within the existing framework. The infrastructure that will be required for 5G networks is likely to be significantly different from what is currently required for 4G. This is not to suggest that maximum heights and numbers of apparatus will always be required but flexibility to deploy infrastructure is equally important.
19. It is vital that when the need for reform is identified it is accelerated to keep up with rapid changes in technology and usage. For example, reform to the Electronic Communications Code, currently being progressed as part of the Digital Economy Bill, was intended for 4G rollout. With 5G round in prospect it is important reforms put in place now are kept under review and adaptable to future demands.
20. Mobile coverage needs to be at the forefront of strategy and planning both at a national and local level. Pro-connectivity policies should be woven into Local Plans and growth strategies and linked across national and subnational bodies, including Local Enterprise Partnerships. It is encouraging that the Government is consulting, as part of its recent Housing White Paper, on requirements on local authorities to have planning policies setting out how high quality digital infrastructure will be delivered in their area, and accessible from a range of providers.

Answers to Specific Questions

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Mobile coverage and capacity must be hard-wired into the planning process. New developments create additional demand on mobile networks impacting upon capacity and bandwidth. It cannot be the sole responsibility of the communications providers but must be a partnership developed at the inception of development planning. Mobile UK supports the NIC's assertion that the mobile network operators and local authorities should work together to build a better picture of local area requirements combined with network expertise.

³ Mobile UK

To achieve this there must be strong commitment at the local level as well as the national level to work with mobile network operators. Local authorities must also show leadership and include pro-connectivity policies as part of their Local Plans and take a 'joined-up' approach to telecoms provision and planning applications, especially considering local economic development, sustainability, and social inclusion considerations.

The Government and the NIC also need to take a stronger approach to the timely adoption of Local Plans to provide certainty to mobile network operators. At present a significant number of councils across the country are still to adopt their local plans. Mobile network operators invest significant resources into the quality of coverage and capacity of their networks. Without accurate projections of local council's growth plans it effectively leaves mobile network operators in the dark as to where demand will come from. Better adoption rates of local plans will provide a better picture of future demand and therefore where future capacity investment will be needed.

Further consideration is required around 'emergency works' or the need for temporary sites. Often mobile network operators are served a Notice to Quit (NTQ) which call on mobile network operators to remove existing infrastructure on new developments with minimal prior notice. Alternative sites are often difficult to find or fail to provide coverage to the original footprint. Even if a suitable site is found it will often result in a break in service as necessary planning permission is sought. In addition, the knock-on effect to other nearby sites can result in cuts to capacity due to the removal of essential network infrastructure or increased traffic to cover the lost equipment.

Mobile UK believes that the planning and regulatory regimes continue to require reform to ensure that the UK's current and future communications requirements are considered.

Mobile UK stands ready to work with the NIC, national and devolved governments and other stakeholders to consider further necessary reform. However, it is important that there is strong leadership and Mobile UK and the mobile network operators would welcome the NIC, with its long-term focus and deep understanding of the UK's future infrastructure needs, adding its powerful voice.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Mobile UK believes that the current planning and regulatory regime continues to require reform, not only to enable mobile network operators to meet their current network obligations but also to provide the flexibility to ensure that future requirements for mobile coverage are met.

As stated previously the mobile network operators are investing more than £2 billion each year in new coverage, capacity and capability.

Mobile UK believes due to the incremental and evolutionary improvements to mobile technology planning must be looked at more broadly and the following needs to be considered:

- Reform to planning regulations for telecommunications apparatus, enhancements to Permitted Development Rights
- Reform to planning regulations for housing and other construction, requiring developers to make greater provision for electronic communications
- Other improvements within local authority planning (LPA): updating planning guidance, better training and more resources for planning officers, so that LPAs do not become a bottleneck
- Access to public assets and other landowners: encourage Government to much more to make it easier for mobile network operators to access suitable locations on which to place their apparatus

The planning system does not encourage investment in infrastructure and often hinders the upgrading of existing infrastructure.

It must be noted that one of the key issues in assessing the effectiveness of the current system is not percentage approval rates, which are generally good. Rather it is the time/cost/resource it takes to navigate the system. It means the industry is building the infrastructure the regulations allow rather than the infrastructure that will deliver the coverage UK consumers and business are demanding. Doing nothing is not an option.

Additionally, changes to the planning system, should, as far as possible, be future proofed to allow for new developments in technology, future releases of spectrum for mobile services and new demands for connectivity in a rapidly changing world.

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Mobile UK cannot project how travel patterns will change but it is clear that mobile connectivity can act as an enabler to more efficient, safer and intelligent transport solutions. Mobile technology can assist in the monitoring and management of traffic flows and direct drivers to avoid traffic thus limiting congestion and reducing commute times. In-car connectivity that calls emergency services automatically in the event of a collision can help to save lives while also providing accurate location data to the emergency services to provide assistance and clear blockages to the transport network.

Mobile connectivity is being embraced by public transit systems to connect vehicles to their operations centres and to the public themselves providing real-time route and schedule management. Mobile broadband also increases productivity as customers and businesses can utilise transit time on rail and public transport to conduct business.

However, it is important to note that to fully realise mobile connectivity on the railways and highways better arrangements and channels of communications are required with the respective bodies.

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

Mobile network capacity is not enhanced by a singular one-off investment, such as a new runway. The mobile network operators are currently investing £2 billion every year to upgrade their networks to improve coverage and customer experience. Mobile network operators will need to invest continually in new capacity, coverage and technologies, as will the transmission providers, to ensure that the sector has the necessary bandwidth to connect mobile masts into the wider network.

Ofcom must continue to release spectrum in a timely manner to meet current and future demand and capacity. There must be a fair and transparent process for allocating spectrum but it must be recognised that higher spectrum costs, both in auction and license fees, impacts on investment potential. The UK has one of the most highly competitive markets and this has proved an efficient engine for economic growth and participation. However, the sector is one of the most intensively regulated. It is important that the balance of regulation is optimal to protect the customer and to keep pace with the advancement of mobile technologies and the internet. Flexible, light touch regulation creates the right environment for continued mobile sector investment and innovation.

Mobile UK also calls on the NIC to take a leadership role in ensuring that the Government and devolved institutions consider mobile infrastructure and coverage when investing in significant public infrastructure. For instance, the high-speed rail project, HS2, has recently passed its third reading in the House of Lords and is expected to receive Royal Assent later this year. With construction yet to begin it provides a unique opportunity to build in mobile infrastructure as it is constructed rather than aiming to retrofit once it is complete, as happened with the Channel tunnel and is now happening in the London Underground.

Mobile infrastructure needs to be hard-wired into national and local government strategic thinking from the outset.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Mobile UK agrees with the NIC that mobile connectivity is an essential service. However, we would disagree with the premise that the mobile sector is a utility such as gas or water because operators seek to differentiate themselves through the quality of the service they provide, e.g. extent of coverage, data speeds, and value added services. This has profound implications for the way in which the sector, which has always been highly competitive, is regulated.

Throughout this response, Mobile UK has proposed a broad range of measures to improve the 'digital communications regime'. While mobile network operators are committed to keep investing in more capacity and coverage, there is no doubt that the task would be made easier with greater collaboration and co-operation with our stakeholders.

We all have a stake in the future of mobile networks. Commercial, personal and Governments are identifying many new applications for mobile platforms, such as e-health, connected cars, pollution management, energy management and water conservation. But none will realise its full potential without delivering the nuts and bolts of the underpinning infrastructure. Mobile UK is willing to work with anyone to identify barriers and bring forward practical solutions that will ease the task of delivering a mobile signal wherever and whenever it is required.

Action for Warm Homes

National Energy Action (NEA) response to the National Infrastructure Assessment Call for Evidence

Introduction

NEA is a national charity that has been working for over 35 years to end fuel poverty and tackle exclusion in the energy market locally and nationally¹. Despite our work and national and local action to reduce fuel poverty, the number of households living on a low income in a home which cannot be kept warm at a reasonable cost has continued to rise and affects approximately 4 million homes across the UK². NEA's vision is that 'no one is living in fuel poverty' but due to a lack of investment in energy efficiency programmes this is unlikely to happen in the average lifetime of a baby born today³.

NEA warmly welcomes this opportunity to respond to the National Infrastructure Commission's (NIC) call for evidence. To date NEA has responded to two NIC consultations⁴ and we welcome NIC responding positively to calls for energy efficiency to be a key focus, indicating energy saving programmes should be closely linked to any strategy for decarbonising the UK's heating supply⁵. We illustrate in our response how enhanced energy efficiency programmes could help reduce the cost to energy consumers of the transition to the low carbon energy system and simultaneously improve the quality of life for the most vulnerable⁶. This action would also help meet existing statutory targets (carbon budgets, fuel poverty targets⁷ and minimum energy performance standards in the private rented sector⁸). We also discuss the need for NIC to adequately address wider distributional impacts when making its recommendations to the UK Government within the NIA and we provide further details on how these areas could be addressed below.

Finally, NEA notes it has engaged constructively with NIC on these areas, at a bespoke workshop and directly in 1-1 meetings to make this strong case. As NIC is aware, EEIG is working with Frontier Economics to create an energy efficiency Delivery Vision report which will be finalised in Spring 2017. NEA is also a key member of the Energy Efficiency Infrastructure Group (EEIG) and works closely with a growing number of Non- Departmental Public Bodies, industry partners and NGOs to highlight the benefits of this approach. This has notable support:

Bright Blue 2016

"The economic benefits of incentivising home energy improvements should be viewed in the same way as infrastructure investment, as they comfortably meet the government criteria⁹"

Policy Exchange 2016

"Make energy efficiency a national infrastructure priority¹⁰"

Committee on Fuel Poverty 2016

"We believe that the benefits of designating energy efficiency as a national infrastructure priority should be assessed, thereby potentially helping to unlock access to public infrastructure funding¹¹"

ResPublica 2015

"Energy Efficiency should be made a national infrastructure priority¹²"

CBI 2015

"A new government must act swiftly to make energy efficiency a national infrastructure priority¹³"

Last year the Climate Change Committee (CCC) also highlighted that the Scottish Government have announced that Scotland's Energy Efficiency Programme will be a National Infrastructure Priority. This move has since been emulated by the Welsh Government and the Infrastructure and Wales' Investment Plan aims to drive improvements in the energy performance of buildings and tackle fuel poverty¹⁴. Mirroring energy efficiency as an infrastructure priority consistently across the whole of the UK would help unlock access to public infrastructure funding and help the Government meet its fuel poverty, private rental sector and carbon reductions commitments.

NEA therefore requests a clear statement from the National Infrastructure Commission that making energy efficiency a key national infrastructure priority will be included as part of the National Infrastructure Assessment. According to Lord Deben (the Chair of the CCC) and Lord Stern (Chair of the Grantham Research Institute on Climate Change and the Environment at the London School of Economics) no other infrastructure investment can deliver so much¹⁵.

Domestic energy efficiency can reduce the UK's energy demand economically

An ambitious energy efficiency programme would capture substantial macro-economic benefits for the UK. The report "Building the Future: The economic and fiscal impacts of making homes energy efficient" produced by Cambridge Econometrics and Verco, noted an ambitious energy efficiency programme can:

- return £3 to the economy per £1 invested by central government;
- help create a 26% reduction in imports of natural gas in 2030;
- save domestic consumers over £8 billion per annum in total energy bill savings;
- increase relative GDP by 0.6% by 2030;
- increase employment by up to 108,000 net jobs; and
- help reduce carbon dioxide emissions by 23.6MtCO₂ per annum by 2030.

UK Government estimated in their 2012 Energy Efficiency Strategy that cost effective investments in energy efficiency could save the UK 196TWh in 2020, equivalent to the output from 22 power stations¹⁶.

The Government also determines cost-effectiveness using Marginal Abatement Cost Curves and this ranks specific household interventions (such as wall insulation) based on their cost-effectiveness for abating greenhouse gas emissions. The MACC allows decision makers to assess how much progress is already being made and subsequently consider what it would cost (or save) to make more (or less) progress from that point. The same approach to constructing MACCs for climate change or overall energy efficiency policy can also be applied to fuel poverty and DECC have established FP-MACCs to assess, at different points in time, what the most cost-effective interventions are and how much progress these interventions could potentially make towards fuel poverty objectives¹⁷. The measures included within the current FP- MAC curves highlight meeting fuel poverty targets can be done cost effectively and will generate positive savings for society.

The benefits of energy efficiency have also been illustrated in an international context. The International Energy Agency (IEA)'s report 'Capturing the multiple benefits of energy efficiency' demonstrated the potential for energy efficiency to deliver new jobs and economic growth, reduce pressure on health services, improve energy security and reduce carbon emissions (at the same time as providing a long-term, sustainable solution to unaffordable fuel bills for all consumers). The report also found that that large scale energy efficiency programmes can lead to increases in GDP of up to 1.1% per year; can create significant employment (8-27 job years per €1million invested) and can have a benefit to cost ratio of 4:1¹⁸.

There is also further evidence that demand on the electricity network can be reduced through energy efficiency and can be implemented as an alternative to network reinforcement. We set out in our previous response to the NIC¹⁹ a summary of a number of those trials, and note that previous Low Carbon Network Fund (LCNF) schemes need to be sustained to provide long term results. Alternatives to reinforcement that may be appropriate could be encouraging a distribution network operator to help replace inefficient electrically heated systems; providing a contribution towards connecting a household to a modern efficient district heating or gas network; helping fund solid wall insulation; providing capital towards lighting improvements, low cost energy saving appliances or battery storage alongside microgeneration.

Improving domestic energy efficiency can improve quality of life

Currently, low income households living in the least energy efficient dwellings face extra costs to keep warm above those for typical households. In England this can be summed for all fuel poor households, a so-called 'aggregate fuel poverty gap'. The difficulties faced by individual households can also be calculated and currently fuel poor households living in the least efficient homes pay an extra £1,345 per year to keep warm compared to a typical household²⁰. These costs are largely outside the control of these households – given the capital investment that would be required to improve their energy efficiency - and instead people rely on trading off the temperatures at which they live against other necessities, exacerbating health related issues. Currently these issues are so acute, the physical impacts of living in a cold, inefficient home causes unnecessary suffering and premature mortality²¹ and is a bigger killer than smoking, lack of exercise and alcohol abuse²². Excess winter deaths in England and Wales alone were an estimated 24,300 in 2015/16²³. Over a five year period, the average number of excess winter deaths in England and Wales is 28,218. Based on the World Health Organisation's estimate that a minimum of 30% of Excess Winter Deaths are due to people living in cold homes, an average of over 8,000 people die each winter because they cannot be kept warm at a reasonable cost²⁴.

Beyond the impacts on the frail and elderly, children living in damp and mouldy homes are particularly at risk; almost three times as likely to suffer from coughing, wheezing and respiratory illness²⁵. Existing evidence also highlights infants living in cold conditions have a 30% greater risk of admission to hospital or primary care facilities²⁶. This in turn impacts on educational attainment, either through increased school absence through illness or children unable to find a quiet, warm place to study in the home²⁷. Home energy improvements have been associated with an 80% decrease in the rate of sickness absence from school for children with asthma and recurrent respiratory infections²⁸. Financial stress about energy bills causes huge anxiety which can exacerbate mental health problems, leading to depression and potentially suicide²⁹. Currently, more than one in four adolescents living in cold housing are at risk of multiple mental health problems³⁰.

Problems such as unhealthy low temperatures and damp are also more likely depending on tenure. In particular, the least efficient privately rented homes (such as poorly converted flats and shared properties such as bedsits and hostels) are causing the greatest hardship and the most acute risks for their residents³¹. Inner city areas have very high numbers and concentrations of Houses of Multiple Occupation (HMOs); 41% of England's shared housing stock is in the capital (195,000 homes)³². Astonishingly, HMO properties will not be fully covered by national standards for PRS³³ despite a recent NEA survey which highlighted these worst rental properties have such inadequate heating and insulation that it is impossible to keep them warm and free from damp³⁴. There is also a pressing need to ensure social landlords maintain the historic improvements in this tenure and tackle the remaining stock not improved by the previous Decent Homes programme. This can be achieved by setting a clear aspiration to bring social housing into line with the aforementioned PRS target.

Finally, whilst it is a scandal that cold homes continue to kill thousands of vulnerable people each year, the associated cost of morbidity is equally stark. The current scale of these problems in England alone costs health services approximately £3.6 million per day and in the past four years alone over £5 billion of tax payers' money has been spent treating the symptoms of cold homes³⁵. Addressing these needless costs through further action on energy efficiency and capturing the full benefits of affordable warmth will help avoid the disastrous costs of inaction.

Distributional impacts on different segments of society must be considered

Between 2004 and 2016 domestic electricity prices increased by 80%, whilst gas prices have doubled. In 2004, the UK was a net exporter of energy. By 2010, more than 25% of UK energy was imported, and 40% of gas. Dependency on imports for all fossil fuels negatively impacts the UK's trade balance and energy imports for gas accounts for approximately £30m per day (over £10bn per year). The extent to which the UK can insulate itself from this import dependency (and other raw products such as steel to build new power stations or over headlines) will have a clear key impact on all types of consumers, particularly the most vulnerable.

The average proportion of a household's income spent on energy has doubled since 2004, with low income households continuing to pay a disproportionately higher percentage of their outgoings on fuel, whilst their incomes have stagnated or reduced. The UK has among the highest rates of fuel poverty and one of the most energy inefficient housing stocks in Europe³⁶. Currently no public money is going to be spent this Parliament on improving energy efficiency levels in domestic properties in England - the only nation without a Government-

funded energy efficiency programme for the first time in over 30 years, with delivery of home energy efficiency improvements slowing dramatically as a result³⁷. This has resulted in there currently being little prospect of meeting fuel poverty commitments in England³⁸ and the other UK nations are not on track to meet similar commitments. The Committee on Fuel Poverty (CFP) have estimated the overall cost of meeting national fuel poverty commitments in England. Overall, an investment of £20bn is required to get all (current) fuel poor homes in England to at least an EPC C by 2030³⁹. According to the Committee on Fuel Poverty⁴⁰, the Climate Change Committee (CCC)⁴¹ and think tanks such as Policy Exchange⁴² current resources are less than half of what is required to meet these commitments.

This lack of public funding is in spite of domestic energy consumers predicted to contribute an estimated £14 billion to the Treasury⁴³ this Parliament, £30 billion over 10 years⁴⁴. Just before the last General Election the Treasury raised an additional £500 million pounds creating higher energy bills⁴⁵ and dramatically impacting low income consumers' ability to heat and power their homes and their life chances. These funds can be used to invest in improving national competitiveness by reducing energy demand - many other EU governments⁴⁶ channel many of these resources back to consumers, future-proofing their economies and helping improving national competitiveness by reducing energy demand.

In addition, whilst NEA fully recognises the need to decarbonise and maintain the competitiveness of energy intensive users, we are deeply concerned by the future impacts of exemptions for Energy Intensive Industries from the indirect costs of the Renewables Obligation and Feed-in Tariff Schemes. Without adequately addressing these concerns, the actions proposed will result in a further erosion of the 'polluter pays principle'. Overall we contest there is no need for the burden of policy costs on energy bills to increasingly be shouldered by domestic consumers. These acute concerns are evident as a result of the UK Government moving away from funding compensation via general taxation. We highlight to NIC that financing any Energy Intensive Industry exemptions out of general taxation is significantly less regressive. If this approach is not adjusted, additional costs presented by this new policy will cost fuel poor households in England somewhere between £115 to £185m over the lifetime of the policy and all domestic consumers (again just in England) broadly between £1.1 to £1.7bn. This additional hardship will put a strain on already stretched public resources and services.

Households living off the gas network

The circumstances of some households leave them particularly vulnerable to high energy prices, when low household income is exacerbated by other factors. For example, some households are reliant on more expensive and inefficient sources of space and water heating. Others live in properties where thermal standards of their dwellings cannot easily be improved in a cost-effective manner.

Currently off-gas customers need to pay far more than gas customers in a similar property. This is clearly illustrated in table 1, below. There is an emerging consensus that different policy solutions are required for urban off-gas consumers, many of whom live in flats and use electricity, and rural off-gas consumers, who generally live in houses and rely on heating oil, LPG and solid fuel.

Table 1: Typical space and water heating costs by fuel type			
Fuel type	Heating system	Tariff	Annual cost
House coal	Open fire with back boiler	-	£1,363
Electricity	Storage heating, electric radiators + immersion heater	Economy 7 DD	£1,680
Natural gas	Gas-fired condensing boiler, radiators + hot water cylinder	Single tier DD	£1,061
	Gas-fired boiler, radiators + hot water cylinder		£1,272
Liquid propane gas	LPG-fired condensing boiler, radiators + hot water cylinder	-	£1,560
	LPG-fired boiler, radiators + hot water cylinder		£1,893
Oil kerosene	Oil-fired condensing boiler, radiators + hot water cylinder	-	£729
	Oil-fired boiler, rads + DHW cylinder		£886
Source: Sutherland Comparative Heating Costs, Northern England, January 2016, based on 3-bedroom semi-detached house.			

The impacts of policies on bills will be particularly acute for electricity only customers. CSE's report for the Fuel Poverty Advisory Group (FPAG) and Consumer Focus 'The Hardest Hit: Going beyond the mean' highlighted that, in 2020, consumers with electric heating (11% of all consumers) will be most affected by the cost of Government policies, as well as tending to have lower incomes than those with other forms of heating. These consumers are projected to pay 19% of the total cost of energy policies yet will only receive 7% of the benefits. Currently, only 27% of consumers with electric heating receive some form of benefit from energy policies, compared to 40% of all consumers. The UK Government's own analysis also highlights that whilst policy costs currently represent c.7% (£89) of the household electricity and gas bill; this is set to double to 14% in 2020. The CCC also found that a further £55 would be added to average annual bills from 2013 to 2020, mainly to support investment in low-carbon electricity and a further £75 from 2020 to 2030 due to assumed increases in the carbon price⁴⁷ (as shown in figure 2, below). We are concerned that the Government has not investigated the impact of these policies on the 'fuel poverty gap'. However, the UK Government's most recent fuel poverty statistics do highlight the relationship between increased fuel poverty risk and living in an off-gas property. In particular:

- **The worst properties are more likely to be located off the gas grid:** 70% of F/G rated fuel poor properties (the least energy efficient housing) are off-gas. Over 70% of F/G properties have expensive and hard to treat solid walls and, on average, fuel poor households in F/G properties face an annual fuel poverty gap (the excess amount a fuel poor household needs to spend to keep warm compared to a typical household) of £966 and £1,345 respectively. This is more than triple the average gap across A to D rated properties
- **Off gas households are more likely to be in severe fuel poverty:** because they heat their homes with more expensive fuels, fuel poor households off the gas grid experience, on average, excess fuel costs of £670 per year, more than double the average fuel poverty gap of the on-gas fuel poor (£302). Overall, the Energy and Utilities Alliance (EUA, 2017) estimates that households not connected to the gas grid are 1.5 times more likely to be in fuel poverty than those with a mains gas connection
- **Off-gas properties are more likely to be located in rural areas:** the extent of off-gas properties increases with increased settlement dispersal, with only around 5% of urban areas off-gas (Baker et al., 2008). Fuel poverty is more prevalent in rural locations than urban areas and rural households also face a number of other pressures, including declining service provision and reduced employment opportunities

We provide further information about the demographics of fuel poverty in our previous response to the NIC⁴⁸.

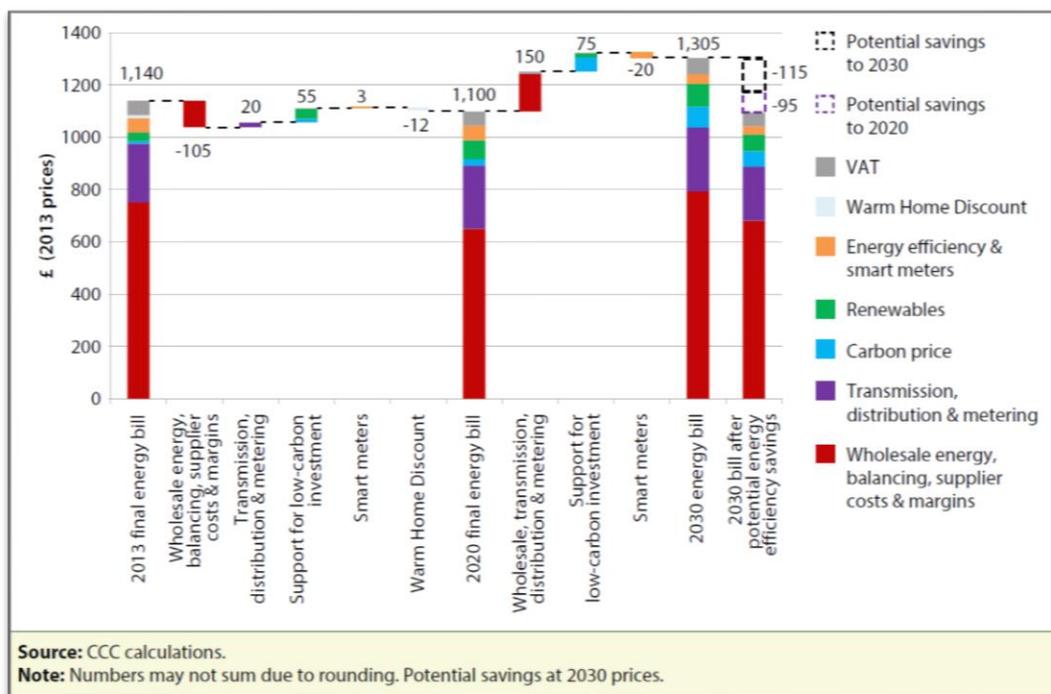

Figure 2: Changes in the typical dual fuel bill, 2013, 2020 and 2030 (reproduced from Committee on Climate Change)

Gas Distribution Networks and their role in helping off gas households

As a result of these issues in off-gas properties, Ofgem has proposed that GDNs will connect 18% more households (91,203 households) to the gas network until 2021 compared to the original GD1 connections target. Whilst in the longer term, a further extension of the gas network may not be compatible with decarbonisation targets, NIC should support the case for assisting GDNs meet the targets out to 2021.

But there is a funding gap which has detrimentally impacted the delivery of gas connections to fuel poor households. Specifically, households eligible for a gas connection under the Fuel Poverty Gas Network Extension Scheme (FPNES) are often not able to access funds that will cover the cost of the gas central heating system. This issue has been raised by GDNs and recognised by Ofgem. For example, the regulator noted stakeholder responses to an August 2014 consultation on the future of FPNES highlighted a 'clear disconnect between the current relevant energy efficiency schemes (ECO and Green Deal) and the Scheme [FPNES]. Specifically, the move to ECO/Green Deal was seen to have had a detrimental impact on the accessibility of in-house funding, especially in England⁴⁹. These concerns are borne out in practice. Following an information request, the four GDNs supplied NEA with data on the number of fuel poor connections completed as part of their RIIO-GD1 targets to date.

	2013/14	'14/15	'15/16	'16/17*	% of target completed
England	7,377	7,638	8,875	6,722	44
Wales	1,440	1,064	882	404	75
Scotland	4,983	3,699	2,616	1,535	75
Great Britain	13,800	12,401	12,373	8,661	52

*Data was collected in December, estimated figures for 2016/17 are up to end November 2016
 Source: NEA calculations based on data provided by GDNs

Table 3 shows that, although GDNs are around halfway to meeting their April 2021 target of 91,203 connections, progress at the regional level is mixed. In particular, connections in Scotland are far ahead of the other nations. With four years remaining to the 2021 target, 75% of the Scottish sub-target of 17,130 connections has been achieved. By contrast, only 44% of connections targeted for England have been completed.

NEA estimates a £43.5 million gap over the ECO transition period. Additional funds are urgently needed for private tenure homes in England and Wales where the majority of connections remain for completion. NEA therefore proposes a £25 million per annum non-gas fund and is pressing for this to be committed by the UK Government in its spring 2017 budget to cover the ECO transition period. These funds should be reserved for first time gas heating systems in non-gas homes which are eligible for connections through FPNES. NEA estimates a £37.5 million fund could support an estimated 9,375 households and deliver up to £142 million in lifetime bill savings. The fund administrator should encourage a whole-house approach to connections through pooling funding and delivery resources across GDNs, suppliers and local partners. Existing work highlights potential exists for the impact of any new funding to be amplified via co-funded initiatives by either local government, private and social landlords; utility companies, electricity network operators as well as other key actors such health agencies, charities and community groups. The exact split of which funds would be available for each GDN area could be based on the current apportionment of the revised targets (see table 4, below) across each GDN area.

GDN	GDN areas								Total	
	England									
	East	London	North West	West Midlands	North East	South	South West	Wales	Scotland	
NGG	12,046	2,880	13,330	8,360						36,616
NGN					14,500					14,500
WWU							12,590			12,590
SGN						10,367			17,130	27,497

This response also draws on NEA's current Technical Innovation Fund. This programme specifically aims to facilitate community-level trials of innovative solutions utilising energy saving measures and approaches not traditionally within the scope of current retrofit or energy saving programmes. Grant recipients from the programme are working to install a range of technologies and work with NEA to ensure that robust monitoring and evaluation takes place. The projects are delivering 1,488 measures, plus further additional measures through match funding. There are 30 technologies being tested using 81 products, providing vulnerable groups with the opportunity to be early adopters of innovative measures. Examples of innovative heating measures being installed include hybrid and ground source heat pumps, district heating, domestic CHP and biomass, new heating control systems, heat stores, battery stores and heat recovery systems. There are also several projects trialling smaller complimentary technologies with the potential to reduce energy consumption or improve comfort. NEA are committed to ensuring the findings of this work feed into the Commission's evidence base for decision making and where relevant this response draws on early learnings, as well as evidence from other programmes and initiatives.

Thermal comfort taking is understood and accounted for in projections

It asserted by some parties that improving the energy efficiency of the homes of low income households has reduced carbon benefits, as these households are likely to take back much of the potential energy savings as extra warmth and hence the carbon savings are less than in the homes of warmer, better-off households. This could, in theory, make interventions less cost effective.

However, whilst it may be true that poorer households may forgo some of the potential energy savings in favour of a warmer internal climate, even within the coldest homes, there are cost effective carbon and monetary savings to be made. Those living in fuel poverty can use the extra money to pay for other essentials, as well as the extra warmth.

Also, the rebound in cold homes also only happens with the first energy efficiency improvements. Once the home has reached a higher level of warmth, there will be less rebound. Government statisticians currently apply a blunt discount in savings in all homes, but we argue that the discount should be weighted towards the least efficient F and G-rated homes, and then at a lower rate thereafter for example when homes are improved to C or better. The rebound effect is less likely to be found in relation to electricity, for instance from more efficient lights and appliances. Finally, there is also less of a rebound, if any, with hot water use, but this has not been properly researched.

It is vital to note, however, that the impacts of such rebound onto the potential for energy savings from energy efficiency in the UK is understood and accounted for in projections.

Key recommendations

We believe that the following action is required:

- I. The National Infrastructure Commission should make energy efficiency a key national infrastructure priority and include it as part of the interim and final National Infrastructure Assessment.
- II. We urge the NIC to highlight the quantum of the shortfall between the level of ambition presented by statutory targets (carbon budgets, fuel poverty targets and minimum energy performance standards in the private rented sector) with current delivery rates and what can be achieved via existing policies to the UK Government.
- III. Given the economic, social and environmental benefits NIC would also press the UK Government to clearly set how statutory fuel poverty commitments in England are to be met and the need for them to be adequately resourced
- IV. An immediate stimulus for the energy efficiency industry would be generated if the Government stated clearly how the worst PRS properties in England and Wales will not be rented out from 2018-2020, in line with national statutory targets and Social housing and HMO properties should be improved to the same national standards as the Private Rented Sector.

- V. In order to monitor ongoing distributional benefits, NIC could urge the UK Government to continue to report on the impact of policy cost on bills each year with a regular timeframe for publication. The Government should also include an estimate of how the overall gross contribution of any energy policies, paid for by energy consumer levies, increases the aggregate and average 'fuel poverty gap' for that year in England. In addition the UK Government should work with the Devolved Nations to assess, and report on, how energy policy costs added to consumer bills impact on fuel poverty levels in NI, Wales and Scotland.
- VI. NIC should recommend that where possible the burden of policy cost on bills should be better balanced between tax payers, electricity and gas customers. In particular, if the Government continues to implement an exemption for Energy Intensive Users from the indirect costs of the Renewables Obligation (RO) and Feed in Tariffs (FiT) schemes these exemptions should be paid for via taxation. This is more progressive as the tax system accounts for differences in income.
- VII. NIC could also recommend HMT should work with HMRC, Ofgem and BEIS so that suppliers do not recover VAT that is currently applied on top of network and/or environmental charges. How levies are recovered is also critical, NIC could also urge for additional relief to be provided for low income energy customers that are reliant on electricity to heat and power their homes as they hardest hit by policy cost on bills and also have the biggest fuel poverty gaps
- VIII. To support first time gas heating systems in homes which are eligible for connection to the gas network through the Fuel Poor Network Extensions scheme, we ask NIC to support our proposal that the UK Government commits to a £25 million per annum non-gas fund in its spring 2017 budget to cover the 18 month ECO transition period.

¹ Please visit www.nea.org.uk

² The UK fuel poverty figures relate to 10% definition published by DECC June 2016. Available at: <https://www.gov.uk/government/collections/fuel-poverty-statistics>.

³ Government has a statutory target to fuel poor households up to an energy rating of band C by 2020. Currently only c. 20,00 fuel poor households are being brought up to band C per year and so we estimate it will take c. 95 years to bring all current fuel poor households up to this level, which would mean the Government could miss their target by 80 years.

⁵ National Infrastructure Assessment, Process and Methodology, Consultation Response, 2016 p. 14

⁶ These opportunities have begun to be responded to in other nations across the UK. The Scottish Government has announced that Scotland's Energy Efficiency Programme will be a "National Infrastructure Priority". This move has been emulated by the Welsh Government and the 'Infrastructure and Wales Investment Plan' which also aims to drive improvements in the energy performance of buildings and tackle fuel poverty.

⁷ In England, the statutory target is to ensure that as many fuel poor homes as is reasonably practicable achieve a minimum energy efficiency rating of Band C, by 2030. This is supported by interim milestones. For more information see Cutting the cost of keeping warm :

A fuel poverty strategy for England, UK Government, March 2015.

⁸ From April 2018, landlords will not be able to rent out properties with energy efficiency ratings below EPC Band E (exemptions apply).

The National Infrastructure Commission call for Evidence

Introduction

The NFU represents 55,000 farm businesses in England and Wales. The NFU welcomes the opportunity of being able to provide evidence which will shape the development of the National Infrastructure Assessment.

Sir John Arnitt said when the call for evidence was announced *'How can infrastructure best support growth, how should we decide what we repair and what we build, and who should pay for it – these are the sorts of big questions we need to answer. That's why the Commission is asking for your views across these and a range of issues as we launch the next stage of our National Infrastructure Assessment.'*

It has been highlighted in the Call for Evidence booklet that *'The Commission will consider the demand and supply of infrastructure services, such as journeys or communication, as well as infrastructure assets, such as roads or fibre optic cables'*. It is further stated that the NIA will be developed by assessing the infrastructure system as a whole using a robust, common methodology to develop needs assessments that take account of strategic cross-sector considerations and resilience implications.

With this in mind the objectives of the National Infrastructure Commission (NIC) are to

- (i) Support sustainable economic growth across all regions of the UK,
- (ii) improve competitiveness and
- (iii) improve quality of life.

Over the last two years a number of nationally important infrastructure schemes have come to the fore with projects going ahead such as the A14 Improvement scheme from Huntingdon to Cambridge, Hinkley Point C Power Station and the proposals for the land take to build HS2 Phase 1. It is clear that farmers and growers are increasingly extremely concerned by the impact of such infrastructure proposals. The concerns are regarding both the land that is to be directly taken to build the infrastructure and the land that is needed to meet all the environmental mitigation requirements that accompany each infrastructure development. Infrastructure in rural areas creates uncertainty as well as the long term damage to farm business livelihoods.

Farmers and growers do though recognise the importance of investing in the nation's infrastructure. This infrastructure is needed to ensure cost effective communication and transfer of goods and services within and beyond our borders and in the long term will help with our national economic growth and competitiveness. But for those in rural areas the practical reality is land being taken out of production for infrastructure, including losing buildings and other fixed equipment and farm diversification projects

NFU Mutual

are being similarly displaced. This risks future farm growth and jobs rather than supporting economic growth in the rural areas. Further, it is hindering rural businesses in being able to improve their competitiveness and is having a negative impact on the quality of life of farmers and their families rather than improving it. Therefore the objectives of the NIA should underlie how governance structures are developed, with the Commission putting in place measures to ensure all projects are 'rural proofed' and can demonstrate how they are benefiting farming and rural communities affected by the proposals.

As an example, HS2 Phase1, the high-speed line will cut through many farms severing land. Some farm businesses will not survive the amount of land that is compulsory purchased and others will have to completely reorganise how they run their businesses in order to survive the impact of scheme. However, they will not benefit from the high-speed train as there are no connecting stations between London and Birmingham.

Further, the NFU has long argued that inadequate Government investment in agricultural infrastructure has undermined our domestic food security and productivity. Investment is needed in reservoirs for water storage for irrigation and rural broadband provision. This includes the removal of planning barriers. Presently infrastructure directly benefitting agriculture does not feature as an area that is being directly looked at by the NIA.

The NIA must look at the impact of infrastructure development in rural areas and on individual rural landowning businesses. There needs to be a balance and the impact of developing and building the infrastructure needs to be reduced so that the impact on rural businesses during construction is minimised. At the present time rural businesses seem to be having to take all the impact from the development of the schemes and then not benefiting in any way from the infrastructure. Infrastructure development needs to be used as a catalyst for getting better infrastructure connections for farmers and rural communities rather than just leading to the blighting of farms.

One of the major infrastructure challenges is the amount of land take required for all infrastructure schemes and it is essential that the Commission must address this. The NFU believes strongly that it is important to treat farmland as part of a critical national business producing our food and not simply as an open space which is automatically available for alternative uses including significant infrastructure projects which are now regularly being brought forward.

As 75% of the UK land area is countryside, it is essential to create a governance structure that takes into account the impact of infrastructure on farmers, farm land and rural businesses and enable them to have a fair deal. Rural areas host around half a million businesses, equivalent to over 25% of all registered businesses in England and 15% of jobs. Unless the resultant assessment addresses these concerns it will potentially leave a productivity gap for farming and rural businesses.

The Rural Productivity Plan made clear the linkages between the National Infrastructure Plan and the need for rural economies to be better connected to the wider economy. However there has been no progress report to date on the Rural Productivity Plan's objectives since they were introduced in August 2015 and the NFU is disappointed that this present Call for Evidence only appears to contain one reference to 'rural' (in a transport planning context).

The NFU has been lobbying on the areas that are being covered by the NIA for a number of years. In the NFU's 2015 Manifesto we specifically asked for Government departments to act together in recognising the importance of agriculture and food production. This places greater emphasis on 'rural-proofing' of all legislation and across all government departments.

The NFU would like to see a major review of the statutory compensation arrangements for nationally important infrastructure projects (e.g. HS2, HS3, A14 widening, A303 Stonehenge, National Grid Richborough Connection and the North West Coast Connection). All of these schemes are compulsory purchasing land and the infrastructure will affect farming practices and operations on a daily basis. The aim has to be for fairer and swifter compensation for property lost. It is going to become more and more

NFU supported by

difficult for landowners to find land to purchase and replace land taken for infrastructure. The value of land around any development will be inflated due to increased demand and so simply valuing land at market value is not enabling a landowner to be no worse off in financial terms after acquisition. In short the principal of equivalence is not working in practice and is failing farm businesses.

Summary of Asks

Summary of particular asks to NIA include:

- To treat farmland as part of a critical national business producing our food and not simply as an open space
- Reduce the impact on farmers from infrastructure development and reduce long term blight
- Farm businesses are being impacted the most by national infrastructure projects but are often less likely to directly benefit leading to a social imbalance
- Review statutory compensation arrangements for compulsory purchase so that equivalence can be achieved – the realisation of how difficult it will be for farm businesses to replace land taken
- The unacceptable undervaluing of farmland and farm businesses over habitat mitigation
- To finding a balance for environmental mitigation which is sustainable
- Increase on-farm water storage and reservoir building with financial support and tax incentives and by reducing red tape for reservoir applications.
- Accelerated rollout of high-speed broadband to all rural areas to provide universal coverage equivalent to urban areas and this to include mobile coverage
- Landowners to be fairly compensated for infrastructure to enable high speed broadband and mobile coverage
- Ensure that planning rules enable farmers and farm enterprises to compete and grow with expanding potential markets and conform with regulatory requirements.
- The need for detail design of projects to be carried out earlier in the process of a DCO application
- The need for early engagement in the design process – farmers often see the important detail far too late in the process
- The lack of proper consideration given in design for the practical functioning of farm businesses
- Environmental Impact Assessments must consider more accurately the effect of land take and loss of buildings on the viability of farm businesses
- Ensure that Defra's reform of the water abstraction licensing regime delivers an adequate supply of water to meet the increasing demand for UK-grown foods such as fruit and vegetables.
- Establish with industry a cross-Government land-based renewable energy strategy utilising anaerobic digestion, biofuels, biomass, by-products, solar and wind.
- Greater consistency in low-carbon energy policy across incentives, planning, grid access and energy storage.

The NFU has responded to the particular questions raised as follows:

Cross-cutting issues:

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time.

The planning system works best when it engages with those communities effectively and provides them with relevant and up to date information and certainty as to when development is to be delivered. If the National Infrastructure Commission develops a plan solely for the benefit of business and people living in urban areas and providing infrastructure for their benefit, then it will perpetuate inequality in rural areas and fail to meet its stated objectives.

The NFU has no objection in principle to the continued use of the Planning Inspectorate to determine national infrastructure projects, but believes there needs to be more upfront meetings and discussions

NFU supported by

between the developer and landowner who is to have land compulsorily purchased prior to the application being submitted for a DCO. This is to allow fuller an understanding of how projects are going to be developed. In some cases such early engagement can reduce the impact on the farming business because it is early enough in the process to slightly change the line/route of the proposed scheme. From our experience, changes to the design can only be accommodated by engineers if consulted at very early stages of the design process.

It is clear to the NFU from their involvement in Development Consent Order (DCO) process for Nationally Significant Infrastructure Projects that developers are often submitting applications for a DCO before they have even designed the scheme to a satisfactory stage to be able to provide the necessary design information to landowners. Even now landowners are waiting to receive the final design of the A14 between Huntingdon and Cambridge when the examination of the application took place in the summer of 2015. The NFU believes that the Planning Inspectorate must look more closely at how developed the design is of the project before accepting applications. Presently when landowners are asking for design details and plans these cannot be given by the developer and the response is always that the final design has not been carried out. Farmers are having land compulsorily purchased from them without actually knowing how the development will finally affect them because design is not completed within the examination window. The Planning Inspectorate therefore needs to be involved at an early stage to ensure parameters are established and achieved before applications are accepted.

The parameters for valuing farmland exist in the National Planning Policy Framework, but there needs to be a more informed view of farm businesses taking into account the need to accommodate valuable land for agricultural use, homes and other rural businesses and services. 61% of farms contain diversified farming activities, with this trend expected to increase. Environmental Impact Assessments (EIA) are slowly improving as the impact on agricultural land and soils is considered, but the EIAs still never highlight the rural jobs that will be lost due to the land and buildings that may be taken for the scheme. As a result the impact on farm businesses is constantly underestimated.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The NFU agrees that it is critical that infrastructure should protect the natural environment and that habitat mitigation planning is a crucial part of any development scheme. But as the NFU has stated over many years in regard to land take for mitigation on HS2 Phase1, where land take required for mitigation has been highlighted in multiples compared to the land lost for the development. This is amplifying agricultural land taken out of production and with no guarantees on environmental success.

The NFU believes that the area of environmental land lost should be replaced with like for like and that it is the quality and management of proposed environmental mitigation is the most important aspect. This will then lead to an enhancement of the natural environment. The NFU strongly disagrees with the suggestion made by Natural England in regard to ancient woodland that for any one hectare of area lost should be replaced with 30 hectares of new planting.

A balance has to be achieved especially when considering the infrastructure that is in the pipeline and will be coming forward for development in the next 5 years. The proposals that have been outlined for environmental mitigation are not sustainable in the future in a country of our size.

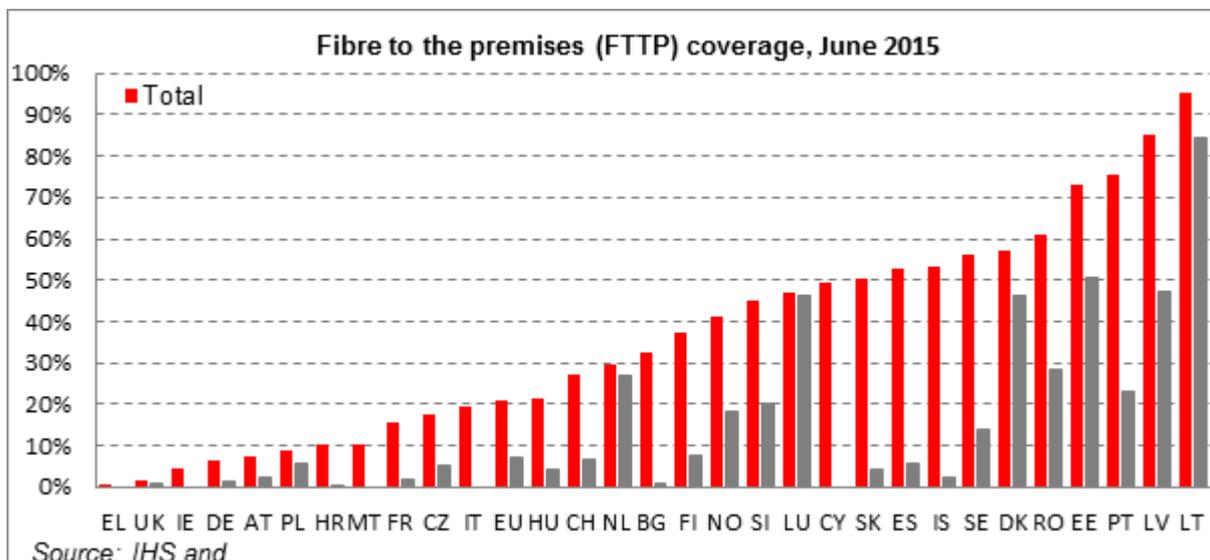

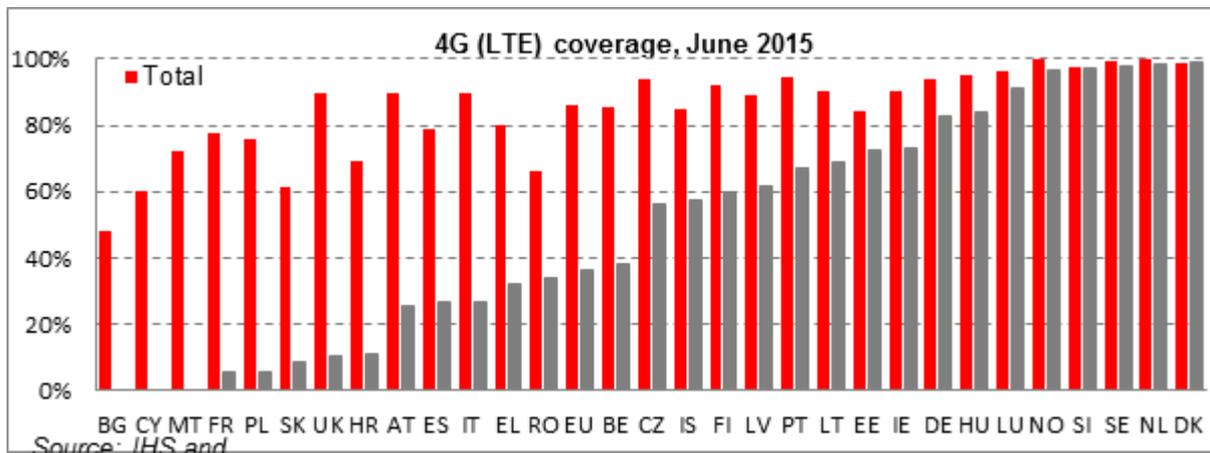

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

The National Infrastructure Assessment has to contribute to the completion of the UK digital network and ensure that future proofed connectivity is available that works across all geographical areas and is accessible by all those who want to use it.

The NFU is not clear what the commission means by *taking into consideration the inherent uncertainty in predicting long-term technology trends*, as Government action by other arguably more forward thinking nations is actually driving such trends. South Korea and China already has 5G technology developed, due their national policy objectives driving technological advance. America and Germany are already advancing their technological needs.

As the graphs below show, the UK is falling behind two key technologies. For fourth generation (4G) and full fibre coverage, especially for rural area (grey columns), the UK urgently needs to develop an integrated strategy if it is going to be relying on them. The National Infrastructure Commission should play a key part in this delivery.

The NFU would stress that the National Infrastructure Commission should make the link at all times between mobile and fixed broadband services and that it ensures that any assessment strategy ensures delivery is complementary and maximises service coverage. This is an area where the UK could excel and deliver more market friendly conditions for farmers and rural businesses, which would ultimately benefit everyone. Connectivity is increasingly expected to be a universal requirement and not one that should stop when someone leaves an urban area or a motorway.

The NFU do not favour any specific technology and recognise that full fibre is only one solution for broadband connectivity and one which has not really been promoted in rural areas, where most farmers still rely on copper connections. When it is offered to farmers (largely without Government incentive) it is prohibitively expensive. Hence there is a concern that full fibre may not deliver full connectivity. It could be used where technically viable or could provide part of the solution when used with other technologies targeting rural coverage. Any assessment needs to work on the premise of incentivising the provision of such technology for farmers and rural communities (such as through wider infrastructure projects) and measure actual delivery on the ground. Access to backhaul services will be important for all technologies used.

There are limitations on accessing digital services via 4G currently due to speed, cost and atmospheric conditions as well as to the availability of the signal due to other market demands. NFU members have reported a reduction in voice signal quality and coverage when 4G has replaced 2G services. It is likely that there will continue to be significant rural gaps in 4G coverage, even if the 90% coverage targets the mobile operators have signed up are reached (95% possibly for EE). Given how the technology is providing an alternative form of communication for farmers across their land holdings, the NFU would welcome positive action to provide resilient broadband and mobile coverage and close the gaps which still exist following the closure of the Mobile Infrastructure Project. We know that the Emergency Services Network being rolled out by EE may offer some opportunity for improved coverage, but understand that it is being delivered primarily for emergency services use. Current issues with the roll out 4G technology should provide lessons about future spectrum releases and in particular how 5G services can be delivered in rural areas.

There are also many different examples of how broadband is being provided across rural areas internationally, the main difference being that other countries are not so reliant on full fibre for connections and are using different technology models and incentives. [HD mesh radio technology](#) has been used to serve communities as remote and mountainous as Hawaii, whilst closer to home [White Space](#) spectrum has been re-used to serve remote areas in Scotland and Wales, with academic research happening in Glasgow.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing “regime” refers to the current market, competition and planning frameworks. “Digital communications” includes both fixed and mobile connectivity.

It will be critical for digital infrastructure to be in place for UK farm businesses and indeed rural businesses if they are going to be progressive, profitable and crucially be able to compete in future world markets. Farmers and growers also need fair deals and practical agreements that allow them to host infrastructure and continue to farm. Market failure will be perpetuated if the National Infrastructure Assessment does not deliver workable solutions that benefit all parties.

Currently there is a major issue of rural market failure with digital communications that needs to be urgently addressed. There is widespread evidence that the existing communication regime is not going to deliver, without positive and accelerated Government intervention and the National Infrastructure Commission needs to ensure this is promoted.

NFU [member evidence](#) of over 800 farmers and growers in 2015 and 2016 confirms the vast majority of NFU members have sub 2Mbps upload and download speed, with only a few percent having speeds in excess of 24Mbps. This is a workforce of 464,000 people serving a wider food and farming sector worth £108 billion in 2016 without adequate digital connectivity and no government programme in place to address this.

With the implementation of the Access to Infrastructure Regulations, telecommunications providers can now gain access to physical infrastructure across different sectors (such as electricity, water and transport services, as well as the telecommunications sector itself). This is an area where the National Infrastructure Commission could make a real difference. There are major projects being proposed throughout the UK to deliver housing, energy infrastructure, road and rail links which cross through farmland and which could include ducts and physical access points for farmers. This should be a prerequisite of every major project and something that could be easily evaluated for success.

The EU set out [ambitious new targets](#) to achieve universal ultrafast broadband coverage (measured at 100Mbps by 2025) with the European Commission and European Investment Bank announcing a fund for broadband infrastructure to invest in infrastructure across underserved areas of Europe. The EU is exploring a range of technologies to achieve this, which the National Infrastructure Commission also needs to ensure are fully explored and exploited. There needs to be support for 5G specifically focused on farming businesses.

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Decarbonising heat is an important subject area, since non-domestic buildings (including farm buildings) are responsible for a significant fraction of national energy use and GHG emissions. Farmers account for around 30% of the uptake of the non-domestic Renewable Heat Incentive (RHI) scheme so far, and biomass heating has been the most successful low-carbon technology, accounting for about 95% of both installation numbers and capacity. Recent cuts to RHI support for biomass boilers is not going to increase uptake of electric heat pumps, since the two technologies occupy different market niches and are rarely in direct competition.

Longer-term decisions about future heat supply and its infrastructure need to be made urgently. The Government does not appear to have identified the UK's likely sources of low-carbon heat beyond 2020. Alternatives to the current reliance on natural gas need to be deployed across the domestic, commercial and industrial sectors, at a rate much faster than current buildings and capital assets can be upgraded. This suggests that technologies best-suited to energy-efficient building envelopes and processes (such as heat pumps) will not be sufficient. Making better use of the gas pipeline network, replacing fossil natural gas with biomethane from AD, biomass-derived synthetic natural gas and hydrogen from power-to-gas plants, is one likely alternative. Much greater investment in local district heat networks (both urban and rural) will also be required.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the "zero carbon power sector" includes the generation, transmission and distribution processes.

The NFU agrees with other independent authorities that the UK power sector is most likely to be decarbonised before other parts of the economy. We believe that technological advances and falling costs are already becoming more important than clean energy incentives as drivers of economic decision-making for investors in a wide range of clean energy options. By the 2030s, we would expect the lowest-cost sources of clean electricity to be solar PV and onshore wind generation, followed by offshore wind power, with high levels of system integration enabled by batteries and other forms of electricity storage (which are also rapidly falling in cost).

Large dedicated biomass power plants and smaller biomass CHP plants are also expected to play a continued role in 'despatchable' power generation towards 2050, and may be coupled to CCS (carbon

capture and storage) in the future to deliver cost-effective carbon-negative energy services - supplemented by other novel technologies like tidal stream and tidal lagoon power.

Clear, consistent, long-term policy signals, a level playing field (free from fossil fuel subsidies) and carbon pricing will all be needed to maintain investor confidence in the transition to a zero carbon or carbon-negative power sector by mid-century.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The NFU agrees with the Department for Transport's assessment that, although sales of light electric and plug-in vehicles are growing rapidly now, their use of renewable electricity is likely to contribute little more than 1% of transport energy use by 2020 - leaving biofuels as the most practicable and deployable form of renewable transport energy for the near future.

In the longer term, we expect the likely introduction of diesel-electric hybrid and battery electric transmissions in a range of tractors and other agricultural vehicles may create an opportunity for 'smart' charging of such vehicles in large solar PV roofed 'carport-style' machinery sheds. In order to limit the impact of electric vehicle charging on weak rural electricity networks, the Government should consider how to support and incentivise such innovation, in our sector and in other industries.

In addition to having access to low-cost solar charging, the NFU anticipates that the battery packs in such vehicles may also be able to earn income towards their recharging and maintenance costs by providing 'vehicle-to-grid' network balancing services while they are on-charge.

Water and Wastewater (drainage and sewerage):

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Farmers rely on directly abstracted freshwater for cooling, washing, incorporating into products and growing crops. In England and Wales, farmers and growers use less than 2% of total water abstracted, so the current water allocation for food production is minor compared to the public supply and energy sectors.

Nevertheless, global climate change means that the UK will need to increase its home food and water security to offset potential disruption of food imports from countries that face even more extreme weather events than us.

We hope that the National Infrastructure Commission will acknowledge the needs of 'water for food production' in its analysis and in the development of its future plans, both for individual farm businesses and the agricultural sector as a whole.

Global climate change means that the UK will need to increase its home food and water security to offset potential disruption of food imports from countries that face even more extreme weather events than us.

In agriculture there is an increasing focus on the installation of farm reservoirs to secure water supplies for crop irrigation. However, it is unlikely that individual farm businesses will be able to make sufficient provision for two and three year dry winters, and multi-sector projects may come to the fore in future.

In our view, there should be a focus on those parts of the country (predominantly the south and east) where we face the greatest challenges to balancing water supply and demand in the future.

The NFU is keen for farmers and other businesses to improve their resilience by working with water companies. For example, Water Resources East (WRE) has brought together water companies, farmers, the energy sector and others to find ways to improve water resilience over the long-term.

The NFU believes that it will be important to find ways of allowing public water companies to develop new water resources; and aligned with additional storage capacity it will be important to use surplus capacity in ways that could also benefit farmers and other businesses.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand? *Note: this can include, but is not necessarily limited to, governance frameworks across the country.*

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

We favour a catchment approach which focuses on the greater involvement of all stakeholders in local water governance. We prefer the introduction of a programme to deliver the infrastructure that works on a catchment-by-catchment basis. This approach means that progress on implementation would be consistent with better understanding of the catchment and reacting to the local needs of users and the environment.

By identifying local areas and regions with different priorities for activity, a 'bottom up' process of engaging local stakeholders could emerge that could make effective links in co-ordinating the provision of new infrastructure with complimentary programmes on, for example, water demand management

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

It is essential that the expectations of the general public is managed as it will never be possible to completely protect anywhere from flooding. There must be greater communication that the more extreme and unpredictable weather patterns that we have experienced in the past few years are the greatest driver of changes in flood risk. The Met Office's 2014 state of UK climate report showed that we are not necessarily seeing an increase in total precipitation levels, but a move towards shorter, more intense rainfall events. To illustrate this point, 2014 saw the highest number of days ever recorded with rainfall above 1cm.

In order to balance the costs of any flood risk scheme against the value of assets it protects, it is first essential to ensure that all areas are properly valued. Currently all agricultural land is given a value for wheat in flood risk appraisals, the most prevalent crop in the UK. This does not reflect the true value of many higher value crops, such as horticultural crops, and our most productive land is predominantly situated in the floodplain, or along the East Coast which is liable to surge events.

A discounted value to agricultural land is also applied in flood risk appraisals. Currently the equivalent of 10 years' worth of direct support payment under CAP is removed for the value of land. Yet land can

become ineligible for CAP funding if frequently flooded and post-Brexit, there is no certainty as to the level of direct support payment farmers will receive.

Current appraisals also don't take into consideration that agricultural land is the conveyor of infrastructure which adjacent urban areas are dependent upon. Furthermore no value is added for the environment and ecosystems services the industry provides. Therefore, we believe reviewing the values of land and other assets is essential in answering the question of the level of flood resilience we should aim for in this country.

We believe it is essential when talking about future flood resilience that both rural and urban communities are considered. We note that the Government's 2016 National Flood Resilience Review made no mention to agriculture, food security and negligible reference to rural communities.

To improve urban and rural resilience, sustainable urban drainage systems (SuDS) should be installed which are able to store and slow the flow of runoff from newly created or altered impermeable surfaces, irrespective of its size or location in respect to the main river channel. The design and capacity of SuDS should consider precipitation levels now and those predicted for the future. In particular they should consider the shorter, more intense rainfall patterns we have mentioned above.

Greater clarity should also be placed on who is responsible for the maintenance of SuDS, as well as the ability to go back and retrofit or amend if it becomes apparent the current system is not sufficient in reducing impact to downstream flow regimes.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

Natural flood management techniques, in the right location, can have their place, but they **are not the universal panacea** and should only be used as part of a cohesive and carefully planned package of measures, such as maintenance and de-silting, looking at upstream attenuation and downstream conveyance to address shorter and longer term flood risk.

We have concerns that some schemes over-emphasise the contribution NFM techniques have in increasing the resilience of downstream people, property and infrastructure from flooding. For example, the c.100 woody debris dams in Pickering have the ability to accumulatively hold about 10,000m³ of water. In comparison the engineered dam built upstream of Pickering can hold 130,000m³ of water. As such 90-95% of the flood mitigation service from Pickering comes from the engineered dam, rather than from natural flood risk measures.

The evidence base for the relative ability for NFM to mitigate flooding events is still developing. As an example, the NFU sits on a working group with the Centre for Ecology and Hydrology which is undertaking a systematic review of all literature into how tree planting affects river flow regimes. Early results from this work show that there is relatively little observed evidence of changes in river flow regime caused by the implementation of NFM schemes, but there is a lot using modelling software.

Overall, NFM options have an important role to play in the flood risk management of a whole catchment, but we believe there is strong evidence that NFM is not a panacea solution. There is scope to trial NFM schemes further in larger catchments, but NFM will not in itself prevent extreme rainfall events which we have experienced at a greater frequency over the last few years.

NFM uptake is also limited because the schemes often do not meet cost-benefit ratios required to

receive central government flood defence grant in aid funding. This is primarily because it is difficult to measure the changes in flow regime they provide. Furthermore there are many regulatory hurdles to cross, such as works in rivers consents, planning permission and Environmental Impact Assessments. These barriers will need to be addressed to enable wider implementation.

Solid Waste:

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Our primary preference would be to follow the waste hierarchy when making waste/circular economy decisions. However these decisions, whether backed up by financial incentives or not need to be evidence based. Ideally with a cost-benefit analysis and an environmental impact assessment/life-cycle assessment alongside.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

The creation of waste and the requirement to dispose of it safely and responsibly is unavoidable to the agricultural sector. Barriers to a more circular economy include lack of facilities to recycle and dispose of agricultural waste locally leading to illegal waste operators targeting the agricultural sector. The rural nature of farming can mean it is often not cost-effective for collection service to operate, however alternative options must be created. The breadth of waste produced on farm can also be challenging which includes domestic waste/hazardous waste/flytipped material/medical and chemical waste. This needs to be addressed as part of the infrastructure challenge.

Utilisation of waste products on-farm through technologies such as anaerobic digestion, biomass boilers, recycling waste to land for agricultural benefit, the use of co-products into animal feed. This forms a significant impact on the circular economy and greater prioritisation needs to be given to these outlets and technologies.

Reducing food waste – this can often be caused by dysfunctional supply chains. Greater food waste reduction could be achieved by the supply chain becoming more integrated to prevent losses. Improvement in infrastructure could improve this situation, for example improving forecast systems used by retailers and processors as this would provide farmers with the ability to undertake important business decisions such as the area of land to rent and the volume of seed to plant

National Grid response to the National Infrastructure Assessment call for evidence.

About National Grid

1. National Grid is the owner of the high-voltage electricity transmission system in England and Wales, and the owner and operator of the national gas transmission system across Great Britain. As the System Operator (SO), for both gas and electricity in Great Britain, we are responsible for balancing supply and demand in the short term for the whole transmission system.

2. We welcome and support the call for evidence. This submission highlights the considerations we believe the National Infrastructure Commission should take account of when producing respective plans for the National Infrastructure Assessment.

Executive Summary

1. The sources of power are moving from large centralised, conventional power stations to decentralised, renewable sources. Therefore, when designing and planning infrastructure, it is important to focus on the system as a whole, rather than on its component parts. For the most appropriate energy solutions to be developed, a macro view of the energy network must be taken. By taking a whole system approach infrastructure can be built in the right place at the right time.
2. Advances in technology are transforming how we consume energy. Policy makers must create an environment that allows consumers transparency over their energy consumption, and the ability to benefit from demand management and smart technology. Smart metering and time of use tariffs can increase the potential for demand management.
3. We also believe that demand management will play an important role in meeting the challenge of delivering energy affordably and sustainably, and will reduce the need for investment both in generation and networks. We are at the forefront of enabling greater demand side participation in the energy market, through our Power Responsive Campaign. We believe that the full value of a smarter, flexible energy system (including electricity, gas, heat and transport) can only be realised with sufficient investment, innovation and necessary market reforms. However, there are unintended consequences of demand management. A uniform demand profile can create additional stresses on infrastructure that was designed to accommodate peak loads. Therefore infrastructure reinforcements may be required to accommodate the transition to a more flexible network.
4. We recognise the importance of the Planning Act 2008 in the development of infrastructure projects. The process of statutory consultation, the acceptance and scrutiny of applications by the Examining Authority and the role that the Secretary of State plays in making a decision provides a clear pathway for developers to follow. However, we believe that Ofgem should take account of the scrutiny that this process affords. The consultation process and the subsequent evidence that this provides demonstrates how regulated businesses are developing major infrastructure projects in an economic and efficient manner.
5. Greater confidence of demand, over a period of at least ten years, would enable planning of the network in the short and medium term to be much more economic and efficient, and would reduce any potential for over/under investment. Incentivising generators to build in optimal locations and at optimal times would introduce more certainty to the industry. It would enable network investment with a guarantee that generation would be built where it is required.

6. We believe there is no simple whole energy system solution for the decarbonisation of heat. It is likely that there will be a patchwork of solutions. Whilst renewable generation, such as wind and solar and the electrification of heat will be important in reducing carbon emissions, gas will continue to play an important part. Further work is required to determine how best heat is decarbonised.
7. To deliver a zero carbon power sector, regulations and incentives would be needed to support the green ambition along with high levels of environmental legislation and punitive taxes for carbon-intensive technologies.

NIA Cross-cutting issues:

How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

We are in the midst of an energy revolution. The economic landscape, developments in technology and consumer behaviour are changing at an unprecedented rate, creating more opportunities than ever for our industry. As we move away from the historical reliance on large thermal power generation, towards a more flexible diverse and smarter system, the need to design plan and deliver infrastructure needs to take into account this shift.

We have a key role in securing our energy future. There are some important choices to make about priorities for investment and focus for innovation in order to provide long-term value for consumers and to ensure we continue to meet their needs. Both gas and electricity can continue to play a key role in the UK's energy mix out to 2050 and beyond, enabling us to meet our carbon emissions target in an affordable way .

When designing and planning infrastructure, it is important that we focus on the system as a whole, rather than on its component parts. This will ensure robust and adaptable solutions for the future are developed. We welcome that the National Infrastructure Commission is following that approach, by considering cross cutting issues when compiling the National Infrastructure Assessment. Our view is that infrastructure development cannot take place in isolation, and must give consideration to the wider implications on other sectors. Energy is at the heart of this, and is inextricably linked to both housing and transport infrastructure. One should not be planned and designed without considering the other.

In understanding how energy infrastructure should be designed, planned and delivered, it is important to firstly reiterate the processes in place today. As part of an annual electricity planning cycle, the System Operator (SO) performs an assessment of the transmission network requirements, to identify where the transmission system requires reinforcement or new investment. From this, the SO reveals information to the three GB Transmission Owners (TO's) via a series of publications, starting with the Electricity Ten Year Statement (ETYS). The Future Energy Scenarios (FES) is then published to set out credible scenarios for the future. Finally, the Network Options Assessment (NOA) recommends which large network projects the TO's should invest in over the coming year. These recommendations safeguard the GB electricity network, making sure projects are delivered only if absolutely necessary and at the optimum time.

With onshore competition being introduced, the SO will provide the investment signals and options to a larger group of market participants. The SO will indicate where necessary developments or reinforcements are required to deliver enduring energy infrastructure. This allows the TOs to identify, plan, and design efficient solutions, and provides opportunity for them to apply their experience and innovation to secure additional value for UK consumers. This means that the range of different futures provided by the FES, allows infrastructure providers to deliver a range of long-term outcomes in the interests of the consumer.

We support a NOA that ensures the costs of building new infrastructure are appropriately balanced against the costs of a no-build solution. We see there is benefit to consumers from keeping infrastructure investment options open.

What is the maximum potential for demand management, recognising behavioural constraints and rebound effects? Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

The move to a low carbon economy coupled with rapid advances in technology and innovation are transforming our electricity supply. Emerging is a network of low carbon and renewable energy. But supply is only half the story. The challenge now is to exploit new opportunities to radically evolve our energy system by changing the way we use electricity.

Demand side response is intelligent energy usage. By knowing when to increase, decrease or shift their electricity consumption, businesses and consumers will save on total energy costs and can reduce their carbon footprints. It is the smart way to create new and efficient patterns of demand.

Our Power Responsive campaign goes some way to publicise the benefits of demand side response. Power Responsive is a collaborative approach to turn debate into action and realise the possibilities created by demand side solutions. It is a practical platform to galvanise businesses, suppliers, policy makers and others to seize the opportunity to shape the growth of demand side response collaboratively, and deliver it in practice at scale by 2020. There are many case studies demonstrating where we've worked with large retailers, manufacturers and the public sector as part of our power responsive campaign. <http://powerresponsive.com/case-studies/>

Demand flexibility covers a broad range of activities that can be undertaken to reduce or shift demand for electricity during peak periods, including the adjustment of consumption of electrical appliances or other facilities or deploying off grid sources of power. Demand flexibility can allow consumers and businesses to change how they use their electricity. Deploying automated systems to reduce consumption at times of high demand and increase it at low demand will allow users to save money and cut emissions without inconvenience. In addition, demand flexibility can support the integration of low carbon generation such as wind, solar or nuclear. Flexibility in how we consume energy lowers the need for flexibility in supply.

There is growing recognition of the important role that demand side flexibility can play in electricity markets. It reduces the need for new conventional generation and network infrastructure; supports the integration of growing intermittent generation; and helps suppliers to manage market risk.

Policy makers and the energy sector envisage that the scale and value of demand side flexibility is likely to grow in the future. BEIS and Ofgem recently released a joint call for evidence on a smart, flexible, energy system. Our own equivalent internal analysis shows increasing flexibility (interconnection, storage and DSR) could deliver up to £2bn of consumer value per year by 2030 and we have set an aspiration for 30–50% of balancing capability from demand side sources by 2020. The National Infrastructure Commission estimated that ‘smart power’ – interconnection, storage and flexible demand – could save consumers up to £8bn a year by 2030; and the Association for Decentralised Energy estimates potential for demand side response of 9.8 GW by 2020.

We believe that Government should provide the right arrangements to enable Smart tariffs to be created. Energy suppliers should be allowed to define these Smart tariffs with an element of freedom, to foster competition and provide benefit to the consumer.

Consumers will benefit from competitive pressure, and consumers will need appropriate (e.g. web portals, In House Display) to understand the impact of new tariffs on their energy bills. Consumers who are not flexible and those who are vulnerable will also need to be protected

In understanding the maximum potential for demand management, it is also important to understand that the existing infrastructure must be considered. With the majority of the electrical transmission infrastructure being designed and installed around the electricity demands of the 1950's and 1960's, the ambition to have increasing levels of demand flexibility must consider the system in which it is being applied to.

Demand management aspires to fundamentally flatten the demand profile, and eradicate unnecessary swings on the electricity system. A flatter, more predictable, load profile allows assets to be managed more efficiently, presenting benefits for the consumer. However, the uniformity of this demand profile can also create additional stresses on infrastructure that was designed to accommodate for time-based swings, and results in the equipment and components being operated closer to its engineering tolerances and thermal constraints. In some cases, the infrastructure reinforcements required to accommodate for the impacts of this could result in increased levels of investment in transmission infrastructure.

It is important to emphasise that we welcome flexibility of both increased connection and demand management. However, given our unique position in the energy market, we are also cognisant of the unintended consequences highlighted above. To this end we would welcome the opportunity to discuss further with the National Infrastructure Commission over the coming months.

How should maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Asset management is a fundamental technique to obtain the most value from a diverse portfolio of assets. It ensures maintenance and repair activities can be effectively balanced against the need to build new assets.

It is possible to determine the optimal time to carry out maintenance activities by having a thorough understanding of an asset. This reduces the risk of failure or the need to carry out a repair. However, in cases where maintenance or repair is not possible or cost effective, the construction of new assets may be required.

As we transition to a more flexible energy system, there is opportunity to balance maintenance and repair of existing assets against new build to meet changing demands. Alternative energy sources and system flexibility can allow, or even restrict, planned outages on the network.

By having an industry wide understanding of asset management, in line with ISO55000 and PAS55, and by looking at the network as a whole, rather than at a single asset, there is a greater ability to understand the net cost of carrying out maintenance versus upgrading or building a new asset.

What changes could be made to the planning system and infrastructure governance requirements?

The Development Consent Order (DCO) was introduced as part of the Planning Act 2008. The legislation set out to simplify and speed up the means of obtaining permission for developments categorised as Nationally Significant Infrastructure Projects (NSIP).

This process requires considerable consultation and engagement with a wide range of stakeholders, including statutory bodies as well as the communities affected by the delivery of a development. The feedback of this engagement shapes the application, which is submitted to the Planning Inspectorate and Secretary of State for determination. We also have to obtain approval from our economic regulator Ofgem in respect of the funding of the development and construction of the project, as they determine whether our plans are economic and efficient.

The significant engagement we undertake through the DCO process could direct us to minimise the impact on the visual landscape. In areas that have the highest level of protection under the planning framework we may be required to bury our infrastructure underground. Whilst this will not be the lowest cost solution it may be necessary to allow us to obtain the appropriate planning consent from the Planning Inspectorate and Secretary of State.

We believe that Ofgem should take account of the scrutiny that this process affords. The consultation process and the subsequent evidence that this provides demonstrates how regulated businesses are developing major infrastructure projects in an economic and efficient manner.

What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Cost benefit analysis would more accurate if there were certainty over future capital costs, delivery times and energy policy. We attempt to lessen this ambiguity through our Future Energy Scenarios (FES), which we use alongside other market data to recommend reinforcements on the network for the Transmission Owner to build.

Greater confidence of demand, over a period of at least ten years, would enable planning of the network in the short and medium term to be much more economic and efficient, and would reduce any potential for over/under investment.

Incentivising generators to build in optimal locations and at optimal times would introduce more certainty to the industry. It would enable network investment with a guarantee that generation would be built where it is required.

Better knowledge of demand profiles obtained from smart meters would improve forecasting and result in more accurate cost benefit analysis. Similarly, greater visibility of behind the meter generation would also provide clarity to enable recommendations for future reinforcements or new build.

NIA Energy specific questions:

What is the highest value solution for decarbonising heat, for both the domestic and commercial consumers?

The decarbonisation of heat is a significant challenge and will require a mix of carbon reduction solutions, where both gas and electricity play a part.

DECC's (sic) 2013 Heat Strategy set out a roadmap that envisaged almost full electrification of heating by 2050. This was based on consumers using heat pumps and heat networks along with a small amount of gas. The industry raised many issues with these proposals due to:

- the huge investment required to increase GB's electricity infrastructure (a recent KPMG study showed a total cost of £274-318bn, costing consumers two and a half to three times more than keeping gas in a decarbonised system);
- challenges associated with heat pumps in the forms of installation disruption, size and high buildings efficiency requirements; and
- gas currently delivers around five times more peak demand in winter than electricity. And electricity alone is unable to meet GB's peak winter heating needs based on predicted capacity levels.

Contrary to the 2013 Strategy, there is a growing consensus among industry and academics that gas can continue to play a significant role in the UK's energy mix out to 2050 and beyond. This would enable us to meet our carbon targets in the most cost-effective way. Gas is seen as a fast and flexible fuel that fits in with people's lifestyles. Eight out of ten UK households currently use gas to heat their homes, and in 2015 gas produced more of the UK's electricity than any other fuel. We already have the network infrastructure to supply gas. Our transmission network comprises approximately 7,660km (4,760m) of high pressure pipe and 24 compressor stations, and it makes a great deal of sense for household and business consumers to continue to make use of these assets.

We believe there is no simple whole energy system solution for the decarbonisation of heat. It is likely that there will need to be a patchwork of solutions best suited to local areas and regions, with decisions made at both a national and local government level. The key options include renewable gas, hydrogen, carbon capture and storage (CCS), heat pumps, heat networks and energy efficiency. More work should be done to explore the viability and potential for each of these, and to understand the comparative costs and benefits. Recent reports have stated that the costs of achieving the 2050 carbon emissions target could be 50-100% higher without CCS, but demonstration projects are needed to prove the technology at commercial scale in the UK. The Government needs to provide a clear policy framework and strategy to incentivise investment in innovation and keep options open by taking incremental steps as technologies mature. Consumers need to be at the heart of any decisions to ensure that heat continues to be supplied reliably in the most affordable way.

What does the most effective zero carbon power sector look like in 2050?

Our Future Energy Scenarios set out credible examples of what the power sector could look like in the future. The Gone Green scenario is a world where policy interventions and innovation are both ambitious and effective in reducing greenhouse gas emissions. The focus on long-term environmental goals, high levels of prosperity and advanced European harmonisation ensure that the 2050 carbon reduction target is achieved. In Gone Green, policy interventions are a driving force behind realising a renewable, low carbon world.

Regulations and incentives are in place to support the green ambition and are effective, resulting in high taxes for carbon-intensive technologies. Funding is available to support innovation in green technologies such as renewable generation and low carbon heating systems and high levels of environmental legislation are in place.

In the building and transport sectors there is fast progress towards a more harmonised energy market, which also favours a high level of green ambition. Disposable incomes, and economic growth rates over time, are high. This allows individuals and businesses to invest in new products and solutions, despite high energy prices resulting from subsidies and taxation. Innovation in demand technologies helps to enable progress towards environmental targets. Society is actively engaged in reducing greenhouse gas emissions, therefore knowledge and adoption rates are high. This results in high installation rates for products such as insulation, home energy management systems and domestic batteries.

It would be likely that the traditional linear chain of Generation > Transmission > Distribution > Consumption has changed, with embedded generation and increasing numbers of consumers opting for their own installed generation solutions to reduce their energy bills.

Increasing numbers of technological developments, such as smarter energy systems, and embedded generation at both domestic and industrial scale, mean that asset investment deferral is the preference to new technology investment.

NIA Call for Evidence
National Infrastructure Commission

**National Grid
Business Development**

By email to: NIAEvidence@nic.gsi.gov.uk

Date: February 2017

Dear Sir,

NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE October 2016

Thank you for the opportunity to respond to the above consultation.

About the Respondent

National Grid Business Development (NGBD) responds in its capacity as an independent owner, operator and prospective developer of multiple classes of infrastructure in energy, transport and cross-cutting/smart sectors. NGBD has been established to deliver the organisation's strategic growth ambitions so it is legally and physically separate from National Grid's RIIO-regulated businesses.

Together with partners, NGBD has recently made commitments for investment of over €2bn in the construction of two new electricity interconnectors: North Sea Link to Norway and NEMO Link to Belgium. Other areas of current interest to us include "grid edge" developments for distributed energy resources, battery storage, smart cities and the development of efficient infrastructure for the larger scale deployment of electric vehicles and electrification of new and existing rail infrastructure. We also have experience from developing Carbon Capture and Storage infrastructure.

Our portfolio of operational businesses already provide a wide range of energy products and services to customers in competitive markets:

- a. National Grid Interconnector Holdings Limited: owns stakes in subsea electricity interconnectors to France and the Netherlands;
- b. Grain LNG: Europe's largest LNG import terminal, which is able to meet 20% of UK gas demand;
- c. National Grid Metering: manages and maintains over 14 million industrial, commercial and domestic gas meters across the UK; and
- d. National Grid Smart: a new smart metering business that provides services to support suppliers with the roll-out of smart meters across the UK.

Nature of our Response

Our response takes the form of this covering letter and an attachment. In the covering letter we explain the nature of our interest and experience as a respondent, and we summarise our key points.

In the attachment we provide specific responses to only those questions in the Call for Evidence where we feel we can add most value.

Key Points

We welcome the work of the National Infrastructure Commission and its intent to use this Call for Evidence to assist it in identifying long-term infrastructure challenges and priority areas for action over the medium term. We consider the following issues to be key with respect to those challenges and priorities:

Long-term infrastructure challenges	Priority areas for action over the medium term	Relevant to Call for Evidence Question No
How to stimulate private sector investment	<ul style="list-style-type: none"> ▪ Long term stability in energy and cross-sector policies backed up by commercial and regulatory frameworks with appropriate risk-reward balance ▪ There should be clear, consistent carbon policies to enable cost effective transitions and minimise asset stranding 	2, 6, 8
The right infrastructure to most effectively harness the smart revolution and distributed energy resources	<ul style="list-style-type: none"> ▪ New more holistic, collaborative, systematic and cross-sector tools for energy system planning especially in the context of cities and regions ▪ Showcase such modern approach in relation to the 14 new garden villages announced by Government ▪ Reforms to the legal and regulatory frameworks around distributed energy and storage to stimulate competition and investment in the sector without undue restrictions on ownership or unnecessary regulation 	1, 3, 6, 9
Optimal infrastructure decision making against a backdrop rapid technology development and uncertainty in future trends	<ul style="list-style-type: none"> ▪ Improved tools to ensure that as a minimum “least worst regrets” commitments are made to build key infrastructure. Do nothing / business as usual methods are likely to be sub-optimal; ▪ Application of whole life & multi-criteria cost/benefit approaches to infrastructure decision making 	5, 12
Decarbonisation of transport and heat sectors in step with changing consumer behaviours	<ul style="list-style-type: none"> ▪ Energy efficiency measures to minimise waste heat particularly from existing buildings ▪ Co-ordinated strategy for electric vehicle charging, which is flexible enough to adapt to future developments (such as bi-directional power flow) ▪ Better alignment between national and regional transport planning e.g. with respect to electrification of rail ▪ Strategy backed up by commercial and regulatory models that stimulate investment in district heating solutions (in urban areas) and heat pumps (in sub-urban areas) 	6, 13, 19

	<ul style="list-style-type: none"> ▪ Penetration of electric vehicles and heat pumps will likely require network upgrades – an opportunity arises to introduce new business models to stimulate competition and innovation 	
Implications of Brexit especially upon cross border trading of electricity and natural gas	<ul style="list-style-type: none"> ▪ Deliver current policy to increase level of electricity interconnection to ensure cost saving, flexibility and security of supply benefits ▪ UK should aim for post-Brexit arrangements whereby energy continues to be traded across borders in an efficient manner without tariff or non-tariff barriers, for the benefit of UK and European consumers 	2, 20
Role of CCS for clean energy and decarbonisation of industrial emissions	<ul style="list-style-type: none"> ▪ Clear CCS strategy backed up with governance arrangements (commercial & regulatory frameworks) to stimulate desired level of investment 	6, 20

We are happy to discuss our views contained within this letter, should that be helpful. For further details, please contact Jonny Hosford (jonny.hosford@nationalgrid.com). We look forward to the National Infrastructure Commissions Vision and Priorities document scheduled for publication in summer 2017.

Yours faithfully

National Grid Business Development

Attachment 1 National Grid Business Development Response to National Infrastructure Assessment Call for Evidence, October 2016

National Grid Business Development (NGBD) responds in its capacity as an independent owner, operator and prospective developer of multiple classes of infrastructure in energy, transport and cross-cutting/smart sectors. NGBD provides specific responses to only those questions in the Call for Evidence where we feel we can add value.

QUESTIONS

The questions that the Commission has identified to assist respondents in focusing their submissions to this call for evidence are set out below:

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support longterm sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

Response:

Distributed energy infrastructure will underpin regional growth and many of the strategic priorities of local authorities. Key city challenges to tackle poverty, housing, transport, business growth, public health and waste all have implications for future energy system design. Set against a backdrop of falling local authority revenues and limited capital to invest, the private sector can be a catalyst to accelerate the delivery of connected city energy systems. These investments will not be high value in isolation but the design and delivery of interconnected technologies to exploit the generation of power and heat, energy storage, the electrification of transport alongside systems to connect citizens and communities will deliver the greatest returns to the region.

Significant progress in many areas of the UK has been made, but these successes have been isolated projects and not part of an overall systematic approach to city or town planning with the connection of energy infrastructure as one lever in the achievement of many strategic priorities. The 14 new garden villages announced in January 2017 offer the UK the opportunity to create the perfect environment for such technologies and to prove that energy may be provided in a sustainable manner using smarter planning for these ‘grid edge’ technologies.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Response:

Government supports a significant increase in the level of electricity grid interconnection between Great Britain and its neighbours. This is backed up by strong consensus (for example from studies undertaken by OFGEM and the System Operator) that increased interconnection brings multiple benefits including: improving the competitiveness of industry by lowering GB wholesale electricity prices, providing the flexibility and capacity to facilitate increased penetration of renewable energy sources, and improving security of supply (including access to more diverse sources of energy) for both the connected networks.

We believe an important priority for the medium term is to deliver the increased level of electricity interconnection that has been identified and to ensure the future trading arrangements with our neighbours enable best value to be obtained from such infrastructure. The prospect of the UK leaving the EU has raised uncertainty about the nature of the trading relationship post-Brexit. We believe a priority objective should be for the UK to secure an outcome whereby energy continues to be traded in an efficient manner without tariff or non-tariff barriers.

Having a flexible energy network with efficiently integrated solutions for heat, power, transport, communications, waste etc. should be a considerable attraction to foreign investment in the UK. Long term planning should provide pathways for optimum connection by new businesses – optimum in terms of ease of access, speed to connect and long term sustainability of competitive energy prices. Increasingly, modern businesses will also provide network services so there should be mutually beneficial outcomes from new connections.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Response:

With reference to response 1, the challenges, priorities, environment and opportunities of each town and city in the UK will be different and therefore the approach to distributed energy systems design needs to start with the strategic aims of the region and a number of scenarios regarding how the area could evolve over time if objectives are to be met. The current approach is for the directorates of local authorities to tackle individual objectives in isolation but utilities infrastructure design crosses directorate boundaries and requires an integrated approach. A piecemeal approach will not only deliver sub-optimal distributed energy solutions but will add considerable time to deliver.

We support the creation of cross-sector platform(s), which bring together a broad range of services for the benefits of customers. This system approach would facilitate diverse contributions, discussions, strategic planning and direction. It will

enable integrated and resilient energy, transport, digital communications, water and waste infrastructure. We consider that it would be appropriate for other key social aspects such as housing, education and health care provision also to be integrated into such thinking, perhaps culminating in all-encompassing regional development plans. Integrated plans with a consortia of technical partners, regional buy-in, cross departmental working and strong political sponsorship would be a constructive way forward.

We think this approach is likely to require greater interactions between government authorities and possible integration. We support consideration of improved (and consistent) metrics to assess overall socio-economic impacts across energy, environment, resilience etc. (which permit scenarios within sub-systems and roll up into the complete system).

National Grid is at the heart of our existing energy networks and we recognise the increasing engagement of customers is driving a shift of value more towards the consumer. Through our Business Development ventures we seek to bring our unique knowledge, footprint and insights into play through the provision of new infrastructure and services supporting decarbonisation and decentralisation. A key challenge going forward is to adopt a systems approach to energy infrastructure and put in place infrastructure governance arrangements that strike the right risk reward balance to underpin private sector investment by organisations such as ourselves.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Response:

We consider there is a significant opportunity for demand management and conceptually it is ultimately limited by the appetite of the connected customers and flexible demand. As more distributed energy resources are rolled out such as batteries, the potential for demand management will increase in tandem.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Response:

We expect that a whole life costing approach should be considered when weighing up the case for replacement or asset life extension. Typically such analysis will involve calculation of the Net Present Value of estimated capital and operating expenditure over the life of the assets in question. Back to back comparison would

be performed to gauge the merit of alternative infrastructure scenarios of repair versus replacement. Sensitivity analysis can be carried out in relation to uncertain variables such as the future level of utilisation.

When considering how the costs and benefits of different infrastructure approaches should be appraised it is important to set objective overall priorities and desired outcomes. For example, recognising the rapid pace of change in the energy sector, the extent to which new solutions contribute to future proofing, consumer empowerment, and harnessing new technology could rank high as high priority objectives alongside cost and reliability. Such multi-criteria cost-benefit analysis is a way to give recognition to the wider enabling benefits that new infrastructure solutions can also bring versus perpetuation of traditional solutions.

Consideration of any new infrastructure projects should include an assessment of the knock-on impacts for existing 'networked' assets (e.g. there may be implications for other investment upgrades or operating costs) to realise the full potential of the identified benefits. This is particularly true when looking at aspects such as plans to electrify rail lines and the need to ensure interconnectivity between routes/operators that can support fully electric trains.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Response:

We believe there is a place for both competition and collaboration in the future provision of infrastructure services. We consider that important keys to unlocking these opportunities are holistic cross-sector planning, provision of appropriate commercial and regulatory structures, and stable policy to underpin investor confidence.

In relation to policies we support the adoption of stable long term energy policy straddling successive Parliaments. For example, prospective investment decisions on new electricity interconnectors are predicated on assumptions around carbon floor price and access to participation in the GB Capacity Market. Therefore, investor confidence for new interconnectors would be improved by setting clear long term commitments to these instruments.

The following are examples from our experience where competition/collaboration tied to regulatory/policy frameworks has already stimulated, or with appropriate actions in the medium term, could stimulate increased investment:

Electricity Interconnectors Cap and Floor. The launch by OFGEM in 2014 of the cap and floor regulatory regime for new cross border electricity interconnectors is a success story of a clear regulatory regime, understood by market participants and striking an appropriate risk reward balance to incentivise the desired action from the private sector. In light of cap and floor, two new interconnector projects, North Sea Link to Norway and NEMOLink to Belgium have entered construction and multiple

additional new interconnectors are under active development by a diverse range of new participants.

Competitively Appointed Transmission Owners (CATO). We support OFGEM's CATO approach where it can bring value to consumers.

Electricity Storage. Prevailing GB regulatory arrangements were not developed with regard to the technological changes in smart, flexible, distributed energy and storage which we now see offering such opportunity. We think priority actions should look at reforms to the governance arrangements for electricity storage. Re-defining storage as a separate class of asset, without undue restrictions on ownership, would ensure the market is opened up to the widest possible pool of participants. New entrants to this sector will drive innovation and formulate working collaborations to deliver new services.

Decarbonising Transport and Heat. A zero carbon vision for 2050 almost certainly places a high reliance upon a near zero carbon electricity system, expanded in capacity compared to today's grid, to facilitate a high penetration of electric vehicles and heat pumps. Such change is likely to necessitate significant upgrades to networks, and as mentioned in earlier responses, maximum societal benefit will come from holistic cross-sector planning. A potential priority action could involve the introduction of competition in the provision of innovative infrastructure solutions at distribution voltage which may be owned and licenced separately to the incumbent distribution networks.

Balancing Services. There is an opportunity to expand competition in the provision of balancing services to the System Operator. Service provision has historically been the domain of large centrally dispatched generators. Looking ahead, new service provision from demand side, distributed energy sources, electricity storage and interconnectors might entail significant up front costs. At present, the relatively short-term balancing services contracts available act as a barrier to such investment.

North Sea Grid. There is a potential opportunity for integrated solutions which create an interconnected offshore grid of transmission lines between countries together with connections of offshore wind farms to the shore. For this to work there need to be new forms of co-operation and co-ordination between governments and developers in relation to the timing of wires (infrastructure) and wind (generation) investments. There could be a role for new forms of regulation that facilitate anticipatory investment in a way that allows the point of commitment for infrastructure and generation investments to be decoupled.

Carbon Capture and Storage. CCS is an example of a sector where government's actions in the period 2007 to 2015 placed a strong emphasis upon competition – in this case competition between generation-led proposals. However this was not backed up by long term policy commitments and appropriate commercial and regulatory frameworks. There was insufficient focus upon the core carbon dioxide transportation and storage infrastructure need to support large scale deployment. The economics point to a strong case for collaboration in sharing transport and storage infrastructure in high intensity CO₂ clusters. The result is that whereas evidence shows CCS has an economic position in the decarbonisation agenda, and

significant UK and EU public funding was used to make detailed designs for two inaugural schemes, there is yet to be an investible pathway for its deployment. The lessons learned from CCS should provide food for thought e.g. when considering governance arrangements for new sectors like electricity storage and offshore grids.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

Response:

Dictated by funding policy, certain Government-led projects adopt a very rigid, phased approach to procurement that inherently leads to inconsistencies and inefficiencies by incorporating various organisational ‘handovers’ between the different phases of project development. With each phase often tendered separately, this potentially results in a lack of long-term alignment and accountability (i.e. the design house will not be responsible for successful operations).

By developing a funding policy that encourages private sector investment in infrastructure projects at the conceptual design phase, through a design, build operate and own contracting type model, this could potentially deliver multiple benefits that include:

- Embedding operational experience in the design and build phase;
- Allocating a single point of responsibility for solution integration;
- Aligning safety requirements throughout all project phases – design through to operation;
- Promoting choices made upon lowest whole-life cost;
- Enabling greater design flexibility;
- Operator-led compressed delivery programme;
- Best placed risk ownership; and
- Access to additional sources of finance through further private sector investment, if required.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

Response:

See our previous response to question 6. Infrastructure projects in the arena of CCS, North Sea Grids, Electricity Storage and Balancing Services are examples where there is investment interest from the private sector, but where the prevailing

market and regulatory arrangements don't yet provide an appropriate risk reward balance to underwrite capital intensive up front project construction costs.

While obstacles to market persist, public co-funding can be a helpful stepping stone for new projects, but this is second best to getting the right policy, market and regulatory frameworks in place.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

Response:

We believe useful medium term actions could be taken forward in relation to holistic regional planning, cross-sector risk assessments and collaboration.

Building on our response to Question 3, we think it is important to foster holistic regional development plans that consider interdependencies across different sectors such as energy and transport. A prime example is the need for cities to decarbonise transport to satisfy mandated clean air zone requirements by 2020. In order to allow a greater uptake of 'clean' modes of transport, it is highly likely that enabling infrastructure will need to be developed at scale.

If Local Authorities are to develop policies to compel a transition from hydrocarbon vehicles to electric (say for taxis), then there is likely to need to be a proliferation of rapid/fast electric vehicle charging points in key strategic locations. As rapid/fast chargers can cause operational problems (e.g. voltage control issues) for electricity Distribution Networks, then network upgrades may be needed to accommodate the required volume of charging points to support demand at the time it is required.

It is imperative that there is a clear, long-term plan that identifies all interdependencies across various sectors and enables optimal investment decisions to be taken. This will need to take into consideration anticipatory demand needs, including those likely to result from national and local policy decisions. Government should proactively seek to engage with different industries, such as the automotive industry, to identify where the major cross sector infrastructure challenges are likely to materialise and take proactive steps to develop a multi-sector response in advance of the problems becoming a potential barrier to economic prosperity and growth.

Making best use of North Sea resources is an area where new forms of collaborative spatial planning could be very beneficial. Collectively the North Sea countries have a shared interest in maximising North Sea resources for a variety of purposes including: oil and natural gas extraction and transportation, offshore wind generation, cross border electricity and natural gas interconnection, CO₂ transportation and storage, fishing, shipping etc. Actions taken in one sector can sterilise future opportunities for infrastructure development in another sector. We support collaborative initiatives such as the June 2016 Political Declaration on Energy Cooperation between the North Seas Countries.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Response:

We respect that local people should have a say in what is developed in their community. Options should be considered and lowest cost or lowest impact solutions should be discussed. In this regard, the framework put in place through the Planning Act 2008 places strong responsibilities upon developers who face significant risks associated with failure to attain planning consent.

Developers are being drawn to invest ever more effort to mitigate planning risks; for example carrying out more and more detailed up front “optioneering” design, or adopting higher cost solutions from the outset that may not be technically the most efficient but are judged to be more likely or faster to attain public acceptance. To the extent developers face abortive costs then planning risk creates a disincentive to bring forward private sector investment in such significant infrastructure schemes.

There should be recognition of the costs to society of this approach in terms of the stifling effect upon development of infrastructure schemes with potentially high socio-economic benefits and higher costs of those schemes that can be taken forward.

We perceive that these difficult societal choices are becoming increasingly important issues to be addressed in our infrastructure governance systems, so this should be one of the areas of long-term infrastructure challenge addressed in the ongoing work of the National Infrastructure Commission.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Response:

Infrastructure can make a highly beneficial contribution to protecting and enhancing the natural environment. For example electricity transportation infrastructure including cross border interconnectors can facilitate the optimal use of natural resources like wind, hydro and solar. In the case of European electricity transmission infrastructure planning ENTSOE uses a multi-criteria benefit assessment technique to recognise the impacts (whether positive or negative) that discrete infrastructure projects have upon the environment. There may be a case for analogous multi-criteria techniques to be deployed in the UK and in sectors other than electricity transmission.

We see increasing trends of heightened awareness in society of the infrastructure trade-offs between economic efficiency and impacts upon the natural environment. For example this is played out in debates about the relative merit of overhead or underground high voltage electricity grid assets. Evolving social attitudes in this area will pose a challenge for our infrastructure governance systems going forward.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

Response:

There could be a case to further build upon approaches already used in electricity and gas transmission (e.g. National Grid’s Future Energy Scenarios, and ENTSOE’s 2030 Visions) and those explored in projects such as DECC’s 2050 Energy Pathways and successor work taken forward through ETI and IET.

Generic methods could be applied in various sectors which might involve common techniques such as:

- (i) use stakeholder input to build transparent, credible scenario analysis of future demand for services;
- (ii) define optimal infrastructure appropriate to the different scenarios – the metrics used need to be tractable and transparent;
- (iii) undertake probabilistic analysis of possible outcomes. The NIC may need to be arbiter on assignment of probabilities;
- (iv) use results to identify “least worst regrets” infrastructure that should be built;
- (v) implement policy and commercial/regulatory framework to stimulate private sector investment in the desired infrastructure;
- (vi) periodic review against progress and recourse to state intervention if insufficient progress is made.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

Response:

We perceive the following trends:

- transition away from diesel into hybrid and ultimately electric or hydrogen transport;
- auto-pilot vehicles being able to operate much closer together thus increasing capacity of existing transport infrastructure;
- smarter education and working will result in less travel per annum;

- evolution of mobility as a service and greater automation is likely to reduce the private ownership of own vehicles, with remaining vehicles travelling further (especially when they are autonomous) – especially in large cities;
- greater stratification of transport options – platforms that optimise differing options e.g. bus / tram into central hub. Essentially, multiple types of vehicles will be optimised through platforms to get individuals from point A to B. Consumers will make the choice of cost of travel solution versus time of travel solution; and
- automation and shared mobility will enhance miles driven for new markets (Disabled, Elderly, Young, etc)

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: “high value transport investments” in this context include those that enable ‘agglomeration economies’ – the increase in productivity in firms locating close to one another.

No Response

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

No Response

16. What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

Response:

Mobility as a service can be expected to increase the utilisation rates of individual vehicles, while potentially reducing the overall population of vehicles. In relation to current methods of taxation, this would imply the ongoing cost of the roads network would need to be smeared across a shrinking population of vehicles.

In parallel it can be expected that with increased uptake in electric vehicles the duty raised from forecourt diesel and petrol fuel sales will decline, or the price per litre would have to rise to collect the equivalent duty from a smaller volume of fuel sales.

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

No Response

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing “regime” refers to the current market, competition and planning frameworks. “Digital communications” includes both fixed and mobile connectivity.

No Response

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Response:

Increasing efficiency will be key to decarbonising heat for both commercial and domestic consumers. Introduction of higher standards for new buildings should be accompanied by a more rigorous approach to assessing the performance of existing buildings, analogous to the MOT test for a car. This would provide a proactive assessment of the state of efficiency of buildings and identify improvement measures. The focus would be to minimise waste heat. In this regard it should be noted that energy efficiency is a separate topic to the social issue referred to as fuel poverty; a focus on reducing the price per unit of energy would not necessarily lead to any reduction in waste heat.

In urban areas, we consider the highest value solution for decarbonising heat is district heating. In priority order, the fuel sources for a heat network should be:

- Waste heat that would otherwise be lost - from conventional or nuclear power plants, energy from waste, waste heat from industry, biomass CHP;
- Renewable sources - Heat pumps using electricity from a decarbonised grid, or solar thermal, biomass, biogas; and
- Gas fired CHP/boilers can be used as interim measure as back-up supplies and to meet peak demand.

In suburban areas, we consider the highest value solution for decarbonising heat is heat pumps using clean sources of electricity.

Our analysis suggests there is no universal optimal solution for the decarbonisation of heat. Instead we anticipate a patchwork of differing solutions tailored make best use of local resources to meet regional circumstances and needs.

Low carbon gasses from local waste are a key biomass resource which should be prioritised – displacing inefficient incinerators or energy from waste plants. See our further remarks on Municipal Solid Waste in response to Question 28.

Hybrid heating solutions can provide an optimized position for low carbon and least cost, which can be applied at both commercial/heat grids and individual domestic scale. In this model consumers retain a gas boiler (providing top-up heat on colder days) complemented by a small scale electric heat pump (for base load heat). The advantages are that value continues to be obtained from existing infrastructure (gas boilers using the gas supply grid) to meet highly seasonal peak demand for space heating. In tandem the significantly higher efficiencies of heat pumps are used to meet base load heat demand. The smaller scale deployment of heat pumps is more manageable in terms of the extent of transformation required of the electricity system. (If all heating duty were to be transitioned to electric heat pumps there would be massive implications for the level of investment needed in the upstream infrastructure in terms of low-carbon generation and electricity grid reinforcement – which in turn would push up costs).

Investment decisions for district heating need made when any new property development goes ahead (e.g. as per the London Plan), whenever there is a major urban regeneration, or whenever a major energy source or demand is investing (e.g. a new hospital, a new energy from waste CHP).

Investment decisions for heat pumps will happen when new homes and refurbishments happen.

Policy decisions should be made twenty plus years before decarbonisation is required, due to the cycle time of major heat investments.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

Response:

We consider that the most effective zero carbon power sector in 2050 will most likely include the following characteristics:

- Demand reduction due to improved efficiency
- A zero carbon electricity supply system facilitated by a combination of renewables, nuclear, CCS and new sources of energy. This acts as an important enabler for the decarbonisation of adjacent sectors in particular transport and heat;
- Some 15-20GW of electricity transmission interconnection to our neighbours as part of a larger national electricity system;

- High penetration of renewables, facilitated by falling technology costs, changing consumer patterns, smarter solutions for distributed energy resources and storage, and competition among new participants providing energy services;
- A step change in the deployment of localised district heating schemes and marked increase in deployment of heat pumps;
- A significant uptake in the deployment of electric vehicles, which both draw from and can back feed the network automatically to optimise against demand;
- An appropriate place in the energy mix for CCS to provide a contribution, most likely from specific regional cluster(s) sharing common transport and storage infrastructure to accommodate industrial and power sector emissions.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Electric vehicles present a significant opportunity to help the transition to a zero carbon power sector. Electric vehicles will require more renewable electricity production, plus investment in adapted and smarter networks. Biogas should be encouraged as a low carbon solution for certain categories of transport (e.g. long range busses, HGVs, etc.) where electric vehicles may not be optimum.

Uptake of Electric vehicles is growing fast in the UK and as a consequence deployment of charging infrastructure is also evolving. We expect electric vehicles uptake to increase and with it the need for associated charging infrastructure. Consideration should be given to how rapid/fast charging solutions can be developed in cities and other key locations at lowest cost for the consumer, and potentially incorporated into broader solutions that deliver benefits for the wider community.

One of the primary challenges to the widespread adoption of electric vehicles is one of convenience. This is particularly true when considering where vehicles can be charged and how quickly this can be done. Assuming residential charging is the primary method of charging electric vehicles, there will still remain a need for rapid charging at key strategic locations. To accommodate such charge points it is likely that in certain locations the electricity networks will require material reinforcement. Looking holistically it is likely to be the combination of electric vehicles and electric heat pumps taken together which trigger more significant network upgrades and more systematic, long term regional planning in this area would be beneficial.

With the increase in reliable distributed energy technologies, such as solar photovoltaic and energy storage, and the continuing fall in prices for such technologies, it is increasingly cost-effective to develop 'off grid' solutions that can support electric vehicle charging requirements. More innovative solutions could be envisaged that offer benefits beyond simply charging vehicles (e.g. Ancillary Services provision to the electricity System Operator). We perceive that such hybrid infrastructure could be part of the low carbon transition if the right risk reward balance can be achieved to underpin investment.

Water and wastewater (drainage and sewerage):

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

No Response

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

No Response

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

No Response

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

No Response

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

No Response

Solid waste:

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

No Response

28. What are the barriers to achieving a more circular economy? What would the

costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

Waste is the UK’s largest biomass resource and managed locally usually via incineration or relatively low efficiency energy from waste plants. Municipal Solid Waste (MSW) is a solid dry waste with heavy aggregates and recyclable materials removed. MSW can be converted via gasification to hydrogen and carbon dioxide. The resulting fuel gases can be converted to bio-Substitute Natural Gas (bio-SNG). methane) and could displace 100-150TWh of U.K. natural gas demand - equivalent to one third or more of domestic gas demand assuming continuing efficiency improvements. Alternatively the fuel can be used to achieve higher efficiencies from conventional energy from waste plants.

Conversion of local waste to bio-SNG is already being demonstrated at large scale and would appear to be a no regret option towards a more circular economy.

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London EC3M 8UD

Via email: NIAEvidence@nic.gsi.gov.uk

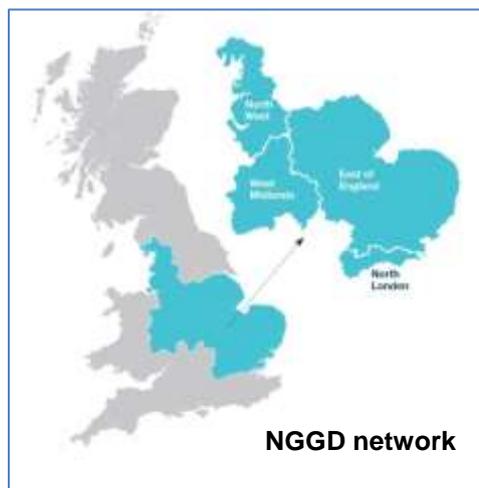

Friday 10 February 2017

Dear Sir/Madam

National Grid Gas Distribution Ltd response to the National Infrastructure Assessment Call for Evidence

National Grid Gas Distribution (NGGD) welcomes the opportunity to respond to this call for evidence. We own and operate four of the UK's gas distribution networks which provide a safe, reliable and efficient gas network that transports gas to eleven million homes, schools and businesses across our network area.

In November 2015 National Grid plc announced its intention to sell a majority stake in NGGD and, having announced the preferred buyers in December 2016, we are aiming for a completion of the sale process during the first quarter of 2017, As a result of the sale we will be the largest gas distribution company in the country and this response represents our first submission to the National Infrastructure Commission as a new entity.

We are delighted to respond to the Call for Evidence and believe that National Infrastructure Assessments present a significant opportunity to help shape the future direction of infrastructure and energy the UK.

We believe that decarbonising the UK's gas network is pivotal in order to assist in the country's transition to a low-carbon energy system and is the least disruptive and cost-effective way of meeting the demands of the 'energy trilemma' – security, affordability and sustainability. In addition to the answers in our submission we would draw your attention to our gas distribution series, 'Energy 2050: Future of Gas' which lays out a range of factors that need to be considered in the context of national infrastructure and the type of energy landscape we need in the future. The series appraises the key trends that will shape future demand for energy, and gas.

We have kept our response in line with the question structure suggested for ease of reference, and summarised the main points at the end of our submission.

We would welcome the opportunity to discuss our response in more detail with you at the earliest convenience. Should you require any additional information, please do not hesitate to contact me.

Yours faithfully

[signature redacted]

[name redacted]
[job title redacted]

NATIONAL GRID GAS DISTRIBUTION LTD

RESPONSE TO NATIONAL INFRASTRUCTURE ASSESSMENT¹

Executive Summary

One of the key investment questions facing our country in the coming decades is: How to decarbonise our heat and transport sectors.

There is an increasingly strong evidence base that shows that re-purposing the gas network to deliver sustainable, renewable, low carbon gas, represents the best value to consumers and tax payers. This is supported by the KPMG report², '2050 Energy Scenarios', the Policy Exchange "Too Hot to Handle" report³ and locational studies for Cornwall and Bridgend.

When planning and optimising our long term infrastructure requirements, whilst new investments must be considered, it is absolutely critical that the full value of existing assets is recognised. When planning the low carbon solutions for the heat and transport sectors, consumers and taxpayers will expect maximum use to be made of the historic investments they have funded in the UK gas networks, thereby minimising overall cost and disruption.

We therefore welcome this work by the NIC to review infrastructure requirements. It presents a timely opportunity for the NIC to provide informed guidance and direction to realise the full value of historic investments in solving one of the country's key infrastructure challenges.

We are happy to offer all the support we can to the NIC to show the role the existing gas network infrastructure can play at the centre of our long term plans to decarbonise our energy systems.

Question 1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

The existing gas network infrastructure is a relatively low cost asset that given the right policy decisions, can be used as the backbone of a low carbon sustainable energy system, heating homes, schools and businesses, and making a significant contribution to fuelling the low carbon transport of the future. We believe that alternatives, such as electrifying heat are both uneconomic and impractical in comparison.⁴

Existing gas infrastructure has great potential to support sustainable growth, both as a seed from which to grow new low carbon networks and as a conduit for sustainable gases. In support of growth and development, we could plan to develop a new strategic offtake from the national gas transmission network in the Northwest.

Similarly, we could examine reinforcing our strategic large diameter local transmission network to support new requirements whether for demand or to transport new sources of gas – shales, hydrogen or biogas.

¹ Please note that we have opted not to respond to all questions posed by the NIC. The question numbers listed correspond to the questions in the NIA Call for Evidence.

⁴ KPMG 2050 Energy Scenarios

<https://www.energynetworks.org/assets/files/gas/futures/KPMG%20Future%20of%20Gas%20Main%20report%20plus%20appendices%20FINAL.pdf> p.72.

We have a substantial programme of asset replacement⁵ on our distribution network, removing old cast iron pipes and moving towards a poly-ethylene (PE) network. The new PE network provides a flexible modern transportation system for a variety of gases.

In addition, we are also expecting to deliver new local networks to support the growth of new towns and commuter belt developments. Gas continues to be the fuel of choice for new housing developments.

Question 3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

Utilities, house builders and local government need to engage with communities to design and deliver holistic energy solutions that are integrated with other infrastructure requirements to meet the needs of that location. For example, facilitating forums with local authorities to gather community based solutions. Similarly, local production of sustainable gas may need to be combined with local gas energy storage or different network solutions. Security and reliability will need to be considered carefully for any decentralised energy solutions.

With regard to energy provision, with over 23m homes using gas as their primary heating source, consideration must be given to the existing energy infrastructure, to ensure it is being utilised effectively. In addition, we need to ensure that whilst designing the infrastructure, the delivery will cause minimal disruption/impact on the surroundings (both during installation and with regard to future maintenance.)

We need to ensure that the evolution of infrastructure matches (supports and responds to) changes in home and consumer requirements. Future gas networks transporting different blends of gas could need complementary evolution in home heating and cooking equipment.

Question 4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

In gas, demand management is a key factor in network design as networks are required to meet regulatory obligations to provide capacity on a 1 in 20 year peak demand day to their customers. To the extent that demand locally might not be met at peak and it is more economic than reinforcing the system, then gas networks can tender for interruption services from large industrial and commercial customers.

At a consumer level smart metering, particularly in electricity could have an important role in managing peak demand through time of use tariffs. More broadly government believes that greater consumer awareness of energy consumption and costs could lead to reductions in gas and electricity usage and capacity requirements, through behavioural change.

Of course energy efficiency must continue to be a focus, and we believe there is the potential for a significant reduction in domestic gas demand overall through this route. Smart meters will play a part, but programmes to target other energy efficiency measures, funded from both business and government will also be key. For example, a scrappage programme for all old non-condensing domestic boilers could on its own result in a large reduction in gas usage and emissions, as would better insulation and more thermally efficient new buildings.

Question 5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The management of an organisation's assets should be directed to achieving the organisation's aims and objectives. Good asset management optimises value-for-money across all assets, timescales and life-cycle activities.

Asset systems provide the means of delivering service to customers and the environment as a whole. Over time, assets deteriorate and demands on them change. Thus, there is a continual need to sustain an asset base that is fit for purpose. This involves operating and maintaining assets so that they achieve an optimal

⁵ Visit <http://bettergaspipes.co.uk/> for additional information.

life, replacing them once that lifespan is complete, providing new assets to fill in gaps in capacity and disposal of unwanted assets.

To meet any objective it is important to consider all options. Therefore, a particular need may be met in a number of ways including operational changes, replacement of assets, uprating assets and building new assets. All possible options should be considered on the same basis. Normally, this is achieved through an analysis of the benefits and costs of each option, considering the whole life aspects relevant to the assets in question.

Benefits of an option can be assessed on a consistent basis through calculating the amount of monetised risk reduction or mitigation that can be achieved. Risks include direct financial consequences to the organisation and indirect or societal costs. Each need for action will carry a total risk value that represents the impact of not carrying out any work – the ‘do nothing’ scenario. Any need may have one or more risk components that can all be translated into monetary terms. Each option will mitigate a certain amount of that risk and that difference represents the benefit.

Costs of options can be calculated using appropriate means such as unit rates, cost models and historical information. Cost benefit analyses taken over an appropriate period provide the means for assessing the best solution.

In addition, all solutions should be examined together to ensure that the overall collection of activities is optimised to produce a plan that is balanced in terms of risk reduction and achievement of cost and performance objectives. In this way, the maintenance and repair of existing assets is most effectively balanced with the construction of new assets.

Question 6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

NGGD recognises the public interest case for having competition in infrastructure services. NGGD, together with other gas distribution network companies, has been highly successful in facilitating competition in connections to, and extension of, the local gas transportation networks in Great Britain.

In 2010/11 only 38% of new and modified gas connections were undertaken by GDNs⁶, compared to 77% of electricity connections being undertaken by DNOs. Ofgem estimates that there are now over one million domestic and commercial consumers are now connected to discrete Independent Gas Transporter (IGT) networks.

Where NGGD does deliver connections or modifications to and extension or replacement of the local gas transportation network, this work is undertaken by our strategic partners who were awarded the work via competitive tender. NGGD also, in accordance with EU procurement rules, holds robust, competitive tenders for the purchasing of equipment and materials.

A significant amount of work is currently underway in terms of collaborating to improve the supply of infrastructure services. The UK Regulators Network has worked with stakeholders across multiple sectors, both regulated and non-regulated, to identify how to minimise costs incurred by developers of new infrastructure when they interact with existing in-situ infrastructure. This led them to publish, in late-2015, a suite of recommendations⁷ for utility and rail companies to improve their interactions with developers.

Question 7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The model used by Ofgem for energy networks ensures the efficient delivery of infrastructure services.

Since privatisation in 1986 until 2013 a “RPI-X”, where X is a measure of efficiency, regulatory framework was used to drive cost efficiency within network companies.

⁶ <https://www.ofgem.gov.uk/ofgem-publications/43258/connections-industry-review-2010-11dec-12.pdf>

⁷ <http://www.ukrn.org.uk/wp-content/uploads/2016/07/2015DecCSI-AnnualReportingGuidance.pdf>

In 2013, Ofgem implemented the “RIIO” (Revenue equals innovation plus incentives plus outputs) regulatory framework for gas distribution, gas transmission and electricity transmission network companies and have subsequently, in 2015, implemented it for electricity distribution network operators as well.

The RIIO framework not only continues to drive cost efficiency but also environmental, social and customer benefits as well as enabling network companies to over-deliver where there is a clear customer-focussed justification such as additional fuel poor connections. To achieve the carbon reduction targets set out in the Climate Change Act 2008, 80% reduction from 1990 levels by 2050, significant investment will be required in Great Britain’s energy infrastructure.

To ensure the most efficient provision of heat/energy to homes and businesses in addition to specific efficiency measures, as seen in RPI-X and RIIO, policy-makers and regulators should consider the holistic costs to consumers when assessing efficiency and making decisions. This holistic approach would include considering the combined costs of the commodity, network infrastructure, in-house appliances and subsidies.

The existing Price Control Review arrangements are broadly working effectively and driving the right industry behaviours.

- The arrangements have facilitated the implementation of well justified business plans and promoted stakeholder engagement particularly in the context of supply of natural gas, domestic heat, and network capability, which are all important priorities for our customers.
- Infrastructure investment leads to low wastage and low leakage, the 8 year RIIO timescale enables networks to plan their investment in a structured fashion to ensure benefits are realised and can be passed to consumers.

The stakeholder engagement for RIIO-2 is starting now, and we would welcome engagement with the NIC to gather their views on strategy for infrastructure and how they see energy networks delivering in the future.

In the area of fuel poverty “getting our customers physically connected” is working well but there could be more joined up thinking regarding fuel poor funding schemes to support delivery of the final solution for the customer (i.e. once the pipe is in, make it easier for the customers to install the boiler/heating etc. currently this can be done via ECO, Warm Zone, etc. but there is merit in reviewing this to provide a “one-stop shop”). Central funding for a boiler scrappage scheme, which could be targeted initially at the fuel poor, could also have significant benefits.

With large new investments, which can take a number of years, such as the national roll out of renewable gas production facilities derived from waste streams (BioSNG), risk can also contribute to project costs. In the energy sector, project risk as well as energy security, network availability, reliability and resilience and other safety risks are critical. To reduce risk, in some circumstances, a regulated delivery model may provide the best value to the consumer or tax payer.

Question 9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Current UK energy policy focuses on electrification for home heating. But electricity is likely to be more expensive for consumers, may not meet future demand and may not achieve the targets for cutting carbon pollution. We believe that gas will play a crucial role as a bridging fuel as the energy system becomes carbon-free and innovative solutions are being developed that could use the existing gas networks.

Building resilience into our network should involve minimising our reliance on a single energy source. By introducing new sources of gas we can use an existing asset, (that is sufficiently flexible to cope with day-by-day changes in demand as well as seasonal shifts), at minimal extra cost, which would be a sustainable, flexible, economic solution.

A key issue for consumers is that gas provides over 80% of the heat for UK homes with most of this consumed during the winter, and increasing levels of primary generation is gas fired, as coal and oil stations,

close as we transition to a low carbon future. On a peak day, a typical home connected to the gas grid will take four to five times as much energy from the gas supply than it will from the electricity grid. Replacing this gas demand from the electricity network, which must be balanced second by second, would be a significant investment challenge as electricity networks are not currently designed for this level of peak load. The UK therefore needs to maintain balanced energy delivery infrastructure to support essential services, economic prosperity and the needs of its citizens at an affordable cost, until viable alternatives emerge over coming decades. Through encouraging biomethane, Synthetic Natural Gas and potentially Hydrogen, the reliability and lower cost benefits of using gas can help the UK meet its climate change targets. This was illustrated in the KPMG report⁸, '2050 Energy Scenarios' which indicated the evolution of the gas network to meet our emissions targets could cost over £8000 less than the scenarios whereby all heat is electrified.

Question 11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

The Natural Capital Committee, amongst other bodies, has highlighted the multiple benefits of a healthy and functioning ecosystem to health and wealth of society. It has also highlighted the need to protect and enhance environmental assets by creating bigger, better and connected spaces for nature.

The National Infrastructure Plan should incorporate natural capital into each of the main infrastructure sectors, following the mitigation hierarchy for managing impacts (avoid, minimise, restore, offset). An investment programme for natural capital should also explicitly feature in the National Infrastructure Plan.

The NIC is in a unique position to promote, embed and mainstream the use of green infrastructure as a tool to enhance the resilience to flood and climate change. Green infrastructure can also increase asset efficiency and reducing the whole life costs of national and local infrastructure assets and maximise their biodiversity and ecosystem service benefits. This includes the incorporation of green infrastructure into new-build linear infrastructure assets, retro-fitting it into existing assets and promoting the appropriate maintenance and management of this green infrastructure. It is also important that this is addressed in both rural and urban environments. In urban environments, infrastructure corridors provide real opportunities to connect people and green space, to embed sustainable drainage solutions and to preserve and plant more urban trees with benefits to temperature regulation, air quality and wellbeing.

The ability to properly account for both loss and restoration of natural capital through infrastructure development is crucial to capturing natural, social and financial value and should underpin decision making in managing, offsetting and compensating impacts.

A number of organisations are highlighting the organisational and societal benefits of such an approach and the value of tools such as natural capital accounting in delivering creative solutions to enhance and manage the environment to support local and national priorities and the delivery of net gain in natural capital value.

The deliveries of effective approaches to protect and enhance the natural environment are multidisciplinary and collaborative. The NIC could play an invaluable role in setting frameworks in place or developing new mechanisms to incentivise linear asset owners and managers to incorporate green infrastructure into their asset design, construction and management.

Question 12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

We support the application of CBA to inform better decision making and the targeting of resources to the right activities. In our business plans and discussions with Ofgem to determine the infrastructure investment for RII0-GD1 (2013/4 to 2020/21), a tractable CBA methodology was developed that improved the level of transparency and credibility. There were, however, both differences in CBA approach between GDNs and within GDNs across different asset types.

⁸ KPMG, 2050 Energy Scenarios
<http://www.energynetworks.org/assets/files/gas/futures/KPMG%202050%20Energy%20Scenarios%20-%20The%20UK%20Gas%20Networks%20role%20in%20a%202050%20whole%20en...1.pdf>

The Gas Distribution Industry has been working with Ofgem to develop a standard methodology for the monetisation of risks (benefits) across all assets types.⁹ This approach has driven a consistency in the way that benefits are quantified and produced a published standard which is available for review and challenge, a key foundation for improving credibility and transparency.

Further improvements could be achieved by involving a wider range of stakeholders in reviewing and refining the approach to CBA, allowing transparency. Whilst some aspects of CBA may remain opaque to non-engineers, economists or statisticians there is much that generalists can contribute in terms of the reason or underlying purpose of the CBA. Our stakeholders can help us maintain focus on what CBA as a tool is trying to deliver, rather than getting caught up in CBA for its own sake. We should also encourage the documentation of stakeholder involvement, whether as specialists or generalists, to help build confidence (credibility) in the models that have been built – i.e. publishing CBA with endorsement by independent specialists or recognisable ‘stakeholder champion’.

The link between CBA models and investment decisions also needs to be made more transparent. CBA may be one of a number of components informing a decision and its role needs to be clearly stated. The risk monetisation work in the gas industry provides a great opportunity to refine our investment choices and produce great benefits for our customers and society.

Question 13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

The adoption of Ultra Low Emissions Zones (ULEZ) and Clean Air Zones across the major cities in the UK, along with national policies to reduce emissions from the transport sector, will change current patterns. Gas is likely to play a significant role, particularly for freight and buses, by driving the adoption of more environmentally friendly vehicle technology.

For buses, there are a number of options for lower emission vehicles; hybrid, electric, compressed natural gas (CNG) and Hydrogen fuel cells. For HGV’s, the most viable route to lower emissions is currently the adoption of CNG as a vehicle fuel.

Compared with diesel, the adoption of CNG HGV’s and buses would have many positive impacts, including:

- Lower levels of NOx and particulate matter emissions
- Lower Well-to-Motion CO2 emissions, c.10-20%. Increasing to 60-70% with the use of BioCNG
- 50% quieter
- 40% cheaper to run in terms of fuel

Gas: The fuel of choice for HGVs and buses

Of total GHG emissions
25%
are attributed to transport

c. **24%**
Road surface emissions from HGVs and buses

c. **1.5%**
of UK vehicles

National Grid believes that gas could and should be the fuel of choice for HGVs and buses in the UK

- Support UK CO₂ reductions and cleaner air in cities
- Thorough utilisation of the gas network into the future
- Gas network forming the backbone of a national filling station infrastructure

A clean, quiet and cheap alternative to diesel

Given the backdrop of the implementation of emission zones, the environmental and economic benefits for bus and HGV fleet operators are compelling.

It has been predicted that changing travel patterns will result in 17,000 buses and 190,000 gas fuelled HGV’s by 2050.¹⁰

⁹ https://www.ofgem.gov.uk/sites/default/files/docs/2015/11/gdn_asset_health_risk_reporting_methodology_-_v2.0.pdf

¹⁰ <http://www.lowcvp.org.uk/assets/reports/LowCVP%20Infrastructure%20Roadmap-Methane%20report.pdf>

NGGD believes that gas could and should be the fuel of choice for HGVs and buses in the UK:

- Support UK CO₂ reductions and cleaner air in cities;
- Thorough utilisation of the gas network into the future;
- Gas infrastructure forming the backbone of a national filling network.
- **A clean, quiet and cheap alternative to diesel.**

Using compressed natural gas for long haul vehicles will act as a bridge to the low carbon economy by helping to decarbonise the sector and get us on the journey towards 2050.

The business case for renewable gas in transport

For renewable methane (bio and synthetic natural gas) used in transport, incentives can be claimed through the Renewable Transport Fuel Certificates (RTFC), which is essentially a subsidy like the Renewable Heat Incentive (see Future of Gas - Domestic Heat chapter.¹¹)

The scheme is currently restricted to gas transported from the source of production straight to the vehicle being fuelled. However, this can place limitations on the use of biomethane, especially where the source of production is located away from the point of demand.

This means the fuel would have to be transported by road tanker, diminishing its environmental benefits (the well-to-motion emissions footprint). NGGD believes RTFCs should apply to bio gas injected into the distribution grid, with a certification scheme to authenticate the source of supply and use.

This would remove the need for tankering fuel from production to vehicles, thereby realising the benefits of utilising the gas distribution network for delivering fuel. It would also decouple the geographic restriction of demand and supply, and act as a catalyst to incentivise the use of renewable gases in transport.

Of course as well, the level of support provided by different schemes must be in line with considered joined up policy across government to ensure the fuels and feedstocks are directed to where they can add the most value.

Question 14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

With the proven environmental and sustainability benefits. The investment in strategically located CNG filling stations is key to efficiently allowing people (buses) and freight (HGV's) to flow around major urban areas.

Public access CNG filling stations are best located where there is strong demand from a number of freight or fleet operators, located within close proximity of each other and with strong links to major traffic routes. Where these locations are close to higher pressure gas grid pipelines, the conditions are perfect for the siting of a filling station.

Vehicles fuelled from stations such as this enjoy Well-to-Motion CO₂ emissions that are lower than any other fossil fuel. This type of station lends itself well to the 'back to depot' refuelling fleet operator.

A small scale CNG filling station dispensing enough fuel for 60 trucks costs c. £300k, a station with the capacity to fuel 500 per day costs c. £1.4m to construct (Capex & Civils costs.)

Building the infrastructure covering all major UK trucking routes for at least 100 HGV friendly CNG refuelling stations will require an investment of around £150 million. The funding could be shared between private companies and the Government, and over time, these stations could dispense increasing amounts of renewable gas.

¹¹ <http://www2.nationalgrid.com/UK/Industry-information/Future-of-Energy/Gas/>

Question 15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Our answer to question 14 addresses some of the key issues posed by this question. However, we have provided additional information below.

In terms of siting CNG filling stations outside of urban areas, consideration should be given to the **major arterial routes that run across the UK**. A fuelling infrastructure built to serve this route would ensure that operators of CNG vehicles did not suffer any 'range anxiety'. Consideration should be given to ensuring a gas refuelling infrastructure was designed to be extendable if demand for new fuels such as hydrogen, that could also be delivered via the existing gas grid.

Development of a CNG fuelling infrastructure across the Trans-European Transport Network (TENT-T) corridor stretching from **Dover to Glasgow would support long-haul HGV's**. More details can be found in Directive 2014/94/EU¹².

To support the 2050 prediction of the number of HGV's and buses fuelled by gas, it is predicted that **800-1,000 filling stations will be required across the UK**.¹³

Question 19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

In summary:

- Of the various technologies that are available, we believe that renewable gas (biomethane) provides the most cost effective and convenient form of renewable heat delivery to consumers, and therefore that policy should be directed at maximising the opportunities for its production and distribution.
- Biomethane from anaerobic digestion can make a significant contribution, but thermal production of biomethane is very well placed to provide a step change in the volume of renewable gas, given a sufficient incentive in the form of a dedicated RHI tariff.
- The development of technologies and infrastructure for carbon capture and storage will enable the production of low carbon hydrogen by steam methane reforming. This offers a route to provide enough low carbon fuel to eventually completely decarbonise domestic and commercial heat.

NGGD has been in the forefront of utilities supporting the development of biomethane from anaerobic digestion (AD). We have facilitated the connection of biomethane plants to our networks, recognising that renewable gas has an important part to play in the decarbonisation of heat and transport. There are now over 60 biomethane plants supplying renewable gas into Britain's gas networks, with more planned to connect in 2017.

The reason NGGD has supported the development of renewable gas so strongly is that we believe it is the most accessible and affordable source of renewable heat, and that delivery of renewable gas through the existing extensive gas pipeline network delivers the best value for consumers. Alternative options for delivering low carbon heat are either more costly or rely on significant infrastructure investment - mainly in the home - which is a significant barrier to deployment for the majority of domestic premises.

Currently gas dominates the UK heat supply curve, with over 80% of the UK's buildings heated by gas, and over 23 million homes, typically using efficient modern gas boilers. Similarly, most industrial heat demands are fuelled by gas.

Heat demand is highly variable, when compared with current electricity loads, as can be seen in the work by Robert Samson, Imperial College below.

¹² <http://eur-lex.europa.eu/legal-content/EN/TXT/?uri=celex%3A32014L0094>

¹³ <http://www.lowcvp.org.uk/assets/reports/LowCVP%20Infrastructure%20Roadmap-Methane%20report.pdf> p.36

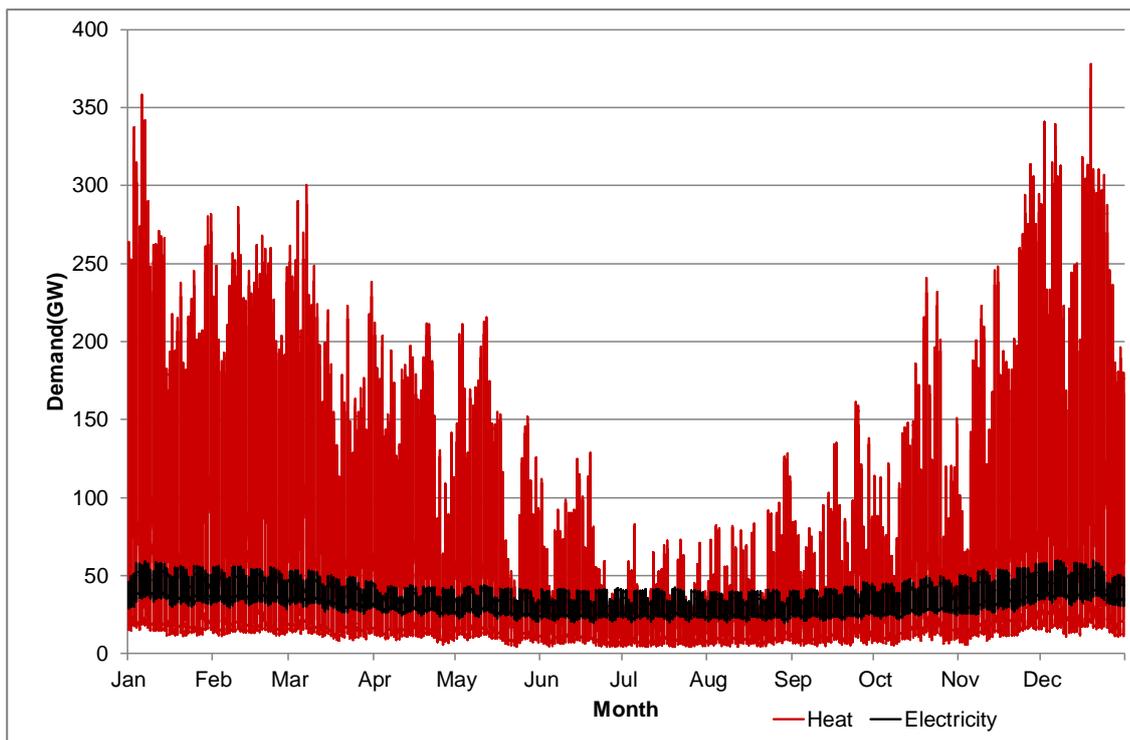

Figure 1: Comparison of half hourly electricity and heat demand variation¹⁴

The peak capacity load on a daily basis is more than five times the lowest day, and the peak capacity hour is more than ten times the lowest hour, which places particular challenges on low carbon solutions for heat.

The current potential options to decarbonise heat are:

Electrification: Efficient electric heat pumps will make an important contribution, but, as recognised in DECC's Heat Strategy¹⁵, major investment would be required to replace current consumer equipment and for the electricity network and generating infrastructure to handle the massive increase and variable demand for heat, making them an expensive solution to meet all heat demand. Persuading consumers to change from existing central heating systems, which have very high levels of customer satisfaction, to new electric solutions, which will require changes in lifestyle, is particularly challenging.

Biomass: Biomass installations require consumers with sufficient space for equipment and storage, limiting their use in urban areas. In practical use, there is concern that small scale biomass boilers can be inefficient and give rise to air quality issues because of high emissions of particulates¹⁶ and potentially nitrogen oxides.

Heat networks: Heat networks require a low carbon source of heat, new infrastructure and sufficient heat density of the load which constrains their use to urban areas (where in general an extensive gas network already exists). As for heat pumps, persuading consumers to move from their existing central heating system is challenging. We believe this option is far less credible in a retrofit scenario, but may be viable for new build when combined with sustainable fuels e.g. biomethane or biomass.

Renewable gas: The gas network is ideally suited to transmitting and distributing variable levels of energy, and is already sized to meet UK demand. Therefore, a solution which utilises the existing gas network to deliver low carbon fuel to existing, efficient installations with no modification to either the grid or end use equipment offers the prospect for best value to gas customers. Renewable gas also supports the continued consumer desire to use gas for domestic cooking purposes. Whilst a relatively small demand, cooking can be an emotive and personal issue for many consumers.

¹⁴ THE IMPACT OF FUTURE HEAT DEMAND PATHWAYS ON THE ECONOMICS OF LOW CARBON HEATING SYSTEMS, Sansom R et al, Imperial College, BIEE – 9TH ACADEMIC CONFERENCE 2012, OXFORD

¹⁵ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/190149/16_04-DECC-The_Future_of_Heating_Accessible-10.pdf

¹⁶ Contribution of wood burning to PM10 in London, 168 Fuller, G. et al Atmospheric Environment, 87-94 (2014)

It is difficult to conceive of alternatives to gas for industrial heat applications, so renewable gas is likely to be the only realistic decarbonisation option for much of our industrial heat usage.

In the context of preparing the business case for National Grid's 2015 bid for funding from Ofgem's Network Innovation Competition for a Commercial Demonstration plant to make biomethane from thermal sources (see below), National Grid's Energy Strategy and Policy Group were commissioned to independently quantify the benefits of renewable gas in the energy system, compared to a scenario without it. The benefits were found to be a £0.5 billion per year energy system cost saving in 2030 (for 37 TWh/a of renewable gas) rising to £3.9 billion per year in 2050 (for 100 TWh/a of renewable gas).¹⁷

NGGD has recently initiated a debate about the place of gas in the UK's future energy supplies and is publishing a series of documents intended to inform this debate, including one on the supply of renewable gas¹⁸. That publication noted that there is a consensus in the industry that UK sources of wastes and residues could generate 80 to 120 TWh/a of renewable gas, and so could meet around one third of future domestic gas demand.

Anaerobic digestion (AD) plants are already producing more than 2TWh/a of biomethane. However, conventional AD can only process some wastes, which limits the potential of the technology to around 20TWh according for an SKM Enviro report for DECC¹⁹. In order for biomethane to make a significant contribution to meeting heat demand it is necessary to develop technologies that can process all types of waste.

This has led NGGD to support the development of Bio Substitute Natural Gas (BioSNG): biomethane produced by the thermal conversion of mixed wastes and residues. We have been working with our partners Advanced Plasma Power and Progressive Energy since 2010 on the development and demonstration of this technology. The consortium has constructed a pilot plant that has demonstrated the technical, commercial and environmental feasibility of the technology and a commercial plant is now being built in Swindon. This will produce 22GWh/a of gas from local household residual waste. Further information about these projects can be found at <http://gogreengas.com/>

The new commercial BioSNG plant will commence operations in early 2018, and the intention is for this plant to lead to the development of large scale thermal biomethane production plants later in the decade. NGGD forecasts that by 2025, BioSNG will be a mature technology. At this point, given a favourable policy environment, the adoption of the technology could accelerate such that by 2030 over 50 large scale plants could be in operation, producing 37TWh/a of BioSNG.

Analysis by the BioSNG consortium partners has shown that, overall, the production of one MWh_{th} of biomethane will result in net negative carbon emissions of 103kgCO_{2eq} compared to emissions of 214kgCO_{2eq}/MWh_{th} for fossil gas. Therefore, overall savings will be 317kgCO_{2eq} per MWh_{th} of biomethane.

Once the BioSNG technology is mature it will produce gas from with the same price as fossil gas and provide consumers with heat for similar prices to those that they pay now.

In relation to the timing of decisions, the Government's Carbon Plan identifies the need to '*deliver between 83-165TWh of low carbon heat*' by 2030. The Renewable Heat Incentive delivered around 4.5TWh in 2015 and the latest RHI consultation document anticipated that the '*scheme will support 23TWh of renewable heat generation in 20/21*'. Therefore a step change is required to meet low carbon heat commitments.

NGGD believes that in view of the very large potential contribution that renewable gas could make to the decarbonisation of heat, **it is important to prioritise the allocation of waste and biomass resources to the production of renewable gas, and to make the decision to do this in the very near future, before such resources are locked into long term contracts for electricity generation.** There are many other ways of generating low or zero carbon electricity (e.g. nuclear, wind, or solar) but few readily-accessible

¹⁷ https://www.ofgem.gov.uk/sites/default/files/docs/national_grid_gas_distribution_-_commercial_biosng_demonstration_plant.pdf

(Appendix 2)

¹⁸ <http://www2.nationalgrid.com/UK/Industry-information/Future-of-Energy/Gas/>

¹⁹ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/48166/2711-SKM-enviros-report-rhi.pdf

alternatives for producing low carbon heat. In addition, the efficiency of energy conversion from waste or biomass to renewable gas (c. 65%) is much higher than the efficiency of electricity generation from waste or biomass (c.25% for conventional incineration plant or 35% for very large ex-coal steam turbine plant).

Role of Hydrogen and Carbon Capture and Storage

BioSNG has the potential to make a significant contribution to heating UK homes and businesses but will not be able to meet all of the UK's heat demand. It could provide 100TWh of gas which is a third of current domestic gas demand, but is ultimately limited by the availability of sustainable feedstocks. Heat pumps and heat network could fill some of the gap but in NNGD's view, in order to fully decarbonise heat it is essential to develop hydrogen production. The existing large scale method for hydrogen production is through steam methane reforming which can be combined with carbon capture and sequestration (SMR with CCS).

Hydrogen can be blended into the existing gas grid and is compatible with existing appliances at higher blends than currently permitted under the gas quality regulations. The NNGD HyDeploy²⁰ project will test the impact of increasing the hydrogen blend to 20% by volume on a real world gas network. This offers another route to reduce emissions and establish low carbon hydrogen production without wholesale conversion of the gas network.

Northern Gas Networks' H21 programme²¹ is examining the benefits and costs of complete conversion of the gas network to hydrogen on a street by street basis. This indicates that hydrogen conversion is viable given enough time and investment. The report estimates that the hydrogen produced by SMR with CCS will have a GHG footprint of 86kgCO_{2eq}/MWh_{th} representing a saving of around 60%. The report also estimates the total capital cost of converting and supplying the major conurbations in the UK, and capturing the CO₂ would be in the order of £50bn.

There are substantial synergies between BioSNG production and the conversion of the gas network to hydrogen. The technology used to produce BioSNG can be easily adapted to produce hydrogen or to produce a blend of hydrogen and BioSNG. BioSNG facilities can offer the flexibility to adapt to increasing levels of hydrogen as the network evolves. This provides a very cost effective and adaptable route to hydrogen production, and unlocks early adoption of hydrogen.

The GHG impact of BioSNG improves dramatically when it is combined with carbon sequestration. The BioSNG process creates a stream of relatively pure carbon dioxide that is suitable for sequestration. If infrastructure for storing carbon dioxide is developed the GHG savings of BioSNG increase by more than 50%. If a BioSNG facility using carbon sequestration is converted to biohydrogen production, even higher savings are achieved because all of the carbon in the feedstock is captured. The biogenic carbon dioxide captured from the atmosphere (which has previously been taken up by the biomass) is sequestered, creating genuinely negative carbon emissions.

Developing technologies with negative carbon emissions is essential in meeting 2050 climate change goals. The negative emissions will offset emissions from hydrogen produced by SMR with CCS and from other sectors that are hard to decarbonise such as aviation and farming. The imperative of this is shown very clearly by the Energy Technologies Institute (ETI) in their ESME Modelling in Figure 5

²⁰ https://www.ofgem.gov.uk/system/files/docs/2016/04/ng_ngn_hydeploy_isp.pdf

²¹ <http://www.northerngasnetworks.co.uk/wp-content/uploads/2016/07/H21-Report-Interactive-PDF-July-2016.pdf>

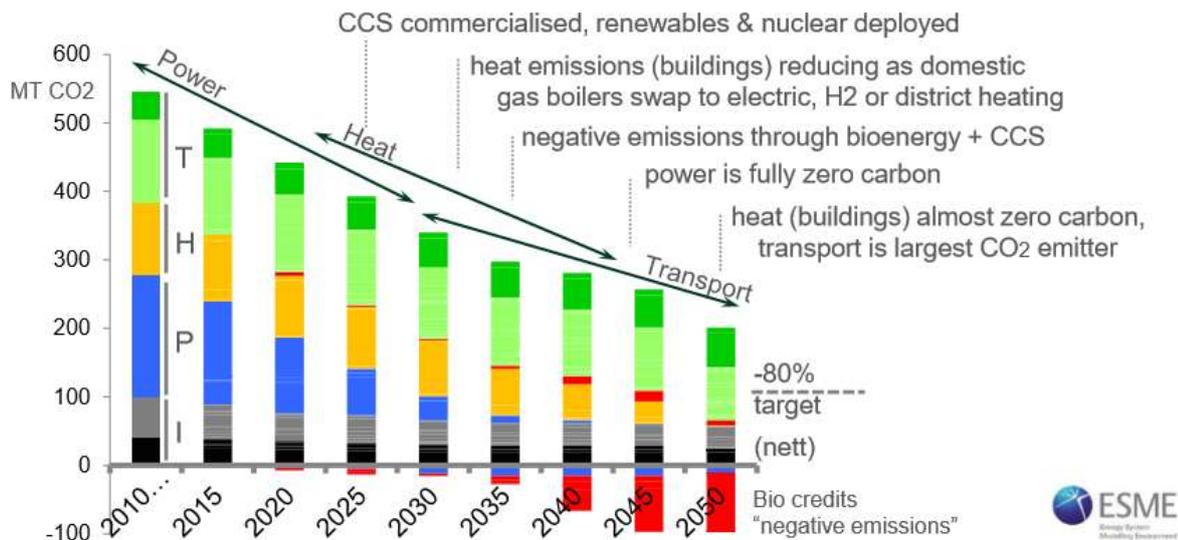

Figure 2: UK Energy system decarbonisation route-map to meet 2050 targets²²

NGGD believes that in view of the important contribution that hydrogen can play in decarbonising heat that it is important **the Government supports the introduction of technologies and infrastructure to enable carbon capture and sequestration** as recommending in the Oxburgh report²³. The incentives for production of low carbon heat should recognise and support the importance of hydrogen whether it comes from renewable sources or fossil sources combined with CCS technology. The Government should provide grants and other support for the development of hydrogen technologies.

Question 21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

The Low Carbon Vehicle Partnership's (LowCVP) methane infrastructure road map²⁴ predicts 190,000 gas fuelled HGV's and 17,000 buses by 2050.

The gas demand associated with that fuel requirement is c. 50TWh/yr. In 2013, the total UK gas demand was 850TWh/yr (including 294.2TWh/yr of domestic gas demand). Against a backdrop of reducing gas demand; the 2050 gas vehicle demand was only 6% of UK demand in 2013.

We believe the gas distribution network can easily support this level of increase in gas demand as a result of the uptake of lower carbon gas vehicles.

Our answers to questions 13, 14 and 15 also cover many issues relevant to this question.

Question 27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

NGGD believes that financial incentives are extremely important in the short term to develop a sustainable waste to energy industry, but that currently they are not correctly aligned between heat, transport and electricity outputs to produce outcomes that optimise least-cost carbon reduction.

Renewable Heat Incentive (RHI)

The RHI provides support to biomethane produced by AD and gasification technologies such as the BioSNG process. However, support drops off rapidly for facilities producing more than 40GWh/a of gas. This is an appropriate limit for AD, which works best in small facilities designed to use locally available agricultural

²² Heat and Energy Systems, Dr David Clarke FEng, Chief Executive ETI, Heat Catapult November 2016

²³ http://www.ccsassociation.org/index.php/download_file/view/1043/508/

²⁴ <http://www2.nationalgrid.com/UK/Industry-information/Future-of-Energy/Gas/>

feedstock, but it is too restrictive for BioSNG, which operates in an urban environment where waste volumes are higher.

DECC launched a consultation on reforms to the RHI in the spring of 2016. NGGD, the Renewable Energy Association, and range of engineering companies responded to ask for more focussed support for BioSNG with a separate RHI band providing 5.87p/kWh without any limits on scale.

BEIS published their response to the consultation on 14th December 2016. They agreed that BioSNG could increase the supply of green gas but rejected setting up a new band because of lack of evidence on costs and the risk of overcompensation.

NGGD and its partners in the BioSNG projects are engaging with waste companies to start development of large scale BioSNG plants. The completion of the first commercial plant in 2018 will be followed by facilities around ten times bigger, **but this will require appropriate support schemes in place.**

Renewable Transport Fuel Obligation (RTFO)

The RTFO is a further scheme that has the potential to incentivise waste to renewable fuel plants. The Department for Transport issued a consultation on changes to the RTFO on 29th November 2016.

In its response to the consultation, NGGD has stated that:

- The proposed changes are good for decarbonising transport and establishing a biofuels and low carbon transport industry that will create jobs, investment and exports.
- Biomethane is one of the best candidates for decarbonising heavy goods vehicles and buses and should be included in the development target.
- The buy-out price for development fuels should be set at a high level to provide strong incentives for this new technology.

Contracts for Difference (CfD) Scheme to support renewable electricity generation

NGGD has recently responded to BEIS's call for evidence on fuelled and geothermal technologies in the CfD scheme. In summary, we have suggested that so-called Advanced Conversion Technologies (ACTs) should no longer be supported by the CfD scheme but that ACT-based heat and fuels are appropriately supported. This is because the current ACT regime means that some projects are receiving a substantial subsidy for converting waste to electricity at efficiencies (<18%) lower than open market projects which operate with no support. This means that consumers are paying a subsidy for a worse carbon outcome; this is certainly not cost effective decarbonisation.

We suggest that removal of support for ACTs under the CfD regime should be undertaken in a co-ordinated way including enabling support for heat and fuels. This must focus on ensuring the future incentive regime for renewable heat provides the transitional support which was formerly delivered to AD, to allow gasification to deliver early commercial projects prior to being able to operate without support. Similar co-ordination is required with the Department for Transport on the Renewable Transport Fuel Obligation which is also currently under consultation.

Question 28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

A circular economy delivers effective resource utilisation. As noted previously, simply burning waste to generate electricity misses the opportunity which this bio-rich resource offers. Reforming the waste to a clean syngas, which can be used as a chemical precursor for production of fungible gas, fuels or chemicals, is an ideal form of molecular recycling.

Production of a clean syngas by gasification of waste also facilitates carbon capture using existing proven carbon dioxide separation technologies which have been operating for many decades. Conversion of a solid

to a gas or a liquid inevitably leads to excess bio-carbon which is rejected as bio-carbon dioxide. This forms the basis for the use of BioEnergy CCS (BECCS) which is recognised by both the Committee on Climate Change²⁵ and the ETI²⁶ as fundamental to meeting our 2050 targets. This approach already delivers captured bio-carbon dioxide today. For example production of methane from solid biomass leads to around half of the carbon separated as storage-ready carbon dioxide. This is already undertaken at all ~70 AD biomethane plants, some of which capture the carbon dioxide and sell it to industry. It will also be demonstrated at the NGGD supported BioSNG project at Swindon, where 5000 tonnes of carbon dioxide per annum will be sold to industry. In the future, this approach can be extended (simplified), with hydrogen produced as the energy vector with separation of all the carbon for storage.

The language used when referencing waste can be unhelpful: thinking of it as resource rather than waste may enable a more positive and constructive approach. It may also facilitate the cross departmental working that is critical to an effective circular economy. Waste must be considered as a valuable resource which needs to be managed efficiently, and within a framework which can recognise strategic priorities such as keeping people warm and our industry fuelled.

Summary of Key Points from Our Response

One of the key investment questions facing our country in the coming decades is: How to decarbonise our heat and transport sectors.

- 1. Approximately two-thirds of residential and commercial energy consumption is met by natural gas (methane.) Gas provides 4/5 of total energy demand for heat at peak times. Reliable and safe gas supply is essential to the UK economy and domestic consumers.**
- 2. Over 80% of UK households use gas²⁷ and for the vulnerable and those in fuel poverty gas is significantly cheaper than coal, oil or electricity.**
3. To achieve the carbon reduction targets set out in the Climate Change Act 2008, 80% reduction from 1990 levels by 2050, significant investment will be required in Great Britain's energy infrastructure.
4. NNGD believes that the role that gas can play in both the short and long term should be considered carefully if we are to meet the demands of the energy trilemma. Maximising the value of the existing gas infrastructure has the greatest potential to support sustainable growth, both as a seed from which to grow new networks and as a conduit for sustainable gases.
5. Electricity is likely to be more expensive for consumers, may not meet future demand and may not achieve the targets for cutting carbon pollution. We believe that natural gas will play a crucial role as a bridging fuel as the energy system becomes carbon-free and innovative solutions developed that could use the existing gas networks such as biomethane or hydrogen.
6. The National Infrastructure Plan should incorporate natural capital into each of the main infrastructure sectors, following the mitigation hierarchy for managing impacts (avoid, minimise, restore, offset). An investment programme for natural capital should also explicitly feature in the National Infrastructure Plan.
7. The adoption of Ultra Low Emissions Zones (ULEZ) and Clean Air Zones across the major cities in the UK, alongside national policies to reduce emissions, will change current patterns for freight and buses by driving the adoption of more environmentally friendly vehicle technology such as compressed natural gas (CNG).
8. NNGD believes that financial incentives are extremely important in the short term to develop a sustainable waste to energy industry, but that currently they are not correctly aligned between heat, transport and electricity outputs to produce outcomes that optimise least-cost carbon reduction.

National Infrastructure Assessment – Call for Evidence

Response from Dorset Local Enterprise Partnership

1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of “highest value” should include benefits and costs, as far as possible taking a comprehensive view of both. “Long-term” refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

Please cross-reference with attached documents;

- 1. Dorset Rail Infrastructure map**
 - 2. Dorset Road Infrastructure map**
 - 3. Wessex North-South Connectivity study**
 - 4. Large Local Transport Majors application (A31-Poole Link)**
- Housing: Investment in major “place” regeneration of socially deprived areas to include accelerated new house building;
 - Road (External links) – Improvements to A31 between Ashley Heath and M27 (Southampton);
 - Road (External links) – major improvements to North-South route(s) accessing M4 via A350, providing significant benefits in closing productivity gap.
 - Road (External links) – improvements to A303/A358/A30/A37 to provide far better access to M5 from Dorset via Yeovil/Taunton.
 - Road (External links) – Provision of major new link road between Poole and A31, unlocking several thousand new homes;
 - Road: (Internal links) – Further dualing of A35 at key locations to ease significant congestion on E-W journeys across Dorset and into neighbouring counties
 - Rail: (External links) – Faster journey times between Bournemouth, Poole, Weymouth & London through significant track and signalling upgrades;
 - Rail: (External links) – greatly improve routes via Weymouth to Exeter, Taunton, Bristol, Swindon, Salisbury – Yeovil South Chord proposal is key.
 - Rail: (External links) – Weymouth to London via Yeovil. Redoubling of track between Wool and Morton. Power supply capacity improvements.
 - Rail: (Internal links) – ‘Dorset Metro’ – new and frequent cross-conurbation commuter train services, including new branch lines to Wimborne and Ferndown and potential for link to proposed Solent Metro;

- Rail: (Internal links) – a new station to serve Bournemouth University and Arts University Bournemouth campus.
- Rail: (Internal links) – creation of Dorset Innovation Park (Enterprise Zone) station, possibly involving relocation of nearby Wool station.
- Public/Low Carbon Transport (Internal Links) – Greater investment in sustainable travel – bus infrastructure, electric buses; cycling infrastructure; multi-purpose transport hubs;
- Public Transport: (Internal links) – creation of new transport interchange at Weymouth train station
- Transport: Air (External links) – Improve capacity and facilities at Bournemouth Airport with a view to increasing flights to and from key trading destinations to enhance export opportunities and the attraction of customers/visitors;
- Transport: Sea (External links) – Increase capacity and capability of Ports at Poole and Portland to enhance export opportunities and attraction of customers/visitors;
- Digital communications – early/quick adoption of 5G infrastructure to prepare for future ways of working and increase productivity

2. How should infrastructure most effectively contribute to the UK’s international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Cross reference with;

1. “A Strategic Economic Vision for Dorset”

The critical elements of successful world class economic regions should inform the prioritisation of investment in infrastructure in the UK and Dorset.

Dorset’s economy generally performs very well. There is very low unemployment¹ and a number of high-performing key sectors, especially financial, digital, creative and advanced manufacturing. However, there are issues with productivity and further growth being constrained by important infrastructure requirements.

The Dorset LEP “Strategic Economic Vision for Dorset” (Feb 2016), agreed and signed by all public sector partners, outlines the aspiration for Dorset to be Britain’s most sustainable core city region by 2033.

The relevant infrastructure elements to deliver the economic vision for Dorset are:-

1. High productivity economy – enabled by fit for purpose physical and digital infrastructure
2. Accessible to markets – good international, national and internal connectivity by road, rail, air and sea including increasing public transport use, reduction in travel times and the roll out of Ultrafast broadband and 5G infrastructure;

¹ Bournemouth has been identified as the fifth-fastest growing area for jobs in the UK over the past 10 years by Centre for Cities

3. A world class workforce – high quality universities and further education colleges providing courses and apprenticeships supporting key local sectors such as finance, digital/media and advance manufacturing;
4. Making the most of the natural environment – ensuring that the area provides a world class environment in which to do business and to attract new business and talent;
5. Provision of housing to facilitate growth – increasing the supply of all housing stock to help address affordability constraints on growth

Investment in infrastructure needs to be analytically and strategically applied to a mix of solutions across a wider range of regional areas to provide the optimum return on investment and contribution to the UK's international competitiveness.

Central infrastructure investment currently seems focused in too few regional areas and only on a handful of significant major (or political) projects, meaning that other areas with great potential for growth are not realising that potential. Investment could be more effectively dispersed across less large but nonetheless important enabling projects in order to unlock greater economic growth. In the recently published Green Paper 'Building our Industrial Strategy' government has acknowledged the need to *"better align central government infrastructure investment with local growth priorities"*.

Gateways for passengers, freight and data are very important for Dorset.

Bournemouth is one of the fastest growing digital/media economies in the country with excellent prospects for further growth. Availability of the latest technology and access to the fastest data transfer services is vital to supporting this growth and spreading the benefits across Dorset. The recent announcement by Ordnance Survey that it is to trial its 5G mapping software in Bournemouth recognises the importance of its potential and is typical of the high-tech investment that is needed if it is to compete on the world stage.

Dorset is home to a number of major financial institutions including JP Morgan which has its UK headquarters and international technology and operations situated in Bournemouth. Due to the international nature of these financial institutions it is vital that there are good quality international connections.

Dorset has numerous language schools and overseas student numbers have increased significantly over recent years with the exponential growth of Bournemouth University and the Arts University Bournemouth. Having effective international gateways to/from Dorset not only supports the schools and universities but brings considerable income into the local economy. Furthermore due to the attractiveness of the area many students often elect to remain in the town using their talents to not only support local businesses but also to establish new businesses.

Another key business sector is the tourism industry. Dorset has an exceptional natural environment, including the World Heritage Jurassic Coast. The area attracts millions of visitors each year, both from home and overseas bringing significant benefits to the economy.

In order to support current business sectors and future growth prospects and in order to make the most of potential international markets it is therefore vital that Bournemouth Airport and the Ports of Poole and Portland are able to provide connections to key international markets and customers.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The quality of the local environment plays a vital role in the ability to attract customers and talent. Future urban infrastructure therefore needs to be designed around people, movement and place, reflecting the priority given to the most successful, attractive and inspiring towns and cities in the world.

In the post war era, too much emphasis has been placed upon function rather than place. Typical of this has been the overemphasis on the provision for cars which has led to unwelcoming major roads, blighting the urban landscape and severing communities. Whilst the strategic road infrastructure between and into and out of towns remains critical for economic success, there is the need to fundamentally reimagine our urban areas with the emphasis being on providing inspiring, attractive and sustainable places for people to live and move around.

Increasingly people are more aware of how their actions and choices impact upon the environment and therefore would actively seek out to live in places which support a more sustainable lifestyle. Dorset's age demographic is changing and the emerging younger generation can catalyse green economic growth in the area. Bournemouth is seeking to become one of the UK's leading 'green' cities and is looking to emulate other 'Green Economy Leaders' such as Vancouver, Stockholm and Copenhagen. For Copenhagen, the title of Green Economy Leader is expected to lead to more than 100,000 people migrating to the city by 2025.

To help attract growth, town and city centres need to have a very high quality public realm supported by sustainable, convenient, clean and attractive transport systems. In the future this would typically involve a mix between the provision of excellent walking and cycling facilities and a modern public transport system, possibly with electric buses, trains and/or trams.

Housing should also be designed with green credentials in mind and located to minimise the need to travel and therefore the need for additional infrastructure. Facilities and utilities need to be provided to new build housing to encourage remote working where possible. Business hubs should also be provided as part of new developments or within existing infrastructure so that employees of different businesses can set down and work remotely whilst still enjoying the interaction and sharing of ideas with others.

For those that do need to travel to work by car there is the need to provide much higher quality, attractive, multi-functional travel exchange hubs (rather than simple and uninviting park and ride sites). This would enable and encourage commuters to switch to more sustainable transport modes for their onward journeys into city and town centres.

Housing again needs to be designed with the need to attract talent in mind. Fast data communication hardware needs to be installed into new housing (for as long as hard wired networks are still required). Access to leisure is also a key requirement for most people therefore sustainable access to parks, shopping, sports facilities and entertainment also needs to be considered.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: "demand management" includes smart pricing, energy efficiency, water efficiency and leakage reduction. "Rebound effects" refer to the tendency for demand to increase

when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Transport demand management should broadly be characterised by two elements. Firstly the avoidance of the need to travel and secondly, if travel is necessary, the need to restrict travel by car.

Within Dorset's main conurbation of Bournemouth and Poole there is the potential to reduce demand significantly. In avoiding the need to travel, a typical intervention would be the encouragement of home or remote working. For this to be successful the right digital infrastructure needs to be in place and there would need to be a culture change facilitating greater take up amongst employers, who can often be resistant due to the perceived lack of control over remote working staff.

Reducing the demand for car travel presents considerable opportunities. Many people are willing to change their travel behaviour but the greatest barrier is the current lack of safe, convenient and affordable alternatives. Addressing this issue requires urgent attention and significant investment.

Where investment is made into alternative, sustainable transport and this leads to modal shift, surplus highway space may be reallocated to provide improved public realm, further sustainable travel networks or space for redevelopment, thereby helping to avoid any rebound effect.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Initially there is a need to identify what infrastructure is required both now and in the future. This assessment needs to be based upon both function and form i.e. does the asset serve an important purpose? Does the asset have any heritage/place making value? For those assets that pass this test generally it is more cost effective to carry out maintenance. However an assessment needs to be made as to whether continued maintenance of the asset is cost-effective or whether it should be replaced or whether a completely new and alternative asset should be provided.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

There is significant potential to improve collaboration between different client agencies that provide infrastructure. The absence of an overarching local infrastructure planning framework often means that agencies operate in isolation. The result can be the inefficient and uncoordinated provision of infrastructure, e.g. the location of a hospital or university facility with poor transport access will require additional and potentially avoidable investment in transport infrastructure.

The current local planning system neither has sufficient scope nor sufficient powers to ensure that all agencies work together to optimise key infrastructure investment. Consideration should therefore be given to the establishment of formal 'local

infrastructure bodies' which would require key agencies to identify, co-ordinate and plan future infrastructure helping to ensure that the right infrastructure is brought forward and is delivered as cost-effectively as possible. In the Green Paper 'Building our Industrial Strategy' government has acknowledged the need to create "... *the right institutions to bring together sectors and places*" and local infrastructure bodies could fulfil that role for infrastructure provision. These bodies could form part of an extended role for Local Enterprise Partnerships and/or in partnership with Combined Authorities and include expert representation typically from each of the following agencies: -

- Key local businesses;
- Political leaders;
- Local planning authorities;
- Urban designers;
- Local transport and highway authorities;
- Local clinical commissioning groups;
- Healthcare providers – GPs/Hospitals etc;
- Environmental bodies;
- Universities and FE Colleges;
- Education authorities/bodies;
- Network rail;
- Train operators;
- Bus and other public transport operators;
- Air and sea port operators;
- Energy providers;
- Water and waste water companies;
- Digital communications companies;
- Agriculture and fishing bodies;
- Waste management authorities;
- Flood risk authorities;
- Housing authorities/providers;
- Landowners;
- Housing developers;
- Other developers;
- Leisure providers;
- Contractors (e.g. Constructing Excellence)

Collaboration between key agencies is the most critical factor in delivering the right infrastructure effectively.

The use of competition can be applied to both client agencies and contractors building the assets. Whilst competition at the client level, e.g. energy companies and train operating companies, can be beneficial there is also concern that commercial interests (profit) have the potential to impede wider benefits. The creation of a 'local infrastructure body' with appropriate powers could help to mitigate this risk. In regard to contractors delivering the physical assets, provided that appropriate procurement options are followed competition is usually beneficial in securing better value for money.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

Current investment in road infrastructure is catered for through LTP and other DfT grant settlements. However other infrastructure, important for creating attractive places to live and work is not directly or adequately catered for. Typically, urban realm and regeneration schemes either have to be funded through developer contributions, which are becoming increasingly difficult to secure to the levels of funding required, or through local authorities’ own budgets which are already under considerable pressure. The identification of funding streams to support the development of both the built and natural environment would therefore be welcomed.

The creation of a funding/grant system that supports a broader infrastructure spectrum, rather than the current systems which primarily focuses on road construction, would be beneficial, and could help deliver the wider aspirations of potential ‘local infrastructure bodies’.

The introduction of longer-term, strategic funding opportunities would be extremely welcome. Too often funding opportunities are issued in very narrow timescales with shovel-readiness seemingly outscoring benefit cost ratios. Greater clarity/transparency on evaluation processes would be very welcome. Feedback on unsuccessful bids is usually very limited at best and does not offer any insight into how to improve future bids. The ability to bid for 10 year (or more) settlements would provide areas with far greater ability to deliver vital infrastructure and enable strategic partnership working as well as the opportunity to collaborate regionally to jointly fund major schemes that have historically been unachievable by local areas/authorities on their own.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

Raising capital for upfront funding of projects, particularly those requiring significant advance investment, is extremely difficult for local authorities. In some cases, upfront investment could be partially reimbursed through the charging of fares or fees or through the franchising of assets – e.g. the creation of a Dorset Metro rail system. However it should be borne in mind that benefits from assets are not always realised directly and even if a project may not be self-financing the wider economic and social benefits also need to be taken into account – e.g. increased tax revenue; reduced health or social care costs. When these indirect benefits are factored in the case for government intervention becomes much stronger.

At present local authorities would find it politically very challenging to introduce road – user charging to help fund projects as for many people there are not convenient alternative transport options in place. The provision of much better rail, cycling and bus infrastructure would make the case for road-charging considerably stronger and the income from this could then be used to offset some of the upfront infrastructure costs for these alternative modes.

The ability of local areas (e.g. through LEP, Combined Authority or 'local infrastructure body') to create rolling investment funds through e.g. use of devolved tax receipts (Stamp Duty, land charges) to enable pump priming of projects would be very useful.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

(Refer also to Q.6) The fundamental problem with current arrangements is that many key agents develop their future infrastructure plans in isolation which can lead to inadequate overall outcomes. A co-ordinated approach through a formal 'local infrastructure body' would address this problem and help to ensure that interdependencies are properly identified and catered for.

A formal local infrastructure body could also take on the explicit responsibility for ensuring resilience is accounted for in the design and construction of infrastructure as well as the ongoing management of resilience risk i.e. need for maintenance or other interventions.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

(Refer also to Q.6 and Q.9)

At present the planning system does not have sufficient scope, powers or resources to be able to fulfil governance effectively. In many respects the planning system can appear to be adversarial. Planners set planning rules and seek to obtain contributions from developers in order to provide the supporting infrastructure necessary to offset the impacts of the development, whereas developers seek to minimise any contributions in order to maximise returns on investment. The result is often a piecemeal, short term, reactive approach to the provision of infrastructure, rather than the strategic, co-ordinated approach that is required.

The provision of a formal local infrastructure body with wider powers and resources would help to address this issue, enabling strategic infrastructure to be properly planned in advance so that all parties are clear about what is required in terms of the infrastructure necessary to support any development. This upfront approach would make a significant contribution to 'fast-tracking' development through the planning system helping it to be delivered far more efficiently and on time.

Other measures that could be taken to speed up the delivery process would be increasing CPO powers over land which has no current intrinsic value.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Dorset's natural environment is a unique and major asset and makes a significant contribution to attracting businesses, customers and talent to the area. As well as the Jurassic Coast World Heritage Site, it also has wide areas of very important heathland

and wetland that is home to rare protected species, birds, flora and fauna. As a result many of these areas are subject to international environmental habitat designations.

It is therefore paramount that the provision of infrastructure should respect Dorset's natural environment, contributing towards its protection whilst enabling appropriate access for its enjoyment. This is clearly recognised in the Dorset LEP "Strategic Economic Vision" and the Natural Capital Investment Strategy produced by the Dorset Local Nature Partnership².

Access roads, car parks, visitor centres, disability friendly footpaths etc. all need to be carefully set out to strike the right balance between protection and access.

The Dorset coastline is particularly vulnerable to erosion. Coast protections and flood defence works can therefore help to protect the coastline as well as important habitats. However great care is required in the design to ensure that the infrastructure provided is sympathetic to the natural environment.

Roads, structures, renewable energy infrastructure, telecoms masts and pylons also all need to be sensitive to their setting within the landscape and should therefore be appropriately located.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: "credible" improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. "Tractable" improvements are those that can generate usable quantitative outputs. "Transparent" improvements are those that do not rely on 'black box' modelling and assumptions.

There is an urgent need to review cost-benefit analysis associated with infrastructure. The Growth Deal initiative has highlighted the inadequacy of current cost benefit analyses. For transport schemes designed to unlock employment land, the main economic benefit is treated as the saving in journey times rather than the considerable GVA generated from the creations of jobs. Current cost-benefit approaches can therefore lead to the wrong outcomes being measured, potentially leading to perverse outcomes with investment being directed into the wrong infrastructure. This issue has been partially recognised but a far better approach is needed.

Cost-benefit analyses should be targeted at a wider range of economic and quality of life 'building blocks' that will deliver the optimum outcomes and return on investment.

Greater focus therefore needs to be given to the ability of any scheme to deliver against key overarching outcomes such as: -

- Creation and protection of jobs;
 - construction of offices, business units, research/innovation centres; factories etc;
 - enhancement in agriculture and fishing facilities;
 - facilities to improve access to markets (local, national and international);

² https://www.dorsetlnp.org.uk/Natural_Capital_Investment_Strategy.html

- facilities to improve access to employment;
- Developing skills;
 - construction of university buildings; FE colleges, training centres; new schools etc;
 - facilities to improve access to education;
- Enhancing the built-environment;
 - construction of attractive public realm infrastructure in business, town, and neighbourhood centres;
 - construction of modern transport hubs;
 - regeneration initiatives;
 - creation of public open space and parks
- Healthier lifestyles;
 - construction of leisure, recreational and sports facilities,
 - creation of better walking and cycling environments;
 - facilities to improve access to leisure, recreation and sport;
- Improved Healthcare;
 - construction of hospital and healthcare facilities;
 - facilities to improve access to healthcare;
- Protection of the environment;
 - construction of sustainable travel networks e.g. rail, bus, cycling and walking;
 - provision of renewable energy;
 - Provision of flood and coastal defences.

Underpinning the above key outcomes is 'enabling infrastructure'. This enabling infrastructure should be assessed to the degree in which it contributes to the delivery of the above outcomes – rather than in its own right which currently can be a particular issue with road schemes. Typical enabling infrastructure may be considered to be: -

- Transport links (external and internal);
 - enhancement and construction of rail, road, bus, cycling and walking infrastructure;
 - enhancement of airports and sea ports.
- Utilities;
 - construction of water and waste water treatment facilities;
 - provision of affordable energy;
 - provision of digital and telecommunications hardware;
 - provision of waste management facilities
- Mineral extraction;
 - quarries, processing plants etc;

Few infrastructure schemes will contribute to all of these outcomes. It is therefore necessary to devise a cost-benefit mechanism that appropriately weighs the various outcomes so that differing schemes can be assessed and compared in terms of which deliver the best overall value for money. It may be difficult to develop credible, tractable or transparent cost-benefit analysis techniques capable of analysing and comparing the ability of differing schemes to deliver such outcomes, this should not be a reason for analysing simpler, alternative, non-critical outcomes. The focus should always remain on assessing the key outcomes, not the degree of difficulty involved in the assessment.

Greater consideration also needs to be given to post-project analysis. Post-project analyses are seldom properly carried out on infrastructure schemes and yet they are very important in answering two key questions;

- 1) Were the intended benefits/outcomes realised?
- 2) If the benefits/outcomes did not align with what was intended, what adjustments need to be made to future cost-benefit assessments?

Furthermore, evidence from post-project analyses has an important role in building a picture of what constitutes successful infrastructure interventions, to help inform future investment decisions. There would be a significant benefit in the NIC developing a national standard for cost-benefit analysis and post-project evaluation.

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

The answer to is highly dependent upon where investment in transport infrastructure and technology is directed. Over the past sixty years the focus has been primarily on road building, which has inevitably led to the significant increase in car use. Similarly the future will be dictated by where transport investment is targeted.

Travel patterns and mode choice in the Dorset region have changed less than predicted over the past decade. Whilst inter-urban transport is likely to continue to be dominated by roads and cars to move people and freight around, land pressures within urban areas and the inability to continually widen roads, coupled with increasing congestion and air quality issues means a different transport regime is inevitable in our towns and cities. Infrastructure targeted at buses, rail, cycling and walking make much better use of available land and assets. With step changes also taking place in travel planning technology there is significant scope to improve sustainable travel making it far more attractive and easier to use. Therefore, with the right investment, in the future far more journeys will be undertaken by bus, rail, bike or on foot.

Growth of outward commuting is anticipated in Dorset as commercial premises are likely to be converted to residential via prior consent. Future development of brownfield sites will be principally residential rather than commercial. If the skills of new residents match the town centre job market, this will result in growth of short distance walking and cycling trips in town centres. If not, this will result in outward commuting which tends to be longer

distance trips to places more difficult to serve by sustainable transport. With the advance in technology, increasingly people will be electing to work from home, further reducing demands on the transport network. Currently daytime travel is dominated by peak hour commuter travel. Over the next 30 years there is likely to be a significant shift towards leisure travel and away from commuter travel. This will also deliver journey time benefits avoiding the need for any further major investment in road building for cars within urban areas.

With the provision of genuinely viable sustainable travel alternatives, demand for car use will be considerably less within towns and cities. This will be reinforced should car-use charging be introduced by which time most cars are likely to be electric, potentially autonomous vehicles.

Advances in autonomous vehicles raise the question of how traffic could be managed in the future. Coupled with advances in technology there is potential for both personal use and freight vehicles to be remotely 'orchestrated' to optimise journeys, although the advent of unforeseen incidents (e.g. potholes, severe and sudden weather events) and how to manage these represents significant difficulties. The number of people without driving licences is likely to grow as society ages and they will be a prime market for autonomous vehicles. Personal mobility is likely to increase; there will be a move to personal automated transport and the taxi and bus markets will change radically. Autonomous vehicles are likely to increase the total number of trips, as people make more trips; the vehicles will be shared and will therefore have more positioning trips/mileage. The demand for car parking on-street will diminish, but autonomous vehicles will still need parking space, which can be in remote locations, not prime town centre locations.

With its diverse population and geography, coupled with significant predicted growth, Dorset will inevitably see a greater demand on air and rail travel in future.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

Movement of people into and out of major urban areas

- Investment in new link road between Poole and A31 trunk road.
- Investment in 'Dorset Metro' commuter train service;
- Reopen key rail branch lines to Wimborne and Ferndown;

Movement of freight into and out of major urban areas

- Investment in new link road between Poole (including Port of Poole) and A31 trunk road;
- Investment in rail freight handling facilities.

Movement of people within major urban areas

- Investment in sustainable transport infrastructure for buses, rail metro, cycling and walking, including travel hubs;
- Investment in 'Dorset Metro' commuter train service;
- Investment in travel information technology.

Movement of freight within major urban areas

- Investment in sustainable transport infrastructure to reduce congestion and help free up internal strategic road network for freight.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

Given that large areas of Dorset are 100 miles from London, 80 Miles to Bristol and 80 miles to Exeter our rail connectivity is far below what is expected and needed. In fact current rail provision hinders economic growth. Inevitably rail is not the quickest method of transport within and outside of Dorset. This hinders the labour market and growth in productivity. Rail has the potential to increase housing supply within Dorset. Dorset LEP has worked with key local stakeholders to articulate the most important required changes to the rail network to address these issues (refer to Rail Infrastructure Map).

Mass transport, such as trains, subways and trams are efficient movers of people. Their ability to move large numbers of people along fixed routes will come under pressure from the convenience and end to end speeds of automated personal public transport provided by automated vehicles. This suggests that these modes need to modernise and achieve shorter journey times.

Network Rail's route studies are the current way to achieve this. The Wessex Route Study covers the period to 2043 and predicts a 40% increase in passenger demand in that timescale. The study suggests ways in which that growth can be accommodated. If the investment isn't forthcoming those additional trips will transfer to other modes, putting pressure on other modes and the transport network. The route study proposes a series of iterative increases in speeds and capacity, rather than a technological step change. Increasing rail capacity to and through Dorset particularly on routes to the east and the rail line to Bristol is an essential part of the transport mix required to facilitate the housing and employment targets. Historically, rail in the Dorset region has not received sufficient investment and there has been a trend to reduce capacity rather than increase it. The current focus on several high profile long-term schemes to provide new facilities, could easily reduce the amount of money available to continue investment in the existing network, which carries and will continue to carry the vast majority of rail passengers and freight. There also appears to be a skills shortage in specialist rail areas such as signalling, which is a substantial constraint on delivering projects and a lack of capacity in

the rail manufacturing sector, which also constrains the number of projects that can be progressed.

Movement of people outside of major urban areas

- Investment in infrastructure to reduce train journey times to London;
- Rail - greatly improve routes via Weymouth to Exeter, Taunton, Bristol, Swindon, and Salisbury.
- Rail – Weymouth to London via Yeovil. Redoubling of track between Wool and Morton. Power supply capacity improvements
- Investment in improving strategic road network – A31 trunk road between Ringwood and Southampton;
- Enhance facilities at Bournemouth Airport
- Enhance facilities at Port of Poole

Movement of freight into outside of major urban areas

- Investment in improving strategic road network
 - A31 trunk road between Ringwood and Southampton;
 - Road – major improvements to North-South route(s) accessing M4 via A350, providing significant benefits in closing productivity gap.
 - Road – improvements to A303/A358/A30/A37 to provide far better access to M5 from Dorset via Yeovil/Taunton.
 - Road – Provision of major new link road between Poole and A31 to create far better access to eastbound freight routes;
 - Road – Further dualing of A35 at key locations to greatly improve congestion and E-W journey times
- Investment in rail freight handling facilities.
- Enhance facilities at Bournemouth Airport
- Enhance facilities at Port of Poole

16. What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

MaaS changes transport from an ownership model to a service model; this makes it easier to charge variable prices for the same journey, by differing time of day, levels of congestion etc. There is an equity argument where the value of a journey is simply converted to the ability to pay, rather than the need for the journey.

However if there are untaxed alternatives, then this would have the effect of making MaaS artificially less attractive and could well slow the take-up of MaaS services.

If autonomous vehicles really take-off in the study period, they are likely to prove very popular and inexpensive to the point where they are the predominant mode deployed to provide MaaS, so rather than optimising the mode to the particular trip, there will be a trend to a single mode provision

There is considerable scope to use 'mobility as a service' not only for road user charging but for helping people to access real-time public transport information and buy tickets online. A fully integrated travel information network has the potential to vastly change travel behaviour and digital Apps are already being developed with this capability.

Mobile technology has tremendous potential to reduce the amount of infrastructure necessary on street such as real-time bus travel information displays. The ability to use phones to geo-spatially track drivers has obvious cost-saving implications on delivering future road user charging regimes; however the greatest potential is with sustainable travel.

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

Dorset is fully supportive of the NIC's Connected Future Report (Jan 2017)) and recommendations.

In addition to the 6 identified areas (1. Putting digital infrastructure at the heart of the UK's industrial strategy; 2. Motorways with mobile telecommunication networks fit for the future; 3. Rail passengers should have high capacity wireless connectivity; 4. Local government should actively facilitate the employment of mobile telecoms infrastructure; 5. Meaningful metrics on coverage; 6. Review the sharing of telecoms infrastructure 7. Regulatory review of mobile communications market) significant investment is needed in data and cloud infrastructure to enable a city region's (as Dorset aims to become) interoperability. A civic intelligence centre, similar to that of the [Mayor's Office of Data Analytics in New York](#), would enable all city region stakeholders to build capacity and capability to collect, analyse and visualise data across departments and fully realise the potential for a Smart City region. Business intelligence teams in local areas need investment in specific skill sets such as data analysts that will unlock the potential of how local data can be used to help inform authorities on how to cut costs, enabling them to become more efficient in their delivery of services, resulting in a data-driven approach to business decisions. Talent attraction into this area remains difficult as public sector employers are not competitive in terms of remuneration and the awareness of the opportunities within Councils is poor. This could be an area in which LEPs and/or Combined Authorities could provide a central, coordinated resource for local economic areas.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing "regime" refers to the current market, competition and planning frameworks. "Digital communications" includes both fixed and mobile connectivity.

Dorset is fully supportive the NIC's Connected Future Report and recommendations. With regard to 'Engaging Local Government as a partner' we would add for central

government to mandate the need for all fixed broadband service providers and MNO's to be fully transparent on where their existing networks are positioned and current coverage so we are able to have the most accurate view of existing infrastructure and connectivity and use this to inform future plans.

Drawing on case studies from Stokab and Bristol, Bournemouth has ambitions to own and commercialise ducting. This model should be replicated across Dorset. Support is needed from central government and knowledge sharing from key cities who have built this capability to develop this concept and investment to realise this ambition. The local authorities would then be able to manage their own network and provide mobile (5G and wifi) and fixed network coverage for residents, utilities and businesses.

Identifying pilot cities will be important to share knowledge and frameworks with other local authorities. Bournemouth is well placed to be a pilot for two important reasons. Firstly, the recent partnership with Ordnance Survey means by April it will already have a 3D model informing where 5G sensors should be positioned. Secondly it has the right mix of topography (urban, rural, and coastal) that is seen as critical to testing different deployment models. Dorset has several areas of considerable natural value, not least the Jurassic Coast, so we would seek to see how high quality design can minimise the visual impact of this kind of infrastructure on an area of outstanding natural beauty.

It would be a significant step change for each local authority (or combined authority) to employ a Chief Digital Officer, reporting to the CEO and overseeing the digital infrastructure, the digitalisation of local authority services and implementation of data strategy. This digital leadership role would drive significant cultural change across the local/combined authority business.

Energy:

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

There is very good evidence that the highest value solution for decarbonising heat use in the UK building stock is to reduce heating demand. For example, through setting high energy efficiency Passive House standards for new construction and to develop a financial support package for energy saving 'deep retrofits' to existing domestic properties and appropriate non-domestic buildings.

Although the UK Government cancelled the Code for Sustainable Homes target of net zero carbon new homes by 2016, the business case for support for Passive House standards is much stronger. Heating requirements are an integral element of building design and construction, whilst in many cases low carbon electricity can be supplied to new and existing properties at increasingly competitive prices by offsite generation through the electricity grid. The Passive House standard, which includes a maximum heat loss of 15kWh/m²/ year, was introduced in Germany 25 years ago.

The main advantages are reduced CO₂ emissions, very low energy bills for householders resulting in a reduction in fuel poverty and more income available in the local economy, a more comfortable internal atmosphere and opportunities for the manufacturing sector to develop new low energy building components such as windows, wall panels and ventilation systems.

Evidence from existing passive house developments in Dorset such as the Perryfields development in Portland have demonstrated construction costs of around £10,000 more than conventional construction costs, which is offset by lower running costs.

The UK's Building Research Establishment (bre) has detailed information about Passive House opportunities at <http://www.passivhaus.org.uk/standard.jsp?id=122> and there is increasing information on technologies for deep renovation based on passive house principles, e.g. see <http://europhit.eu/>

A strategic decision should be made by the National Infrastructure Commission to develop policies that would support all new housing in the UK to be built to Passive House standards by 2025- 2030 and as an interim measure offer support for training of architects and builders and a financial incentive for developers, such as a 50% grant towards architects fees for passive house design.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

It is encouraging that the National Infrastructure Commission has framed this question in line with the commitment in the 2008 Climate Change Act to reduce the UK greenhouse gas emissions 80% by 2050 compared to a 1990 baseline. Due to difficulties in full decarbonisation of the heat and transport sectors, achieving the target set out in the Act will require a zero carbon power sector by 2050, if not before.

It is noted that National Infrastructure Commission undertook an independent public opinion survey of national infrastructure priorities in 2015. The survey included responses from 2000 UK residents aged over 18 and was led by Copper Consultancy.

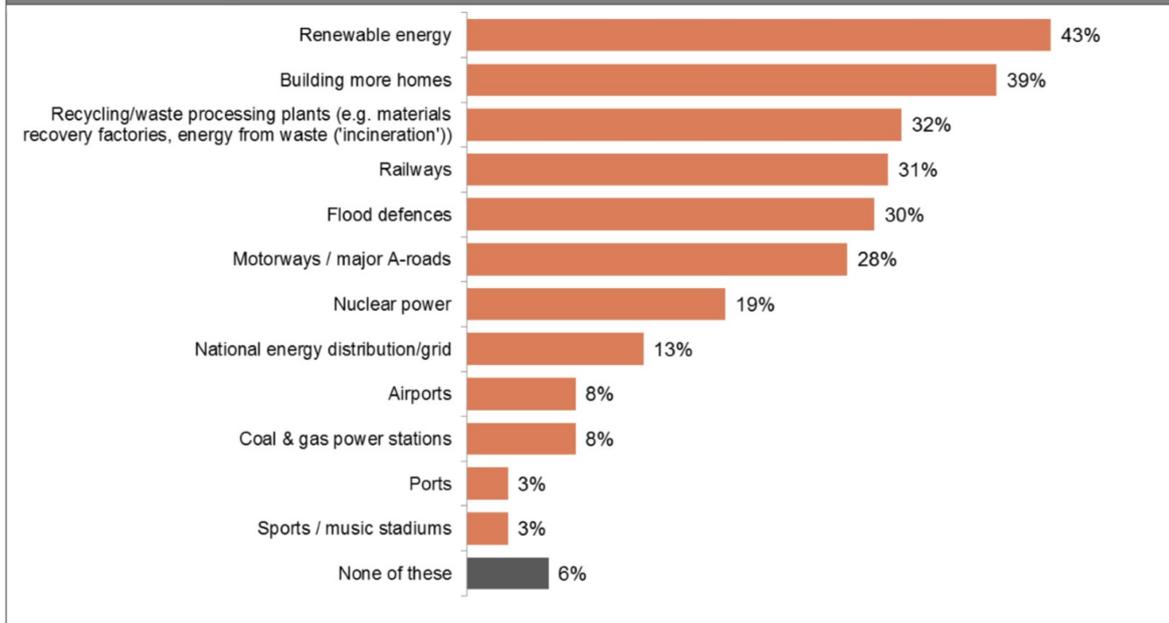

Independent survey of attitudes to infrastructure in Great Britain 2015

The results, summarized below, show that renewable energy infrastructure, with 43% support, was the highest public priority, higher than support for new nuclear power stations (19%) and much higher than for new coal and gas power stations (8%).

Figure 2 – National infrastructure priorities

Question: Which of these infrastructure types, if any, would be your investment priorities for the country? (Select up to 3)

Base: 2,000 GB adults aged 18+, June 2015

Similar consistent high levels of public support for renewable energy have also been evidenced through the DECC / BEIS Energy and Climate Change Public Attitudes Tracker e.g. see October 2016 data:

<https://www.gov.uk/government/statistics/public-attitudes-tracking-survey-wave-19>

As National Infrastructure support programmes are likely to be partly funded through public taxation there would appear to be a case for delivering the infrastructure that the public desires, subject to an objective economic and technical analysis and wider consideration of the national benefits.

Renewable energy infrastructure scores highly on all the above points. Renewable energy technology is mature and generated 25% of UK electricity supply in 2016 and 23% of global electricity production. According to the International Renewable Energy Agency IRENA, half of all new global energy generation capacity installed since 2012 has been renewable energy and 146 countries have policies to support renewables. The 2016 IRENA Power to Change report predicts that on current trends by 2015 electricity from utility scale solar power will decrease in cost by 59%, onshore wind energy by 26% and offshore wind energy by 35%. See:

<http://www.irena.org/menu/index.aspx?mnu=Subcat&PriMenuID=36&CatID=141&SubcatID=2733>

These predictions are in line with the recent BEIS report on the Levelised Cost of Energy (LCOE) in 2025

<https://www.gov.uk/government/publications/beis-electricity-generation-costs-november-2016>

The key table in the report shows that for future UK energy projects expected to be commissioned in 2025, onshore wind and large scale solar generation will have lower levelised costs than the next generation of Combined Cycle Gas Turbine (CCGT).

A summary from the report shows continuing cost decreases for renewable energy:

Commissioning		2016		2020		2030	
		DECC 2013	This report	DECC 2013	This report	DECC 2013	This report
Large scale solar PV	High	116	94	98	80	73	73
	Central	108	80	92	67	69	60
	Low	101	71	86	59	65	52
Onshore wind >5MW UK	High	108	78	104	76	100	72
	Central	88	64	85	63	82	60
	Low	72	48	69	47	67	45
Offshore Wind Round 3	High	179	123	158	119	140	109
	Central	155	109	136	106	120	96
	Low	137	96	119	93	104	85

NB. Prices are in pence per kWh (at 2014 prices).

In comparison, new gas fired generation is estimated to have a LCOE of 8p/ kWh in 2025. Nuclear power has been offered a 35-year subsidy at 9.2p/ kWh at 2012 prices, index linked annually by the RPI. In addition, the long term costs and risks of nuclear decommissioning and waste storage are unknown, but are currently costing UK taxpayers over £2bn per year.

The UK renewable energy sector is badly in need of consistent long-term policy in order to provide investor confidence and lower capital costs for investments. It is disappointing that the recently published BEIS Industrial Strategy has not identified renewable energy as a priority for the UK's industrial strategy.

It is noted from paragraphs 1.2 and 1.3 of the National Infrastructure Assessment Call for Evidence that:

1.2 'The National Infrastructure Commission has been established to provide the government with impartial, expert advice on major long-term infrastructure challenges.

The government will provide the Commission with clear guidance by issuing a public remit letter, which will include a binding fiscal remit to ensure that the Commission's recommendations are affordable. While the government will set the Commission's remit (and the terms of reference for the in-depth studies that it undertakes), in all other respects it will have complete discretion to independently determine its work programme, methodology and recommendations, and the content of its reports and public statements.'

1.3 'The objectives of the National Infrastructure Commission are to: (i) support sustainable economic growth across all regions of the UK, (ii) improve competitiveness and (iii) improve quality of life.'

It is suggested that the National Infrastructure Commission uses the powers specified in paragraph 1.2 to recommend to the government that developing the UK's indigenous

renewable energy resources, including offshore renewable energy, will be the most appropriate means of achieving the objectives specified in paragraph 1.3 and represents the best value and most publicly acceptable means of achieving a zero carbon power sector by 2050.

The transformation could mirror and learn from similar energy transition programmes in France and Germany and would be complimentary to current policies relating to the roll out of smart meters and a smart decentralised grid. A suggested initial study would be as assessment of the maximum potential for renewable power generation to meet real time half-hourly electricity demand in the UK. Similar research for the German government, the Kombikraftwerk project lead by Emeritus Professor of Physics at Imperial College London, Prof Keith Barnham, provided evidence that 80% of German real-time electricity demand could be met from a mixture of wind energy and solar power, with 15% supplied by biogas power plants and 5% battery storage. There is evidence that perceived problems with the intermittency of a mix of renewable energy technologies have been exaggerated. The UK renewable energy sector has been held back by misinformation and inconsistent policies. An informed long-term strategic approach is urgently needed.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Government's stated objective of decarbonising the transport network by 2040, which falls within the timeline of this study, is welcomed. However this generates a whole series of issues associated with the demand for Electric Vehicle on the electricity grid, and intelligent management, as the predicted additional battery capacity of road vehicles will exceed the total existing capacity of the National Grid.

There needs to be a push to local energy generation, with additional PV generating capacity provided on building roofs, wind generation elsewhere (The Borough of Poole installed the first example in the UK of linking large scale PV generation to EV Charging). Research into PV road surfaces should be prioritised and funding mechanisms identified to install PV road surfaces as the technology moves from pilot demonstrators (reported in France) to the mainstream. As the sun always shines in Dorset, the south coast would be a good area to roll out this technology!

NATIONAL INFRASTRUCTURE ASSESSMENT CALL FOR EVIDENCE

NATS DRAFT RESPONSE

NATS, the UK's leading provider of air navigation services, welcomes the opportunity to provide inputs into the development of the forthcoming National Infrastructure Assessment. We consider longer-term assessment of infrastructure needs to be vital to ensure the UK economy has the infrastructure it requires and allow for the correct planning and supporting legislative measures to be put in place.

We remain acutely aware that the environment in which we operate is continually changing and it is our challenge to develop and adapt to meet those changes. In particular there is a growing body of analysis relating to major long term trends ("Mega-trends") which point to a number of considerations for the transport sector.

Notable amongst these is the prediction that, in order to address the anticipated resource crunch caused by the rapid increase in global population (particularly in the middle classes), there is a trend towards increased urbanisation. Compact "mega-cities" like Singapore are seen as a part of the solution in a more resource-efficient future. Similar analysis done by ICAO suggests that there will be a complimentary increase in air traffic, the bulk of which will be along existing routes. To support this future "connectedness", aviation mega-hubs will develop, either at existing places (e.g. Heathrow) or new ones (e.g. Istanbul) – and they will be multi-runway, high intensity operations.

From a UK perspective, air traffic is set to continue to grow, reaching 3.1 million aircraft movements and 350 million passengers by 2030; the UK's airspace, the invisible pillar of national infrastructure, needs significant change today to manage this demand. Airspace change is complex and doesn't happen quickly, it takes a significant time to design and deploy and we are already behind schedule. It is therefore critical that the industry and Government now work together to deliver modernisation, moving from traditional ground-based beacons to modern satellite navigation, the capability for which already exists on modern aircraft.

Modernising airspace requires long term strategic decision making and we believe that there is significant merit in its inclusion in the assessment of the UK's national infrastructure.

The UK is at the forefront of aerospace technological development, and since 2005 UK airlines alone have introduced over 470 new aircraft into service, representing an investment of over \$49 billion whilst at the same time withdrawing their older and less efficient aircraft from their fleets. We now need to modernise our airspace to match this investment, this will have the potential to improve safety and increase efficiency and capacity whilst minimising the impact on the global environment.

Through better operating procedures which can be utilised with a modern airspace structure, there is a potential carbon saving to UK aviation by 2050 of between 9% and 14% and alongside the introduction of quieter aircraft ‘the potential to reduce UK aviation noise output by 2050 compared to 2010’ according to Sustainable Aviation.

Using modern technologies and improved procedures, aircraft can:

- Fly more directly and routes can be designed to avoid noise sensitive areas or provide a more equitable spread of noise as aircraft are not constrained by ground-based navigation aids.
- Make greater use of Continuous Descent and Climb operations which in turn reduces noise and CO2 emissions.
- Reduce the need for conventional orbital holding; instead aircraft can be readied for landing higher and thereby reduce noise and CO2 emissions. In essence, aircraft would be able to fly quieter and more efficient routes.

Modern airspace will also facilitate advances in technology where Air Traffic Control transitions from a tactical (on the day) to a pre planned operation, this will mean that aircraft will operate to plan, airports can then rely and structure their day to day operation to this plan with this predictability reducing costs for the whole industry.

All of the above will benefit the UK economy; airspace modernisation across Europe will deliver over £29bn to UK GDP and 116,000 jobs by 2035 (IATA,2016) whilst without it delays faced by passengers are likely to soar to 4 million minutes by 2030, up from 90,000 minutes in 2015 (NATS, 2015).

However, plans to modernise our airspace through the Future Airspace Strategy, have been delayed due to the Government’s decision to review of its airspace and noise policy due in large part to the negative reaction from some local communities who have been sensitised to aircraft noise by airspace trials. Short-term political need meant that Government reduced its support for modernisation due to these very vocal groups that dominated the public debate.

Airspace modernisation is a pillar of the CAA’s Future Airspace Strategy and of the UK’s infrastructure; it can support the economy and meet our environmental objectives. We believe the development of this invisible yet vital part of our infrastructure be included in the UK’s National Infrastructure Assessment to ensure it can continue provide the safe and effective connectivity the UK economy requires.

Dear Sir / Madam

Re: National Infrastructure Assessment Call for Evidence

Please find enclosed Natural England's response to the current call for evidence for the National Infrastructure Assessment. If you would like to discuss any aspect of our response in more detail, please contact <name and email address redacted>, in the first instance.

Yours faithfully

<name redacted>
<position redacted>
Natural England

Consultation on the Call for Evidence for the National Infrastructure Assessment

Natural England's purpose is to ensure that the natural environment is conserved, enhanced, and managed for the benefit of present and future generations, thereby contributing to sustainable development. Natural England has responsibility for ensuring that England's unique natural environment including its flora and fauna, land and seascapes, geology and soils are protected and improved.

Natural England is a statutory consultee for all National Policy Statements (NPS) regarding Infrastructure (and their supporting environmental assessments (SEA/HRA)) and for all Nationally Significant Infrastructure Projects (NSIPs) (and their supporting environmental assessments (EIA/HRA)). We routinely advise on the delivery of Infrastructure projects and their impacts on the natural environment, working with Developers to identify strategic solutions to the delivery of infrastructure whilst achieving positive outcomes for the natural environment.

Green Infrastructure (GI) is a strategically planned and delivered network comprising the broadest range of high quality green spaces and other environmental features, including rivers, coast line, parks, woodland, etc.. It should be designed and managed as a multifunctional resource capable of delivering those ecological services and quality of life benefits required by the communities it serves and needed to underpin sustainability. GI is about putting the environment right at the centre of the planning process and producing a strategic and linked, multifunctional network of spaces with benefits for people and wildlife. It's also about underpinning the sustainability of a town or city, including making it resilient to the effects of climate change and enabling the conservation of biodiversity. To achieve this we strongly recommend that GI is factored into the strategy for the delivery of new infrastructure, and the assessments that will identify where new infrastructure is delivered.

We have responded to the consultation questions as set out in the paper, but our points can be summarised as:

- The delivery and enhancement of 'Green Infrastructure' is essential for the delivery and operation of infrastructure envisaged in the NIA. There exists a wide body of evidence of the successes that have been achieved where green infrastructure / ecosystem services approach have been used to inform the development process.
- Infrastructure Projects delivered through the NIA should demonstrate a commitment to achieving a 'net gain' for the natural environment, (including biodiversity, landscape, recreation, etc.) in order to contribute to the Governments aims as expressed in the 25 year Environment Plan.
- Natural Capital is a way of accounting and factoring in these benefits at the planning stage and that the NIA strategy should include natural capital as a guiding principle for considering the potential impacts / benefits of future infrastructure projects.
- Collaborative working between those planning and delivering infrastructure alongside those that will manage and live with their impacts is essential for the achievement of sustainable development. This will ensure that long term issues are addressed and multiple benefits can be achieved.

Cross-cutting issues:

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

Note: this can apply to national, regional or local infrastructure, where you consider it would best support sustainable growth in your city or region in practice. Considerations of "highest value" should include benefits and costs, as far as possible taking a comprehensive view of both. "Long-term" refers to the horizon to 2050 and should exclude projects that are already in the pipeline.

1. Investing in well-designed and maintained green infrastructure networks at national, regional and local scale will deliver increased resilience (both of communities and of 'hard' infrastructure), sustainable economic growth and improved health and well-being. Investing in enhanced natural capital and green infrastructure will help support inward investment, secure an enhanced return on investment and help increase productivity.
2. The London Infrastructure plan recognises the value of investing in GI in order to achieve the long term sustainable growth of the city. It promotes a GI network that will provide flood protection,

shade, biodiversity, cleaner air, a greener environment visually, pedestrian and cycling routes and space for recreation.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

3. Reliable, well-performing and resilient Infrastructure is essential to supporting international competitiveness. The resilience and performance of linear infrastructure can be enhanced depending upon whether the green infrastructure alongside or incorporated into them is well designed and maintained.

Evidence

- <http://publications.naturalengland.org.uk/publication/5752930789490688> Review of Literature: how transport's soft estate has enhanced green infrastructure, ecosystem services, and transport resilience in the EU (NECR169)
- https://www.ciria.org/News/blog/LINet_sets_out_the_benefits_of_green_infrastructure_to_enhance_infrastructure_resilience.aspx see *Maximising linear infrastructure resilience, environmental performance and return on investment*
- 4. Our natural capital and the existence of high quality green infrastructure also plays a key role in attracting tourism and inward investment through our international gateways.

Evidence

- <http://publications.naturalengland.org.uk/publication/6692039286587392> Microeconomic Evidence for the Benefits of Investment in the Environment 2 (MEBIE2) (NERR057) – see Chapter 3e: *Economic competitiveness - Tourism and recreation*
- <http://www.snh.gov.uk/docs/B732000.pdf> Valuing Nature Based Tourism in Scotland

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

5. The planning and design of infrastructure is key to enabling it to make a positive contribution to the natural environment. Planning of new infrastructure should seek to avoid environmental impacts by considering spatial aspects such as location, context, place etc. Understanding the context and setting for new infrastructure is essential, and within this context seeking to conserve and enhance culture, heritage and natural capital, wherever possible having an ambition for net environmental gain. It should use and re-use materials sustainably and avoid a high carbon and energy footprint.
6. Good design should also allow for future adaptation and technological advances. Alongside this designing for future management and maintenance is essential – what will this structure and its environs look like and how will it be managed in 20/50/100 years' time, is a key consideration.
7. Green infrastructure can make a major contribution to the attractiveness of a place to live and work within. Cities with a strong network of GI will be more attractive to a modern mobile professional workforce, furthermore the efficient functioning of GI is essential to the wellbeing of those that reside within a settlement, both in terms of protection from extreme events (heat, floods) and general health (recreational potential, tranquillity, etc.).
8. Infrastructure investment should deliver a 'net environmental gain', ensuring that the natural environment is in a better state after the creation of the infrastructure, than before, helping to realise the biggest natural capital return on the investment. Investment in green infrastructure would deliver;
 - Quality of place;
 - Health and wellbeing;
 - Environmental resilience.
9. Investing in well-designed and maintained Green Infrastructure will deliver the ecosystem services that businesses and communities depend on and thus build local Natural Capital. In terms of housing, green infrastructure should be incorporated in such a way as to:
 - Ensure places are adapted to cope with the impacts of expected climate change;
 - Deliver green spaces that are accessible, natural and deliver a range of functions;
 - Ensure that development and growth can be brought forward sustainably;
 - Support communities and businesses by delivering the ecosystem services they depend on;
 - Support the improvement and maintenance of high levels of health and wellbeing;
 - Manage natural hazards such as flood risks;
 - Help to improve air quality where required;
 - Address diffuse pollution of terrestrial waters and reduce pollution inputs to the marine environment to help maintain the quality of our coasts and seas;
 - Support and enhance our biodiversity and deliver functional ecosystems and ecological networks.

Evidence

- The Highways England Design Panel and HS2 Design Panel are exploring the contribution that good design can make to the success of infrastructure projects. There is potential to extend this concept to other infrastructure and to establish design principles and processes that help to embed place-responsive design.

10. Multi-disciplinary and collaborative approaches to the design and development of infrastructure are likely to deliver assets that provide the widest range of benefits. The Linear Infrastructure Network (LINet) demonstrates how a collaboration between industry, contractors and environmental organisations can help secure resilience and environmental performance win-wins.
- https://www.ciria.org/News/blog/LINet_sets_out_the_benefits_of_green_infrastructure_to_enhance_infrastructure_resilience.aspx see *Maximising linear infrastructure resilience, environmental performance and return on investment*
 - <http://www2.nationalgrid.com/UK/In-your-area/Visual-Impact-Provision/> National Grid’s Visual Impact Provision Project is an example which addresses ways of improving landscape character.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

11. No comment.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

12. The Government’s Natural Capital Committee emphasises that efforts should be placed on securing and enhancing the maximum natural capital value from infrastructure, with considerations of value for money factoring in the whole life costs to avoid short-sighted and short-term interventions that cost more in the long-run. An example is the cost differential over the whole life of traditional urban drainage techniques versus sustainable urban drainage (SUDs). Existing deficits in natural capital should be addressed through investment in new, multi-functional green infrastructure that seek to deliver an environmental ‘net gain’ whilst existing green infrastructure assets should be maintained and enhanced. To secure the best return on investment it is essential to have a good understanding of local needs and the effects of proposed developments on ecosystem services.

Evidence

- <http://www.susdrain.org/resources/ciria-guidance.html> for evidence etc. on SUDs including costings

- <https://www.evidence.nhs.uk/Search?q=Cost+benefit+analysis+urban+green+space> reports on costs and benefits for health outcomes of green infrastructure

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

13. The supply of infrastructure services are often interdependent in terms of their reliance and management of natural resources. For instance, transport infrastructure has significant impacts on where waste water is created and needs to be treated. Provision of clean water will determine where new infrastructure is required e.g. flood defences, transport, digital communications, etc. The land take and severance caused by new infrastructure (particularly linear infrastructure) will impact on the functioning natural environment. Greater collaboration and consideration of multiple impacts in the planning of infrastructure can demonstrate where solutions can achieve multiple benefits both for the delivery and operation of the infrastructure and the natural environment.
14. We have submitted the following case studies as examples of where collaboration in the supply of infrastructure services has achieved multiple outcomes that benefit suppliers, users and developers of new infrastructure, whilst meeting the Government's environmental aims and commitments.

Evidence

- **River Mease – Catchment-based, Strategic approach** to tackling phosphorus and increased flow identified from Sewage Treatment Works (STW) outflows. Individual housing applications that contributed to increases in STW outflow were being refused due to an increase in pollution in the River Mease and reduced likelihood of meeting conservation objectives for this Special Area of Conservation (SAC). A strategic approach to exploring phosphorus removal and flow reduction/control measures was required. The River Mease Partnership, which includes the local authorities and Severn Trent Water in the catchment, was formed to help implement a Developer Contribution Scheme (DCS). The DCS enabled individual proposals to provide a proportionate contribution to a fund that helped implement research and technology required to protect the River Mease's water quality and flow whilst supporting development needs. More information on the DCS can be found at <http://www.rivermease.co.uk/improving-the-river/developer-contributions-scheme-2/>
- **River Clun – nutrient management approach: joining air and water considerations** – The River Clun is designated as a Special Area of Conservation (SAC) due to the presence of the rare freshwater pearl mussel which is sensitive to increases in nitrogen compounds in the river. Any proposal that increased airborne or water-related nitrogen was potentially refused consent due to the risk of impacts on the River Clun. This cost individual applicants time and money whilst making it difficult to balance development needs. Natural England worked with Shropshire Council to gather evidence about nitrogen sources and to liaise with farmers in the Clun catchment to decide on potential solutions. As a result, Shropshire Council has published [guidelines for assessment at planning](#) and farmers have agreed to this strategic approach which minimises nutrient loading in the Clun. This approach includes reducing fertiliser application on fields adjacent to the Clun if an increase in aerial nitrogen (especially ammonia) is expected through expansion of housing or increase in slurry store/lagoon size.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered? Note: by “funding”, the Commission means who pays for infrastructure services and how, e.g. user charges, general taxation etc.

15. Projects should maximise resource efficiency by delivering the maximum range of ecosystem service benefits. One mechanism to support this outcome would be for projects to adopt a 'net gain' approach to delivery, whereby they seek to deliver a net increase in environmental outcomes benefitting people and nature. This in turn would serve to increase natural capital value over time. Currently, there is often no financial benefit to those who enhance ecosystem service provision. We consider that support could be given for Payment for Ecosystem Services (PES) initiatives, through infrastructure developments.
16. New sustainable and long-term funding mechanisms are emerging which have the potential to provide significant new and long-term resource for green infrastructure asset enhancement and maintenance. The adoption of 'net gain' approaches¹ to development provides one mechanism to

¹ E.g. The Defra Biodiversity offsetting metric <https://www.gov.uk/government/collections/biodiversity-offsetting>

secure long-term financial resource for green infrastructure maintenance. Green bonds could also provide another potential revenue stream. The maintenance of green infrastructure assets is critical if they are to perform well and deliver the optimum benefits.

17. The Highways England Environment Designated Fund is a good example of how public funding has been used in innovative ways. The £300m fund, which represents less than 0.01% of the overall budget for the strategic road network for the period 2015-2021, has been used to secure capital works that enhance the environmental performance of the network. The fund has enabled the active engagement of partners in delivering Highways England Key Performance Indicators (KPIs), such as the biodiversity KPI. Contributions have been levered in from partner organisations, and this has helped to secure additional funding from others such as Heritage Lottery Funding for key projects, enabling delivery of considerably wider benefits beyond the boundary of the highways estate. This partnership approach demonstrates the benefits of a collaborative approach for all.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets? Note: projects that “can be funded” but “will not be financed” refers to projects that can be paid for, but where the upfront costs of construction cannot be raised at an efficient price and/or with an appropriate risk sharing balance between the different parties. General government financing policy (i.e. the issuance of gilts) is out of scope.

18. No comment.

9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

Note: this includes resilience against external risks and/or problems that arise in one or more parts of the system.

19. There is strong inter-dependent relationship between infrastructure and the natural environment and this is often not recognised in design, planning and management of infrastructure assets. Extreme weather events associated with climate change in recent years have brought this to the forefront of our minds, with flooding causing significant disruption for example to transport networks resulting in closure of roads and rail lines, increased risk of landslip and earthworks failure, failure of equipment due to inundation of water, bridge scour and other impacts that affect the operation of the networks. These impacts have been identified by infrastructure developers in recent climate change adaptation reports². Our response to Q11 expands on these points and highlights how these relationships and inter-dependencies should be taken into consideration.

20. Based on Natural England’s experience of working with major infrastructure companies such as Highways England, Network Rail, HS2, National Grid, water companies and airports, and our

² Network Rail Climate Change Adaptation Plan 2015 <http://www.networkrail.co.uk/publications/weather-and-climate-change-resilience/>

engagement in relevant cross-sector groups such as the Linear Infrastructure Network (LINet) chaired by National Grid, Highways England's Design Panel and Natural England's Developer Industry Group, we recommend that that infrastructure takes account of the following issues and opportunities to most effectively contribute to protecting and enhancing the natural environment:

21. In this context it will be important for the National Infrastructure Commission to take account of evidence and expert opinion from environmental professionals. We would recommend that experts from the environment sector, including ecologists and landscape architects, are represented on expert panels and roundtables. This will be the key to enabling the inter-dependencies between infrastructure and the natural environment to be fully understood.
22. Further information on the methods that can be applied to increase resilience in infrastructure, are included in our response to Q11.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

23. Natural England engages with the planning system for nationally significant infrastructure (Town Planning Act 2008) and other infrastructure developments (Town & Country Planning Act 1990) as a statutory consultee. We consider that the planning system must seek to achieve a clear strategy for the delivery of infrastructure in a way that adds to natural capital and provides an overall net-gain for nature (including biodiversity, landscape and access).
24. The decline in UK biodiversity identified in the Lawton Review: Making Space for Nature (2010), should be addressed through a strategy of providing more, bigger, better and joined up sites for nature. We consider that the delivery of infrastructure through the planning system will be better achieved if strategic improvements to the natural environment are considered as part of the infrastructure planning process. Direct site impacts which cannot be effectively avoided or mitigated, could then be compensated or offset through an agreed 'infrastructure plan' for the environment. A strategy that considered the 'green infrastructure' of the country should look at the full range of benefits and how these can be delivered (including new habitat creation but also payments for the delivery of ecosystem services that new infrastructure provides, or that is provided elsewhere, enabling new infrastructure to achieve a 'net-gain'). We consider that this would speed up the delivery of infrastructure projects and provide a clear direction for improvements that new infrastructure projects could make.

Evidence

- <http://webarchive.nationalarchives.gov.uk/20130402151656/http://archive.defra.gov.uk/environment/biodiversity/documents/201009space-for-nature.pdf> Making Space for Nature: The Lawton Review (2010)
- <http://www.humbournature.co.uk/about/> Humber Nature Partnership: An example of new infrastructure development being collaboratively delivered within a protected habitat.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

25. Infrastructure investment should focus on providing well-designed and maintained infrastructure assets that deliver sustainable economic growth, enhance natural capital, increase resilience and improve health and well-being. Investing in existing or new GI (in areas of natural capital deficit) will significantly contribute to protecting and enhancing the natural environment, whilst enabling new infrastructure. The biggest natural capital return on this investment will be achieved where GI assets are managed as part of existing or new GI networks. GI assets and networks provide important habitats and also assist species move across the landscape and adapt to climate change.
26. Green infrastructure alongside or incorporated into existing or new 'grey' infrastructure assets provides significant benefits to the natural environment (in terms of habitats for species) as wider ecosystem service benefits.
27. We consider that all infrastructure projects should follow the mitigation hierarchy (Avoid, Mitigate,

Offset, Compensate) and also commit to deliver environmental 'net gain' to ensure they most effectively protect and enhance the natural environment. A number of major infrastructure projects and developers have committed to delivering net gain including Network Rail Infrastructure Projects, Highways England and Berkeley Strategic Land.

28. Specifically we consider that the following approaches should be endorsed in the planning and delivery of infrastructure, in order that the natural environment can be enhanced:

- Embedding and mainstreaming the use of green infrastructure (GI) as a tool for enhancing the resilience to climate change and reducing the whole life costs of infrastructure assets, and to maximise biodiversity and ecosystem service benefits. This will be particularly important for linear infrastructure assets which traverse a variety of landscapes and have the potential to contribute to ecological corridors but also to fragment important habitats. Incorporating the full spectrum of GI, including the use of hard design features that have ecological and/or ecosystem service benefits in situations where these are appropriate. Incorporation of GI into new infrastructure assets must be done in a way that allows for cost effective management and maintenance beyond construction and into the operational period. GI can help to mitigate impacts of development and maximise opportunities presented by it: from improved air quality, low carbon fuel cropping, wildlife corridors to access to recreational space that positively impacts on quality of life and human wellbeing.
- Targeting investment in GI at places where the highest value return on the investment can be achieved (in terms of enhanced ecosystem service delivery). For example where GI enhancements would deliver long term enhancements to local Natural Capital; develop improved community resilience; contribute to achieving local economic objectives; improve the sustainability of development and overall Quality of Life for communities living and working alongside infrastructure assets.
- Incorporating thinking on Natural Capital and Ecosystems Approach, building on the work of the [Natural Capital Committee](#)³ and the National Ecosystems Assessment⁴. Taking a Natural Capital approach will enable the environment to deliver the improved ecosystem services that infrastructure, communities and businesses depend on.
- Recognising the contribution that the UK's protected landscapes (National Parks and Areas of Outstanding Natural Beauty) and nationally and internationally designated sites for nature conservation make to defining a sense of place and the importance of place-based design that reflects local character and contributes to attractive places to live, do business and invest in.
- Ensuring consideration of the health and well-being needs of local communities and making sure that the UK's GI is recognised for the contribution to health and well-being (both physical and mental) that it can make.
- Understanding the cross boundary environmental issues facing different areas including those derived from the impacts of ecosystem service flows between urban and rural areas.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

29. We consider that there are two main areas where improvements should be made to cost-benefit analysis techniques. Firstly, we support the Natural Capital Committee’s (NCC’s) view that **natural capital⁵ as a concept should be fully incorporated into cost benefit analysis (CBA) techniques⁶**. As the NCC states, this should be the case for all projects that impact on the environment, regardless of whether the environment is the main purpose of the project. Properly accounting for the environment is as important for an analysis of concrete infrastructure as it is of green infrastructure. This will not only improve the credibility of analysis by better accounting for all impacts but also transparency by demonstrating the impacts of infrastructure projects on the environment. Additionally, natural capital aims to consider impacts at a wider level than CBA has tended to. The piecemeal nature of CBA has led to environmental impacts being dismissed as insignificant whilst overall stocks of natural capital decline. A more strategic approach to the consideration of natural capital, considering the effects of all infrastructure requirements will better account for environmental impacts, whilst also better identifying how the environment can contribute to wide-scale solutions.

30. Secondly, **greater emphasis needs to be paid to the assessment of expected environmental and social effects**. Valuation should follow a three-step process:

⁵ The Natural Capital Committee (NCC) has defined natural capital as “the elements of nature that directly or indirectly produce value to people, including ecosystems, species, freshwater, land, minerals, the air and oceans, as well as natural processes and functions”

⁶Improving Cost Benefit Analysis Guidance, A report to the Natural Capital Committee, <https://www.gov.uk/government/publications/natural-capital-committee-research-improving-cost-benefit-analysis-guidance>

31. Too often, though, analysis focuses overly on this final step without firstly understanding the actual impacts of the project(s). One consequence of this is that the monetary valuations placed on environmental changes are inaccurate if the underlying environmental and/or social change is not properly understood.
32. A further, important, consequence of this is that the analysis concentrates on aspects we can monetise, rather than where best value can be delivered. Where environmental opportunities, solutions or consequences are important but difficult to monetise it is vital that they are incorporated into decision-making, rather than being ignored simply because it is difficult to value them. Further consideration of how to bring these important, but non-monetised, costs and benefits into decision-making alongside monetary values would be a significant improvement to current cost-benefit techniques.

Evidence

33. **Environmental valuation guidance** - There are a number of pieces of guidance that could assist in improving consistency in approach. We recommend the following reports and toolkits as useful pieces of evidence:

Transport:

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

Note: “travel patterns” include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

34. The Department for Transport (2015) forecasts⁷ a 19% to 55% growth in traffic between 2010 and 2040, with the size of that growth depending on three uncertainties in road demand - the number and types of journeys that people make, the effect of rising incomes on car ownership and car use, and future trends in income growth and fuel prices.
35. The substantial, 60% growth in GB rail travel⁸ between 1995 and 2007 is thought to be the result of more people starting to travel by train, rather than existing rail users travelling more, with rail mileage growing most rapidly for business purposes.
36. New infrastructure is likely to be needed to address this anticipated growth in travel. Network Rail has commitments in Control period 5 and 6 to electrification of many of its mainline routes. HS2 phase one is expected to be completed by 2026. Highways England has commitments to over 100 major schemes in its first Roads Investment Strategy (RIS) and further development is expected in RIS2 (to 2025).
37. There will be significant impacts and opportunities for the natural environment from transport

⁷ DfT Road Traffic Forecasts 2015

https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/411471/road-traffic-forecasts-2015.pdf

⁸ On the Move: making sense of car and train travel trends in Britain <http://orr.gov.uk/publications/reports/car-and-train-travel-trends-in-britain>

infrastructure development of this scale. As a statutory consultee, Natural England advises on all major transport infrastructure schemes, facilitating early engagement through our Discretionary Advice Service.

38. Both Network Rail Infrastructure Projects and Highways England have commitments to biodiversity net gain, with HS2 having a commitment to no net loss in biodiversity.
- Highways England's Roads Investment Strategy commits them to delivering No Net Loss in biodiversity by 2020 and Biodiversity Net Gain by 2040
 - Network Rail's Infrastructure Projects have set the target of "a measurable net positive contribution towards biodiversity in the UK" by March 2019.
39. New technologies are likely to change travel patterns and could bring about changes to the impacts of transport infrastructure development. For roads, technological changes such as low emissions vehicles which have the potential to reduce the air quality impacts that roads have on local communities and the natural environment.⁹
40. Platooning, connected and autonomous vehicles have the potential to allow road space to be utilised more efficiently, reduce emissions and be safer places. They could also change the way we engage with transport and prompt us to rethink our car ownership and usage. This could impact on the way that roads are designed, reducing the need for signage and helping to minimise roadside clutter so that roads are better integrated into the surrounding landscape - something of keen interest to the Highways England Design Panel.

Evidence

- https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/411471/road-traffic-forecasts-2015.pdf DfT Road Traffic Forecasts 2015
- <http://orr.gov.uk/publications/reports/car-and-train-travel-trends-in-britain> On the Move: making sense of car and train travel trends in Britain

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: "high value transport investments" in this context include those that enable 'agglomeration economies' – the increase in productivity in firms locating close to one another.

41. See response to Q15.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

42. We have covered questions 14 and 15 together below:

43. Transport corridors are often the gateway to places where people live and work – be they villages, towns or cities. Any transport investment that connects people and places needs to consider the user experience, including non-motorised users. The importance of the design and management of the green infrastructure alongside road and rail networks is important for defining sense of place and can contribute significantly to the aesthetic for 'beautiful roads'¹⁰.
44. Green infrastructure alongside road and rail assets provides important ecological connectivity and wider ecosystem services, such as air and water quality management, pollination and biomass, as well as forming part of the bigger, better more and joined up vision for ecological connectivity set out

⁹ The ecological effects of road pollution from road transport: an updated review
<http://publications.naturalengland.org.uk/publication/6212190873845760>

¹⁰ <https://www.gov.uk/government/speeches/beautiful-roads> Rt Hon John Hayes MP vision

in the Lawton¹¹ Review. Investment in the design and ongoing management of this green infrastructure can help the transport networks to function more effectively and operate more safely.

45. Through the Green Transport Corridors Initiative¹², Natural England has been working with Network Rail and Highways England to look at how the green infrastructure alongside road and rail lines, as well as the land adjacent to, and upstream of, major infrastructure can be used as a tool for enhancing their resilience to climate change, safety and performance, and reducing the whole life costs, as well as delivering biodiversity and ecosystem service benefits.

46. This approach could help to reduce significant risks to infrastructure such as of flooding, where the work has identified that there is significant scope to look at the use of natural flood risk management approaches on a catchment-scale to reduce the impacts on linear infrastructure.

Evidence

47. The paragraphs below set out the contribution that investment in the design and management of green infrastructure alongside road and rail assets can have on their resilience and operation:

Safety

- In 2013/14 there were 1,500 incidents of trees falling on Network Rail lines.¹³ One third of these fallen trees were hit by trains. Well designed and managed green infrastructure can reduce tree and leaf fall realising improved safety and performance and a safer environment for staff/contractors when working on or at the lineside.
- Reduction in deer and other mammal induced collisions and accidents.
- Green street furniture is increasingly being used alongside hard infrastructure as a security measure, acting as barriers at rail stations, airports and prominent visitor destinations.

Asset Resilience and Performance

48. Well managed vegetation can improve access for inspections, maintenance, repairs and emergency access to services. Vegetation can help protect and defend under-lying hard assets, extending its life and optimising its performance:

- Natural flood risk management on a catchment scale and use of vegetated sustainable drainage systems on the adjacent land, and on the transport network can reduce the risk of surface water flooding and the associated safety risks;
- The right vegetation can increase bank stability, preventing landslip. In 2015-16 Network Rail earthworks risk had risen 63% compared to the previous year¹⁴;
- <http://www.treeconomics.co.uk/wp-content/uploads/Area-1-iTree-Report.pdf> In Devon/Cornwall, Kier Highways calculate the 300,000 trees on the estate prevent 76,000 cubic metres of run-off per year;
- In Scotland capital costs of traditional drainage were more than double the capital costs of SUDS, annual maintenance costs were 20 – 25% cheaper and SUDS is around half the cost over a 60 year life span¹⁵;

Reputation with Customers/Neighbours

¹¹ Making Space for Nature, 2010 <https://www.gov.uk/government/news/making-space-for-nature-a-review-of-englands-wildlife-sites-published-today>

¹² Natural England NEWP 32 Transport Green Corridors Options Appraisal and Opportunity Mapping 2014, <http://publications.naturalengland.org.uk/publication/5485064148221952>

¹³ <http://www.networkrail.co.uk/community-relations/trees-and-plants/>

¹⁴ Network Rail Monitor Period 8-13 2015-16, ORR, July 2016

¹⁵ Duffy, Jefferies et al. 2008

49. Vegetation management issues account for the highest number of complaints to Network Rail - almost 25,000 complaints per annum. Complaint reduction and better customer and community relations would be significantly reduced if GI were well designed and managed.
- 1.69 billion passenger rail journeys¹⁶ were made in Great Britain in 2015/16. For people travelling by rail every day, the rail-side vegetation and the views it frames into the wider countryside can be their main daily contact with nature.
 - Improved aesthetic that reflects sense of place and allows road and rail corridors to serve as attractive gateways to business and tourist destinations, and provide a better user experience for passengers, both on network and at customer interface areas eg stations and motorway service areas.
 - Greened linear features help to connect communities and enhance local economy for tourism. HS2 is incorporating 16 green bridges into its network.

Wider Benefits for Society and Quality of Life

- Vegetation can remove air and water pollutants and reduce noise pollution thereby protecting ecosystems and neighbourhoods.
- Vegetation stores and sequesters large amounts of carbon, helping to offset the 48.4 grams of CO₂ emitted per rail passenger km¹⁷.
- Benefits for farmers: flowering plants along these corridors provide food for the pollinators that are vital for agriculture.
- Wildlife connectivity, contributing to Lawton's principles of 'Bigger, better, more and joined up' spaces for nature¹⁸.
- Kings Cross: Transformation of 67 acres of disused sidings between St Pancras and Kings Cross Station alongside the new Eurostar station has created natural habitat for birds, butterflies, amphibians and a rich variety of plant life.
- <http://www.treeconomics.co.uk/wp-content/uploads/Area-1-iTree-Report.pdf> Devon/Cornwall: 300,000 trees on the strategic road estate are estimated to remove 29 tonnes pollution per year and store over 22,000 tonnes of carbon

Spending to save

- Network Rail estimate that the impact of vegetation on train performance costs the UK economy £100m annually¹⁹. Spending on management will help to save on performance costs.
- Reduction in whole life asset costs through regular interventions to retain early successional plants such as grasses, preventing growth of woody vegetation,
- Simplified estate management that can be undertaken regularly without disruption to services.

Generating income and reducing waste

¹⁶ Passenger Rail Usage 2015-16 Q4 Statistical Release http://orr.gov.uk/data/assets/pdf_file/0015/22056/passenger-rail-usage-2015-16-q4.pdf

¹⁷ Rail infrastructure, assets and environment 2014-15 Annual Statistical Release http://orr.gov.uk/data/assets/pdf_file/0007/19537/rail-infrastructure-assets-and-environment-2014-15.pdf

¹⁸ Making space for nature: a review of England's wildlife sites, 2010

¹⁹ <http://www.networkrail.co.uk/community-relations/trees-and-plants/>

- Biomass harvesting for income and energy generation and reducing waste. Network Rail and Highways England conservatively estimate a potential biomass revenue forgone over 25 years of more than £90million and a renewable energy source for three cities the size of Leeds for a year.
- Lincolnshire (2016): Preliminary results from a large scale road verge harvesting trial indicate that it may be possible to cover the operational management costs with the revenue from anaerobic digestion (AD) generation of biogas from harvested roadside grass cuttings.
- Denmark (2014): From harvest, collection, transport, storage and digestion of roadside vegetation the energy return on invested energy (EROEI) was found to range from 2.17 to 2.88.(for 18,000ha of annual harvestable area based on 1.3m width).²⁰

16. What opportunities does ‘mobility as a service’ create for road user charging? How would this affect road usage?

50. No comment.

Digital communications:

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long-term technology trends)? When would decisions need to be made?

51. No comment.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Note: the existing “regime” refers to the current market, competition and planning frameworks. “Digital communications” includes both fixed and mobile connectivity.

52. No comment

Energy:

53. We have no specific comments to make in regard to the questions posed on energy, however our response to the cross-cutting issues section is relevant to the choices to be made when delivering energy infrastructure.

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

54. No comment.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

55. No comment

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

56. No comment.

²⁰ Bioenergy production from roadside grass: A case study of the feasibility of using roadside grass for biogas production in Denmark, A.K.P. Meyer, E.A. Ehimen, J.B. Holm-Nielsen, Resources, Conservation and Recycling (2014) 124–133

Water and wastewater (drainage and sewerage):

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Note: “demand” includes domestic, commercial, power generation and other major sources of demand.

Future resilience in determining new infrastructure demands on environmental capacity

57. In drawing resources from the environment such as water, or in requiring the environment to absorb future waste (in, e.g., domestic or industry discharges) infrastructure development competes with the requirements from other parts of the system including biodiversity (which needs for example adequate river flows or water levels for ecosystem hydrological functioning, and water quality to support a range of freshwater and marine biological processes) and with other polluting or resource-requiring human activities.

58. When the needs of future infrastructure are estimated, the future needs both of vulnerable or dependent ecosystems and of competing human activities under future scenarios of (e.g. climate change) and of changing demands for land use for (e.g. food production) must be taken into account. This matters especially where the capacity of the water treatment systems is needed to cope with similar types of pollutants from different sources. In the case of nutrients such as Nitrogen and Phosphate, which are the main drivers for declines in habitat quality in many freshwater and coastal ecosystems including designated sites, both diffuse agricultural and point sources (sewerage systems) are important. The capacity for agriculture to reduce nutrient (and other pollutants) losses to the environment via measures to tackle diffuse agriculture pollution to the extent needed to meet environmental targets is still far from clear, though measures are underway (e.g. catchment sensitive farming, diffuse pollution measures under agri-environment schemes and regulation).

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

Identifying customer beneficiaries

59. In relation to water services and sewerage infrastructure provisions, the beneficiaries from investment in a given location may include stakeholders who are not themselves the customers of the relevant water supply / service company. For example, environmental improvements resulting from investment in sewerage treatment (e.g. bathing waters improvements, or improved biological status of water bodies) benefit visitors as well as the local customers / bill-payers. Such beneficiaries are difficult to take into account in evaluations of willingness to pay targeted at the more strictly defined customers. This broader sense of customer beneficiary should be taken into account in evaluating environmental risks as well as evaluating the range of options in managing those risks from new infrastructure development.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

60. The perceived “headroom” for new infrastructure development will need to take into account limitations in the ability to manage down diffuse agricultural emissions (and those from other sources) into the future if environmental quality is to be restored over the long-term.

61. Where situations arise like that above, it is sensible to manage overall nutrient budgets (emissions from various sources) at the catchment level. This would imply taking into account the specific requirements of receiving waters (which may vary within a catchment according to, e.g., habitat or species vulnerability, or designation status) and the proportional contribution, now and in the future, from different sectors operating within the catchment in order that the most resilient and cost effective measures can be taken to addressing the different sectoral (including national infrastructure) contributions. The use of existing catchment level stakeholder processes (such as Catchment Based Approach partnerships) would be valuable in building in stakeholder support as

well as drawing in local knowledge in determining how further environmental capacity is to be managed).

Flood risk management:

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

62. Natural England's responsibilities are focussed on the natural environment rather than flood risk to people and property. Our interests are therefore in ensuring that in determining a suitable level of flood resilience that natural environment issues are addressed. There are two specific points that we would wish to make:

- While much can be done to address current and future flood risks through traditional forms of flood defence and the deployment of natural flood management measures there remain flood risk challenges that need to be addressed, at least in part, through the land use planning system. These primarily relate to the location of assets, be they infrastructure, homes or businesses, that cannot be protected in situ because either it is unsustainable to do so (e.g. low lying assets threatened by sea level rise) or because if they were protected flood risk would be increased elsewhere (e.g. man-made bottlenecks in river corridors in urban areas). We believe that the importance of planning based solutions to securing a more sustainable approach to flood resilience is often neglected and, if used more widely, would provide greater security for national infrastructure and conserve and enhance the natural environment.
- There are significant areas of nationally and internationally important wildlife habitats in coastal flood plains protected by seawalls. In the long term we recognise that it will be unsustainable to conserve many of these in-situ. We have been working closely with a variety of partners to address this issue over the last 20 years and have developed good practice examples including providing compensatory habitat elsewhere and lowering sea defences, so that although the frequency of inundations is increased, the seawalls remain undamaged and flood waters can be quickly evacuated.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: "innovative technologies and practices" can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

63. We believe that natural flood management (NFM) has a key role to play alongside traditional forms of flood defence and planning based solutions in reducing flood risk. Natural England has recently reviewed the evidence for NFM (report to Natural England Board December 2016) and concluded that it has an important role to play if used in the right place and in the right way.

64. Its key value is in helping to reduce flood risk in locations where traditional forms of flood defence are not justified; in doing so it can deliver a wide range of ecosystem services including substantial benefits to biodiversity. On the downside it is challenging to deploy over large catchments.

Solid waste:

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

65. No comment

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

66. The classification of a materials (eg whether a material is classified as a ‘waste’ or ‘biomass crop’ etc) and the permits required, can pose barriers to the development of a circular economy. An example is the permits needed for the use of verge arisings (e.g. grass clippings etc.) in anaerobic digesters. There is currently no waste code for grass arisings from roads and this impacts on permitting. If these materials were clearly categorised then it would be easier and simpler to obtain the correct permits and the material could be utilised as a fuel creating a circular economy where infrastructure providers have an incentive to manage their estates to achieve multiple benefits.

NAWDO Response to Call for Evidence on the Development of the National Infrastructure Assessment.

The National Association of Waste Disposal Authorities (NAWDO) would like to take the opportunity to comment on the National Infrastructure Commission call for evidence to provide input into the development of its National Infrastructure Assessment specifically in regard to questions on solid waste.

The National Association of Waste Disposal Officers (NAWDO) is the primary network for senior waste managers working for Waste Disposal Authorities in England and Wales. Membership of NAWDO comprises over 100 representatives from all types of statutory Waste Disposal Authorities including: London Boroughs, Metropolitan, Unitary and County Councils.

This is a joint response on behalf of all of our members, but it does not prohibit individual authority members from submitting separate responses.

Whilst we try to ensure that this response represents a consensus view; there may be specific instances within it where individual authorities do not feel that their view is wholly consistent with that included in this document.

NAWDO welcomes the opportunity to present its views via this consultation response and hope you find our response helpful. We are happy to provide further comments or clarification.

Solid waste

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

Since its introduction in 1996, Landfill Tax has been an effective financial incentive in diverting waste away from landfill disposal. The £8.00 per tonne per annum escalator was changed in 2014 to an annual RPI increase and this increase should remain in place as it continues to encourage diversion from landfill, although not always by innovative means which can be costly.

NATIONAL ASSOCIATION OF WASTE DISPOSAL OFFICERS

As a direct consequence there has been an increase in recycling rates, however the sometimes volatile nature of the recycle markets, and in some areas the lack of local infrastructure to cost effectively collect and process recyclable materials, can be limiting.

A comprehensive long term strategy to create clear policy and regulation for waste prevention, re-use and recycling would be beneficial. This should include all business sectors and encompass full producer responsibility which ensures that the cost of collection and treatment is funded, which will drive the business sector to rethink how it operates and will effectively reduce the amount of waste produced due to the financial incentive to do so. For example, designing out waste, by designing in reusability, recyclability and light-weighting will result in a reduction in the overall quantity of waste produced. Where these form part of primary thinking, it should follow that infrastructure throughout the Country must be adequate to fulfil the demand in all areas.

A minimum recycled content requirement in packaging will also help to stimulate and stabilise markets. In addition, a commitment to redistribute some of the substantial PRN receipts and HMT receipts for Landfill Tax, back to Unitary and Waste Disposal Authorities to invest in the infrastructure required for their local/regional areas could result in a significant increase in the amount of waste re-used and/or recycled.

When married to the growth agendas of councils across the UK, this can be viewed as essential to the delivery of, and the ongoing support services for that growth.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Note: A “circular economy” is an alternative to a traditional ‘linear economy’ (i.e. make, use, dispose) in which products are designed and packaged to minimise waste, and resources are kept in use for as long as possible, e.g. through re-use, recycling and greater recovery of materials through the waste management process.

To establish and accomplish a circular economy, strong leadership from policy makers is needed which ensures that the principles are embedded across all levels of government, and that those principles are championed in a positive and effective way.

To enable sensible and well informed decisions to be made, the availability of accurate information is essential. Whilst Local Authority Collected Municipal Waste is recorded through the Waste Data Flow System by Local Authorities, this is not the case for other business sectors leading to inaccurate data availability. A system of recording accurate data for all sectors needs to be established to ensure that sound decisions are taken on the locations of infrastructure to maximise re-use and recycling.

Whilst it is accepted that waste cannot be completely eradicated, it is essential that viewing it as a resource is adopted. This approach needs to be adopted at inception

NATIONAL ASSOCIATION OF WASTE DISPOSAL OFFICERS

of an idea to enable waste to be designed out wherever possible, and where impossible to do that, to ensure that the lifetime and end of life use is fully understood and forms part of the overall design. This must be a co-ordinated country wide understanding. Currently there is little incentive for designers and manufacturers to consider this, unless specifically required to do so by their clients.

Substantial investment is needed to see the principles of the circular economy implemented and succeed across all sectors. As commented above, full producer responsibility which ensures that the cost of collection and treatment is funded will drive all sectors to rethink their approach to waste and, coupled with a commitment to redistribute a large portion of the substantial PRN receipts and HMT receipts for Landfill Tax back to Unitary and Waste Disposal Authorities to invest in the infrastructure, it will naturally drive the principles of a circular economy.

It is hoped that all these comments prove helpful; if however you have any comments or queries please contact myself in the first instance.

Consultation Response

National Infrastructure Assessment – Call for Evidence

North East England Chamber of Commerce Response

Introduction

The North East England Chamber of Commerce is the region's leading business membership organisation and one of the largest chambers of commerce in the country. We represent more than 3,000 businesses from across Northumberland, Tyne & Wear, the Tees Valley and County Durham. Our members include businesses of all sizes – from SMEs to multi-national organisations – and from across all sectors.

The region's infrastructure needs rank highly among the concerns of our members, with the North East's transport, energy and digital infrastructure seen as key to helping the region reach its potential.

These issues form the backbone of our [Chamber Manifesto 2017](#), which sets out the areas we will campaign on for the year on behalf of the business community of North East England. We also recently set out our [transport infrastructure investment priorities](#), highlighting the region's requirements across road, rail, air and sea transport.

This response will summarise our members' views on the region's infrastructure requirements by addressing the relevant questions in the National Infrastructure Assessment Call for Evidence document.

Cross-Cutting Issues

1) What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Each and every infrastructure investment should help move the region towards unlocking its economic potential, however there are two key gateway infrastructure projects in the region which have the potential to unlock long term growth and regeneration in their parts of the North East, at Newcastle Central Station and Darlington Station.

Ambitious plans for Newcastle Central Station will see accessibility improved, platform capacity increased to prepare the station for High Speed Rail, and a new southern entrance, opening up an entire section of the city – the historic Stephenson Quarter and neighbouring Forth Yards – to regeneration. Newcastle Central is a gateway to the north of the region, acting as the primary link between Tyne and Wear and the rest of the country via the East Coast Mainline.

Similarly, Darlington Station acts as the gateway to the Tees Valley. For that part of the region to flourish, Darlington Station requires redevelopment and realignment, to allow greater capacity for trains to pass through and prepare the station for High Speed Rail, while preserving a key access point to Middlesbrough and Teesport.

2) How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

North East England is a region with a global outlook and is the UK's leading export region. To maintain this successful global foothold in an increasingly competitive environment, the region needs investment both on a local and a national level.

The Government's commitment to expand London's Heathrow Airport is a welcome one, securing the region's current links via Newcastle International Airport to the UK's international hub, and opening up the potential for a new

link between Heathrow and Durham Tees Valley Airport. However, now the expansion of runway capacity is out to consultation, it is important the project continues to gather support and continues to move along the process towards delivery as quickly as possible.

To ensure that the region continues to benefit from the excellent connectivity it currently enjoys, and with the room for growth, it is important that surface access to our ports and airports is improved. This includes improvements in road access across the region, and ensuring the correct loading gauge and capacity for rail lines is available linking Teesport and Port of Tyne to logistics centres across the country.

12) What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

The Chamber is currently engaged in a project working with members to understand some of the issues they face around public procurement, and identify ways in which current approaches could be improved to achieve better outcomes.

This work is at an early stage, but we would urge the National Infrastructure Commission to look closely at ways to include a more extensive range of measures in the cost-benefit analysis. Efforts should be made to ensure the full impact of a scheme – on local jobs, on societal inclusion and on local growth – are included in analysis, and that the potential for largescale, nationally significant investment to transform a region.

Rebalancing the economy, delivering an industrial strategy and enabling the northern powerhouse will require an ambitious programme from government, and one which goes beyond the current capability of the public procurement and project assessment processes, to understand aspiration and unlock potential in regions like North East England.

Transport

14) What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

In addition to the projects already outlined, the region has one key ask to improve the reliability of its transport networks – new rolling stock for the Tyne & Wear Metro.

The current Metro fleet is approaching 40 years old, and has operated since the service opened. It is beyond the end of its operational life, and reliability issues mean that without a new fleet, the Metro will not be able to expand and improve the service to meet the growing needs of Newcastle, Gateshead, North Tyneside, South Tyneside and Sunderland.

Expansion plans, linked to the delivery of new trains, include extending the network onto the national rail system, potentially linking currently isolated parts of Northumberland and Co. Durham in particular to the system and to the East Coast Mainline. New trains, new signalling and new routes will help unlock additional freight paths across the region, better linking Co. Durham and Port of Tyne in particular with the East Coast Mainline.

The Tyne & Wear Metro is a tremendous asset for the region, but needs substantial investment in order to continue to play this vital role in the regional economy.

15) What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

North East England is in a unique position within the UK, with strong existing links to London and Edinburgh, and strong international links via our ports and airports.

Where the region's connectivity must improve is in strengthening links with our neighbours in the north.

Improvements are needed on the East Coast Mainline, not only to enable planned improvements to passenger services, but also to relieve bottlenecks and open up new freight paths. Estimates by the Consortium of East Coast Mainline Authorities suggest improvements to the East Coast Mainline will be worth £12.2m a year in increased GDP thanks to better links between the North East and London, and £12m a year in increased GDP from better links between the North East and Scotland.

Improvements to the existing national rail network in North East England are also vital to allow HS2 trains to run on and into the region before high speed track arrives, adding additional capacity and opening up links to new connections across the country.

The timely delivery of HS2, and its swift progression into North East England, should be viewed as part of improving connectivity to the region's neighbours, including to across the Pennines. Providing these links, via the A66 and A69 on the road, and also via trans-Pennine rail services, will play a significant role in enabling the north of England as a whole to achieve its aims for economic growth and sectoral development.

Digital Communications

18) Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Digital connectivity is crucial to North East England, as a region with a diverse geography combining the rural and urban and with many areas still struggling with broadband access. The region needs continued support, both for the roll out of existing fibre broadband technology and for the delivery of the next generation of digital communication technologies like 5G.

The current schemes for superfast broadband rollout across North East England have set ambitious targets for the number of households they hope to reach. The nature of the region's geography however, makes it likely that some more remote parts of the region will remain isolated unless alternative methods are found. The example of iNorthumberland, who have used microwave radio to reach isolated settlements – those which are too far from existing fibre to be connected directly – points the way for the use of alternatives to provide the connectivity the region needs.

Energy

20) What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

As set out by the work of IPPR's Northern Energy Taskforce, the North – including North East England – has long been at the forefront of energy generation in the UK, and has the natural assets, skilled workforce and industrial expertise to remain so. Not only is North East England a leader in the renewables sector, it also enjoys the

presence of many energy-intensive industries, whose competitiveness is linked to the cost and reliability of their energy supply.

Efforts should be made to support industrial investment in new technologies around energy generation – including industrial Carbon Capture and Storage – and help reduce costs for high-intensity users and pave the way for a zero carbon power sector in the future. This must include long term certainty around the energy sector, offering clear sight for investors as they plan and deliver schemes over the medium to long term.

This certainty of policy would unlock private investment across the sector, allowing the region to continue to play that role at the centre of the UK's energy generation, drawing on and developing our expertise in advanced manufacturing, subsea oil and gas, and renewable energy.

Network Rail response to the National Infrastructure Commission's consultation on the National Infrastructure Assessment: 'Call for evidence'

Network Rail Infrastructure Ltd. welcomes the opportunity to contribute to the National Infrastructure Commission (NIC) 'call for evidence' consultation on their forthcoming National Infrastructure Assessment (NIA). Network Rail is the owner and operator of the rail network in Great Britain, and is responsible for its safe operation, maintenance, renewal and enhancement.

As established in previous consultations to the NIC, Network Rail recognises the objectives of the NIA as complementary to its own vision to deliver a railway which will support a thriving, sustainable economy and improved quality of life. Although this response provides a high level view to the questions provided, for further detailed development of the NIA we would welcome bilateral engagement with the NIC on any, or all, of our responses.

The key points of Network Rail's response are:

- Rail infrastructure serves a vital role in the UK's economy and society, connecting new, and strengthening existing, markets for passenger and freight users.
- The current network faces considerable capacity and performance challenges in a number of areas. Significant investment is required to satisfy both current rail infrastructure challenges and meet the growth in demand in the long-term.
- Network rail has a planning pipeline for long-term investments over the timescale of the NIA. Long-term planning is done in collaboration with the rail industry through an established Long Term Planning Process (LTPP). Current emerging opportunities for long-term investment include:
 - The Digital Railway programme.
 - Brighton Mainline, South West Mainline, and station capacity improvements.
 - Further pipeline developments from the LTPP route studies.
 - Long term transformational enhancement schemes such as Northern Powerhouse Rail, HS2, and East-West Rail.
- Any enhancement or expansion of rail infrastructure should be planned alongside other infrastructure changes to ensure the maximum benefits can be delivered.
- Network Rail is exploring new methods of funding and financing to improve efficiency of infrastructure delivery.
- Network Rail welcomes collaboration and competition, where appropriate, to provide best value to its funders and users.
- There are opportunities for the NIC to assist in several areas for benefit of cross-sector infrastructure planning: for example, investigating interdependencies and resilience, and by reviewing effectiveness of planning systems and consents approval.
- Network Rail believes, however, that care should be taken not to undermine the independence of sectoral regulators, and that recognition should be provided to the unique characteristics of each infrastructure industry.

Cross-cutting Issues

Q1. What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Network Rail is a national organisation which owns and operates the majority of the rail network across Great Britain. Although the rail infrastructure serves a vital role in supporting long-term sustainable growth across the UK's cities and regions, it faces considerable capacity and performance challenges in several locations. To meet these challenges, Network Rail is committed to plan for the future role of the railway in the UK economy. It undertakes planning through the Industry established Long Term Planning Process (LTPP), and further development of specific interventions through a progressive 'pipeline' in order to present effective investment options for funders.

The contribution of rail to the British economy is increasingly recognised. Rail infrastructure can provide connectivity to open up new, and strengthen existing, markets for passengers and freight across the country. A study produced for the Rail Delivery Group in 2014 reported that the rail industry in Great Britain, and its supply chain, employ around 212,000 people and generate £9.3bn of gross value added (GVA) per year¹. Furthermore, the sector provides benefits worth up to £13bn a year to its passengers and freight users, and enhances the productive potential of the economy by up to £10.2bn per year.

In delivering these benefits, Great Britain has one of the fastest growing railways in Europe and the second most intensively used². Demand has grown significantly in the past two decades bringing both benefits and challenges. In London, in 2015, rail delivered on average over 580,000 commuters into the central business district during the morning peak each weekday with around 5.8% of these passengers in excess of capacity³. As a consequence of this capacity challenge, the performance of the network is not achieving the required levels and user experience of service can drop.

In the next 25 years passenger demand is yet expected to double, and freight markets are faced with modal shift to predominantly intermodal traffic. These demands will not be met within the capacity of the existing infrastructure network. If further capacity is not provided, then it will significantly constrain the ability of the network to meet demand for rail infrastructure services, and further lead the rail network to become a constraint on the future economic growth of the national economy.

In planning to meet demand effectively, Network Rail works with rail industry to produce the LTPP⁴. This is an industry established process which takes a network wide perspective in providing strategic options for investment in the railway. As the process is embedded, and broadly aligned with the timescales of the NIC, it is recommended that the NIA utilise the outputs of the LTPP as an integral 'building block' for long term planning. The LTPP comprises a set of documents and activities that:

- Address the demands that are likely to be placed on Britain's rail network over the next 30 years (to 2043).
- Capture stakeholder aspirations to develop new train services in the light of continuing rail investments.
- Present investment choices for funders to accommodate demand and future aspirations.

The LTPP proposes ways in which train services and infrastructure enhancement could develop over the longer term to 2043, and provides an evidence base for near-term investment in the next Control Period (CP6) from 2019 – 2024. Due to the uncertainties of a 30-year planning horizon, the LTPP is an iterative process. Future planning cycles enable an updated view to take into account the changing context and requirements of the industry and economy. The LTPP acts as a key input to the industry's ongoing discussions with funders concerning the future outputs, investment choices and funding requirements for the railway.

The LTPP consists of a number of essential elements:

- **Market Studies**⁵. These forecast future rail demand, and develop conditional outputs for future rail services. These outputs are based on stakeholders' views of how rail services can support delivery of the industry's strategic goals.
- **Cross-Boundary Analysis**⁶. This analysis considers options for services that run across multiple routes, providing consistent assumptions across Route Studies.
- **Route Studies**⁷. These develop options for future services and identify options for investment in the rail network for each of Network Rail's devolved routes. Options are based on the conditional outputs and demand forecasts from the Market Studies, and are assessed against industry appraisal criteria to provide choices for funders.

Acknowledging the consultation's note that "considerations of 'highest value' should include benefits and costs, as far as possible taking a comprehensive view of both", Network Rail incorporates value consideration and appraisal at several stages through the LTPP and 'pipeline' scheme development. The use of a 'conditional output' importantly recognises that outputs from the market studies, such as increasing frequency of service, are conditional upon affordability and a value for money (VfM) business case being determined.

The LTPP route studies offer the best way to understand long-term options for investment across the rail network. As each route study is aligned to route geography, the requirements of a variety of rail markets serving a 'city or region' can be located within the relevant study produced. However, although the LTPP identifies options for funders to invest in the rail network, to produce a deliverable project or programme these options must pass through a 'pipeline' of further development. As further introduced in Q10, this pipeline is being adopted as a progressive process for funders to invest in the railway, and to improve governance of projects and programmes

Current investments emerging in this pipeline to address the growing capacity and performance challenges on the network, and improve connectivity, include opportunities of:

Digital Railway⁸ – Other travel modes, such as Aviation and the London Underground, already benefit through use of Digital Control systems. Through deployment of digital railway signalling, it is possible that several currently congested routes would have capacity released for more efficient use on the existing network. Alongside this, Digital Railway traffic management systems have the possibility to provide performance benefits through efficient monitoring and control of rail infrastructure systems.

Investment in key rail capacity 'hotspots' – As introduced, the current rail network faces immediate challenges if growth persists on existing infrastructure. Notably, capacity is required on several economically vital routes into London. Mirroring the expected benefits of the forthcoming Elizabeth line (Crossrail), a North-East to South-West Crossrail 2 would provide additional connectivity to markets in central London and relieve capacity on existing lines⁹. Investment in economically vital lines into urban areas, such as the congested South-West Mainline and Brighton Mainline to London, would also release capacity and provide performance improvement.

Investment in key stations – In addition to capacity pressures on rail infrastructure, investment will be required in key stations to ensure they can provide safe and effective means to change trains, interchange with other transport modes, and provide access to local economies, when passenger footfall increases place pressure on existing station provision. Birmingham New Street is a recent example of the transformational opportunities such investment can provide¹⁰.

Investment in key freight corridors - As identified in the Freight Network Study¹¹, developing capacity and capability along a core arterial, nationally cohesive freight network would allow the rail network to reflect forecast growth in intermodal rail traffic between key nodal sites such as Ports and regional distribution centres.

Investment in supporting interregional connectivity – HS2 will revolutionise rail travel, by providing very fast connectivity between London, Birmingham and the Midlands, and Manchester and Leeds in the North¹². Opportunities to integrate benefits of HS2 with the existing rail network, such as a 'Midlands Hub', could further increase regional connectivity¹³. Beyond this, other major programmes are promoted by potential funders and local partnerships. A 'Northern Powerhouse Rail' providing fast and frequent interurban travel between the northern cities has been promoted by Transport for the North (TfN) to assist in delivering the economic potential of cities in the north of England¹⁴. Similarly, delivery of a completed 'East-West Rail' could connect high-value and knowledge based industries with housing growth across an area promoted as 'England's Economic Heartland'¹⁵.

Q2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight, and data in ensuring this?

One of the wider goals identified in the market studies for transport, and for rail markets to assist in meeting, is to enable economic growth⁵ – a benefit contingent upon increased competitiveness.

Although each rail market has different capabilities to assist in meeting this wider goal, broadly rail infrastructure can most effectively contribute to the UK's competitiveness through four ways:

Firstly, rail infrastructure can improve **connectivity** to open up new, and strengthen existing, markets across the country. Improving the journey time, frequency, and network of rail connections can all contribute to a more competitive economy for labour, housing, goods, ideas, leisure, and customers. Resultant outcomes, such as increased agglomeration economies and access to labour markets, also have the potential to assist in 're-balancing' the competitiveness of regions within the UK¹⁶.

International gateways increasingly depend upon rail infrastructure connectivity for access into, and out of, British markets along identifiable 'corridors'. The freight market is shifting to intermodal traffic, resulting in reliance upon connectivity along strategic corridors between vital nodal sites such as deep sea ports and distribution centres⁵. For services and leisure markets, corridors of connectivity are required between centres of economic activity and airports. Maximising the benefit of airport rail links can be provided through improved connectivity to urban transport modes, and business districts through 'gateway' stations.

Secondly, rail infrastructure can provide sufficient **capacity** for economically productive activities. On point-to-point mobility, rail can transport relatively large volumes of people and goods efficiently with a competitive journey time. Demand for rail transport is high on the majority of routes, and has been growing consistently since 1994¹⁷. In most rail markets, even in pessimistic scenarios, growth looks to continue. Where this growth can't be accommodated, it provides a constraint on the competitive benefits provided by connectivity. Already, freight transport is limited by capacity constraints on a number of key corridors between markets and international gateways. For passengers, a constraint on capacity can limit access to business and labour markets, and vastly decrease satisfaction with service. Capacity improvements can meet existing demand, and increase competitiveness by opening up infrastructure to increased economic benefit.

Thirdly, improvement of **performance** allows goods and people to flow across the country effectively. Delays and poor reliability negatively impact competitiveness through perceptions of uncertain end-to-end journey times, difficulty of connectivity to markets, and poorer quality of life for travellers. For goods markets especially, competitiveness is extremely sensitive to journey time. As such, pressure on operators' reliability will likely increase. Improvements in resilience and reliability can then provide confidence in economic delivery, and could provide a boost to UK competitiveness.

Lastly, development of new technologies and talent could allow the UK to export **expertise and skills**. The UK has a relative advantage in a number of areas associated with infrastructure delivery and management – for example, digital signalling and train control¹⁸. By providing a basis for increased exports, this expertise could benefit the UK economy through job and skills creation.

Q3. How should infrastructure be designed, planned, and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

As infrastructure projects and programmes are taken through a 'pipeline' of design, planning, and delivery, the best way to assess and deliver the benefits of better places to live and work is to collaborate effectively with a variety of stakeholders – such as funders, business groups, local authorities, operating companies, and user groups. Through collaborative and joint working, a variety of contingent developments such as housing may additionally be identified and considered.

In planning and design, Network Rail's LTPP process is strongly collaborative at all levels of study. In Market Studies, future demand and requirements (expressed as 'conditional outputs') of the rail network is built upon stakeholders' views, and thorough review of how rail services can support delivery of the market's strategic goals. In Route Studies, when options are developed for geographically aligned routes they are assessed against the identified market study outputs, funder and stakeholder criteria, and an early assessment of value for money. At this early stage of project design and planning, stakeholder collaboration and strategic review increases the chances of effective delivery of railway infrastructure strategic outcomes and benefits.

Likewise, where contingent developments such as housing are dependent upon infrastructures, early collaboration and integration is key to successful delivery of ultimate benefits. For example, large housing developments can deliver benefits of better living and working if they are situated near a station. However, with capacity on many routes often low, early collaboration is essential to ensure that any new station proposal is the correct transport strategy without detriment to overall rail service and wider regional quality of living and working¹⁹. Indeed, a mixture of transport means to undertake 'last mile' mobility need to be integrated with existing hubs to deliver benefits more effectively.

Early stage planning and design could arguably be further improved to focus upon 'better places to live and work' through increasing consideration of social value planning and wider benefits in the appraisal of options. Wider benefits such as community improvement, jobs creation, and social value can be difficult to capture in an economically aligned business case. Expansion upon this point is provided in response to question 12.

Q4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Demand for rail infrastructure services has increased consistently in recent years, and is set to continue under any forecast scenario⁵. Where demand is seen to outstrip capacity, the LTPP works to identify options to address them. Notwithstanding required infrastructure enhancements of varying scales, in a capital and capacity constrained environment, demand management can provide additional tools to alleviate or redistribute some demand for the benefit of increased efficient use of an existing network.

On a sectoral level, long-term demand for transportation may be managed by efficient planned use of infrastructure modes for different markets. A freight train, for example, is capable of conveying the equivalent of approximately 60 lorry loads²⁰. Over long distances, this can reduce congestion on the road network, emissions into the environment, and maximise economic benefit from connectivity. On a national scale, the ORR notes that in 2013/14 rail transported an equivalent of 1.78 billion lorry kms²¹. Management of demand at this level is contingent upon competitive benefits to the market and capacity, and effective planning policy; for example, the ability for goods to be delivered efficiently requires planned nodal warehouse sites and investment in the Strategic Railfreight Network.

On an industry level, demand may be managed through micro-economics strategies of regulating access of operators to the network, and of ticket pricing to the consumer – both of which are beyond the scope of Network Rail’s duties to the rail network²². For the former, changes to access charges are determined by the ORR, and done so on basis of cost recovery. However, changes of access charge to reflect a value of capacity may present large commercially sensitive challenges with limited benefits, including potential to ‘price off’ valuable traffic from rail infrastructure such as freight, at detriment to wider benefits such as increasing environmental emissions and road congestion. For the latter, tickets are already split into peak and off-peak fares around service demand trends during the ‘working week’, and by regulated and unregulated structures. To further improve service to passengers, an action plan for information on rail fares & ticketing was released jointly by the DfT, RDG, and Transport focus setting out clear and agreed steps between the Government, Industry and consumer groups to help passengers find and choose the best ticket for their journey²³.

On an infrastructure level, day-to-day demand spikes and recovery from incidents can be managed through improved traffic management technologies and performance strategies. For example, one element of the Digital Railway programme is deployment of a traffic management system which could assist signallers and operators to more efficiently manage increased levels of train service on the infrastructure⁸.

Q5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Network Rail is committed to effective asset management to a safe and reliable standard, both for the construction of new assets and the maintenance of existing assets. As such, where planning for new assets takes place it should take into account existing asset maintenance on a minimum whole life costing basis. The latest update to Network Rail’s Asset Management policy was issued in 2014, compliant with ISO 55000 standards²⁴.

Any activity on assets should be directed to support statutory and customer requirements. In the case of infrastructure, this normally means delivering safe, reliable assets that have capacity and functionality when the customer requires them. With these requirements in mind, a balance can be struck between ensuring that the established capability of existing infrastructure is retained (where it remains key to customer requirement), and investment to offer new and improved capabilities, providing expanded services to existing and new customers.

To determine an effective balance, life cycle ‘asset management’ analysis is required. This involves use of decision supporting tools to confirm how risks to service levels change with different patterns of investment of maintenance and improvement. These tools need to reflect cost, performance, and risk relationships over time for both a discrete asset, and a portfolio of assets. These methodologies are sensitive to long term patterns of degradation; for example, often a short term reduction in maintenance may only reveal itself as risks to service reliability in the medium term. For this reason it is essential that the degradation models that are used within the lifecycle tools are created from historical records of change and are peer reviewed / independently verified to confirm that tools are valid and that uncertainty within the analysis is understood.

Instead of provisioning a balance, tools can provide options and choices to funders. These will offer differing short and long term patterns of investment, maintenance and improvement scenarios, and the consequential impact on short and longer-term patterns of performance and risk. Often, the best time to improve an asset is when it is up for renewal. For example, on the digital railway programme, where demand for additional train service capacity or enhanced performance exists, a targeted approach could be aligned with the need for asset renewals so that there is an overall minimisation of both the value of assets which must be replaced, and the level of disruption to service provision for end users.

It is with such evidence, that an informed judgment can be taken on balance between maintenance and construction of new assets – one that won’t create any unintended or perverse consequence, and one that can be aligned with funding constraints and market capacity, which can be essential to support medium-term sustainability within the supply chain.

Q6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Network Rail recognises that collaboration and competition in different areas of the supply of infrastructure services, when effectively applied, can deliver a variety of benefits.

Already one of the most liberalised rail sectors in the EU, the GB rail market has train operation provided by franchised competitors for passenger services and private companies for freight services²⁵. To further improve infrastructure activities and operation, Network Rail further recognises the benefits of collaborating with train operators in an increasing number of ‘railway alliances’. These can be undertaken through a number of models, such as the joint management of ScotRail and Network Rail Scotland²⁶, with ultimate aim of providing enhanced service and value to users and funders.

In project delivery of rail infrastructure, Network Rail additionally welcomes increased contestability. Indeed, railway renewals and enhancements are already provisioned through market competitions in order to increase efficiency of delivery. To investigate barriers preventing further alternative project delivery models on the British rail network, Network Rail's CEO has tasked [name redacted] to conduct an independent review²⁷.

For long-term innovative technological enhancement, the Digital Railway programme is currently collaborating closely with the supply chain through early contractor involvement (ECI)²⁸. ECI aims to maximise supplier buy-in from an early stage to drive down costs and ensure alignment of supplier capability with the emerging needs of a digital railway. Diverse workstreams such as new technology business case development, collaborative cost reduction, optimisation of commercial structural and operational arrangements, and the joint development of technical specifications all provide examples of opportunities of collaboration in the supply of a new infrastructure service.

Successful collaboration and competition in the identified areas of infrastructure service provision identified generally depend upon a number of factors. The provision of a correct benefit-sharing model for relevant parties and tools to support sectoral strengths, correct apportionment of risk, implementation of a robust joint management system, and the selection of partners based upon strategic goals, capability, and value potential are all required to deliver the benefits.

With regards to collaboration and competition in the sector, relevant sectoral regulators have unique sets of duties as legislated by parliament. It is noted that there was consideration of making economic regulators have regard to recommendations provided by the NIC²⁹. Network Rail believes care should be taken not to undermine the independence of sectoral regulators, and that recognition should be provided to the unique characteristics of each infrastructure industry where a uniform policy may provide a variety of outcomes in a commercially sensitive sector. Therefore clarity on the statutory status of the NIC in this scenario would be welcomed.

Q7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The delivery of rail infrastructure services, for which Network Rail is responsible, is currently largely funded from Government. Policy could aid in a number of areas to improve rail infrastructure service delivery, including examples in assisting possible changes to funding origin, the process by which funding is gathered, and structure of funding provision.

With regards to how railway enhancements are paid for, there is increasing desire to see contribution from third parties and ultimate beneficiaries. For established third party investors, coordination and collaboration between industry and government partners would increase attractiveness of a business case for investment in various projects. In areas surrounding new infrastructure enhancements, beneficiaries of the enhancements, such as property developers, should be expected to help pay for the investments. For example, this could be through methods such as 'section 106' and the community infrastructure levy. Other beneficiaries could also potentially provide indirect funding if primary legislation provided targeted tax (such as on properties and businesses set to benefit) powers to local authorities.

Network Rail generally receives much of its funding through 5-year 'control periods', with funding provided for delivery of agreed outputs. The control period model, however, doesn't always provide an efficient model for complex longer-term strategies and enhancements such as digital railway and HS2 enablement as their programme lifecycles span beyond one single control period. Network Rail is instead moving its enhancements model towards a progressive funding model – with funding of enhancements agreed outside the periodic review process. Cross-border projects also require an approach which recognises the beneficiaries of investments. For example, clear agreement on priorities and responsibilities of funding between Scottish and central Government would allow for efficient investment in any cross-border rail infrastructure projects.

Q8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Funding and financing are terms which are sometimes used interchangeably. For rail infrastructure, funding refers to enhancements that are paid for 'upfront' with cash whereas financing refers to enhancements being paid for through borrowing money.

Existing models developed both in other sectors and rail that could be used include the PPP/PFI approach; concession arrangements the structures used in rolling stock procurement, property-related models (e.g. Northern Line Extension), regulatory licensed models (Thames Tideway, Oftos), models for delivering and financing construction (such as Evergreen) or joint ventures.

Possible sources of incremental value through use of private sector capital may include:

- optimised costs through more effective whole-life asset management;
- effective risk transfer, robust cost control and operational efficiencies;
- benchmarking of differing procurement strategies;
- innovative delivery approaches (for example, pricing and mitigating disruption more efficiently);

- better alignment of interests between Network Rail, its train operator customers and contractors and deliverers; and
- current availability of private sector capital at a historically low cost.

Generally, however, the cost of private sector finance will be higher than the public sector cost of capital faced by Network Rail. Therefore, the use of private sector capital will create incremental VfM if the efficiency, performance gains, and the risk transferred outweigh the extra cost of finance.

Network Rail is actively considering raising private sector finance where appropriate at project levels, but conditions for effective financing are likely drawn from a combination of external and internal conditions.

Potential issues

- **Industry engagement and support** on the mixed delivery approach to new investment models, and how they will be regulated and managed within the industry's implementation plan
- **The availability of funds looking to invest in infrastructure.** There is a range of sources depending upon different schemes. A pipeline of appropriately structured deals could potentially either offer a self-generating revenue stream for investors and/or which provide opportunities for efficiency and innovation.
- **Interface issues.** However these could be seen as more of an issue to manage effectively rather than a problem per se. Often, many of the developers are also Network Rail contractors and have experience of working on the rail themselves or working with construction companies who do. Behind them is a group of investors who are less risk averse and more likely to consider construction risk.
- **Clarity of the revenue model.** It will be necessary to structure availability or usage payments to the project deliverers based on the availability and performance of their assets. Many schemes may not be fully self-funding, meaning that funders may need to consider how it allocates its long-term support to privately financed assets, including some projects which may have some element of other funding as well as generating project income.
- **Protection for investors.** Infrastructure assets are, in general, not freely transferable and financial security cannot be exercised by removing rail assets. The primary protection for investors is the essential nature of assets' outputs, but investors could remain exposed to changes in Government policy (including the duties of regulators) which can affect revenues and/ or costs.
- It is assumed that the **principles of the existing Track Access regime** are not undermined by a greater volume of projects financed with private sector capital. System capacity will continue to be sold to operators by Network Rail as system operator; project promoters will potentially bear risk on the outputs of the assets they deliver, but not on wider system outputs (which they could not effectively control and to attempt to transfer this risk to them would be poor value for money). The exception to these assumptions might be a concession under which a whole region of network is to be recapitalised by the private sector which takes over as a network owner and operator.

Internal/delivery conditions:

- **Testing the Value for Money case.** It is important to choose which of the wide range of projects are more suitable for private investors, with mind that social and environmental benefits are challenging to monetise for and available for repayment to private sector project parties.
- **The railway operational environment (including interface complexity)** may make investment less suitable in some cases. Effective risk transfer (hence value for money) is predicated on giving the relevant party the risks they are best placed to manage.
- There must be **confidence that the project will be delivered**, or that the procurement will lead to a transaction. Lengthy, expensive and uncertain procurement processes should be avoided, as these impose unacceptable cost and risk on bidding parties. The current average time from OJEU to Close is more than four years.
- **Payment mechanisms.** Preference for payment mechanisms that reward asset performance (controllable by the investor) over those that transfer usage risk (e.g. track access charges and compensation payments) with a general investor preference for financing approaches that avoid demand risk.

Q9. How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

There are a variety of interdependencies which arise between infrastructure sectors, some of which have been identified by the NIC for investigation, which can provide uncertain and varied risks to service provision. Increased collaboration and visibility between sectors, alongside effective integration of 'resilience' in planning, asset management, and operations, can help identify and mitigate these risks. Across infrastructure, however, there is no generally agreed definition of 'resilience', and this can challenge benefits from collaboration. For example, levels of resilience can be interpreted in other sectors as levels of reliability, and resilience can be hard to assess and model within business cases for enhancement. As such, this could be an area of future research for the NIC to undertake.

On a strategic level, long-term consideration for interdependence and resilience could be built into planning through engagement between contingent system operators, regulators, government organisations and stakeholders in different sectors and supply chains. For example, working with key stakeholders such as Highways England, National Grid, MI5, and the Environment Agency could allow for information sharing and the development of strategies cognizant with identified interdependencies and risks in areas as diverse as climate change, environmental management, energy policy, and security incidents etc.

On an asset level, resilience can be provided through whole life costing effective design and implementation. Features such as standardisation, modularisation of equipment, remote monitoring and diagnostics can be designed into assets to increase reliability and resilience. Although initial capital costs may be higher, a whole life costing model captures the economic benefit of resilience over time through reduced economic impact of failures within a transport system. Sharing information between sectors could further improve accuracy of costing models and strengthen cases for investment.

On an operational level, standardised traffic management and driver advisory systems (such as those provided by Digital Railway investment) could increase resilience to delays and provide increased accuracy to timetable planning. In addition to continual performance improvement within rail industry with traffic management, collaborative working with other transport operators can produce resilient operational strategies where interdependent risks arise. For example, a failure of a transport mode – such as a major road incident - may significantly increase pressure upon rail transport along a geographically similar route.

Q10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

The planning processes of Network Rail's Enhancement Programme 2014-2019 were recently the subject of review by [name redacted]³⁰. In response, Network Rail and the Department for Transport issued a memorandum of understanding outlining a process for improving the joint delivery of infrastructure projects³¹. The issues highlighted, and processes put in place, could provide lessons learnt for wider how infrastructure planning and governance is conducted with a variety of funders.

Additional governance has been put in place to assist in the timely and efficient delivery of works, and to recognise that projects and programmes in early development are highly immature. Network Rail now aims to develop a pipeline of projects to be put through a series of joint decision points, so that funding is committed progressively and the value for money of delivered outputs is tested at key points in development. Funding should only be committed to progress to the subsequent joint decision point, to ensure clarity of cost and outcome expectations. Through this process, it is envisioned that at each stage planning faces discipline to investigate an increasing clarity of scope, outputs, outcomes, and benefits, as well as decreasing risk to funding and timely delivery.

The delivery of infrastructure, particularly rail, is dependent upon securing a range of necessary consents and permissions, including planning, land acquisition, but also environmental or listed building consents. Over the years Government has provided new tools for the delivery of multi-consenting schemes – such as Transport and Works Act (TWA), Development Consent Order (DCO's) or Hybrid Bills (such as HS2). It would be opportune for the NIC to review the effectiveness of such regimes, particularly TWA and DCO, and to make recommendations for best practice to be shared across the sectors or for improvements to be made. DCO's, for example, were established in the 2008 Planning Act and whilst the time taken for formal decision making period is prescribed, the front loading requirements mean that periods of 2-3 years are required before the scheme is formally submitted. A review may reveal and suggest opportunities to streamline this, increasing the efficiency of delivery.

Continued review of processes and planning strategies on a variety of levels is required to ensure that supporting processes are effective, and that infrastructure developments have line of sight to national, regional, and local goals. If timelines and strategies of delivery for contingent projects and programmes (such as infrastructure developments and local authority zoned housing) are not properly aligned, then it can lead to frustration of stakeholders and delays to benefits. Collaborative working and transparency through such processes can provide opportunities of continuous improvement and likelihood of efficient delivery on time.

Q11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Network Rail recognises the impact rail infrastructure can have on the natural environment, and believes that sustainable development and improving environmental performance is essential to being a responsible and successful organisation³². Through recognition of the impact of infrastructure on the environment, effective collaboration with partner organisations, and working to build sustainability principles in business management and project development, it is possible for rail infrastructure to protect and enhance the natural environment without detriment to service provision.

Existing rail infrastructures and assets do not always have space available to dedicate to the enhancement of the natural environment, but have potential for consolidation of the many species which currently inhabit them. For example, embankments and land alongside railways can sometimes act as a series of fenced off habitats. However, difficulty arises when

the primary use of this land, safe railway operation, requires clearance or interference with these environmental benefits. As such, proper planning and an understanding of estate and ecological management are required to provide both transport and environmental benefits. By working collaboratively with partner organisations, environmental data could be gathered and built into national datasets on habitats and species within railway land. This information can be used to inform effective ecological management, further improved by sharing data and best practice through partner organisations such as the Linear Infrastructure Network (LINet)³³.

Collaboration and inclusion of sustainability principles can additionally minimise the disruption of providing new rail infrastructure. Through effective planning, project resource use and asset design could lead to long-term efficiency benefits and a reduction in waste and pollution. In addition, major rail investments in the existing network such as the Great Western route modernisation, or in new networks such as HS2, are often required to enhance natural environments such as involvement in biodiversity 'net gain' trials. As such schemes are often 'pioneering', it is vital that learnings are shared with other operating and delivery organisations to provide industry and sectoral best practice on effective design and delivery of infrastructure around the natural environment.

Q12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable, and transparent?

Although specific techniques can always be improved, the most significant issues that call for improvement are arguably broader than the question provided.

First, cost-benefit analysis should be more widely acknowledged for what it is: one of the key things that inform a business case and thus decision-making, but not the only one. There are few, if any, major investments for which cost-benefit analysis is likely to accurately quantify, let alone value, all the relevant considerations. Ironically, appraisal guidance itself often recognises this, stressing the importance of qualitative considerations in the overall decision. In practice, however, an arguably disproportionate amount of effort is sometimes put into the quantitative cost-benefit analysis.

Second, cost-benefit analysis – and planning and decision-making in general – needs to be more clearly objective led. Current cost-benefit analysis, for example as set out by the HMT Green Book³⁴ and DfT Transport Appraisal Guidance (WebTAG)³⁵, uses welfare benefits (for example, the value of savings in travel time) as its key measure. However, maximising welfare benefits is not always the sole or even main objective of decision-makers. Economic growth, rebalancing the economy and deficit reduction – to take three examples – are not the same thing as welfare benefits; and the investments that would be most effective at achieving these objectives are not necessarily the same as those that would maximise a traditional Benefit / Cost Ratio. It is important that business cases consider the extent to which the investments are likely to achieve the desired objectives, even if this is difficult to quantify precisely, rather than the extent to which they meet objectives which are easier to measure but are not the primary goal of decision makers.

Third, current cost-benefit analysis is based on assessing the proposed investment in isolation. For example, transport appraisal compares the world with and the world without the proposed transport investment, with all other things being equal. However, transport investments are increasingly being planned as part of wider development strategies that include multiple investments in transport, housing and other infrastructure, as well as non-infrastructure investments such as in skills and training. Assessing each investment in isolation will not necessarily give a fair assessment of the overall strategy.

These considerations suggest that the most valuable improvements to cost-benefit analysis – at least in respect of major investments that aim to have significant effects on the economy – would be increased emphasis on the narrative explaining how proposed investments are expected to achieve their objectives, and guidance on the nature of the supporting evidence that should be provided.

Finally, it is not clear how best to value resilience of systems. This is becoming a more important objective, particularly following a number of extreme weather events in recent years and the prospect of increased risk due to climate change (although resilience is not limited to weather issues). However, there is little quantitative evidence of the effects of system failures (e.g. impact on the economy), and hence of the value of avoiding them in future. As mentioned in Q9, research in this area would be beneficial.

Transport

Q13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

As part of the LTPP, Network Rail issued four Market Studies to set out how demand is expected to change over the subsequent 30 years in the Long Distance, London & South-East, Regional Urban, and Freight rail markets⁵.

Growth in rail travel markets, or indeed any mode, is dependent on a number of changing factors and trends: macro- economics such as employment and economic activity, micro-economics such as travel costs and competition, demographics of population

and age, consumer tastes and perceptions, and the supply of travel opportunities such as modal generalised journey times can all affect travel pattern changes.

In addition to these factors influencing demand, change in rail markets is framed within four scenarios combining economic performance with social and environmental planning, which includes national technological capability: prospering in global stability, prospering in isolation, struggling in global turmoil, and struggling in isolation.

Travel between modes, and between different markets of rail transport, could vary depending on a combination of these factors. However, even in the poorest scenario, rail transport still displays positive demand. This may be due to entrenched trends of increases in population and urbanisation, which are favourable trends to the use of rail as they increase demand for modes of transportation that move large numbers of people between, and around, urban areas efficiently. Indeed, the most likely scenarios indicate that rail passenger transport demand will double again over the next 30 years.

For rail freight transport, a rapid structural change in the commodity base has been prompted by change in generational policy and globalisation of steel manufacturing. Despite this, overall demand is growing, mostly from intermodal traffic between deep sea ports. Indeed, in 2014 the RDG reported that 1 in 4 containers entering the UK were received by rail freight³⁶. Future growth in this sector is likely to follow this trend, but is notably sensitive to modal competitiveness and capacity.

Major new technologies of note emerging in the UK rail sector include those which enhance national and regional infrastructure capability (such as High Speed Rail and Digital Railway signalling), and those which enhance transport service provision (such as 'Smart Ticketing' and digital communications technologies). The former should build upon rail's established economic benefits with technologies providing opportunities of enhanced inter-regional connectivity, increased capacity on congested routes, and better operational performance. The latter may allow for increased user experience and productivity, as passengers can prospectively integrate journey planning, efficiently purchase travel, and work on the move with high-speed internet connectivity³⁷.

Technologies of note emerging in other sectors include the possible development of new transport modes, such as Autonomous Vehicles (AVs) along road networks. If technology develops to maturity where AVs can operate safely at high speed in a coordinated manner, it could arguably provide large benefits and advantages to road transport. However, rail may still maintain an advantage with the efficiency it transports large volumes of passengers. Indeed, AVs could be regarded less as a competitive threat, but as a complimentary means to plan for – for example, station planning and development could integrate AVs as an additional transport mode in a customer's journey.

While modelling forecasts are useful to long-term planning processes, caution is urged with regard to accuracy of predictions over timeframes as extensive as 30 years.

Q14. What are the highest value transport investments to allow people and freight to get into, out of, and around major urban areas?

In the response to Q1, Network Rail's LTPP was introduced as an established process through which high-value investments in rail infrastructure are identified over a planning horizon aligned to the forthcoming NIA. Whereas Q1 offered a national snapshot, rail infrastructure has particular opportunities and challenges in delivering high value transport within an urban context. It should be noted, however, that railway planning takes a holistic approach to the mixed markets urban rail infrastructure serves, with route studies identifying solutions which provide a variety of benefits. An 'urban scheme', such as the examples listed below, will often serve both commuter or metro style service, and long distance high speed services requiring access to inner city stations. With this in mind, although the limits of Q14 and Q15 are useful to consider challenges and opportunities to rail infrastructure in different geographies, any potential investments will likely provide wider benefits.

Cities are important centres of national economic activity. As urbanisation has progressed, and the national industry base has shifted to services, the importance of major urban areas to the British economy has increased. Often high-value and knowledge-based sectors are located in cities providing competitive labour markets and growth. The capital, London, has such industries on an internationally competitive scale that it can be classified as a 'world city'³⁸. Furthermore, this worldcity is expected to also reach the classification of a 'megacity' in 2030, as population is projected to reach 10 million persons³⁹. This trend of urbanisation and service sector productivity can be observed in several of the UK's major urban areas, although it is notable that growth in London has been much higher. Continued growth, and the general competitiveness of urban areas, can be supported by connectivity to a variety of markets – for example, labour can be efficiently connected from areas of available housing to centres of employment, leisure and business services can access a wider number of customers, and goods can be imported and exported.

Rail offers an efficient means to provide connectivity for major urban areas. As cities grow, rail can generally offer advantage for flows of commuter and leisure markets serving principal urban centres if journey times, frequencies of service, and costs are competitive over the distances served. Train services can then provide an efficient means of point-to-point travel, transporting high volumes of people and goods into central locations of economic activity. This can provide secondary benefits of relieving

congestion on road networks, and reducing emissions through train travel's relatively low carbon emissions⁴⁰. This is especially notable for freight; the large consumer population of a city provides large demand for goods which, if transported entirely by HGVs, can congest key road arteries. Efficient supply chains could then be supported through integrated nodal railfreight sites. Indeed, urban travel is often intermodal, and further connectivity across an urban area can be promoted through integration with other modes such as metro, bus, trams, or bicycle sharing to complete the 'last mile' from train station to destination. Indeed, a trend to 'mobility as a service', supported by such innovations as integrated ticketing, smart cards, and digital applications, can increase efficient transport by integrating the benefits of a rail service into a user's personal journey.

Investment in the rail network is required to provide capacity for sustained demand. Although long-term demand forecasts are not without uncertainty, it is unlikely rail's advantages will be eroded. Both the 'Regional Urban' market study of the 13 largest regional urban centres in the UK⁴¹, and the 'London & South East' market study⁴², predict urban rail growth in every scenario. In London, in 2015, rail delivered on average over 580,000 commuters into the central business district during the morning peak each weekday with around 5.8% of these passengers in excess of capacity⁴³. Without further investment in capacity, the benefits of connectivity will be eroded and rail could act as a constraint to regional and national long-term growth.

Digital Railway offers potential for urban transport in several locations, with core technologies to enable more efficient transportation of people and goods in and out of major urban areas. The adoption of ETCS could allow trains to run safely closer together on existing infrastructure, providing capacity for increased passenger services on busy routes. For freight, this capacity could be provided to freight paths and ETCS could allow for more efficient braking and acceleration curves. These benefits are further increased when combined with the other main technology of traffic management which can aid signallers' and controllers' decision making on busy vital lines. For major urban areas, this means that passenger and freight services could be more reliable and delay response more effective. Both a future digital railway, and current day to day operations, will be underpinned by the Network Rail Telecoms (NRT) national fixed and wireless network. However, further investment is required to improve today's constrained telecommunications infrastructure to one which will enable the future service requirements in a transformed, digitally enabled railway, delivering vital improvements in capacity, performance, safety, security, and a customer experience. There are a number of investment options that could drive the development and delivery of an accessible national, open, digital platform that meets the needs of the future digital railway those of service providers, train operating companies, and mobile network operators whose services traverse a rail corridor.

In London, the scale of both the capacity and performance challenge requires immediate significant infrastructure investment. Mirroring the benefits delivered by the opening of the Elizabeth Line (Crossrail), the NIC have notably endorsed Crossrail 2 as a new artery effectively connecting areas of North-East and South-West London to the job and leisure markets of the centre⁴⁴. Secondly, this new line could relieve capacity on existing congested routes into busy terminals such as Waterloo and Liverpool Street further supporting the economic potential of the London city region. Additional investment in congested commuter routes, such as the South West Mainline and Brighton Mainline, would also assist in relieving capacity for areas of need. Both routes already face significant crowding and performance issues, constraining the economic benefits delivered by commuter markets and significantly lowering user satisfaction.

In addition to enhancing rail infrastructure, the ability of key stations to provide safe capacity for pedestrian traffic and serve as effective 'gateway' hubs for business districts and urban transport will need to be addressed. The success of recent enhancements to Birmingham New Street serves as an example of how investment can increase capacity for passenger movement and provide an attractive means to interchange and enter a city for leisure and business⁴⁵. For London, key station capacity schemes for investment might include hotspots such as the major interchange at Clapham Junction, and terminus at London Liverpool Street. To serve an increasingly intermodal transport market in urban areas, enhancement and design of future stations will have to be built with effective exchange and interfaces in mind as passengers pass from rail to means such as walking, bicycles, buses, cars, or even autonomous vehicles.

Q15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

In addition to supporting the economies of single urban areas, rail infrastructure additionally provides essential connectivity between the country's regions and urban areas. Alongside investments within urban areas introduced in Q14, several strategies are emerging for valuable investments in regional and interregional rail infrastructure to support long-term sustainable growth.

Connectivity between Great Britain's regions and principal cities of Scotland, the North, Midlands and London is primarily provided by two electrified high speed routes: the ECML and WCML. Both routes carry a mixture of traffic including long distance high speed passenger traffic, and significant portions of cross-country, cross-pennine, and national freight traffic. Both routes, and supporting lines, have a number of capacity constraints reflecting their intensive use and economic reliance. Over the next five years, significant enhancements of the rail network will be completed to increase capacity. However, it is considered that with limited options to increase capacity (e.g. train lengthening), interventions will only be sufficient to meet demand until approximately the mid-2020s⁴⁶.

The very-fast interregional services of HS2, between London, and the principal cities and regions of Birmingham and the Midlands, and Manchester and Leeds in the North, will provide a significant expansion in capacity and connectivity. Without HS2, WCML service will be unable to meet the demands placed on it by passengers, freight, or the economy. When phase 2 is expected to open in 2033, new infrastructure could provide up to 18 trains per hour at speeds of up to 225mph providing significant capacity and connectivity benefits⁴⁷. By providing investment to effectively integrate HS2 into regional rail networks, the benefits of this increased capacity and connectivity could be maximized to further assist in boosting regional growth across areas such as the North and Midlands. Additionally, HS2 will provide links to international gateways through access at key locations of a possible 'UK Central' development around Birmingham International Airport⁴⁸, and a further interchange at Manchester Airport.

Partnerships have formed to promote the role of transport connectivity in regional economic growth. For example, Midlands Connect is a partnership of local authorities and LEPs to argue that long-term sustainable growth potential of the Midlands – termed the 'Midlands Engine' – can be facilitated by further investment in connectivity across the region, notably by effectively integrating HS2⁴⁹. Due to a central location, existing regional economic capabilities, such as manufacturing and logistics, benefit from access to other regions for business. Investments in regional connectivity, such as a 'Midlands Rail Hub' identified in the local Network Rail route study⁵⁰, could make best use of the benefits provided from HS2 and assist in alleviating the local capacity constraints in the commuter and regional interurban markets.

Similarly, Transport for the North (TfN) and the NIC have reported that investment in rail infrastructure in the North of England would support the growth potential of a 'Northern Powerhouse'⁵¹. Currently a productivity gap exists whereby Northern GVA per capita has been consistently 25% below the UK average, with sub-optimal transport links and investment having been identified as main factors driving this gap⁵². Although several infrastructure developments are underway in northern cities, significant future growth of passenger numbers is forecast to continue. In order to meet further growth, and assist in delivering connectivity to support regional growth, a 'Northern Powerhouse Rail' is an emerging strategy of a network delivering fast frequent interurban rail transport between the principal northern cities and key international gateways, such as Manchester Airport and the Ports of Immingham and Liverpool⁵³.

In other examples, the NIC has already highlighted the benefits of new east-west transport links in the Cambridge – Milton Keynes – Oxford corridor⁵⁴. Supported by local partnerships, such as the East-West Rail consortium and 'England's Economic Heartland'⁵⁵, the connectivity of an effective transport corridor would maximise the potential of the existing knowledge-intensive clusters, protect the environment, and provide access between these competitive labour markets and areas of housing development.

For freight, the investments in connectivity identified often provide contingent benefits for goods transport. For example, the construction of HS2 could release capacity on the congested WCML for vital north-south traffic, and investment in a Northern Powerhouse Rail network would provide improved transport between the principal northern cities. However, the majority of freight traffic is transported along corridors of a strategic freight network identified in the Network Rail Freight route study⁵⁶. Investment in key capacity constraints and nodal sites such as Ports, Airports, and rail connected distribution centres around this network will be essential to support the economic growth of industries which depend upon it.

Q16. What opportunities does 'mobility as a service' create for road service charging? How would this affect road usage?

Network Rail doesn't have means to respond on this topic.

Digital Communications, Energy, Water & Wastewater, Flood risk management, and Solid waste

Network Rail manages and operates a variety of infrastructures and assets which evidently interface with the above areas of input to the NIC's NIA. In Digital Communications, for example, Network Rail's Digital Railway programme may interface and draw benefit from changing digital infrastructures, and operations depend upon an established telecommunications network. Energy can see interfaces with increased demand from Network Rail's electrification programmes, asset management of rail infrastructure can interface with flood risk management in floodplain areas, and delivery of large projects requires effective solid waste management, to give further examples.

Network Rail will continue to contribute to the NIC's research, and will welcome opportunities for bilateral cooperation on long term planning and investments where appropriate. Alongside this submission, responses will be provided to the discussion papers on The Impact of technological change on future Infrastructure supply and demand⁵⁷, and Population change and Demography⁵⁸ with further relevant detail.

National Infrastructure Commission consultation

The National Flood Forum

The National Flood Forum is a national charity that supports and represents flood risk communities. It helps people to take control of the flood risk in their lives by:

1. Helping people to prepare for flooding
2. Helping them to recover their lives when they have been flooded
3. Working with government and other organisations to put flood risk communities at the heart of policy making and operational delivery

Impact of flooding

The impact of flooding is normally calculated in the direct costs; the additional costs to local authorities (such as through the Belwin formula), insurance claims, damages to agriculture and to business. More recently, society has begun to recognise non-market impacts, but these are largely unrecorded, are under recorded or are only recorded in terms of the costs to the delivery of the services they affect. The examples below are illustrative; the two references are two new documents that you may not be aware of and are relevant:

1. Health – PHE 2017 Thomas David Waite, Katerina Chaintarli, Charles R. Beck, Angie Bone, Richard Amlôt, Sari Kovats, Mark Reacher, Ben Armstrong, Giovanni Leonardi, G. James Rubin and Isabel Oliver The English national cohort study of flooding and health: cross-sectional analysis of mental health outcomes at year one, BMC Public Health
2. Education – Lancaster University
3. Employment
4. Secondary impacts on businesses Economic Impact Assessment of the Boxing Day Floods (2015) on SMEs in the Borough of Calderdale University of Leeds
 1. Community economic resilience
 2. Environment
 3. Food supply chain
 4. Costs of maintaining critical infrastructure systems (assets and interdependencies)

However, as many people testify, recovering from flooding puts people's lives on hold and often causes long term damage to individuals' and communities life chances. The ongoing trauma that we deal with in the National Flood Forum affects many thousands of lives.

Therefore, the costs of flooding to society are rather greater than we record.

The UK Climate Change Risk Assessment 2017 projects that the risk of flooding is likely to get worse. Without an adaptive, focussed, cross societal response the

[Phone number redacted]

impact on people's lives, on businesses' viability and critical infrastructure resilience are likely to increase significantly.

Flooding is an infrastructure issue

The National Infrastructure Commission is right to consider flood risk management as critical infrastructure. However, it is particularly complex as managing the risk is dependent upon the actions of many organisations, businesses and people. A few examples follow:

1. Assets are in multiple ownership and number many thousands in any area
2. Maintenance of assets is a major concern and failings in this area are almost always implicated in every flooding event. Detailed management of local assets such as drains, road gullies, culverts and walls is required to maximise their efficacy and to ensure that they work when most needed. Local knowledge from within communities is often critically important and is often not recognised
3. Natural processes and their management are at the core of flooding (and drought issues) at each point from where rain falls on the ground to the sea, slowing and speeding water at different points and times in a flooding incident, storing water at the right moment and in the right place and ensuring that water flows do not synchronise where rivers meet This includes agricultural land management, river management and maintenance, as well as managing water through urban spaces
4. The planning system and its delivery plays a major and central role in long term prevention of flood risk. To misquote a recent report by the Town and Country Planning Association, *Planning for the climate challenge? understanding the performance of english local plans* - We couldn't have planned it better if we tried to make it flood. This also reflects the feedback that we get back from many communities that proposals for development are frequently a major cause of worry because they fail to take account of flooding properly and rarely incorporate the knowledge and skills held by people in the locality. In the light of this we held a national conference on 1 February on the theme of *Are we planning to flood? The very strong retort was that we are.* A major review is required both of whether we have the right policies in place and whether the system is delivering the outcomes that we expect. Are we delivering development that will be resilient in 30 years time? At the moment we have almost no evidence that this is the case and it seems a fundamental point if critical infrastructure is to be developed and secured for the future. There is no point in investing in assets if this is negated through inappropriate development elsewhere.
5. People and communities lie at the heart of flooding. They are the ones who suffer if flooding occurs or if their services are lost. They are often the ones who have the local knowledge and skills that need to be combined with

[Phone number redacted]

technical expertise to deliver practical results and they are usually the ones who are listened to least of all and rarely involved. This needs to change.

Level of ambition

There are no published targets for flood risk management about what we are trying to achieve, unlike many sectors, such education, health, water quality, etc. However, Flood Re, the measure to improve affordability of household insurance, set up under the Water Act 2015 has a sunset clause requiring that the market returns to risk reflective pricing by 2039, with intermediate transition points and plans along the way. In reality this means that we do have a statutory target requiring us to ensure that people can get affordable insurance on the open market by 2039.

An ambition of a similar nature is required for critical infrastructure.

This has consequences on how we approach flood risk management.

National Strategy needed

A national strategy is needed in order to attain a national ambition; otherwise there is little chance of focussing on what is needed, where and when, and which combination of partners needs to deliver it.

There are several considerations:

1. The strategy needs to focus on what is needed for the long term, what should be avoided to avoid later regrets, what strategic actions are required to ensure that future costs are reduced and what needs to be done when.
2. It needs to be adaptive, with a series of operational plans ensuring delivery
3. It must go much wider than the Defra and Environment Agency remit. Most of the areas of activity that can make a really significant difference lie in other areas of responsibility, notably planning, housing, transport, business and economy, Health and Wellbeing. Therefore, the plan must encompass all of these and other sectors. It must be owned across Government.

To be effective, more localised strategic plans are required at catchment and place level that cover the same considerations as the national plan. This is not the same as current Lead Local Flood Authority Strategic Flood Risk Management Plans, which are too narrow in focus and are often led by rather junior staff. These plans need to be director or chief Executive led, involving the relevant partners at senior level. It is:

1. How many homes, and businesses, will struggle to obtain property insurance at risk reflective pricing, what will current plans deliver (and when), what is the gap and what needs to be done strategically to meet the gap across the full range of sectors.

[Phone number redacted]

2. What standards do we need for assets and the linkages between them; these could be operational targets for example, how can these best be achieved strategically through actions of all sectors and what is it important to deliver and when?

All of this equates to a long term strategic and adaptive approach.

10th February 2017

NHBC Submission: National Infrastructure Assessment Call for Evidence, 10th February 2017

- 1.1 NHBC's submission focuses on the cross-cutting issue of infrastructure and housing and how we can support the development of an evidenced-based National Infrastructure Assessment (NIA).
- 1.2 NHBC is the UK's leading standard-setting body and provider of warranty and insurance for new homes. Our purpose is to work with the house-building industry to raise the standards of new homes and to provide protection for homebuyers in the form of Buildmark warranty and insurance. Established in 1936, NHBC is the home warranty provider of choice, currently insuring over 1.6 million homes, with a market share of approximately 80%.

Provision of housing data

- 1.3 We welcome the development of the NIA, which will assess the infrastructure system as a whole using robust evidence. To support the development of the NIA, NHBC is able to offer access to our statistics, which are a unique source of detailed up-to-date information on new home construction and the house-building industry. The figures relate to new homes registered with NHBC for its 10-year warranty, which covers around 80% of all new homes built in the UK. NHBC figures are available well ahead of Government figures and as such, we represent the only source of up-to-date information on new home registrations, starts and completions.
- 1.4 NHBC is currently supporting the Housing & Finance Institute (HFI) with data on new builds to support their work in examining how infrastructure networks can open up housing development. Our data demonstrates information on, for example, the lag between initial 'site notification' and starts in the South East region, which has seen some of the strongest housing growth in the last few years.

Support to infrastructure providers

- 1.5 Furthermore, NHBC is supporting infrastructure providers such as Openreach to increase the speed of delivery of high-speed broadband infrastructure to new homes in a variety of ways, including:
 - 1.5.1 Providing Openreach with a platform to communicate with senior technical staff at large and medium sized house builders via NHBC 'Building for Tomorrow' seminars around the UK;
 - 1.5.2 Carrying out quarterly customer satisfaction surveys of owners of new homes to understand their experience of broadband provision, to help Openreach improve their customer experience;
 - 1.5.3 Promoting surveys to builders and developers to understand their experience of dealing with broadband providers;
 - 1.5.4 Communicating improvements and changes to processes for broadband delivery in new homes;
 - 1.5.5 Using NHBC site registration data to identify new developments to enable broadband providers to plan future digital infrastructure better.

National Infrastructure Assessment Call for Evidence

February 2017

Executive Summary

Blueprint for Water is a unique coalition of environmental, water efficiency, fisheries and angling organisations and a campaign of Wildlife and Countryside Link. Blueprint is calling for the Government and its agencies to set out the necessary steps to achieve “sustainable water” by 2021.

We welcome the opportunity to respond to the National Infrastructure Commission’s (NIC) call for evidence on the National Infrastructure Assessment (NIA). We highlight the importance of building resilience into the system and ensuring that impacts on the environment are minimised. This requires careful consideration of the various options available and taking an ecosystems approach to decision making. We urge the NIC to integrate natural infrastructure, where possible, into the design of strategic infrastructure projects from the outset and promote opportunities for retrofitting natural infrastructure into existing assets. These are small but significant ways of bolstering our resilience to the challenges of climate change and population growth.

In addition to integrating natural infrastructure, there is a strong case for habitat creation and restoration to deliver our infrastructure needs. For example, managed realignment projects to protect against flooding; creation of farm ponds to reduce water demand from agriculture; and large scale urban green and blue space development, to reduce pressure on our sewerage systems. Such options also deliver other benefits including health and well-being, reduced urban heat island effect, improved water quality and enhanced biodiversity, which more traditional infrastructure lacks.

Please see our answers to specific questions below:

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage.

Demand management is currently underutilised within the water sector. Innovation in this area is low, and encouraging innovation could make great improvements.

Greater demand management could be driven through the development of a wide package of measures through the next Price Review (PR) process. This needs buy in from, and to be facilitated

Registered Charity No. 1107460

by, Government and Ofwat, to encourage such measures before resorting to large supply side preferences. Packages of measures should include a combination education measures for the general public to better understand issues around water scarcity, smart metering, as well as social and environmental tariffs. Initially, we would welcome a number of in depth pilots. These pilots need to be set up and monitored for a number of years, not only 6 months. This will help inform further Price Review processes and address issues such as uncertainty. Universal metering and, in particular a wider role out of smart meters, would assist water companies in better understanding the actual scale of leakage within assets. The sustainable economic level of leakage (SELL) is not helpful in driving leakage reduction, as water companies are able to do the minimum required, rather than drive distinction.

However, it is not just water companies who are responsible for reducing water demand. Industry and the general public need to better understand that water is a finite resource and needs to be managed sustainably. It is important for all stakeholders to take responsibility for demand reduction and there are efficiencies to be made within various industries and the retail sector. Regarding the former, there is currently little incentive for efficiency, as water is inexpensive and abstraction licenses allow, in most situations, the amount that companies need. Regarding the latter, there is concern that the new competition market may in fact reduce efficiency in this sector rather than drive it, as it is likely to drive prices even lower.

Irrigated agriculture is one of the biggest users of water globally. Management practices that increase efficiency in irrigation methods can greatly increase the availability of water for other human and environmental uses. Of all sectoral water demands, climate change will affect the irrigation sector most strongly¹. It is areas in the UK with greatest risk of water scarcity, which have the greatest agricultural demand for water. To date, little has been done to incentivise demand change in agricultural water use, but there is potential for substantial savings to be made.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

It is important that in an effort to increase infrastructure (and housing) development and reduce the time taken for delivery, there should not be short cuts around quality or analysis of need and impact. Good quality infrastructure, where it is most needed and where it has been designed to minimise impact on the environment, will last longer and have greater use.

We urge caution that the checks and balances in place to ensure good quality are not weakened. It is vital that whilst ensuring efficient and prompt delivery of infrastructure, environmental safeguards remain.

Delivering natural infrastructure

Current national and local policy does not provide clear governance arrangements around sustainable drainage systems (SuDS), whilst it promotes SuDS in large developments. Without clear direction and responsibility for delivering, adopting and maintaining SuDS leads to long discussions between developers and planning authorities around SuDS options.

In addition, Highways Authorities can have a contradictory approach to developers, and local authority proposed SuDS schemes, leading to further delay. Highways Authorities have no legal driver to adopt SuDS and have an automatic right for run-off to be released direct into water courses, regardless of quality. This conflicts with work being done to improve water quality under the Water Framework Directive by water companies, local authorities and others. If water run-off from highways was required to pass through SuDS in new development, it could help improve quality and reduce SuDS design issues and drainage in a new development. In turn, this would facilitate development and agreement over drainage systems,.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Those delivering infrastructure systems should include ecological expertise from the project outset, designing for multiple benefits, including maintenance planning. The Wildfowl & Wetlands Trust, in partnership with RSPB, have [published guidance](#) on designing SuDS for multiple benefits which can be useful for anyone working on this topic. It is not enough to assume biodiversity benefits from green infrastructure. To benefit wildlife and the environment, the type of the system, as well as how that system is designed and managed is paramount. For example, a simple sedum green roof offers less biodiversity benefit compared to those with more diverse vegetation.

The importance of protecting existing high value habitats and species should be considered for any project. Remnant natural habitat is usually more diverse than newly created habitat. There are two important factors to this: understanding where important areas for biodiversity are which shouldn't have infrastructure built on them, and retaining pre-development habitat within a development site, where possible.

Natural infrastructure should also be integrated into the design of more traditional infrastructure and retrofitted into maintenance and renovation projects. Additionally, it is important to consider whether a natural infrastructure approach could meet the objective, as opposed to hard infrastructure or using a combination of both.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Note: “credible” improvements are those that generate results that are in line with robust evaluation findings for comparable schemes. “Tractable” improvements are those that can generate usable quantitative outputs. “Transparent” improvements are those that do not rely on ‘black box’ modelling and assumptions.

The Natural Capital Committee, in their third report, recommended that the National Infrastructure Plan should incorporate natural capital into each of the main infrastructure sectors, following the mitigation hierarchy for managing impacts (avoid, minimise, restore, offset). An investment programme for natural capital should also explicitly feature in the National Infrastructure Plan. Within a natural capital approach, social and environmental costs and benefits, including non-financial, are accounted for within decision making.

Natural infrastructure can offer a great value-for-money approach, if accounted for properly. The discount rate applied to cost benefit analysis must be quite low - considerably closer to zero than the Treasury’s Green Book value. A low discount rate does not simply highlight environmental impacts; it increases the relative importance of the future, compared to the present. Many large scale infrastructure projects are very long-lasting, with expected economic lifetimes spanning many decades, such as airports or nuclear power plants. It is vital that a precautionary approach is taken towards environmental harm and a low discount rate is applied to help prevent this future risk.

Reframing the question – for example, asking “What is the least-cost strategy for reducing congestion on a highway by a given amount?” rather than limiting the analysis to the status quo vs. one preferred alternative may yield a different solution². In particular, natural infrastructure options should be considered as alternatives wherever possible.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

Evidence indicates that campaigns to tackle water demand could be used to reduce the daily peak demand patterns, which reduces the pressure on network pumping energy costs during peak use times. Additionally, water companies could use demand-side strategies to also achieve efficiencies in

² Ackerman, F. (2008) Critique of Cost-Benefit Analysis, and Alternative Approaches to Decision-Making, Friends of the Earth.

the distribution of urban water (e.g. reduced energy for pumping in pressurised water system, pipe augmentation deferrals, peak energy demands)³.

However, we also pose the question, if we are looking at zero carbon, why not water efficiency as well?

22. *What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?*

Note: "demand" includes domestic, commercial, power generation and other major sources of demand.

Within the UK water is not valued appropriately. In both domestic and industry sectors water continues to be treated as a low-value and unlimited resource.

The Water UK [Water resources long-term planning framework](#) looked at the resilience of long term water supplies, concluding that significant effort and investment was needed to ensure droughts did not impact on consumers, businesses and the freshwater environment. One of the most effective tools they identified to boost resilience is rigorous demand management, through household metering.

Currently, only half of the households in the country pay for water based on the amount they use. The percentage of metered households needs to increase significantly if we are to empower consumers to control their own water bills, and incentivise water efficiency. Under current legislation, water meters cannot be introduced on a universal basis in large parts of the country, even when it is clear that these systems could go a long way to securing long term resilience of regional and national water supplies. **Water companies should be able to introduce universal metering** if, after consultation with customers through the existing Water Resources Management Plan and Business Plan processes, it is found to be the most affordable option for customers overall, as well as being the best option for water resources management and resilience. High users who would find increased bills difficult to pay could be supported using social tariffs.

The NIC is encouraged to refer to Waterwise's recent [water efficiency strategy](#) document for further ideas and case studies around demand management.

Regarding supply options, there are environmental risks to be considered on a case by case basis, which should be taken into account during decision making in order to minimise environmental risk and damage. Before large supply options are given approval, it should be clear how demand options

³ Beala, C.D., Gurung, T.R., Stewart, R.A. (2016) Demand-side management for supply-side efficiency: Modeling tailored strategies for reducing peak residential water demand, *Sustainable Production and Consumption*, 6: 1-11

and leakage reductions have been optimised and considered. One simple option would be to ensure all new houses are built to energy and water efficient standards.

To increase resilience, we should have a package of options, but we also need to ensure that cumulative supply options do not cause environmental degradation, as well as considering the merits and risks of each individual option.

There is currently no join up between water resources, waste water management and flood management. A joined up, holistic approach at a catchment scale is needed, as suggested in Q24. By slowing the flow throughout a catchment, the environment will have a greater resilience to drying out in times of low precipitation, which ultimately will slow down our lead in to drought scenarios.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

Long term waste water plans

Water companies are required to produce long term (at least 25 year) Water Resource Management Plans, to ensure that water supply systems are sufficient to meet future demand and resilient to climate change and other pressures. We believe that this process has delivered a step-change and fostered a forward looking, collaborative and innovative approach to ensure the needs of people and the environment are met in relation to water supplies. A similar process for wastewater is essential to address the outstanding and significant problem of sewage pollution in rivers and streams. The Government should require **water companies to produce, consult on and publish statutory long term wastewater management plans that secure the delivery of resilient wastewater services.**

Manage water more holistically

A more holistic approach between water supply, waste water and flood management is essential. The 2013 National Policy Statement for waste water states that demand management measures could achieve a reduction in sewer and treatment capacity required for England of greater than 1 billion litres per day⁴.

Currently, developers have an automatic right to connect new development to the sewerage system, even if that system is at capacity. As a minimum, sewerage companies should be statutory consultees in designing new developments, and the automatic right to connect should be removed. This will allow sewerage companies to have better control over sewerage capacity. Additionally, as

⁴ https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/69505/pb13709-waste-water-nps.pdf

mentioned above, reducing water demand can help to alleviate pressure on the sewerage system. As such, new water efficient homes, commercial developments and infrastructure could help ensure our sewerage system is able to cope with an increasing population. Small changes to existing infrastructure and considering the role of natural infrastructure within new design can help address diffuse pollution problems, reducing pressures on the system.

A network of sustainable drainage systems

Reducing surface water run off could substantially reduce pressure on the sewerage system. SuDS should be designed into new developments from the outset. Together with a suitable retrofit programme, SuDS will provide a buffer to future challenges. SuDS need a strategic, rather than simply opportunistic, approach looking at where they could be best applied. Therefore, an opportunity mapping exercise should be undertaken in our major urban areas (at the very least). This can identify where SuDS would be best placed from a geological and surface water flood risk perspective, but also connecting them to current green space as well as joining up or creating stepping stones between habitats. How such a network of SuDS could work within a wider catchment approach, should also be investigated.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

We fully endorse this question and believe that a catchment approach to water management, integrating management of supply, waste water and flood risk, is hugely important. The question of how this could be managed is an important one.

Whilst it is widely recognised that the catchment is the ideal scale in which to undertake and integrate water management activities to achieve more for less (see Defra 2013 [Catchment Based Approach](#) or Dieter Helm, 2015, [Water Catchments](#)), it can be argued that, to date, we have failed to make it happen, and certainly to make it happen effectively. This failure has been recognised by the water sector, which has increasingly attempted to intervene on behalf of their customers, at a catchment scale, to address a range of issues such as pollution and flooding.

We recommend the following:

- **Better integration of both governance and planning around water management at a catchment scale.** Potentially through having fewer organisations responsible for water management and through less but better joined up plans at a catchment scale.
- **A stronger regulatory baseline** that is adequately enforced by regulators to tackle inappropriate and illegal activities within a catchment such as agricultural pollution.
- **Better targeting of funding so that it can, and does, deliver multiple benefits and addresses problems at source, rather than dealing with consequences.** For example, funding sources

and rules that preferentially promote solutions such as better land management; delivers flood attenuation water quality and biodiversity benefits at source, rather than separate funding streams that deal with consequences, including providing enhanced water treatment or ever higher flood walls.

- **Greater partnership working at a catchment scale.** Involving local communities and stakeholders in planning, decision making and delivery. Building on the existing catchment partnerships.

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

Many attendants at the recent NIC workshop on flood risk management suggested that the Government should aspire to deliver a set level of resilience to future flooding. In practice, this may be difficult to achieve without a significant shift away from current policy, which is to deliver the maximum flood benefit from a defined budget, to one where the level of resilience is defined and budget and policy are set to meet that standard. However, we welcome the shift from a sole focus on flood defence, to a broader view that recognises the importance of making communities, businesses and infrastructure more resilient to flooding.

Although it is widely recognised that universal flood defence is not attainable, there seems little recognition that not all floods are equally damaging. Indeed, many of our most important wildlife sites are associated with and thrive from regular, shallow winter floods and have been farmed for many generations. Failures to make adequate distinction between protecting homes and essential infrastructure, and investing in agricultural land drainage, can result in suboptimal decisions being made about where public investment in flood risk management should be directed. Communities are often not given the information necessary to make informed choices. There is value in understanding international projects on similar issues; such as the Netherlands [‘Room for the River’](#) programme, where farm buildings have been relocated to higher ground in recognition that fields will periodically flood. Allowing for such approaches and other natural flood management measures can help our communities buffer the effects of climate change.

We understand that river maintenance is needed in some circumstances to improve conveyance around critical pinch points, yet much discussion continues to react to a call for river maintenance. Instead there is a need for a wider debate about ensuring land use planning sufficiently manages water during and after extreme rainfall events. This principle is fundamental to the Room for the River programme in the Netherlands, as well as the [Blue Green City](#) principles in the UK. The Government will have to make difficult decisions around where to invest in defence, where to provide support in improving resilience, and where to remove or step back defences, however, natural flood management and habitat creation such as floodplain marshes and managed realignment can help increase resilience and longevity of defences.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

The evidence for the effectiveness of natural flood management is growing and our ability to incorporate it into our approach to reduce flood risk will also increase (see <https://www.gov.uk/government/publications/working-with-natural-processes-to-reduce-flood-risk-a-research-and-development-framework>).

Reconnecting rivers with their floodplains, new washlands and coastal habitats, stepping back embankments and incorporating green and blue infrastructure in urban areas to take flood water are all forms of natural flood management. However, we know that these methods work and they will be critical in order to avoid the worst impacts of future floods.

There is a growing body of evidence that upstream measures can be very effective at preventing flooding. However this effect depends on a complex array of factors, including the size of the catchment, topography, geology, soil type and critically, the duration and magnitude of the rainfall event. Specific interventions, such as installing in-stream features to stretch the storm hydrograph and reduce its peak, must be carried out in the right place and in sufficient quantity, if they are to be effective. These schemes will prove invaluable in certain catchments, when sufficient thought can be put to design, location and maintenance. Inclusion of such measures in agri-environment schemes would need to be strategically targeted to be effective and would need to be designed to deliver biodiversity benefits to ensure flood management does not come at a cost to the environment.

Significant gains could be delivered by preventing damaging practice and recognising the role of land use change in slowing flows into streams and rivers. The creation of new native woodland and scrub, the restoration of blanket bogs and rivers and creating salt marsh and mudflats through managed realignment can contribute to flood management objectives alongside restoring biodiversity, sequestering carbon and improving water quality. As they deliver a wide range of benefits, there are many organisations and landowners interested in contributing towards building a shared evidence base, delivering projects and supporting ongoing costs.

Additionally, more could be accomplished by removing perverse incentives which result in increased flood risk through damaging land management. Measures to conserve our soils, such as prohibiting the growth of high risk crops such as maize on vulnerable slopes, maintaining broad hedgerows and buffer strips, could contribute to reducing flood risk, slowing the rate at which water flows off of hillsides and preventing the silting up of watercourses.

We consider the best outcomes will arise from a catchment approach to considering flood risk and using a combined suite of measures. These should include but not restricted to: upstream measures (designed to 'slow the flow' of water), downstream measures, (designed to make 'room for the river' and increase capacity to store flood water), coastal measures such as managed realignment where appropriate, together with measures in the urban environment such as SuDS and other green and blue infrastructure, traditional hard defences where necessary and improved land management.

National Infrastructure Assessment / call for evidence.

4. QUESTIONS

Water and wastewater (drainage and sewerage):

22) What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

Submissions of evidence should be no longer than 20 sides of A4 paper and should be emailed to NIAEvidence@nic.gsi.gov.uk. 5.3

Please provide submissions and evidence by Friday 10 February 2017.

Addressing the difference between supply and demand for (drinking) water.

Reading reports from the water industry it appears they are more interested in big schemes to increase the water supply. For example new reservoirs, or a national water grid.

The other side is to look at reducing demand. This is unpopular within the water industry as, on metered properties, which is being encouraged, it will result in reducing income. Although Ofwat has offered to compensate water companies for loss of income from water efficiency measures, it is highly likely that reducing domestic consumption will, eventually, result in a loss of income for the water companies.

An easy way to reduce demand is to use rainwater harvesting. At the moment water companies collect water from aquifers, rivers and reservoirs, which they then filter and add chemicals to, to ensure that it is high quality drinking water. Then they pump it back to our homes where 30% is flushed down the toilet. Some is used to water the garden or wash the car!

How about we collect the rainwater that falls on the roof of our homes, collect it, filter it, store it and then flush it down the toilet? This could save up to 30% of domestic drinking water consumption.

Adding a water butt with a pump (solar powered) could save an extra 7% by using rainwater to water the garden and wash the car.

One water company says it does not consider rainwater harvesting as a viable resource as "it doesn't work in a drought". Neither will their system as they will install standpipes. Rainwater harvesting will reduce droughts, by leaving more water in reservoirs and aquifers.

Managing the water that falls on the roof of houses will happen, the only question is when?

The technology, using solar power, is already available. It is easy to store 2,000 litres of rainwater domestically for non-potable use.

This would add to the SuDS sustainable drainage systems as the storage could be emptied some time in advance of a major rain event, either locally, by the home occupier, or remotely by the water company, to enable the 2,000 litre storage to be refilled by the first downpour of a large rainfall event. Home owners could have an “app” which had details of their stored rainwater.

This would help reduce flooding as part of a local SuDS system.

The tools to reduce the domestic consumption of drinking water is available now. See www.flushrain.co.uk

Water companies must be encouraged by tax relief and investment allowances to bear the cost with only small, less than 1%, increases in charges to customers.

National Infrastructure Planning Association

National Infrastructure Assessment: Call for Evidence

NIPA: National Infrastructure Planning Association

1. The National Infrastructure Planning Association (NIPA) was launched in November 2010 with the aim of bringing together individuals and organisations involved in the planning and authorisation of major infrastructure projects. Our principal focus is the planning and authorisation regime for nationally significant infrastructure projects introduced by the Planning Act 2008.
2. NIPA was created to develop and disseminate learning and best practice for both promoters and those affected by proposed projects. Our membership of around 500 provides a forum for those with an interest in the planning and authorisation of national infrastructure projects in the UK, particularly those brought forward within the framework of the Planning Act 2008. In summary, we:
 - advocate and promote an effective, accountable, efficient, fair and inclusive system for the planning and authorisation of national infrastructure projects and act as a single voice for those involved in national infrastructure planning and authorisation;
 - participate in debate on the practice and future of national infrastructure planning and act as a consultee on proposed changes to national infrastructure planning and authorisation regimes and other relevant consultations; and
 - improve knowledge, skills, understanding and engagement and so provide learning and education opportunities on national infrastructure planning, develop, share and champion best practice in national infrastructure planning.
3. The efficiency of delivering projects through the planning process, and the effectiveness of subsequent project delivery is therefore of particular interest to NIPA. Our response only deals with question 10, as that is the only one about the planning process.

Response to Question 10: *What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?*

NIPA Insights Research Project

4. In February 2016, discussion amongst NIPA Members indicated that there was a concern amongst many stakeholders in the Planning Act regime about:
 - the level of detail which some major infrastructure projects were being asked to assess and then be scrutinised against at examination, as well as
 - the limits on flexibility in the specification for some major infrastructure projects within the resulting Development Consent Order.
5. As a result, NIPA prepared a brief for a research project to look at these issues, and instructed UCL Bartlett School of Planning as the research team. The title of the research study which was launched in August 2016 was: **Does the Planning Act process deliver the certainty and flexibility necessary to attract investment, permit innovation during the design and construction process, and support cost effective infrastructure delivery – whilst providing appropriate protection for affected landowners and communities?**

6. **Context:** The context for the study is the creation of the Planning Act Regime in 2008. This was a reaction to the long and tortuous processes for consenting major infrastructure projects, epitomised by the Heathrow Terminal 5 Public Inquiry. The Planning Act created a regime for the examination and approval of major infrastructure projects, with a system of National Policy Statements providing national policy backing for the need case, and strict timescales for the examination and determination of each project.
7. The primary trade off required to achieve this time bound process relates to the pre-application process, and the need to ensure that the proposal being put forward for acceptance was complete and unlikely to need to change during the examination and determination processes. This requirement has led to a significant increase in pre-application timescales and costs.
8. The regime has been amended and updated several times over the intervening years, but the essential structure of the process has remained intact. There has been some recognition that some changes are inevitably necessary during the examination process in more recent changes to the regime, and this has been facilitated by the transition of oversight for the regime from the independent Infrastructure Planning Commission, to the Planning Inspectorate with the final decision being made by the relevant Secretary of State.
9. However, there is a perception amongst many stakeholders that the level of detail which is required during the preparation of the application, and which is required to be scrutinised during the decision-making process, has continued to increase. Many participants in the DCO process have highlighted this as an issue of concern, for a range of reasons, for example:
 - The sheer cost of preparing a detailed design for a scheme before it secures an in-principle consent;
 - Highly complex, technically dense and long documents being prepared which are costly, and impenetrable by the lay person wishing to engage with the process;
 - A focus on detail at examination which does little to improve the quality of decision making, or in the event of a consent, the quality of the resulting project;
 - Highly constrained requirements and S106 obligations tend to over complicate the process of discharge of requirements/ obligations for both promoter and regulator; and
 - Over specified projects tend to restrict innovation and technological development during the design and construction process, limiting future opportunities for reducing costs, and improving environmental and community protection in the final project.
10. **The Project:** The membership of NIPA is drawn from a wide spectrum of stakeholders in the DCO process, but is very aware that the views expressed above may not represent those of the wider stakeholder group. The NIPA Insights Research project therefore set out to take an academic-led research approach with the following objectives:
 - To collate evidence and industry views about the **issues** – identified as being the level of detail required in assessment, application, examination and consent of/for national infrastructure projects; versus the **impacts** - of current practice on the quality of the process for all stakeholders, the impact of current practice on the quality of decision-making, and on the quality of resultant schemes, including their delivery.

- To objectively identify the principal issues and impacts based on evidence and industry views, based on a strong cross industry conversation about this issue;
 - To identify practical recommendations which can support a move towards an optimum balance between detail, flexibility, process, decision-making and project outcomes for the planning and authorisation of national infrastructure projects;
11. The issues of detail vs flexibility in the planning and authorisation of national infrastructure projects are relevant to many of the existing authorisation procedures in the UK. However, for the purposes of this piece of work, the focus is on the planning and authorisation of national infrastructure projects through the Planning Act process.
12. **Approach:** The approach adopted to NIPA's research has been as follows:
- **Stage 1A:** Desktop review of the issues to determine current policy and practice. Issues to include level of detail in EIA and DCO application generally, examination practice, and in the DCO itself; and impacts for the project in terms of flexibility, scope for innovation, cost, construction and operational effects.
 - **Stage 1B:** Consultation with stakeholders based on an interview and focus group pro forma approach, to determine their experiences and consequences for projects of which they have experience. Stakeholders included Government Departments, Promoters, Advisers, Contractors, Local Authorities, Statutory Consultees, and Community Representatives.
 - **Preliminary Report** on the principal issues and impacts, (eg social & economic effects, skills and capacity within each stakeholder group, as well as risk, cost and programme for project outcomes), arising from the desktop review and stakeholder consultation. Consideration was also given to any differences between industry sectors within the scope of Nationally Significant Infrastructure Projects as defined in the Planning Act, including commercial and business schemes.
 - **Stage 2:** Engagement with stakeholders about the findings of the Preliminary Report, including the principal issues and impacts identified and preliminary recommendations. This will include meetings with Statutory Consultees, Promoters, Practitioners and with DCLG and PINS explore opportunities and constraints to future changes in policy or practice, and potential changes which could lead to a more optimal balance between detail, flexibility and project outcomes.
 - **Final Report** to summarise evidence to investigate and inform principal issues and impacts identified, summarise stakeholder views following consultation, and identify recommendations aimed at achieving an optimum balance between detail, flexibility, process, decision-making and project outcomes.
13. **The study has now reached the halfway point, with the production of the Preliminary Report. This response provides a summary of the preliminary findings and recommendations.**

Preliminary Findings

14. As this study has progressed, responses from stakeholders have suggested that the critical focus of this work should be to identify ways in which the Planning Act process, on which the delivery of much national infrastructure will depend, can produce projects **which optimise the balance between detail and flexibility so as to define major infrastructure projects that can be delivered cost effectively and efficiently**, whilst continuing to meet their social, environmental and economic objectives, and protect the interests of interested stakeholders and communities.
15. The study has found that most participants in the Planning Act process believe that it is generally operating effectively, and that the incremental improvements made to the process over the years have been beneficial. However, the study has also uncovered a range of evidence about unnecessary detail being considered during the planning stages of projects, and about project flexibility being constrained through Development Consent Orders, both leading to inefficiencies and additional cost in delivering major infrastructure projects.
16. **Detail of Assessment:** There seem to be a wide range of reasons for detail being assessed and specified too early during the Planning Act process, and that this is driven by a range of different actors involved, including promoters, local communities, local authorities, statutory consultees, and examining authorities. Our research suggests that some of the drivers of detail include:
 - perceptions and requirements of environmental regulation and requirements for assessment;
 - provision for the rights of affected landowners through the process of compulsory purchase;
 - a desire amongst local stakeholders, communities and statutory consultees to understand more about the impacts of the proposed scheme or its construction; and
 - a risk averse approach by promoters, their advisors and examining authorities to increase the robustness of consents, often as a result of risk of Judicial Review.
17. Conversely, there is also evidence that there are circumstances when detail of assessment and consent are perfectly reasonable, particularly when there are particularly constrained sites, or issues of important environmental sensitivity.
18. **Flexibility of Consent:** There is also a wide range of reasons why flexibility appears to be constrained within Development Consent Orders, including:
 - A perceived need to understand the nature of a scheme to provide greater certainty to local communities about the design and future operation of a scheme;
 - A perceived need to understand the impacts of a scheme to ensure that local communities, local authorities, and statutory consultees understand the nature of the mitigation requirements;
 - a lack of confidence from local communities, local authorities and statutory consultees about the processes that will follow to refine the detail during the implementation process;
 - a lack of knowledge about the construction techniques available, particularly amongst those stakeholders who are not regularly engaged in the process; and

- a perceived need to tie down compulsory purchase requirements, and therefore provide greater certainty for land owners.
19. However, the need for greater flexibility in project design and consent arises for a range of different reasons, and this is dependent on project type, sector, and location, for example to:
- provide for future changes that might take place because of uncertainty about future construction methodology;
 - allow for alternative scheme options that might be required by regulators, project funders or investors;
 - to accommodate potential technological change over very long delivery periods; and
 - to avoid time-consuming and expensive post consent changes to Development Consent Orders.
20. Conversely, some projects are achieving a good level of flexibility in their Development Consent Orders, and there is evidence that this can also lead to better outcomes for landowners, local authorities, local communities, statutory consultees and the environment. The attainment of this flexibility does – reasonably – require greater detail to be assessed in order to be able to define a wider envelope in which the project can be progressed, but this seems to be an accepted consequence of seeking greater flexibility for project delivery.
21. There is, however, a risk that too much flexibility can make schemes harder to assess, and provide mitigation for, as well as creating a risk of slowing down implementation because of the complexity of providing the level of flexibility sought, and delivering it through project development and discharge of requirements. A balance therefore has to be sought.

Towards Some Preliminary Recommendations

22. As discussed above, this study suggests that there are reasonable reasons for seeking flexibility in Development Consent Orders, and that it is reasonable for this to be justified and judged on a ‘case by case’ basis, with an appropriate level of detail being required to test a range of potential options and identify the reasonable worst case. Evidence suggests that this is well understood and accepted by some, and that this is necessary to ensure that the needs of efficient and effective project delivery is balanced against the need to protect the interests of landowners, communities and the environment.
23. However, the risk of Judicial Review and the need for certainty is a key driver for many, and the criticality of achieving a consent often creates perverse incentives in the system. **Achieving a Development Consent has therefore, for many, become an end in itself, and this can reduce the focus on what is needed to deliver the project effectively.** This is not good for efficient and effective project delivery.
24. The wide range of evidence considered in this study so far suggests that there is no ‘one size fits all’ solution to this issue. However, there seems to be an opportunity to refocus the planning process to include greater consideration of deliverability issues, and the flexibility and detail required to deliver this through into the project delivery phase.
25. The preliminary recommendations therefore seek to put the Planning Act process in the wider context of project delivery by establishing **a greater focus on the need for project delivery all the**

way through the planning, design, engagement and consenting processes. A range of small changes in process or behaviour, by all actors in the regime, are proposed. Together, these changes are aimed at increasing the confidence in creating project flexibility through the Development Consent, and that this can take place satisfactorily alongside the need to project the interests of stakeholders. Four broad areas for recommendations have been identified.

26. **Legislation, Policy and Guidance:** There would appear to be an opportunity to address the issues of detail, flexibility and deliverability in the drafting of National Policy Statements. Many of the current NPSs are approaching the time at which they will need to be updated, and this could be addressed through this process, perhaps with the National Infrastructure Commission taking a role of providing evidence about any particular sectoral requirements.
27. There is also the potential to address these issues more cohesively through guidance. The issues of detail, flexibility and deliverability are dealt with patchily across current DCLG Guidance and PINS Advice Notes, and there may be benefit of drawing this together into one place to establish greater focus on these issues through the DCO process.
28. There have been many consultees to this work who have suggested that the current process for non-material amendments could usefully have a statutory timescale. Current experience suggests that there is a risk that this process can take a long time, and be very costly in terms of delays during the design and delivery process, and this creates a perverse incentive in the system to avoid the process altogether, and accept avoidable cost increases on the project. A more user friendly resolution to non-material amendments would, it is suggested, avoid this.
29. **The DCO Application, Examination and Consent:** Often, the issue is seen as being about how to create an appropriate level of flexibility in the Development Consent Order. However, there are a number of examples of flexibility being provided within an Order; of greater relevance therefore are the stages of the process leading up to the approval of the Order which have a defining influence on how it is drafted, and the process thereafter leading towards implementation. It is therefore important that any recommendations flowing from this work considers all aspects of the process of the planning process.
30. A point often raised is the extensive nature of application documentation, covering a range of assessments and evidence of engagement. This study suggests that it is hard to get away from this because of the large scale and complex nature of many of the projects, although there is no doubt scope for clearer, more consider reporting and accessibility to be provided. Our research supports the view that many of the tools and techniques required to deliver more cost effective, deliverable major infrastructure projects are already available, but that these are not employed consistently across the industry.
31. The question raised therefore is whether or not the engagement, assessment and examination of projects can address these issues more directly, demonstrating how the need for flexibility and detail has been resolved through engagement, design development and assessment of the project, addressing the need for effective and efficient delivery, as well as protection of the interests of local communities and the environment.
32. Where the need for resolution of detail is not required at the DCO stage, and it is possible to make provision for decisions to be taken at later project stages, the study finds that there is a differing range of practice in the drafting of DCOs. The study has identified that it is possible for provision to be reasonably made through discharge of requirements to resolve matters of detail, **and** for this to be good for project promoters, local authorities, land owners and affected communities alike.

Greater consistency and awareness of alternative mechanisms to achieve this, and the benefits this can lead to, is considered necessary.

Project Management and Delivery

33. There is evidence that the priorities of promoters to achieve robust consents leads to contract arrangements for promoters' teams to be incentivised on attainment of the consent, and not on the cost effectiveness or deliverability of the resulting scheme. This seems to encourage a risk averse culture which tends towards detail and limited flexibility. Consideration might be given to alternative arrangements.
34. The study suggests that there is potential to improve deliverability and constructability by appointing a project manager/ management team which oversees the project through planning and delivery, and in particular through the handover period between consent and construction contracts. This would improve the transfer of information about what is proposed in terms of flexibility, and why, to the design and construction team – who are otherwise on a steep learning curve at the beginning of the delivery process.
35. The study also suggests that the engagement of construction partners or advice in the early planning and design development stages of projects would better inform their requirements for flexibility and reduce requests for detail further into the process.

Training and Dissemination

36. Regular promoters in the system are now clearly learning lessons about how to improve project flexibility and deliverability through the Planning Act process, however, the evidence suggests that those who are less regularly exposed to the system are not benefiting from the lesson learned. A process of dissemination, beyond the high level information available through conferences and the like, particularly targeted at key sections of the stakeholder group, would seem to be a sensible idea.
37. In particular, greater dissemination of case studies which show both the methods to deliver greater flexibility, and the potential for benefits to accrue to promoters, consultees and affected communities would help to increase confidence in the use of requirements which allow further detail to be agreed at later stages of projects, when more information is available about design, construction process, and technology. This suggests that there is a need for more rigorous post project monitoring and evaluation.

Preliminary Recommendations

38. The preliminary recommendations of this study are described above. Our next steps are to test these recommendations with stakeholders more fully to make an assessment of their potential feasibility and usefulness in terms of improving project delivery. This will lead to a series of final recommendations, and a proposed action plan setting out how it is proposed to take them forward.
39. NIPA would be very keen to engage with the National Infrastructure Commission during the completion of this work, as it seems very likely that it will provide many useful suggestions which answer the question it has asked. The final report will be provided in due course.

- network infrastructure can be designed, planned and delivered to create better places to live and work by minimising the impact through effective collaboration of works, and where appropriate, providing upfront funding to facilitate early installation of utility corridors.
- **Superfast Broadband** – Multi-billion pound investment programmes are being undertaken to deliver Government's commitment to provide superfast broadband coverage to 95% of the UK by the end of this year.
 - **Low Carbon Vehicles / Electrification of Cars (Question 21)** – Delivering the Government's objectives for electrification of vehicles requires multiple charging points and will also require reinforcement of electricity networks to meet additional demand.
 - **Low Carbon Heat** – The Government's Renewable Heat Incentive (RHI) is designed to decarbonise heat by encouraging the installation of air / ground source heat pumps and other renewable technologies for existing homes. Whilst the uptake of these technologies is currently small, it is growing steadily, and if Government decide to extend the RHI post 2020, uptake could increase quickly, resulting in increased street works. Additionally, should the Government choose to incentivise the electrification of heat (currently only 7% of UK homes use electric heating), then this would require additional capacity and upgrades to electricity network infrastructure.

NJUG welcomes the Commission's recognition of some of the cross-cutting issues that could affect the cost and delivery of the UK's infrastructure needs, and would particularly highlight:

- **Alignment of Funding Cycles (Question 7)** – Currently, local authorities are subject to annual funding rounds for their road investment planning, whereas utilities' investment programmes are typically agreed with their economic regulators for 5-8 year periods. Local authorities have all the necessary powers to manage utility street works effectively, however **closer alignment of local authority and utility funding cycles would enable greater long-term co-ordination of works, benefitting the UK and local economies.**
- **Earlier Sight of Planned Major Development / Infrastructure (Questions 9 and 10)** – To ensure efficient delivery of utility services or their diversion, early engagement with utilities is vital. Currently, there is no requirement to consult with utilities until a major infrastructure project or housing developer wishes to request a price for diversion or connection, often near the end of a development.
- However, NJUG's experience shows that there are significant benefits to be gained from **early consultation with utilities by primary infrastructure or housing developers** – providing greater opportunity to design diversions or connections and co-ordinate works in advance, leading to reduced delays and costs and avoiding excavating newly laid or resurfaced roads, thereby reducing disruption to the surrounding community.
- **Clarity** – It is also imperative that major infrastructure or housing developers provide accurate information on the design of their project (route / utility requirements etc.) This to enables accurate estimates and designs to be provided, so as to reduce delays and costs.
- **Increasing Capacity** – Housing, commercial and transport infrastructure growth will lead to increased demand for electricity, gas, water and communications. As well as street works in the immediate vicinity, increasing the capacity in utility networks can often lead to remote reinforcement away from a main development, and so early consultation with utilities at planning application or consent stage is vital.
- **Resources and Skills** – The street works sector is already struggling to recruit sufficient experienced and qualified operatives and supervisors who can undertake safe and high quality street works. As the scale of infrastructure construction rises this will only increase.
- **Minimising Road Occupation** – In the context of more people², more traffic³, more housing and infrastructure building, and increasing road maintenance and utility network investment,

NIA Call for Evidence
National Infrastructure Commission
11 Philpot Lane
London EC3M 8UD

Sent by email: NIAEvidence@nic.gsi.gov.uk

6th February 2017

Dear Sir / Madam

NJUG Response to the National Infrastructure Assessment Call for Evidence

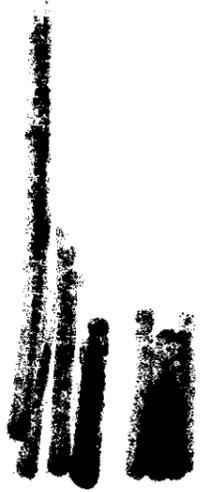

The National Joint Utilities Group Ltd. is the UK's only cross-sector trade association focusing solely on road and street works matters, covering gas, electricity, water, sewage and communications. NJUG represents 56 utility companies and contractors, and 18 specialist sub-contractors who provide equipment, materials and services supporting street works activities. Together they make a major contribution to the delivery of the Government's recently published Industrial Strategy, through multi-billion utility investment programmes to deliver safe, secure and reliable utility services that underpin the UK and local economies.

Whilst we recognise that the current scope of the National Infrastructure Assessment (NIA) does not specifically focus on the delivery of utility network infrastructure investment, much of which involves street works, we wanted to emphasise the role of street works in supporting and facilitating Government's objectives, and the interdependencies between delivery of the infrastructure included within the NIA scope, and utility infrastructure investment.

The Commission recognises some of these interdependencies in its response to the NIA Process and Methodology Consultation Response, but it is important to highlight the sheer scale of street works¹ necessary to deliver the UK's wider infrastructure needs, including:

- **Diversion of apparatus and supply of utility services for major infrastructure** - Connecting or diverting pipes, cables and ducts to facilitate the delivery of major transport and urban regeneration projects e.g. Crossrail; HS2 etc., and providing gas, electricity, water and communications supplies during construction and ongoing operation.
- **Commercial Development and Housing Growth (Question 3)** – We are pleased that the Commission has confirmed its intention to consider the interactions between infrastructure and housing in the context of the Government's commitment to substantial housing growth. This, alongside significant commercial development, will require connection of new utility services and some reinforcement of networks to provide additional capacity. The Ebbsfleet Garden City and Heineken Project examples listed below show positive ways of how utility

¹ In 2014/15 the number of street works in England and Wales was 1.37m and the cost of undertaking those works in the street was £1.6 billion – PA Consulting Delivering a Step Change in NJUG Information Independent Report

yet little increase in the capacity of local roads, if the UK is to avoid becoming gridlocked, **it is vital that everyone works together to minimise road occupation through innovation and even greater collaboration of works.**

- There are many ways to improve the efficiency of undertaking road and street works to deliver the key services / infrastructure that underpin the UK economy. NJUG and our members are:
 - Promoting innovative techniques and materials including Roadmender⁴, the Street Works Compliance Mobile App⁵, Coring and Vacuum techniques⁶, National Grid's keyhole technology⁷ and Southern Gas Networks' remote control robot^{8,1}
 - Collaborating street works to reduce the duration of works – including the Bristol Code of Conduct⁹ and London Communal Entry Chambers Initiative¹⁰ amongst others.
 - Working with Staffordshire County Council and Future Cities Catapult to support the Heineken Project, which includes a street works hub where utility and authority staff can co-locate to jointly plan street and road works. Future Cities Catapult are also producing an economic white paper identifying key benefits of collaborative works and barriers and potential solutions to their delivery.
 - Working with the Infrastructure and Projects Authority and the Ebbfleet Development Corporation to deliver efficient utility services across the Ebbfleet Garden City, via utility corridors and effective forward planning. This innovative project has included the forward funding of core utility infrastructure corridors to enable co-ordinated installation of key utility apparatus prior to developers being able to ask for connections for individual developments, thus reducing the time and costs of works. We hope that such an approach will be mirrored for the recently announced new Government-backed garden cities.
- **Future of Street Works Strategy** – In addition, NJUG will this year launch the 'Future of Street Works Strategy' which will bring together a broad range of stakeholders and interest groups to comprehensively examine the future of street works and provide the Government with a future vision of the sector, as well as suggested policy measures that the Government could enact to benefit to the industry and wider society as a whole.
- **Policy Stability** – For NJUG and our members to contribute to the right solutions for the UK's economy and communities through the above initiatives and more, **a period of policy stability is necessary to enable a continued focus on driving up standards and minimising road occupation through even greater collaboration and innovation.**

NJUG appreciates the opportunity to respond to this Call for Evidence and would welcome the opportunity to meet with the Commission to discuss the above points further.

Yours faithfully

& UHDWLYH 'LJLWDO LV RQH RI 1RUIRWN, Norfolk, Norwich, Great Yarmouth, King's Lynn, Cromwell, Dereham, Thetford, Wells, and other towns in the county.

support and enable the digital economy in rural areas? Companies in Norfolk are at forefront of developing new technologies and need the required ICT infrastructure to carry on their work and to attract new business. A similar situation exists for our financial/professional services. Norfolk has a strong manufacturing sector and investment in ICT infrastructure for roads would improve the movement of goods.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

More national research is required on how to improve efficiencies and reduce the cost to maintain infrastructure. Maintenance/operational costs should also be factored into business cases so this element of cost can be planned for. The government should investigate sources of funding for maintenance costs, ways to reduce maintenance costs and ways to increase investment in new assets.

6. What opportunities are there to improve the role of competition or collaboration in different areas of the supply of infrastructure services?

Infrastructure needs to be funded and in place upfront to release housing and ultimately create better communities. Norfolk County Council has paid for the delivery of infrastructure upfront at one of our largest housing site in Thetford and will recoup the costs from the developer. The Government needs to ensure mechanisms are in place for this front loading of infrastructure so the public sector can confidently invest in infrastructure to unlock growth. Utilities companies should be required to collaborate with local planning authorities to ensure infrastructure is provided in an efficient way. There should be longer term strategic planning for utilities such as the power that will be generated by the offshore wind farms in Norfolk and suppliers should be encouraged to collaborate for the most efficient provision of infrastructure. The government should encourage more innovative solutions that are not so capital intensive and the private sector should be given more opportunities/capacity to problem-solve.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

The current system is not efficient and a long term funding stream needs to be provided to give certainty to borrowing which would provide local authorities confidence to invest.

8. Are there circumstances where projects that can be funded will not be financed?

Land banking is a problem for Norfolk where land has been bought at peak values leading to viability issues for development and infrastructure investment decreases as a result. The marketplace in Norfolk is different to much of the southeast and the private sector needs to be made accountable for the upfront investment to support growth.

Land in Norfolk for development schemes should be seen as a long term investment with any increase in value spread overtime as opposed to one upfront sum, having to pay this large upfront sum can lead to viability issues. I I W K H F X U U H Q W P D U N H W Z R U N H C any need for interventions.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

Once a planning permission is approved this is not the end of the planning system's role as there are often post-approval infrastructure issues for new development. Government needs to facilitate infrastructure provision by identifying infrastructure gaps or blockages and provide mechanisms to overcome these issues.

11. How should infrastructure most effectively contribute to protecting and enhancing the natural environment?

Infrastructure should use natural processes and offer a multifunctional approach to help meet infrastructure and wider social needs. E.g. grey water re-use and SUDS for black water cleansing. SUDS can aesthetically and ecologically improve the environment, providing greenspaces for the public to enjoy, responding to the health agenda.

Access to the countryside and green corridors for movement of fauna should be considered in transport infrastructure projects. These considerations will ensure the robustness of our environment and allow people to access the wider countryside more easily, offering wider health and well-being benefits.

Growth should contribute to the local green infrastructure network and be designed to integrate and enhance the commute and recreational pedestrian / cycle network. Ecological corridors should not necessarily be treated as a separate entity, with mitigation, integration and enhancements to the network on and off-site being provided as integral parts of any project to deliver net gains for biodiversity; responding to the NPPF, climate change and emissions targets to contribute to a healthier environment and lifestyles.

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

The appraisal does not allow one to easily factor-in wider economic benefits likely to arise from the intervention, such as GVA uplift, or (acceleration of) housing and jobs growth. Increasingly transport schemes are being developed and delivered to bring forward the economic growth rather than deliver transport benefits per se. The appraisal and the calculation of benefit to cost ratio needs to be able to take account of this.

Current appraisal of transport schemes places undue emphasis on the value of small time savings. At present time savings insignificant to users can be valued very highly in the appraisal where there are significant numbers of users who would have a time saving.

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

The New Anglia Local Transport Board is working on a transport strategy for Norfolk and Suffolk; the New Anglia area. This is developing a range of future economic scenarios looking 30-40 years hence. For each scenario the work will set out how transport systems should evolve, be innovatively developed, or change organically, to reflect the different ways that economic activity might be carried out in the future; and how transport might best support the desired economic scenarios. The work to date has identified that there are a number of drivers of change in travel patterns including: changes in the way that the

economy works; demographic and social change; and technological change. These can be influenced by policy directives or legislation.

In New Anglia the Strategic Economic Plan identifies a number of economic sectors. The work on the transport strategy is examining likely future changes in travel patterns arising from major changes within the economic sectors; or to support development of the sectors. Although this work has yet to be completed some changes, and their drivers, arising from this and the other drivers listed above might be:

- x Reduction of numbers of people working in offices: due to technology allowing for more dispersed / home working; cost of maintaining the office space;
- x On-demand production or delivery: 3D at-home printing allowing people to avoid trips to shops for basic items; items not being held bulk in-store or warehouses, but produced / manufactured as and when they are demanded (e.g. books being printed and dispatched as a result of an order); a growing expectation from consumers that items will be delivered next-day
- x Logistics sector, first and last-mile changes: Imported goods no longer being delivered to distribution centres, but instead sorted at dockside and dispatched directly to local stores;
- x Demographic change: Society is generally ageing. Evidence shows that older people make fewer journeys. These journeys are also likely to be outside of the times of peak travel demand. Evidence is also showing that fewer young people are learning to drive. If there continues to be a concentration within urban centres such patterns might become increasingly strong. Also, the model of car ownership and travel consumption generally is changing. People are increasingly moving towards the need it whether this be at different times of the day there will be a shift in the travel patterns

Technological change in transport will also affect travel directly, including:

- x Increasing use of automation in vehicles, ultimately leading to autonomous vehicles
- x Advances in fuel technology

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

It is likely that urban centres would benefit most from high capacity public transport systems, most likely tram, metro or rail systems. It is vital that these local systems connect not only the high value, economically strategic employment sites, but also to major transport hubs in the centres, typified by national rail stations or international airports, as well as to the residential and retail areas. However, high value economic returns are most likely through connecting the business districts together either locally or via the national and international networks.

Norfolk recognises that investment in transport infrastructure outside of our boundary can unlock growth for the county; this is particularly relevant for Ely North Junction where a major enhancement of rail infrastructure is essential. Ely is a major constraint for Norfolk in terms of passenger service connections to London, Cambridge, Stansted Airport and beyond and for freight services out of Felixstowe Port. Improvement in the Ely area will allow additional frequency passenger trains and additional freight movements.

Work within Norfolk indicates that –especially given the planned levels of growth –Norwich has a population that could support a tram system; and such a system could add significant added value to the UK economy by boosting employment sites and opportunities in the county, and –if it were connected to Norwich International Airport –significantly add to the value of a regional airport with international connections as well as one that serves the Great Yarmouth, are probably not sufficiently large enough to support tram systems. Both however would benefit from investment into the heavy rail network so that more frequent services and better quality services could be provided.

Within Great Yarmouth the county council has received investment from government to progress work on the Great Yarmouth Third River Crossing. This lifting bridge would connect the South Denes Enterprise Zone and the port to the trunk road network and significantly improve connections to the southern tip of the Great Yarmouth peninsula, reducing traffic through the town centre. Major, high-value investments such as this require government support where the business case can demonstrate economic benefits (jobs growth, productivity, etc. « Well as transport benefits.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Investment into the heavy rail network, and the strategic (trunk) and major local road network are required. Heavy rail needs to provide fast, frequent and reliable services that have the capacity to accommodate the demands from users. Services need to be –at the minimum – every half hour, even on the services connecting the smaller market towns.

The strategic road network needs to be complete dual carriageway with grade separation. Smart networks need to be implemented to provide drivers with information and, in the busiest areas, to control traffic flow through variable speed limits or other traffic management measures. Increasingly, the networks will need to provide the technology to enable the

Within Norfolk, the highest value investments required are:

- x Investment into the Norwich to London rail line to provide fast, reliable services that offer adequate capacity. 90 minute journeys are planned, but investment needs to build on this to ensure that all journeys have a maximum running time of 90 minutes. Additional services need to be provided at the southern end of the line to accommodate the growing commuter market into London. This requires major infrastructure investment.
- x East West Rail: east west connections into and across East Anglia are very poor. East West Rail, connecting Ipswich and Norwich to Oxford and the south west via Cambridge, needs to be implemented at the earliest possible opportunity.
- x A47 upgrades: This road, providing the main strategic road route across northern East Anglia to connect to the Midlands and the north of England and Scotland, is poor. It is a mixture of single and dual carriageway. Journey times are long and unreliable. Whilst a number of major upgrades, including dualling, are planned, much of the road will remain to single carriageway standard.

The roll-out of technology to allow for management of networks, and information to drivers is essential. This includes the provision of up to date travel information directly available to SDVVHQJHUV DQG FDU XVHUV WKURXJK PRELOH QHWZRUNV information systems, rather than via sign gantries, or real-time public transport information). Across Norfolk the lack of alternatives for the strategic road and rail networks means that there is a vital requirement for better management and information, yet the trunk road network in particular has no real time management or information provision.

16. What opportunities GRHV μPRELOLW\ DV D VHUYLFH† FUHDWH IRU
How would this affect road usage?

Mobility as a service will, essentially, charge consumers for travel. This charge will depend on a number of factors including mode of travel, time of day, and quality of the experience (e.g. vehicle quality). It would be relatively easy for the digital infrastructure (required for the ERNLQJ V\ VWHP YHKLFOH WUDFNLQJ HWF « WREH EXLO overall charge to go back to government or towards the infrastructure provider (the local KLJKZD\ DXWKRULW\ 7KDW LV μURDG XVHU FKDUJLQJ† FR travel for the consumer. Moreover, the road user charging element could easily be varied to take account of factors such as overall demand for travel at certain times of day, congestion on the networks, where the journey takes place, or the types of infrastructure used (e.g. motorway or local road), or for pollution.

For the charge to affect road usage it would need to be transparent. That is, the consumer would need to be able to compare the different options ±as noted above ±to be able to make an informed choice about how to travel, or the time of travel.

Norfolk understands this concept of mobility but how does this system work in a predominantly rural county such as Norfolk? Car ownership is unavoidably high and the proposals such as charging road users would not provide suitable solutions for our county.
: KDW LV WKH JRYHUQPHQW † sva seWde D Wrel Jeds? U PRELOLW

17. What are the highest value infrastructure investments to secure digital connectivity across the country (taking into consideration the inherent uncertainty in predicting long -term technology trends)? When would decisions need to be made?

Fixed line infrastructure has undergone a step change since the start of the Broadband Delivery UK (BDUK) deployments in 2013; with access to Superfast coverage (24Mbp+) expected to reach 95% of properties by the end of 2017, and further increases after that. Having reached this level of penetration, with the most expensive element of the infrastructure in place (civil engineering elements e.g. thousands of kilometres of ducted fibre) the active electronic components within the infrastructure which determine speeds available will continue to evolve and drive available speeds up. It can be expected that this will take place via the commercial sector.

However, large disparity still exists in mobile coverage. To achieve the benefits from the Internet of Things and beyond, there needs to be universal access to each new Generation of mobile infrastructure as it becomes available. Currently as each new Generation emerges, because it relies almost entirely on commercial investment, understandably

densely populated areas with existing mast infrastructure gain access whilst less populated rural areas with less mast infrastructure lag further and further behind.

5G is not here yet, but with the addition of embedded IT sensors, the functionality of EXLOGLQJV YHKLFOHV DQG RWKHU SK\VLFDQ DVVHWV FDQ are not to be islands of isolation they need to be enabled to share data, allowing things to be sensed, changed and enacted remotely. Although some of this can be achieved via fixed line infrastructure, in many cases connectivity will need to be via non fixed line infrastructure.

This ability to integrate the physical and virtual world will transform the way we do business, live our lives and interact with the world around us, resulting in better public services, improved efficiency across all aspects of our lives, and deliver economic benefit. In practical terms, the Internet of Things will allow a range of activities that support these objectives, including:

- x Intelligent buildings
- x Smart energy management and remote control of household appliances, providing convenience and saving money for residents and businesses
- x Assistive technologies to allow people to stay at home for longer as can wider e-Care opportunities
- x Intelligent vehicles
- x Emergency vehicles informing action and sharing real time data with others
- x Allowing public transport to be targeted both learning from past activity and enacting FKDQJHV ZKQDUMH stand, avoiding traffic jams
- x Intelligent devices
- x Allowing scarce specialist resources such as medical consultants to be available in a range of locations without having to physically be there
- x Monitoring implants e.g. for heart conditions, so that problems can be identified early and managed
- x Devices to sense people in their homes ±KDV DQ ROGHU SHUVRQ¶V GDLC FKDQJHG L H WKH\ KDYHQ¶W RSHQHGWKH IULGJH DOC
- x Assist in search and rescue
- x Intelligent traffic management based on real time information
- x Biochip response devices that transmit data on current events, e.g. for floods, or DQLPDQV¶ KHDQWK VXFK DV PRQLWRULQJ YLWDO V LJQ
- x Broadcast messaging, particularly when dealing with emergency situations

Many of the technologies needed to undertake the type of activities listed above are already proven, but the necessary network infrastructure is not universally in place to support them, particularly mobile networks in rural areas.

In common with Fixed Line infrastructure, the expensive elements and those which take time to implement tend to be the civil engineering based assets e.g. masts, power provision etc. Once a mast is available, as the next Generation of mobile technology becomes available it can be provided. If there is no mast infrastructure it is a much more difficult and expensive task. Therefore the deployment of sufficient mast sites to provide extensive geographical coverage is vital and should be implemented as soon as possible. The Government should consider investment in new mast sites, albeit requiring these sites to be available to all operators and needing to overcome State Aid restrictions.

18. Is the existing digital communications regime going to deliver what is needed, when it is needed, in the areas that require it, if digital connectivity is becoming a utility? If not, how can we facilitate this?

Digital connectivity should be seen as an essential utility that facilitates and enables the digital economy. The digital economy is a key sector for Norfolk and will have an impact on every business in the county from the financial and business sector to agriculture. Norfolk has ambitious plans for its digital economy and as it is unlikely Norfolk will receive the level of hard or physical infrastructure other areas will have it is of even greater importance that we have the digital infrastructure in place for our digital economy to prosper and grow as planned.

³ 'L J L W D O F R P P X Q L F D W L R Q V ' L Q F O X G H V E R W K I L [H G e d Q G P R

Line infrastructure is often possible in the Highway, and as such it avoids the complexity and expense of securing private way-leaves to implement infrastructure. The infrastructure tends to be smaller and less intrusive than mobile infrastructure; it also tends to serve people close to the actual infrastructure and therefore causes less overall concern for residents. Critically, public subsidy has created a step change in the deployment of fixed line infrastructure. Mobile signals tend to depend on mast infrastructure in the right locations, to allow mobile operators to site their equipment. For improvements to happen, mobile operators will need to add equipment to current masts, and in some cases install new masts, and if this does not happen cove U D J H Z R Q ¶ W L P S U R Y H

During 2016, the Government consulted on reforms to the planning regime to support the mobile industry in the rapid rollout of 4G technology. The proposed reforms include the ability to erect larger structures and increase the size of existing ones, lifting the restrictions on the number of antennae allowed on certain structures and lifting a variety of restrictions on smaller structures.

The Government is also reforming the Electronic Communications Code (ECC). The reformed ECC will make major reforms to the rights that communications providers have to access land. This will ensure property owners will be fairly compensated for use of their land, but also explicitly acknowledge the economic value for all of society created from investment in digital infrastructure. In this respect, it will put digital communications infrastructure on a similar regime to utilities like electricity and water.

New rights to upgrade and share infrastructure will allow future generations of technology to be quickly rolled out as it becomes commercially viable. There will also be administrative changes to court processes to allow for improved dispute resolution, ensuring that disagreements between communications providers and landowners do not hold up investment and create uncertainty. These rights should mean that as each new mobile Generation is released it will be rolled out across existing infrastructure, however it is unlikely to make rural locations commercially viable for the implementation of new mast sites and therefore the Government should consider investment in new mast sites, albeit requiring these sites to be available to all operators.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

As outlined below and throughout this response renewable energy and particularly offshore wind is an incredibly important sector for Norfolk. A considerable amount of the offshore wind projects will be making landfall in Norfolk, this impact is significant and can be unwelcomed so we need to ensure Norfolk also gains from these projects. Our economic strategy outlines established key growth locations such as the A11 Tech Corridor, which have already received considerable investment but still suffer from power supply issues.

As suggested below the government needs to provide a strategy or mechanism to fill these gaps which would then fuel growth.

Strategic Assessment - Way forward

The following recommendations are made to the NIC with regard to offshore wind Energy and Grid connection issues:

Firstly there needs to be a strategic approach at a National Level governing how offshore not adequately address the long term supply and delivery of electricity to the end user. It is also inefficient in terms of infrastructure required on the ground with the lack of strategic join up between future OFTOs i.e. many cable routes and grid connection points instead of an integrated approach benefiting from economies of scale and moreover being less environmentally damaging as well as causing less disruption to local resident and businesses;

Secondly There probably needs to be legislation put in place making it a mandatory requirement to any energy producer to consider sharing existing or planned infrastructure where there are two or more developers bringing forward projects in broadly the same time horizon.

Thirdly Allow existing and future Offshore Transmission Operators (OFTOs), which have a connection to the National Grid to also connect to the local transmission networks i.e. direct to the Distribution Network Operators (DNO). This would assist in over-coming local deficiencies in the electricity transmission network as outlined above.

The offshore wind energy sector has the potential to make a significant contribution to the supply mix, which will include energy from other sources such as oil, gas and nuclear. The benefits of exploiting wind energy, particularly offshore, is that it is renewable and can be There are currently 8 operational and consented offshore windfarms off the Norfolk coast under Rounds 1 and 2 of the wind energy licencing programme (see table 1 below). These projects have the potential to supply over 2 million households electricity from these eight projects comes ashore either in Norfolk or Lincolnshire.

Table 1 - Round 1 and 2 offshore wind energy projects off the Norfolk Coast

Wind farm	No of Turbines and total capacity (MW)	Height of Turbines Metres	Distance off Coast (KM)	Number of Homes - Supplied	Status
1. Scroby Sands	30 (60)	92	3	40,000	Operational
2. Lynn	27 (97)	N/A	18	65,000	Operational
3. Inner Dowsing	27(97)	N/A	23	65,000	Operational
4. Sheringham Shoal	88(317)	172	17	220,000	Operational
5. Lincs	75(270)	170	18	150,000	Operational
6. Dudgeon Shoal	187 (402)	190	32	410,000	Approved Construction Started
7. Race Bank	91 (573)	180	27	400,000	Approved Construction Started
8. Triton Knoll	288 (900)	220	48	800,000	Approved not started
Total	813 (2,716)			2,150,000	

In addition to these Round 1 & 2 projects there are a series of Round 3 projects off the Norfolk and Suffolk Coast, which comprise the following:

Table 2 - Round 3 Offshore wind energy projects off the Norfolk Coast

Wind farm	No of Turbines and total capacity (MW)	Height of Turbines Metres	Distance off Coast (KM)	Number of Homes - Supplied	Status
1. East Anglia One	102 (714)	-	43km	500,000	Approved Construction Started
2. East Anglia Three	172 (1,200)	145	79km	850,000	At planning stage
3. East Anglia Two	TBC (800)	TBC	31km	-	Pre-planning
5.Norfolk Vanguard	TBC (1,800)	TBC	47km	1,300,000	Pre-planning
6.Norfolk Boreas	TBC (1,800)	-	54km	1,300,000	Pre-planning

Total	274 (6,314)		-	3,950,000	
-------	-------------	--	---	-----------	--

Norfolk will provide the landfall and grid connection points for projects 5 (Vanguard) and 6 further 2.6 million households (3.6 GW). Both these offshore projects will be progressed as Nationally Significant Infrastructure Projects (NSIPs) and will ultimately be determined by the Secretary of State. The Vanguard project is likely to be determined around late 2019, with the Boreas project being determined the following year.

Infrastructure Implications for Norfolk

The social and economic benefits arising from those offshore proposals making landfall in Norfolk are potentially significant in terms of extra business for local companies and attracting inward investment that could lead to jobs created in:

- x Manufacturing of key Components (e.g. blades; gear-box; tower assembly);
- x Assembling and constructing the turbines and various major components;
- x Logistical support, surveying and other forms of offshore support;
- x Other lower tier supply chain companies to support any of the above
- x On-going operations and maintenance (O&M) (port related). It is hoped that more bases to support this activity will be established locally that will have at least a 25 year time frame, to add to those already established by Sheringham Shoal and Dudgeon for example;

Much of the opportunity around offshore wind is enabled by the ports of both Great Yarmouth and Lowestoft. They are already seen as the major energy support focus for the Southern North Sea and one of England's However, it is the deep water facilities of East Port Outer Harbour that is attracting most interest from potential investors related to the renewable energy sector, although the river port and Lowestoft port will have key roles to play as well, especially supporting O&M. The port of Wells has already shown the benefits that can be derived from offshore wind, which it is hoped will be repeated once further investment takes place off the North Norfolk Coast.

There are, however, wider issues of grid connection which need a nationally strategic overview / plan to ensure:

- x that the local transmission network operators (operating below 400 kV) in Norfolk are able to benefit from the offshore power supply; and
- x the electricity connects to the National Grid efficiently.

Grid Connection Issues

Local Transmission Network - Norfolk

Within Norfolk the Distribution Network Operator (DNO) is UK Power Networks which provides electricity to homes and businesses across the County at 132 kV and below. Given the nature of Norfolk as a large rural County, the electricity transmission network across the County varies significantly with some urban and built up areas having reasonable supply, but with major deficits in others, along with several more remote rural areas all struggling to cater for growth. Among those areas of the County with supply issues are:

(a) The A11 (T) corridor, from Colney (where the Norwich Research Park is located) through Hethel, Wymondham, Attleborough, Snetterton, and on to Thetford. This is the Norfolk section of the Cambridge Norwich Tech Corridor, where much of the other technology is projected to be. As well as localised issues, there is a need for a fundamental upgrade at the Norwich Main substation, which was part of the 2015-2023 programme but so far there are no plans to instigate this.

(b) Parts of North Norfolk to the north of North Walsham.

These gaps in the transmission network (see map attached) are creating difficulties for local businesses and attracting inward investment into the County.

National Grid - Offshore Wind Connection

The offshore wind energy sector, as referred to above, will have a significant impact on Norfolk as many of the projects will make landfall in the County and connect to the National Grid (400 kV) network. Connection to the Grid will involve cable routes being buried between the respective landfall points up to where they connect to the grid.

The most significant projects to connect to the grid in Norfolk are:

- (a) Dudgeon Wind Farm to connect to the Grid at Necton;
- (b) Vanguard Wind Farm to connect to the Grid at Necton;
- (c) Boreas Wind Farm - to connect to the Grid at Necton; and
- (d) Hornsea Project Three to connect to the Grid at Norwich Main.

(See grid map with substations identified).

While the Dudgeon scheme has full planning consent both for the offshore and onshore elements, including approval for connection to the grid involving a new sub-station, the remaining projects are the subject of planning approval through the NSIP process.

The County Council has been in close contact throughout the pre-application process with the applicants (Vattenfall and DONG Energy) of the above projects (yet to be approved). The County Council has also met up with National Grid to discuss grid connection issues.

The County Council has raised with the two applicants whether there is any opportunity for:

- (a) Sharing some of the onshore infrastructure, such as landfall points; cables routes; and grid connection points;
- (b) Providing electricity to those parts of the County where there are local transmission shortfalls e.g. A11 corridor and around North Walsham.

These discussions are on-going with the respective applicants and National Grid, but initial response would suggest that:

- (a) Sharing onshore infrastructure may prove difficult as National Grid have different locations. These grid offers have been accepted by the two applicants. Planning involved;
- (b) Achieved according to the National Grid as the onshore cables from the wind

farms will belong to a future Offshore Transmission Operator (OFTO). In such circumstances, where the main connection point for the OFTO system is at a transmission substation (National Grid), the regulatory arrangements governing OFTO infrastructure do not provide for secondary interconnection between the OFTO system and a local distribution network operator (DNO)(i.e. UK Power Networks).

27. Are financial and regulatory incentives correctly aligned to provide sufficient long term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

The landfill tax is the primary driver for finding alternative recycling and disposal options but it does not necessarily encourage innovation. Cost is a key driver for local authorities and this does not always promote supporting innovation.

Additionally funding is not available to Local Authorities in order to pay to drive materials up the waste hierarchy. For example, the cost of separating and recycling some bulky items exceeds the cost of disposal when considering transportation and treatment. Commercial waste infrastructure seems to be particularly lacking in this area and there doesn't seem to be any regulatory or financial drivers to provide it. Infrastructure provision for long term treatment capacity often has long payback periods and uncertainty in obtaining planning and the high costs associated with providing the infrastructure can be a barrier to development of new facilities.

Data is crucial to managing waste holistically. Industry should provide data in the same way that Local Authorities do through Waste Disposal Facilities, which would allow waste to be treated the same, irrespective of its source.

28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

A circular economy is a growing focus for EU legislation and is one in which we keep resources in use for as long as possible, extract the maximum value from them whilst in use, then recover and regenerate products and materials at the end of each service life.

Supporting the circular economy maintains the value of the materials and energy used in products in the value chain for the optimal duration and by minimising waste and resource use. This can promote competitiveness, innovation, a high level of protection for humans and the environment, and bring with it major economic benefits, thus contributing to growth and job creation. It can also provide consumers with more durable and innovative products that provide monetary savings and an increased quality of life. The development of innovative solutions and new markets also need to be supported as a key element of the circular economy.

Barriers to the circular economy include the scale of change and number of stakeholders
LQYROYHG ZKR PD\ KDYH GLIIHULQJ LQWHUSUHWDWLRQV R
a long term approach is needed and this can be difficult when set within a financial context where, for example, local authorities need to make savings.

North East Combined Authority response to National Infrastructure Assessment call for evidence. [Name redacted][email redacted][telephone redacted].

Date 10th February 2017

Dear Lord Adonis,

National Infrastructure Commission call for evidence

The North East Combined Authority (NECA) welcomes the opportunity to respond to the National Infrastructure Commission's call for evidence. Our response to the questions posed by the Commission is attached and we would be happy to provide further information or to answer any questions you may have.

Yours sincerely,

Leader of Newcastle City Council
Transport Portfolio Holder for the North East Combined Authority

North East Combined Authority Response to the National Infrastructure Commission Call for Evidence

The NECA consists of the seven local authorities of Durham County Council, Gateshead Council, Newcastle City Council, North Tyneside Council, Northumberland County Council, South Tyneside Council and Sunderland City Council. The Combined Authority reinforces and strengthens existing partnership arrangements to collectively drive forward change and enable economic growth across an area of almost 2 million people. Maintaining and improving an integrated transport network that supports economic growth and enhances the mobility of residents, visitors and businesses is a key goal of the Authority.

1. What are the highest value infrastructure investments that would support long term sustainable growth in your city or region?

There has been a historic lack of investment in transport infrastructure in the north of England. This has resulted in lengthy, infrequent and unreliable journey times for city to city travel, which is a constraint to productivity, jobs, and housing growth. In economic terms, cities in the north of England are performing well individually but they are not realising their full potential partly as a result of this poor connectivity to other cities in the north and elsewhere^{1 2 3}.

Where investments are made, it should be the case that these are created as part of an integrated transport system where possible. Users view the transport system as a whole, crossing multiple modes and boundaries, rather than separate sets and investments should reflect this.

In terms of transport infrastructure investments, these can be broadly split by mode:

Rail

The East Coast Mainline (ECML) is an extremely important rail route to NECA and to the nation as a whole and we are full members of the East Coast Mainline Authorities group (ECMA). Investments to improve capacity on the ECML along the route, but particularly north of York, have been identified as essential through multiple processes, including by Network Rail, local authorities, operating companies^{4 5 6 7} and Transport for the North (TfN)⁸. The current two-tracking north of Northallerton represents a constraint on both inter-city capacity (linking the North East to Leeds and Manchester city-regions in the North and to the economic centre of London) and intra-regional capacity, restricting the ability to increase the quantum of regional services, limiting local labour markets.

⁷ *Network Rail* East Coast Main Line Capacity Options Report (2014)

⁸ *Transport for the North* The Northern Powerhouse: One Agenda, One Economy, One North (2015)

Further, it is expected that there will be future restrictions on the ability to assign freight paths on the route due to high demand for passenger services operating at high speed. As a result, the growth of freight and logistics within the region faces future constraints, and some freight may switch to the highway network, with attendant negative consequences.

A cost-effective and short-term measure would begin with provision of passing loops for freight services north of Northallerton, as identified in CP5 and the Hendy Review. However, this does not represent a long-term solution to match anticipated growth, which is estimated at 144% for passengers up to 2043⁹ and 13.2% annually for key biomass traffic or 11.9% for domestic intermodal up to 2043¹⁰. The best way to match both estimated growth and the ambitions for the corridor would entail four-tracking the route between Northallerton and Newcastle and investigating capacity enhancements on the line north of Newcastle up to the Scottish border.

However, considerations for improvements should not be limited to simply four-tracking along the existing route. There are other ways to grow capacity along the ECML corridor and allow for greater resilience and further development. NECA supports investigating the re-opening of the Leamside line, linking the ECML to Pelaw via Leamside and Fencehouses. The benefits from re-opening of this line have been noted in work by Network Rail, Local Development Plans, the North East LEP's Strategic Economic Plan and in TfN's 'Northern Powerhouse Rail' workstream. The initial benefits of reopening this line have been examined¹¹ and it would represent an investment in transport infrastructure in the region which would serve multiple functions. Not only would it significantly increase capacity on the corridor and allow for the development of more local and regional services, it would also increase resilience to disruption on the ECML which frequently isolates the North East from the rest of England.

The NECA also believes that improvements to other rail lines in the region are vital in continuing to support economic growth. In terms of existing passenger routes, the Bishop Auckland, Durham Coast and Tyne Valley Lines all have great potential to drive economic growth and support local connectivity, whilst improvements to the latter two routes would also enhance the resilience of the ECML. The Durham Coast Line links six of the largest areas in Durham. Sunderland and the Tees Valley and is a strategic asset for the region which has not historically received appropriate levels of investment.

The NECA is supporting improvements to these lines through Rail North, including development of a new station at Horden. The NECA also strongly supports a scheme led by Sunderland City Council to redevelop Sunderland station which, in its present state, is acting as a deterrent to economic growth when it should be acting as a stimulus.

⁹ *Network Rail, Long Distance Market Study (2013)*

¹⁰ *Network Rail, Freight Network Study (2016)*

¹¹ *AECOM Conditional Output Statement for Reintroducing Rail Services Between Newcastle and Northallerton (2014)*

A new railway station at Cramlington in South East Northumberland has been identified as an opportunity to facilitate growth in the town and take advantage of the opportunities presented to the town by its location on the strategically important ECML. This would involve re-siting the current station to a location closer to an important and growing interchange with a large catchment and more able to provide effective interchange with other transport modes.

Some of the strongest potential for sustainable growth comes from unlocking growth in areas which are currently not well connected by rail to large employment areas. In the North East, we strongly support reopening the Ashington, Blyth and Tyne line to passenger traffic. This has the potential to support up to 280,000 return journeys per year for the 150,000 residents along the corridor and halve public transport journey times from the densely populated area of South East Northumberland to Newcastle City Centre¹². This would contribute to the sustainable economic growth of an area with ambitious plans for growth of over 200 hectares of strategic employment land and 12,840 houses¹³.

High Speed Rail

As highlighted above, improvements to the ECML corridor are essential to the economic well-being of the North East and its contribution to the national economy. However, these improvements are unlikely to be sufficient to cope with forecast demand, both passenger and freight, and deliver the growth we seek in the long-term (defined in the Call for Evidence as up to 2050). Therefore, if these long term travel requirements are to be met, the existing commitment to deliver High Speed 2 needs to be developed further, in conjunction with local authorities.

Working as part of Northern Powerhouse Rail, with Rail North, we support a link from HS2 phase 2b to the East Coast Main Line. This is planned at Church Fenton. Linking HS2 phase 2b from Leeds to the East Coast Main Line will function to provide £44bn of GDP up to 2093¹⁴.

In 2016 HS2 Ltd published its report "Broad options for upgraded and high speed railways to the north of England and Scotland"¹⁵ which explored options to:

- improve journey times from Edinburgh and Glasgow to cities further south, including options that could reduce journey times to London to 3 hours or under
- provide additional passenger and freight capacity where it is projected that future demand will not otherwise be met

NECA advocates an Eastern route for HS2 Scotland, whether by a completely new route or upgrades to the existing ECML. The Eastern Route is ideal compared to the

¹⁴ HS2 Ltd High Speed 2 phase 2b Strategic Outline Business Case Economic Case (2016)

¹⁵ HS2 Ltd [Broad options for upgraded and high speed railways to the North of England and Scotland](#) (2016)

Western Route as it connects large existing centres of population more effectively, with fewer environmental constraints.

When HS2 phase 2b is delivered, stations need to be ready for the demands placed upon them by this additional capacity. Newcastle Station has been identified as a future pinch-point by Network Rail¹⁶ and there is a need to make it ready for HS2 services and increase capacity.

Light rail

The Metro system connects the key centres of population in Tyne and Wear. Many employment sites are accessible by Metro, either directly or via interchange. Universities and Further Education Colleges can be easily accessed by Metro, along with many retail facilities, hospitals, GP surgeries and clinics. Metro is readily accessible¹⁷ to 350,000 individuals. Passenger surveys¹⁸ suggest that approximately one quarter of the Tyne and Wear population (297,600 i.e. 27% of 1.1m) uses Metro, with many Metro stations serving as interchanges with other modes of public transport, mainly local bus services but also taxi, national and local rail services and also air transportation.

This connectivity is important to allow people to access employment opportunities, to travel for leisure purposes or for education and training. The economic importance of these links is recognised by the North East Local Enterprise Partnership's (NELEP) Strategic Economic Plan (SEP).

The Metro and Local Rail Strategy sets out proposals to expand, improve and integrate local rail and Metro services. This is fundamentally important for the economic growth plans of the North East, and is reflected in the Transport Manifesto and SEP. Metro extensions have the potential to improve the economy of the North East and to be better integrated with our local rail network as well as serving areas of housing and business growth. With the timescale of this Commission covering a period up to 2050, these extensions may go beyond those already identified in the Metro and Local Rail Strategy. The vision for the strategy is "An integrated, modern and sustainable Metro and local rail network for the NECA region that supports the local economy, environment and society". In order to take Metro into the future by developing Metro and local rail services together to enable the North East to thrive economically and socially, the objectives are:

- To provide Metro and local rail services that are reliable, accessible and comfortable with high levels of customer satisfaction, within available resources;
- To grow the Metro and local rail network and their modal share as part of an integrated public transport network; and
- To achieve value for money.

¹⁶ Office of Rail and Road and Network Rail [ECML 2020 Capacity – Timetable Assessment Report](#)

¹⁷ Defined as living within 800m of a Metro station

¹⁸ Nexus Business Intelligence patronage figures, adjusted for the frequency of Metro travel

In addition to this, Nexus is seeking funding and investment for a new fleet of Metrocars as the current 90-car fleet was built in the late 1970's and many components are life expired. A new fleet of Metrocars will provide improved reliability, journey time benefits and a better passenger experience.

Cities and their hinterlands within the NECA region would significantly benefit from investment in a new Tyne and Wear Metro fleet, which could be dual voltage and inter-operable with the local rail network. This would rejuvenate and revitalise a system by replacing a fleet which has served since the inception of the Metro in 1980. Viewed over the life of the trains, this would represent a cost-effective investment, particularly when compared to a do-minimum alternative. This would allow a more flexible and comprehensive local rail network that creates new journey opportunities for the region.

Connectivity to major employment, rail and airport hubs is integral to securing job growth and productivity not simply between but also within city-regions. In this respect, investments in expansion of light rail and metro systems can be complementary to larger inter-city investments, which can represent the 'hubs' of a 'hub and spoke' model. Correspondingly, expansion of the Metro system would represent one of the highest value infrastructure investments in the region and in the North more widely.

Highways

NECA supports the delivery of schemes identified and committed to within the current Road Investment Strategy (RIS) to 2020 and beyond in the North East. These schemes are integral to managing growth on the Strategic Road Network in the future and to addressing current, longstanding congestion issues. It is important that where funding has been secured for works, such as improvements on the A1 between Scotswood and North Brunton or A19 improvements at Testos and Downhill Lane, timely delivery is ensured to enable the benefits to be secured as early as possible.

It is the ambition of NECA to achieve an upgrade of the A1 to provide continuous dual carriageway standard between London and the Scottish Border and we believe this should be a priority as it addresses identified weaknesses in city-to-city connectivity and inter-regional connectivity. We welcome commitments made by the Government as part of the RIS, City Deals and through other mechanisms to address existing capacity issues.

The A19 Corridor and A1 Western Bypass are integral to passenger and freight movements in and through the region, including for access to regional ports.

The A19 is vital to both city-to-city (the Tees Valley to Tyne & Wear) and enterprise (industrial to international gateway) connectivity. NECA welcomes current Highways England (HE) investment on key links such as the Testos and Silverlink junctions. Future investment along this corridor must be prioritised in order to unlock further enterprise growth such as that planned for the International Advanced Manufacturing Park (IAMP).

The A1 Western Bypass has already been recognised as nationally important and NECA support the current RIS programmes. However, in order to unlock additional

capacity, further investment must be made a priority within the region and form a significant part of RIS2 to continue to unlock growth and drive productivity.

The NECA has consistently supported the case for investment in the A66 and A69 to improve connectivity between this region and North-West England. We welcome the improvements announced in the Autumn Statement but note that, as part of the Transport for the North programme, studies are continuing into the benefits of further upgrading TransPennine routes.

While delivering the above improvements is essential, there will still likely be future capacity issues on our network. In particular, this applies to capacity across our major rivers. We are looking to work with partners, particularly Highways England, to explore this issue.

Where improvements to the Strategic Road Network are prioritised, this must be done with consideration of the impacts this will have on the associated local road network. The interface between the two must be considered holistically to ensure the greatest possible support of growth from any intervention. This should also be a consideration with regard to asset management as well as new infrastructure.

Active Travel

Investment in cycling and active travel is among the most cost-effective forms of infrastructure investment^{19 20}. The relative proximity of the North East's towns and cities means cycling infrastructure is well placed to replace car journeys for shorter trips. By removing many car based local commuter journeys, particularly on the Strategic Road Network, cycling infrastructure supports the efficient functioning of highway infrastructure in general. Air quality issues are becoming a major concern for the future health and wellbeing of our region. We are clear that investment in Active Travel, together with our ongoing work to improve public transport and promote low-emission vehicles, will help improve our quality of life as well as our economy.

NECA would expect investment in the strategic road network to include cycling infrastructure improvements, including cycle routes along road corridors as well as reducing severance at interchanges. This will complement investment at a local level through local resources and the Government's forthcoming Cycling and Walking Investment Strategy.

The North East Independent Economic Review noted that ensuring consistent investment in cycling facilities was required to secure continuous improvement to the quality of the built environment, community life and public health and thereby retain the skills needed to deliver the economic strategy.

Technology

The NECA is strongly in favour of low-emission vehicle technology, and the international expertise of the region in this sector is emphasised within our Strategic Economic Plan (SEP). We believe that it should be a priority to future-proof the

¹⁹ Raje, F., Department for Transport [The Value of Cycling](#) (2015)

²⁰ Cabinet Office Strategy Unit [An Analysis of Urban Transport](#) (2009)

Northern road network so that it is capable of supporting the next generation of vehicles. We have incorporated this aspiration into our bid to OLEV as part of the Go Ultra Low City Scheme opportunity, emphasising the region's role at the forefront of Low Emission Vehicle adoption.

There are further additional technology opportunities which can complement and enhance transport investments. With increases in both the number of people with flexible working patterns and an increasing recognition of the importance of being productive while travelling, the provision of fast and reliable 4G coverage across the transport network is a priority. When allied to Wi-Fi at public transport nodes and on vehicles, this can dramatically improve the productivity benefits of investment although this is not currently picked up in appraisal practices.

2. How should infrastructure most effectively contribute to the UK's international competitiveness? What is the role of international gateways for passengers, freight and data in ensuring this?

Two of the ways in which international competitiveness can be addressed are to improve access to and from international gateways (such as ports and airports) but also to improve connectivity within the country for freight and passengers. The NECA believe that both aspects need to be tackled equally to improve competitiveness.

While the North East has a well-developed freight and logistics industry, lifting 88 million tonnes per year by road²¹ we are hampered by the lack of a Strategic Rail Freight Interchange (SRFI), providing the facilities to enable large volumes of freight to be transferred to and from road vehicles and freight trains. The provision of Rail Freight Interchanges is a national government objective and the National Planning Statement (NPS) on National Networks²² is clear about the need for new Strategic Rail Freight Interchanges (SRFIs) across the regions to boost economic growth. The NPS stresses that rail freight interchanges are required 'particularly in areas poorly served by facilities at present' and that new SRFIs 'are likely to attract substantial business, generally new to rail'. The NECA has therefore identified the need for an SRFI as a goal in our Transport Manifesto and also in our submissions to the Transport for the North Freight and Logistics workstream.

NECA welcomes the National Infrastructure Commission's focus on the long-term future international needs of the region. As the only region in the UK with a positive balance of trade and over £13bn of annual exports across the globe, international connectivity is at the heart of the economic strategy of the NECA.

Our ports serve dual roles as key international gateways for not only goods but people. We have seen strong growth, particularly in the cruise sector, an industry with growth potential²³. As a region, we have the second largest municipal Port in the UK at

²² Department for Transport [National Policy Statement on National Networks](#) (2014)

²³ 43 cruises visited the region in 2016 – this included the Disney Magic vessel and the Koningsdam, the largest cruise ship to berth at a Northumbrian Quay. 60 cruise ships are expected to visit the Port of Tyne in 2017

Sunderland, which has grown 64% in just 3 years²⁴ and the Port of Tyne contributes £710m in GVA to our economy annually²⁵. Exports and imports from our ports amount to more than 10,000,000 tonnes per year and are integral to our regional exports that amount to more than £12bn a year. Ensuring that ports in the UK are not only more accessible for freight movements but for the movement of people by improving surface access will improve the UK's international competitiveness.

The NECA would welcome improved surface access to Newcastle International Airport which, due to its location, has a unique catchment area. Improved surface access is likely to increase the attractiveness of the airport to both passengers and airlines with a view to improving international connectivity. Improved surface access can also widen the catchment area by bringing more people to within two hours journey time of the area which has the potential to increase demand for services. Airlines may choose to address this demand through increasing the frequency of new routes and introducing new services. In particular we would welcome improvements to the A696 and its junctions associated with the A1 in order to accommodate forecast growth at the airport. These measures will enhance the North East's connections to international markets and will contribute to our ability to compete in the global marketplace.

3. How should infrastructure be designed, planned and delivered to create better places to live and work? How should the interaction between infrastructure and housing be incorporated into this?

The NECA supports the government's wish to see new development centred on brownfield sites as these are likely to be close to existing town and city centres and current transport routes. Where new housing or business developments take place outside these locations, it is essential that these are permeable, encouraging rather than deterring sustainable travel modes, and that, by use of the Community Infrastructure Levy where applicable, they are underpinned by investment in suitable transport links, including bus services and infrastructure, cycling and walking routes.

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

The North East Combined Authority recently responded to a Transport Select Committee on urban congestion²⁶ and we support measures which enable demand management, particularly in the urban areas where it is most appropriate. Demand management may not be appropriate for all areas and should be part of an overall package of integrated transport where appropriate.

Being able to guide people and influence behaviour change is a key aspect of addressing congestion in urban areas where there are feasible transport alternatives. In central Newcastle, measures have recently been introduced to try to remove cars from the core of the city centre and create more space for public transport, cycling and

²⁴ Department for Transport Port Freight Statistics PORT0101

²⁵ Port of Tyne Annual Report (2015)

²⁶ Transport Select Committee [Urban Congestion Inquiry](#) (2016)

walking. These schemes can result in less congested roads in the city centre and encourage car users to think about alternative travel options.

The NECA recognises the contribution sustainable travel can make to congestion reduction and our Go Smarter programme for Tyne and Wear, Durham and Northumberland encourages everyone to think about changing their behaviour to use more sustainable ways of travelling on their daily journeys to work and school. Previous research has indicated that this can have a meaningful impact, with schools targeted for intervention experiencing declines in car trips and increases in walking and cycling.²⁷

Changing travel behaviour to more sustainable modes of transport can cut congestion, tackle poor air quality, improve health and ultimately help improve our economy. The Go Smarter to Work business engagement programme focuses on key employment sites served by the A1 Western Bypass and A19 corridors, and motivates employers and their staff to travel more sustainably. Schools Go Smarter encourages pupils and their parents to travel more actively on their daily journeys to school, helping to keep young people fitter and healthier, and reducing congestion around the school gates and local areas. Go Smarter can also help people gain greater access into employment and training.

When there are attractive active travel options, this can help reduce future demand on networks by encouraging modal shift and help sustain the travel time and congestion benefits of investment over longer periods.

The NECA believes that, addressed in the right way, disruption and congestion can provide an opportunity to encourage sustainable travel. Go Smarter's Make the Switch²⁸ campaign seizes the opportunity to leverage the frustration felt by motorists held up in traffic congestion caused by major road improvement schemes that are happening across the area as a 'hook' or opportunity to encourage behaviour change to make the switch to more sustainable modes of transport.

The Go Smarter programme aligns with the DfT's draft Cycling and Walking Investment Strategy which states that increased cycling and walking improves health, enhances air quality and eases congestion. The NECA acknowledges that the draft strategy aims to deliver benefits through increased cycling and walking. However, we are concerned at the lack of funding allocated to delivering on the ambition.

Current national appraisal and assurance frameworks present challenges when developing innovative cycling, walking and public transport infrastructure in congested urban areas. As user benefits and travel time are such a great proportion of the benefits of urban transport schemes, investments which aim to reduce and reallocate road space away from motor vehicles often do not meet Cost-Benefit thresholds despite very positive air quality, health and environmental impacts. In spite of their

²⁷ *Go Smarter* Monitoring data (2015) Using data up to 2014 proportion of car trips in intervention schools declined from 34% to 30%; whereas car use increased by a similar level in control schools, from 32% to 36%. Walking mode share declined from 54% to 48% in control schools throughout the period while the proportion increased slightly in intervention schools from 55% to 56%. Cycling mode share increased slightly by 2% in intervention schools whereas it remained roughly similar in control schools.

²⁸ [Go Smarter Make the Switch](#) (2016)

widespread use there remains very limited empirical evidence to support the emphasis given to cost/benefit calculations in transport appraisal.

Safety of road users, particularly cyclists and pedestrians, needs to be a key consideration when determining proposals to ease congestion and a balanced package of measures will help to achieve this.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

The role of Tyne and Wear Metro is fundamentally important to the economy and people of Tyne and Wear. It connects key centres of population allowing access to employment opportunities, to travel for leisure purposes or for education and training. Following, the acceptance of Nexus' business case by government in 2007, the DfT granted Nexus significant capital funding to undertake the Asset Renewal Programme which, when combined with a 10% local contribution amounts to around £352 million spread over 11 years. This has meant that life expired assets have been renewed and replaced. This includes track, overhead lines, lifts, escalators and refurbishment of the current Metro Rolling Stock. This investment has improved the operational performance of the system's infrastructure across a number of factors.

In recognising the importance of renewals and maintenance, Nexus had developed ambitions plans to continue the long term approach to capital funding, through an Outline Business Case submission to the DfT.

As well as the plans for Metro renewal, the North East has an ambitious programme to construct a new generation of transport infrastructure in the region. However, this should be balanced with commensurate investment in revenue funding.

Prizing capital investment at the expense of revenue²⁹ could lead to perverse incentives for local authorities to build new infrastructure at the expense of maintaining their existing assets. In order to better balance this, revenue funding made available to local authorities to provide activities such as maintenance and planning should be increased.

Recent work from the Urban Transport Group indicates that increasing maintenance funding could provide returns of £6.50 for every £1 invested³⁰ and TRL suggested that cuts in road maintenance budgets could result in wider costs to the economy of between £1.50 and £2 for every £1 saved³¹. This has been backed up by the National Audit Office, which has called for long-term certainty in funding of road maintenance³². This should also be backed by more balanced investment in maintenance between the strategic and local road networks. The Highways England Network has a spend of £111,000 per km per year, while Local Authority B, C and U roads only spend £7,000

²⁹ Urban Transport Group [The Revenue-Capital Mismatch](#) (2015)

³⁰ Urban Transport Group [A Bumpy Ride: The Funding and Economics of Highways Maintenance on local roads in the English City Regions](#) (2015)

³¹ TRL for Transport Scotland, National Roads Maintenance Review (2012)

³² National Audit Office, [Maintaining strategic infrastructure: roads](#) (2014)

per km per year³³. While these are different types of road, these gaps should be narrowed.

7. What changes in funding policy could improve the efficiency with which infrastructure services are delivered?

One of the primary barriers to efficient transport funding is a preponderance of competition-based funding. While this may have some merit in allowing a more flexible approach from central government in terms of project selection, on the ground at a local level it produces challenges in terms of project selection and delivery. This means that it is challenging to bring forward projects which fall outside traditional 5 year funding envelopes or are at a very early stage and there is a bias toward 'shovel ready' projects, which may not be the most optimal to achieve long-term benefits.

As noted under Question 5, the preponderance of capital funding over revenue based funding means that there are significant challenges for authorities to deliver infrastructure services efficiently. The lack of revenue funding can mean that longer term priorities are not addressed efficiently.

10. What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

This response can be broadly split into two points, one on the devolution of existing powers and another on alterations to the planning and governance structure.

The NECA is supportive of the principle of the government's proposals for devolution of powers, which if developed appropriately, will have significant benefits for delivery of areas such as transport and housing in all devolved areas. Devolution of powers would mean that a long term programme of activity can be planned, rather than dealing with schemes on an ad hoc basis, therefore enabling projects with transformational impacts to be properly planned, appraised and delivered.

Transport for the North (TfN) is establishing unique governance arrangements to enhance its role as the voice of the North on Transport, bringing together representatives for the whole of the North through Combined Authorities and Local Enterprise Partnerships with an independent chair.

An embedding of the governance of TfN in its constituent transport authorities provides for the ability to better align strategic priorities both inter and intra-regionally. When allied to long-term planning and appraisal this presents the most effective governance to deliver transformative infrastructure.

In terms of alterations to the planning and governance structure, NECA is a transport authority rather than a highway authority and does not currently believe highway authority powers would be appropriate over the large spatial area of the region.

³³ See 30

However, there are potential alterations to the planning and governance structure which would help ensure that infrastructure is delivered efficiently.

NECA believes in delivering not merely transformational infrastructure, but public transport service delivery in the North and has pursued innovative governance and management solutions to enhance long term planning and outcomes for stakeholders. In terms of rail, it is anticipated that the North East Rail Management Unit, involving the North East Combined Authority, Tees Valley, Cumbria, and North Yorkshire, will be integral to our ambitions to deliver a step change in quality for rail users in the North and support this model of more localised service delivery. This partnership, which includes train operators, is the first of its kind and will be helping the authorities in the North East ensure that new franchises truly deliver their ambitious upgrades for the regions trains.³⁴

The NECA would like to see full implementation of the 2004 Traffic Management Act which would equip local authorities with the powers to enforce and issue penalties for moving traffic offences such as blocking yellow box junctions, ignoring one-way systems and banned turns. The Local Government Association notes that ‘gaps in council powers at even the most prosaic level hamper attempts to manage transport as a whole.’

As stated by the Local Government Association in their response to the Bus Services Bill, enforcement by local authorities will help to improve traffic flow at congestion hotspots and improve journey times. The NECA believes that full implementation of the Traffic Management Act would significantly enhance traffic flows in urban areas and therefore encourages government to fully implement the Act. This improved traffic flow would prevent the need for significantly more expensive infrastructure investment. It is disappointing to see that the Department for Transport does not currently wish to endorse this.³⁵

12. What improvements could be made to current cost-benefit analysis techniques that are credible, tractable and transparent?

Contemporary cost-benefit techniques are frequently critiqued within^{36 37 38 39} and outside the transport industry⁴⁰. NECA welcomes the DfT, and government more widely, being open to the review of their analysis and methodologies and has been supportive of the Understanding and Valuing Impacts of Transport Investment (UVITI) programme at the DfT. This has included partnership working with the Urban Transport group on a joint response to the recent DfT consultation on changes to wider economic impact assessment and on values of time.⁴¹

⁴¹ *Urban Transport Group* [Response to Value of Time Consultation](#) (2016)

However, there are a number of further changes which would make the system credible and transparent, reducing its appearance as a 'black box' and ultimately increasing public trust in the appraisal process.

These are:-

- Current DfT guidance assumes that there is 100% displacement of employment from transport schemes, unless they are additive at a national level⁴². We would question this, particularly in the context of Foreign Direct Investment (FDI). The North East has an extremely strong record in FDI, competing to win contracts internationally. When global businesses choose to locate in the North East, they are frequently not choosing against other parts of the UK (as assumed in current guidance) but against the wider world.
- As noted in our response to question 3, we are committed to making better places to live and work in the region. Part of this has been done through successful urban regeneration and improvement projects such as Newcastle Station Portico⁴³ funded through the Regional Growth Fund. However, the current appraisal system does not allow us to capture the land value increases caused by these improvement schemes and consequently there are challenges in terms of their appraisal. A more open appraisal system would better capture these benefits
- The current appraisal system struggles with appraisal of highway and public transport maintenance schemes. As noted in our response to Question 5, with declining revenue budgets, highway maintenance is more and more being addressed through competitive bid funding. However, to put these schemes up against capital improvement projects puts other schemes at a disadvantage. Ultimately, the solution to this is to increase revenue budgets available to local authorities.
- It can often be challenging to present a positive cost-benefit analysis case for public transport projects, particularly ones which extend into areas experiencing significant deprivation. This is despite such projects meeting many of central and local government's wider policy objectives. Social and Distributional Impacts are currently accounted for in transport guidance, but should play a far greater role in infrastructure appraisal, even for national-scale projects.

13. How will travel patterns change between now and 2050? What will be the impact of the adoption of new technologies?

This is an exciting time for transport. Travel demand has varied considerably over the past 50 years and technological developments mean that changes are likely to continue apace over next 33 years. We believe that the North East is well placed to be at the forefront of new technologies and adaptation to change.

However, we must be clear that transport does not always lead development. When planning transport infrastructure for the long term, we should consider the future locations of development and the sorts of places in which we want to live. This means

⁴² Department for Transport [Understanding and Valuing Impacts of Transport Investment: Updating Wider Economic Impacts Guidance](#), (2016)

⁴³ Ryder Architecture, [Newcastle Central Station](#) (2014)

that at all stages in the transport planning process we should consider future locations, future development and the travel patterns which emerge from this.

NECA anticipates the following changes in travel patterns between now and 2050, resulting from the impact of new technologies and other trends:

1. Continuation of the trend away from traditional “Monday to Friday 9 to 5” working patterns, with technology enabling more homeworking, flexible working, video conferencing, dispersed employment locations and part-time working⁴⁴
2. A readiness among younger people, especially in urban areas, to consider alternatives to the car, where these are supported by an adequate public transport, cycling and walking network. This has led to a fall in mileage travelled by these people⁴⁵
3. Increased online shopping and banking, with consequent rise in delivery van traffic and reduced off-peak home to city centre or retail development travel demand⁴⁶
4. An increasingly older population, resulting in : fewer work-related trips ; much greater focus on travel to health facilities ; more leisure journeys ; higher expectations of independent mobility ; increased need for appropriately designed infrastructure and services including door-to-door transport provision⁴⁷
5. Increased expectations of the quality of public transport in terms of speed, reliability punctuality, comfort, seamless ticketing and comprehensive technology-based information before, during and after a journey ⁴⁸
6. The potential for new technologies, such as driverless cars, to change the way in which we approach car ownership, mobility and the user of our time while travelling⁴⁹

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

The NECA contains major urban areas of Tyneside and Wearside and supports a number of transport investments which will allow people and freight to move more freely in and around these areas. The NECA Transport Manifesto outlines our position on major investments in our region⁵⁰ and sets out our key themes and guiding principles for transport. This builds upon our Strategic Economic Plan⁵¹, which set out our region’s ambition for investment that would enable more and better jobs.

⁴⁴ There is a large body of work on this literature. Some relevant publications are: *Department for Transport, National Travel Survey* (2015); *Gordon Stokes Has Car Use Per Person Peaked?* Transport Statistics User Group (2012);

⁵⁰ *North East Combined Authority, Transport Manifesto* (2016)

⁵¹ *North East Local Enterprise Partnership, Strategic Economic Plan* (2014)

Some of the highest value investment in urban transport can come from complementary investment in traffic management and control. In the North East, Tyne and Wear and Durham have Urban Traffic Management and Control (UTMC) systems which provide notice of disruption, help us to manage major events and enable the smooth flow of traffic through connected traffic signals. Research⁵² indicates that further investment in these systems can deliver high value for money, with UTMC services providing £60m of network benefits over a decade. These systems also provide an ideal testbed for future research projects to better understand the impact of transport investment. In Tyne and Wear, the UTMC Centre is working with Newcastle University and other partners as part of the Newcastle Urban Observatory and Compass4D projects⁵³ which will deliver significant benefits to the city.

The benefit cost ratio of cycle schemes can be as much as 20:1⁵⁴. Findings from Cycle Demonstration Towns have found that for every £1 invested in cycle measures, the value of decreased mortality was £2.59. When considering infrastructure costs alone, it was found that a piece of cycle infrastructure costing £1 million, only requires an extra 109 people each year to become regular cyclists for payback when considering the benefits to health, congestion and pollution⁵⁵. Enabling greater use of these active modes will also lead to reduced levels of congestion, fewer Greenhouse Gas emissions, lower noise levels and improved air quality.

To maximise their benefits both walking and cycling provision must be fully integrated with the road and public transport networks. Moreover, although cycling has been declining in much of the country prior to changes in government policy, there are still places where it has retained a significant modal share of journeys, such as Oxford and Cambridge, and there are cities in Europe like Copenhagen and Stockholm that have successfully increased cycle use to even greater levels, more than a third of journeys to work, and are frequently rated highly for quality of life and liveability.

In dense urban areas which suffer from motor traffic congestion, cycling is an ideal solution which can allow for rapid commuting between different parts of the city, and this is ideal for assisting in the benefits of agglomeration. There is a growing use of cycling in many congested cities for not only cycling for the movement of people, but also for the rapid movement of goods as well, for larger packages using adapted bicycles such as cargo bicycles. The efficiency gains from switching from motorised transport to pedal powered transport in congested urban areas are enormous.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

The NECA has the largest rural footprint of any Combined Authority area and contains large rural areas of Durham, Northumberland and Gateshead. Rural transport

⁵² ITS UK, [Intelligent Transport Systems and their benefits](#) (2016); AECOM NECA UTMC Review (2016); Kolosz, B. Extending cost-benefit analysis for the sustainability impact of inter-urban Intelligent Transport Systems, Environmental Impact Assessment Review, Vol 50. p167-177 (2015)

⁵³ [Compass 4D Newcastle's 'talking' traffic lights could cut congestion](#) (2015)

⁵⁴ Sustrans Economic Appraisal of Local Walking and Cycling Routes (2005)

⁵⁵ Department for Transport, Valuing Increased Cycling in the Demonstration Towns (2009)

presents different issues to that in single urban areas and it can be difficult for it to secure equal funding opportunities. This is highlighted in our recent Transport Manifesto and Strategic Economic Plan, as noted in our response to Question 14.

In more rural areas, it is important for capital investment to be matched by revenue spending which can help support the provision of services that are vital lifelines to communities. While these investments may perform less well on traditional Value for Money metrics they are crucial to sustaining the vitality of these areas. This includes not only improving rural to rural connectivity but also rural to urban connectivity, enabling more people to get around without relying on private car travel.

In terms of connecting multiple urban areas and regions, as noted in Question 10, the Combined Authority and its constituent authorities is a member of a sub-national transport body, Transport for the North. This body will, through its Strategic Transport Plan, identify the highest value transport investments to deliver economic growth across the urban and rural areas of the North of England.

Response to the NIC Call for Evidence, North East Combined Transport Activists' Roundtable (NECTAR)

Introduction

NECTAR is one of a network of Transport Activists' Roundtables working together with the Campaign for Better Transport and similar national bodies that share the core aim to promote sustainable transport. It covers the North East of England from the North Sea coast to the Pennines and from Scotland to North Yorkshire. It is an open, voluntary, umbrella body, established to provide a forum in which the many organisations with an interest in sustainable transport in all its forms can develop a co-ordinated view on contemporary transport issues. NECTAR provides opportunity for the exchange of news, studies and information and provides a voice for dialogue with government, transport providers, transport users and similar bodies concerned with transport and related policy and practice locally, nationally and internationally.

Membership of NECTAR is open to organisations which:

- o support the use of sustainable transport and sustainable changes to the transport infrastructure.
- o broadly support integrated transport and land use policies which reduce the need to travel
- o promote better provision for public transport, walking and cycling.
- o seek to minimise any negative environmental or social impacts of transport, whilst maximising accessibility, safety, good health and quality of life for all.

Responses

Cross-cutting issues: 1. Highest value infrastructure investments

Sustainable development should take environmental and social objectives into consideration, rather than focusing solely or mainly on the sustainability of economic growth. With regard to transport, it is important to consider the environmental impacts of major schemes, such as air and noise pollution, land take, severance, and carbon emissions.

We consider the following projects to be the most important for the future of a sustainable transport system in the North East. They are described in detail in Appendix 1.

- a) Expansion of the Tyne & Wear Metro system as described in the Metro Strategy 2030.
- b) Reopening of the railway line from Ferryhill to Pelaw (21 miles) utilising the former Leamside track bed.
- c) Upgrade of the Stillington (Ferryhill - Stockton) freight only line (circa 10 miles) to passenger train standard.
- d) Creation of strategic radial cycle routes in Newcastle-upon-Tyne, the region's most significant employment hub.
- e) Ashington, Blyth and Tyne railway line reopening

Other important projects in the area are:

- f) A new rail halt at Horden, Peterlee (supported by the North East LEP)
- g) A new station at Ferryhill
- h) A new station at Team Valley
- i) Newburn – Blaydon footbridge

2. Contribution of infrastructure to international competitiveness.

The priority should be international welcome – ensuring transition between international arrivals and regional transport networks, particularly with regard to passenger transit to regional

destinations. As well as ports and airports, a priority should be the East Coast link to Eurostar services; it reflects the importance for the North East of St Pancras International station as a gateway to/from Europe.

3. Planning and designing infrastructure to create better places to live and work.

The most important thing is to ensure that infrastructure is considered at all stages of the development process. The aims should be, firstly, to reduce the need to travel; secondly, to prioritise more environmentally sustainable and space-efficient modes, establishing a hierarchy of users - from top to bottom, pedestrians, then cyclists, then public transport users, then private car users.

At the strategic level:

- planning for growth in locations with existing good public transport routes, or with routes nearby that could be extended to new developments - particularly passenger transit.
- Assuming higher densities in order to generate more compact cities that can be more easily served by transport infrastructure and which create shorter journeys to facilities and services, amenable to active travel and the development of efficient public transport services. (Metro identifies low population density as one of the constraints on its efficiency.)

At development level:

- Design to ensure characteristics which facilitate use of sustainable transport modes: density, legibility, interconnectivity, and safe and segregated pedestrian and cycle routes.
- Reducing the need to travel by incorporating adequate and accessible facilities and services.

4. Potential for demand management, recognising behavioural constraints and rebound effects.

Demand management for road space should prioritise users higher up in the hierarchy of users, as described above. Demand for road space by users of motorised transport can be managed by:

- temporal distribution: seeking incentives for peak spreading, such as flexible working hours, extension of retail hours, and cheaper off-peak travel and parking.
- modal distribution: encouraging cycling and walking by better, safer and segregated cycle and pedestrian infrastructure and parking; encouraging use of public transport by better and more efficient transport planning. 2/3 of car trips are less than 5k, so many of these could be made by cycle; but without safe cycling infrastructure, modal shift won't happen.

Attempting to spread demand spatially is not an environmentally sustainable option. More dispersed origins and destinations mean that a greater amount of pollution is spread over a wider area and that it is harder to service the network by public transport – whereas a centripetal network based upon local hubs facilitates simpler and more viable public transport networks. However, reducing the need to travel, so that facilities and services can be accessed locally, is viable.

It is possible that demand management could result in a different equilibrium, where better cycling, walking and public transport facilities might free up road capacity only for it to be filled again by motorists. However, the level of congestion at which this equilibrium settles would be lower than if no genuine choice exists and people are forced to drive through the inadequacy of other modes. Mechanisms to dissuade car use could also be used, such as constraints on particular types of vehicle (particularly the most polluting), increased parking charges, and traffic management that did not prioritise vehicular access in town centres.

5. Balancing maintenance and repair with the construction of new assets.

At present, decades of under-investment in cycle and pedestrian networks in the North-East of England, and the absence of a good regional rail network except in Tyne and Wear, means that in some places there is little to maintain. The priority, therefore, has to be bringing facilities for non-car modes up to an acceptable level, while restricting expenditure on roads to repair, maintenance and safety enhancements. (Road maintenance is as important for cyclists as for motorised vehicles, since cyclists will always have to use roads in some situations.)

6. Opportunities to improve the role of competition or collaboration.

Experience has shown that public transport services cannot be delivered efficiently by the private sector. This means that private operators focus on the most profitable routes, limiting the potential for cross-subsidy of socially necessary but unprofitable ones – so that these must be funded publicly - and causing congestion, especially where multiple operators compete along overlapping routes. It also reduces the ability for co-operation between operators and across modes in matters such as alignment of timetables, creation of interchange points, and through ticketing. A return to central planning of public transport is needed to deliver a functional and credible service. In this respect the Bus Services Bill, with its emphasis on franchising and partnership working, is welcomed, although its bar on local authority-owned bus companies seems to be a manifestation of blinkered ideology.

7. Desirable changes in funding policies

Funding policy should take into account environmental and social objectives, and cost-benefit analyses should resist monetising of drivers' time as a proxy for economic growth, as discussed below. Funding decisions should be strongly influenced by the need to cut carbon emissions and reduce air pollution. Long-term certainty of funding is required (as opposed to a feast-or-famine style of allocating funding). Specifically with regard to rail infrastructure, measures are needed to ensure that Network Rail responds positively to proposals rather than wishing that they'd go away.

8. Circumstances where projects that can be funded will not be financed.

Proposals that would increase carbon emissions or air pollution should not be financed even if they already have funding.

9. Ensuring resilience against the risks arising from increasing interdependence across sectors.

The first priority has to be increased resilience of the component parts, followed by improved collaboration and communications between sectors.

10. Desirable changes to planning and infrastructure governance.

Better co-operation is needed between the LTP and Local Plan development process. They should really be planned together in authorities where the same area is covered by both, so that an interlinked strategy is created, in which development planning always takes account of the need to provide infrastructure and takes up the opportunities presented by new transport infrastructure, and where transport planning takes into account likely increases in population and industry and is able to influence their location. Where the spatial scope of the LTP differs from that of the Local Plan, collaborative working is likely to be more difficult and complex. Unfortunately, we seem to be moving in the wrong direction here: transport is to be planned at a combined authority level, and land use development by local authorities.

Specifically with regard to rail improvement projects, we understand that difficulties have been encountered through both Network Rail's GRIP process, which sometimes proves to be expensive and lengthy, and its apparent shortage of technical staff with relevant expertise.

The early stages of the GRIP process essentially involve Network Rail charging the sponsoring client for a study to confirm the client's intentions. Thus the process seems to be trying to impose an internal project management process onto an external commercial environment. This gives the impression that there is no inherent desire within Network Rail to grow the network.

Besides this, there is a tendency for Network Rail to add in functionality that is not required for the immediate project. That may be the appropriate thing to do from the point of view of the wider rail network, but the extra functionality should not need to be funded by the local project sponsor. We suggest Network Rail should have their own capital improvement funds to invest in such cases.

In summary, Network Rail have no competitor, and little apparent appetite to "win" the business or to keep the price to within reasonable levels that the project sponsor can justify. It should be possible to deliver projects much quicker and more cheaply than the current arrangements allow.

11. Contribution of infrastructure to protecting and enhancing the natural environment?

The global environment can be best protected by fostering the deep cuts in carbon emissions which are required by the Paris Agreement. In transport terms, this should be done by focusing on reducing the impact of motorised transport by encouraging and facilitating modal shift.

Measures to reduce car use and, hence, carbon emissions, should also reduce the local impact of transport upon the natural environment. Regulatory measures such as fostering innovation and efficiency are also needed to reduce use of the most polluting vehicles.

The local natural and built environment can best be protected by reducing the land-take of transport infrastructure. Again, this can best be done via a shift away from the private car and by resisting demands for new roads and car parks, taking due note of the low occupancy of cars, generally averaging around 1.2 occupants per car in peak time journeys (DfT data).

In rural areas, demand for increased tourism is now saturating many car parks. A strategic review of locations, shuttle arrangements etc at key tourist nodes might usefully be carried out.

12. Desirable improvements to cost-benefit analysis techniques.

Changes are needed to the way in which the costs and benefits of road projects are assessed. At present, drivers' time is monetised, so that the delays experienced by motorists within a given country or region are interpreted as an economic cost which the area has to bear. This hypothetical cost is used in order to justify schemes to speed up motorists' journeys. However, the evidence for an inverse correlation between congestion and economic growth is patchy. That's not really very surprising; more economically successful places attract more travellers, and therefore have more congestion; you could argue that congestion causes economic growth, although this would probably have the causal mechanism the wrong way round.

It is sometimes assumed that quicker travelling frees up people to spend more time being economically productive. This may not be the case. Sometimes it simply facilitates longer commutes. Monetising of drivers' time is particularly problematic where a very small delay affects a large number of motorists. The cumulative cost of the delay is assumed to be very large, even though the impact upon any road user's quality of life or economic potential will be negligible.

So monetising of drivers' time is a poor way to assess the costs and benefits of road schemes. It also has significant negative effects in terms of the way funding is allocated. It is used to justify road-building schemes which may not, in actual fact, have broader economic benefits, and which may have significant impacts in terms of land-take and induced demand, as more people find it

convenient to use clearer roads, and faster journeys facilitate increased commuting distances. All of this has negative consequences in terms of local air pollution and carbon emissions. Conversely, there needs to be a stronger emphasis on monetising the indirect costs of motorised transport. While there have been changes to WebTAG over the years, we do not believe that air pollution and carbon emissions, issues that government is now obliged to address in a significantly shorter timeframe than it wanted, feature as prominently as they should.

Transport: 13. Changes in travel patterns between now and 2050.

The development of autonomous vehicles will have both positive and negative consequences. Negative consequences will include: a reduction in driver jobs ; potentially, an increase in the total number of motorised vehicles, as on-demand vehicles become cheaper, and are able to be driven by anyone - and hence an increase in land-take, carbon emissions, severance, noise, etc. Positive consequences could include: more efficient use of vehicles through the use of “mobility as service” ; uptake of autonomous vehicles by those currently unable to drive, thus conferring additional freedoms.

Increasing carbon emissions and climate change are likely to have the following consequences: increased levies on carbon emissions and hence, an increase in the costs of driving (although cars are also likely to become more efficient) and a squeeze on the costs versus benefits of buses and light rail; warmer weather facilitating more cycling and walking; direct impacts of climate change and volatility upon transport infrastructure, such as melting, buckling or flooding.

If trends continue, the number of journeys may not rise very much, or may change (more home-working, more click-and-collect shopping, changing recreational journeys) but journeys on average are becoming longer – meaning greater carbon emissions and their consequences.

There will be an increased requirement to address air pollution, particularly in major cities, and reduce carbon emissions. Policy-makers should seek to reduce demand for travel and to prioritise transport modes higher up the hierarchy of users, as described above. There will also be a need to increase the electrification of motorised transport (rail, bus and car).

14. Highest value transport investments around major urban areas.

In the NECTAR view, this has to be the investments that facilitate the transit of the greatest number of people for the lowest possible cost - not just financially, but in terms of land-take, carbon emissions, and other environmental impacts. Recent judgements on the legality of the Government’s action on air pollution, and findings about the impact of air pollution on physical and mental health, indicate the need to prioritise less polluting modes wherever possible. Hence NECTAR suggests that, in the area, extensions to the Tyne and Wear Metro system and their connectivity with other transport networks are likely to be the highest-value investments.

15. Highest value transport investments outside a single urban area.

Rail links, as described above and in Appendix 1.

16. Opportunities and effects of ‘mobility as a service’ for road user charging.

Establishing the concept of ‘mobility as a service’ facilitates the recognition of the real costs of provision, eg of motoring. Currently motoring costs are normally hidden behind road subsidies, standing charges etc. Motorists notoriously perceive motoring costs to be synonymous with fuel costs when comparing costs with other modes. However, when claiming expenses, the maximum HMRC permitted charge (4 to 5 times higher) suddenly is recognised!

Appendix 1: Description and justification for strategic projects

Descriptions of the projects

Project a) Tyne and Wear Metro improvements as described in the Metro Strategy 2030

This project is described elsewhere and is supported by NECA. It is therefore not discussed in detail here, but we reiterate our support for it as a strategic project with the potential to make a significant social and economic contribution, and support environmentally sustainable transport.

<http://www.nexus.org.uk/sites/default/files/Metro%20Strategy%20Background%20document.pdf>

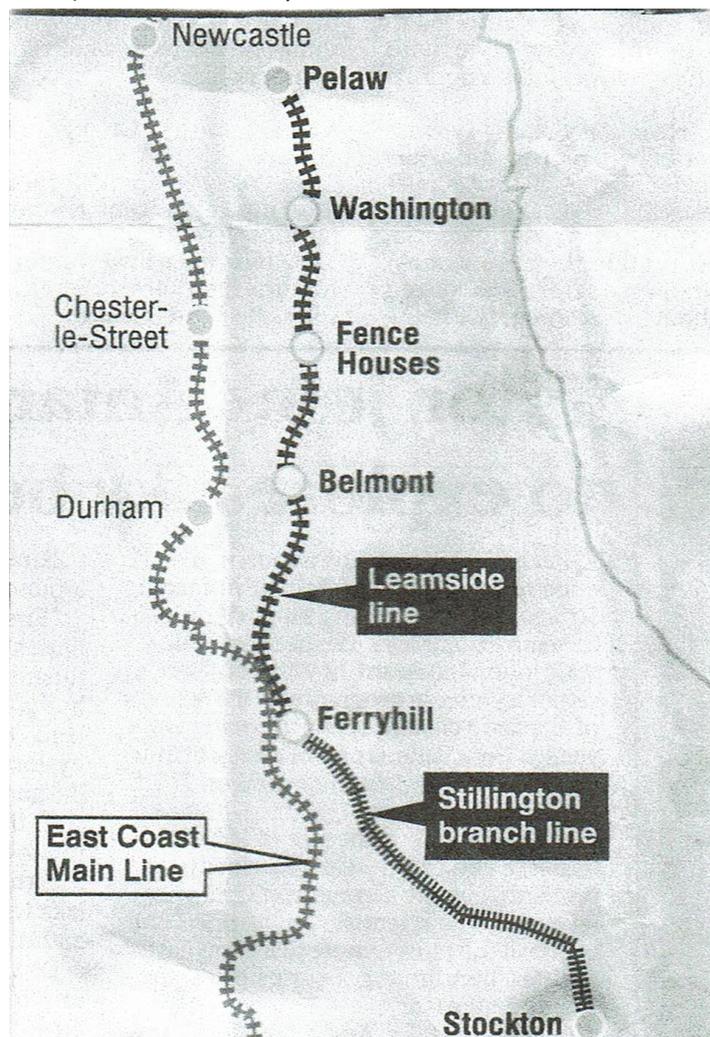

Project b): Construction of a railway from Pelaw to Ferryhill utilising the former Leamside track bed.

1: Project Title

Construction of Leamside Railway Line

2: Location

The Leamside track bed runs largely unimpeded from Pelaw (near Gateshead) via Washington, Penshaw and Belmont to Tursdale Junction at Ferryhill on the East Coast Main Line (ECML). The total length is 21 miles. At Pelaw there is ready access to both the Middlesbrough to Newcastle (Durham Coast) line and to the Tyne & Wear Metro.

3: What the project entails – its scope and its vision

The Leamside project requires the construction of a double track, electrified (25kv) railway from Pelaw in Tyne and Wear to Ferryhill, County Durham. Passenger stations would be required to serve Washington (pop 55,000), a Park and Ride facility created at Penshaw, an interchange station at Belmont (three miles from Durham City) and at Ferryhill. The route would be suitable for freight trains, for a local Newcastle-Middlesbrough service (via Ferryhill and an upgraded Stillington line); and as a diversionary route for long distance passenger trains.

The line would galvanise local rail travel within the relevant catchment area, create enhanced public transport connectivity, act as a driver of economic regeneration and improve quality of life. It could provide freight services to Nissan and to the national warehousing centre at Washington.

The project is endorsed by Durham County Council (DCC), Newcastle City Council, North East LEP, Nexus (operators of Tyne & Wear Metro), local MPs, Transport for the North (TfN) and Rail North.

4: History

Until 1872 when the present ECML was opened, Leamside was part of the primary route from Newcastle to London. Thereafter it was used for freight and for local passenger services, which ceased in 1962. Leamside was closed after the ECML was electrified in 1991. In 1995 DCC drafted (unfunded) proposals for a passenger service over Leamside in the County Durham Structure Plan. In 1999 Railtrack announced that it intended to re-open Leamside. The aims were to alleviate forecast capacity constraints and separate freight trains from high speed passenger ones between Newcastle and Northallerton. Project completion was estimated for 2004. Funding for the construction of new stations at Washington and Belmont was secured - the latter to include a Park and Ride interchange facility - and a new station at Ferryhill was proposed. Preliminary work commenced late 2001, but ceased the following year when Railtrack went into receivership. However, DCC reiterated its hopes for the line in its Local Transport Plan (LTP2) published in 2006. In 2006, key Leamside players commissioned Faber Maunsell to produce a feasibility study to assess the line's potential, which reported at the end of 2007 and favoured reopening. A report (in 2009) by the Association of Train Operators (ATOC) pointed to Washington as one of the largest centres of population in Britain without a rail link. By implication ATOC supported Leamside reinstatement. During 2012/13 the track was lifted by Network Rail and all disposable items removed due to serious vandalism and deterioration - on the understanding that the route would remain unimpeded. DCC, NELEP and Nexus remain committed to reinstatement. In 2016 HS2 Limited investigated the construction of a new bypass line to the east of Durham city utilising the Leamside track bed, in order to cater for the arrival of the dedicated high speed line at Leeds post-2033.

5: Economic Benefits

The Faber Maunsell Study of 2007 demonstrated that Leamside could bring substantial economic benefits to present and future employers along the route in terms of access to freight flows and in increasing the size of the labour pool able to commute by rail. The combined population of the city regions of Tyne and Wear and Tees Valley (Middlesbrough) – 1.42 million – is the fourth largest urban area in the UK. Trains could run between Middlesbrough and Newcastle in less than one hour and also serve Washington.

6: Impact on employment and education

Besides increasing access to employment opportunities, the passenger service would broaden choice of and access to colleges of education, an especially important factor in the lives of young people.

7: Mobility and Housing

New key journey opportunities would be created by the line in its catchment area enhancing travel mobility enormously. Leamside could also unlock the potential of adjacent development sites,

housing and commercial, which have poor access by road, or which lend themselves to innovative spatial planning designs, based upon minimal use of the private car.

8: Operational advantages to the wider rail network and aspects of resilience

Besides offering opportunities for the creation of a much needed local passenger service and enabling freight trains to keep clear of the Newcastle to Ferryhill section of the ECML, Leamside would provide an excellent diversionary route for long distance passenger trains during periods of disruption. At present any closure of the ECML between Newcastle and Ferryhill requires an inconvenient and expensive bus replacement, since the alternative (Durham) Coast route can only cope with one of the five long distance trains per hour that currently operate on this section. This same section contains three major viaducts as well as a number of embankments. In the event of significant failures involving any of these structures, especially over a lengthy period, the train operators would have to 'shut up shop' between Newcastle and Darlington since in reality there is no viable diversionary route.

9: Contribution to joined up transport

Leamside offers easy access to the Metro at Heworth with destinations including Newcastle International Airport. Heworth is also a large bus interchange point and boasts a park and ride facility. At Belmont, Leamside would link up with the Durham City park and ride bus services that operate from the Belmont Interchange located a short distance from Junction 62 of the A1(M). Construction of a significant park and ride facility where Leamside crosses the A182 near Penshaw should be possible and would provide an alternative mode of travel for the many car commuters making for Newcastle and Durham. Assuming the Metro would be extended from South Hylton to Penshaw and link with Leamside there, new rail access into Sunderland would be established.

10: Impact on car usage

Leamside is expected to encourage a significant modal shift from car to train, notably during traditional peak periods, along the A1(M) corridor between Durham and Newcastle, between Washington and the A1 Western By-Pass, and between Ferryhill and Middlesbrough area with some shift as well on the A19 between Houghton-le-Spring and Newcastle.

11: Impact on Air Quality and Carbon Emissions

Any modal switch from cars that can be achieved will clearly have a positive effect on both air quality and on carbon emissions.

12: Contribution to International Gateways.

Not only will a reopened Leamside route provide good access to Newcastle International Airport via Heworth (see section 9), but if the wish of Nexus to operate dual voltage and bi-mode trains over both the existing Metro lines and heavy rail ones is fulfilled, then through running between the likes of Hartlepool and the Airport become possible. There is the opportunity to create a passenger train service in and around the Tyne and Wear Metro system which would otherwise not be possible. Leamside also opens up the prospect of more rail traffic running to and from the Port of Tyne which is already well established as an international gateway point in the North East.

13: Project Financing

Funding will be sought from national/central sources with some assistance possibly available from the Government's local growth fund.

14: Impact on Quality of Life

Quality of life enhancements will arise from increasing employment and educational opportunities, economic rejuvenation of the area, better public transport to hospitals and leisure facilities and improved health as a consequence of better air quality.

Project c) Upgrade of Ferryhill to Stockton freight only line to passenger train standard

1 Project title:

Quicker Tees-Tyne Rail Services

2 Location:

The project involves the section of freight-only track between Norton South Junction (north of Stockton-on-Tees railway station) and Ferryhill south junction (where this line joins the East Coast main line between Darlington and Durham). It is just over 10 miles in length.

3 Scheme History:

Passenger services ceased along this section on March 31, 1952, when its three local stations (Sedgefield, Stillington, and Redmarshall) closed. The line itself, however, did not close, as freight services have been routed along it from that day to this. From time to time, it has been used for main-line long-distance passenger trains when the 'normal' route through Darlington was being maintained and/or repaired, usually at weekends.

Occasional efforts were made, by British Rail, to introduce a direct Middlesbrough - Durham - Newcastle passenger service, but they never succeeded. Arriva Northern's desire to introduce something similar, as one of the "Northern Connect" group of semi-fast passenger services, is the latest bid to speed up Tees-Tyne rail travel.

4, 5 Likely Economic Benefits (including access to employment, tourism, and higher education):

Three background factors affect any meaningful estimate of these. They are:-

(a) The Tees Valley Combined Authority spans the 27-mile distance between Darlington and Saltburn, including Stockton and Middlesbrough (11 miles and 15 miles eastward respectively). The nearest main line train services are accessed at Darlington. No other comparable area of (post)industrial Britain is treated like this - Stoke-on-Trent, 15 miles east of Crewe, has its own twice-hourly London expresses (from Manchester), and Nottingham, 16 miles east of Derby, has a similarly-generous range of direct through trains to and from London. So why not Tees-siders?

(b) In 1992, British Rail extended their Transpennine network northwards and eastwards to Thornaby and Middlesbrough, whose populations could now reach York, Leeds and Manchester by through semi-fast trains without touching Darlington or changing trains. This service has been outstandingly successful, often overcrowded on Saturdays all the year round.

(c) Three rail routes connect the two conurbations.

(i) the 47-mile Coast line via Hartlepool and Sunderland, whose trains take 78 minutes from Middlesbrough to Newcastle. These are often hopelessly overcrowded, especially on Saturdays, leaving intending passengers behind from as far south as Hartlepool itself:

(ii) the Middlesbrough-Darlington-Durham-Newcastle line, 51 miles in all, whose few remaining local all-stations trains need some 70 minutes northbound and 66 south:

(iii) the Middlesbrough - Stockton - Norton - Stillington - Ferryhill - Durham - Newcastle line, just under 42 miles - on which no passenger trains run at all!

So if passenger services begin on the Stockton-Ferryhill route, they will save over 20 minutes each way between the two conurbations, as an overall Middlesbrough-Newcastle time of 55 minutes is possible, even with the present 50mph speed-limit on the freight-only section. Such trains will help to relieve overcrowding on the Coast line more or less from the day they begin, in that those in Middlesbrough, Thornaby or Stockton wanting to go to Newcastle will no longer need to use Coast line trains to do this. Nor will they need to divert via Darlington. This route also transforms intermediate journey-times, especially that from Stockton to Durham.

Durham university established an outpost in Stockton some years ago, and an express bus service (X12) connects the two; but it takes at least 48 minutes, even if there is no traffic delay in and around Durham. This would compare with a 28-minute booking, start to stop, even before any track refurbishment occurred. Quite apart from the time-reductions, of course, a restored rail service via Stockton-Ferryhill brings an entirely new, hassle-free way for all in and around Tees-side to visit Durham as a tourist attraction. If a new station is built at Ferryhill itself, as advocated by another project in this series, the value of the Stockton route as a way to employment in Tees-side is added to that of the main line to Newcastle for all who live within range of Ferryhill.

6 Housing development possibilities:

As this project does not, at least in its earliest stages, involve any new station-building, little effect can be guessed at, unless the potential of an enlarged station at Stockton is exploited so that some main-line services between York and Newcastle are routed via Stockton rather than Darlington. Stockton, with 190,000 inhabitants, should arguably be prioritised over Darlington, with 105,000.

7 Operational advantages for the railway:

Background factor (a) above, headings 4 and 5, is evidently leading the Tees Valley Combined Authority to prescribe ambitious but unnecessary expansion of facilities at Darlington Bank Top - for a station handling fewer trains on its through lines than Northallerton. The gross imbalance of provision, when compared with population distribution, means that Stockton, with so much spare capacity thanks to its currently vestigial one-short-train-per-hour each way, can readily cope with some York-Newcastle express services, to the overwhelming benefit of all in the borough. Journey time to and from York can reduce to just over 40 minutes (depending on intermediate stops) just as it will to Newcastle via the Ferryhill line.

First Transpennine's additional trains from York to Newcastle, extensions of its Manchester Airport service, are prime candidates for just such a diversion via Stockton and the line to Ferryhill. Their maximum speed is lower than those of any other of the mainline operators, so, by omitting Darlington in favour of Stockton, they ease incipient congestion along the main line and, at the same time, radically improve the quality of train service through Stockton itself.

7, 8 HS2 potential, and joined-up transport possibilities:

There does not seem much scope for this, thanks to the scattered nature of bus stop and bus station distribution in the central areas of Tees-side boroughs in general, but, if the whole Northallerton-Stockton-Ferryhill line were upgraded for speeds up to 90mph throughout, and electrified in the process, the case for enlarging Stockton's station could include custom-built bus interchanges at each end of it - off Bishopton Road, already served by several local buses, to the south and off the A177 to the north, where much apparently unused land seems suitable for park-and-ride use. More still could be made of Stockton's potential as Tees-side's main rail-head for an eventual HS2.

9, 10, 11 Sustainability, reduced car usage, and air quality:

Inasmuch as an improved train service via Stockton, even if still diesel-powered, removes motorised journeys to and from Darlington station, their absence will improve air-quality and reduce car use over the 11 miles separating Darlington Bank Top from Stockton. The more varied and numerous the destinations served by main-line trains calling at Stockton, the greater the level of overall reduction. Electrification of the lines through Stockton would reduce local air pollution.

12, 16 Resilience and the quality of people's lives:

This line has formed a diversionary facility for decades - yet, although it offers much shorter journey-times between Stockton and Newcastle than does the Coast route, publicity for it has been poor.

Project d) Newcastle 9 + 2 Strategic Cycle Routes

1: Project Title

Newcastle 9 + 2 Strategic Cycle Routes

2: Location

The strategic cycle route network as identified in the 2011 Newcastle City Council document, “Delivering Cycling Improvements in Newcastle: A ten year strategy” consists of seven radial routes. These routes will lead from the city centre to the following destinations: Newburn, West Denton, Great Park, Gosforth, Longbenton, Benfield and Walker. However, the Newcastle Cycle Campaign identify a need for two additional radial cycle routes – to Woolsington and Haddrick’s Mill – and two circular strategic routes, one inner route around the city centre and one outer route linking inner suburbs.

3: Scheme History

The first phase of the scheme (CCAF1) was funded in 2013 with £5.7m of funding from the DfT’s Cycle City Ambition Fund. The second phase of funding was granted in 2015 and will consist of £10.6m over the period to April 2018. The Newcastle Cycling Campaign would like to see a 30-year plan, developing and expanding a comprehensive network throughout the city, which is integrated with new housing and employment development.

4: Economic Benefits and Tourism

Improved cycle networks within the city, linking it to its suburbs, will improve the city’s tourism offer by: a) linking in to the Metro system and Newcastle Central railway station bringing international visitors from the Port of Tyne, Newcastle Airport, and Eurostar services via St Pancras and the East Coast Main Line b) providing a better quality and cleaner city centre environment c) providing opportunities for cycle tours of the city and its suburbs.

By providing another good alternative to the private car, the programme should reduce congestion and thus make journey times by all modes more predictable.

5: Impact on Employment and Education

By linking Newcastle’s concentric suburbs with its city centre, this programme will improve access to the region’s most important employment centre, the two universities, and other city centre educational institutions. Reducing travel costs by facilitating a healthy and low-cost means of transport should help to remove barriers to participation both in employment and education. In subsequent years, a comprehensive network of cycle routes throughout the city should improve access to employment and education sites throughout the city.

6: Mobility and Housing

A priority for Newcastle Cycling Campaign’s additional (Woolsington and Haddricks Mill) routes will be to link in to new housing development to the north-east of the existing conurbation and in the Jesmond area. This should help to reduce the transport impact of the proposed housing development and to give new residents genuine choice in terms of transport modes.

7: Contribution to Joined up Transport

The proposed radial routes will link in to the city centre transport hub, integrating a convenient and safe cycling system with public transport (bus and rail) services, and, via them, to international transport routes.

8: Contribution to Sustainability

The project will contribute towards the three “pillars” of sustainability as follows:

Economic contribution: the project will ease congestion by bringing about modal shift. Delays will be reduced and journey times by all transport modes will be made more predictable, thus reducing

unforeseen time losses to business. The city's tourism industry will benefit from a cleaner and more pleasant city centre environment.

Environmental contribution: the project will reduce air pollution and carbon emissions by encouraging a shift to less polluting modes. The physical environment of the city centre and its suburbs will be made more pleasant by improvements to the public realm.

Social contribution: residents will benefit from a cleaner and more pleasant city environment. Residents will have an increased choice of safe and convenient means of accessing the city centre, which will help to reduce barriers to employment and education. Residents' health will be improved by encouraging active travel and by reducing air pollution.

9: Impact on Car Use

Currently, 2/3 of car journeys are under 5km. Many of these journeys could potentially be taken by cycle, but evidence indicates that an absence of safe and convenient cycle routes dissuades people, particularly women, from cycling. This project will help to give people a genuine choice in travel modes and therefore bring about modal shift from cars to cycles.

10: Impact on Air Quality and Carbon Emissions

Air pollution and carbon emissions will be reduced by bringing about modal shift to less polluting modes.

11: Impact on Rail Resilience

Links to regional and national rail services from Newcastle Central Station will help to support rail services.

12: Contribution to International Gateways

The project will provide good-quality links to the Metro system and Newcastle Central railway station bringing international visitors from the Port of Tyne, Newcastle Airport, and Eurostar services via St Pancras and the East Coast Main Line.

13: Project Financing

The project has already received two instalments of funding: £5.7m in 2013 and £10.6m in 2015. To bring about a citywide transformation, we estimate that some £50m will be needed, with a proper budget beyond that for improvements.

14: Project Downsides

None identified

15: Impact on Quality of Life

Residents will benefit from a cleaner and more pleasant city environment. Residents will have an increased choice of safe and convenient means of accessing the city centre, which will help to reduce barriers to employment and education. Residents' health will be improved by encouraging active travel and by reducing air pollution.

Project e) Ashington, Blyth and Tyne reopening

1: Project Title

Ashington Blyth & Tyne Rail Re-opening

2: Location

The rail route connects Newcastle with Ashington in South East Northumberland, plus intermediate stations at Manors (to be confirmed), Northumberland Park (for connection to Tyne & Wear Metro), Seghill, Seaton Delaval, Newsham for Blyth, Bebside, and Bedlington. Beyond Ashington, the route continues to Woodhorn; a station here would act as a Park & Ride and serve the adjacent Museum of Mining and Northumberland Life. Newcastle and Manors are existing stations. Both platforms at Ashington and one at Bedlington remain in situ. In addition to the core route proposed for initial re-opening, the line has several further branches including a) Bedlington to Morpeth (working line for freight and diversionary services), b) West Sleekburn / Marchey's House to North Blyth (working freight line to Port of Blyth), c) Woodhorn to Newbiggin d) Newsham to Blyth Coast Main Line east of Ulgham village.

3: Scheme History

The route is part of a working freight network and still carries occasional passenger trains on emergency diversionary routes or excursion charters. Re-opening of the core route as described at Section 2 is now being progressed by Northumberland County Council, who are close to Commissioning the GRIP 3 Study with Network Rail. NCC are not, however, proposing a station at Seghill; SENRUG therefore request passive provision be made for this to be opened subsequently.

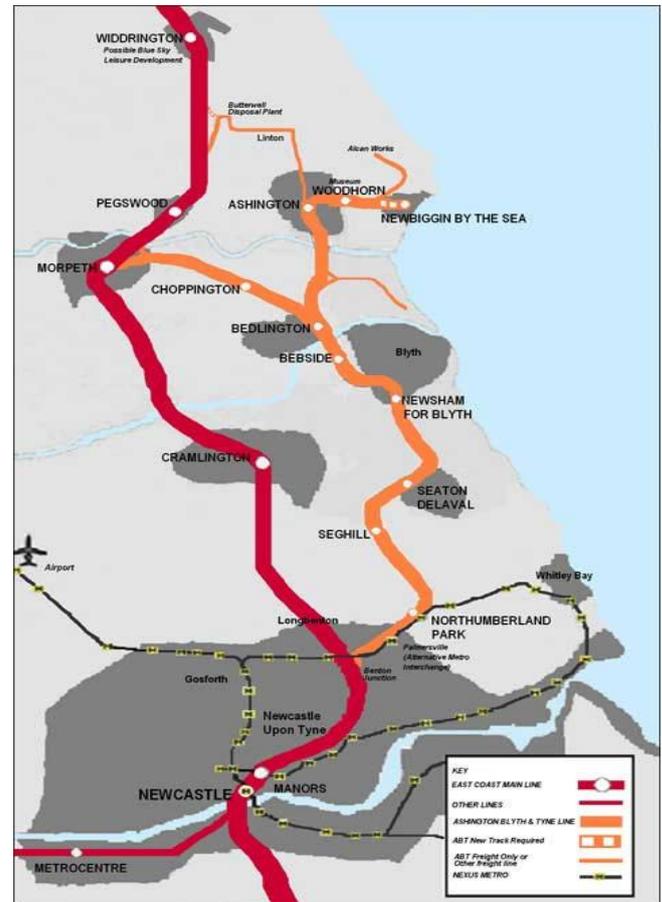

4: Economic Benefits and Tourism

The area to be served, South East Northumberland, experiences a high degree of economic deprivation. The line would connect it to an area of opportunity (Newcastle) – providing access to employment for existing residents, and increasing the attractiveness of the area to commuters to Newcastle, bringing more spending money into the local economy. Woodhorn Station would serve the Museum of Mining and Northumberland Life (one of Northumberland's premier tourist attractions) and Seaton Delaval station would be close to the National Trust's Delaval Hall.

5: Impact on Employment and Education

The line would create access to employment from Ashington, Bedlington and Blyth to opportunities at Cobalt Business Park (served by Northumberland Park station) and Newcastle, as well as to a wider range of places served on the Metro and wider rail network. It creates a direct transport link from South East Northumberland to the University of Northumberland campus at Manors Station.

Town and e) Ashington to Butterwell Junction on the East .

6: Mobility & Housing

The re-opening would support further housing development in South East Northumberland, currently hindered by lack of public transport infrastructure. It also creates access to the national rail network from Newcastle (buses from South East Northumberland do not serve Newcastle station). Woodhorn station also serves Wansbeck General Hospital and Seaton Delaval station would become the nearest station to the brand-new Northumberland Specialist Emergency Care Hospital at Cramlington and it is envisaged would be linked by a bus shuttle service.

7: Operational Advantages to Wider Rail Network

The line is also a freight route serving Port of Blyth and Lynemouth Power Station (currently being converted to Biomass). The route as far as Bedlington coupled with the Bedlington – Morpeth north branch is already used as an emergency diversionary route for intercity services and freight between Newcastle and Scotland. This section of the route is included within the design specification for the new Hitachi IEP trains. The Ashington – Butterwell Junction branch coupled with the addition of a north-to-east connection at Butterwell, has the potential to be used as a much larger diversionary and alternative route to the East Coast Main Line between Benton and Butterwell Junctions, taking freight off this section of the ECML and allowing more passenger services between Newcastle and Edinburgh and thus London and Edinburgh.

8: Contribution to Joined Up Transport

The route offers interconnection with the Metro at Northumberland Park and Newcastle, and provides access to Newcastle Station. Buses from Northumberland do not serve Newcastle Station, making public transport access to the wider range of services available from Newcastle difficult.

9: Contribution to Sustainability

No specific input

10: Impact on Car Usage.

The re-opening is expected to reduce car usage on the main north-south A1 and A189-A19 corridors, as commuting to work by rail becomes feasible.

11: Impact on Air Quality and Carbon Emissions

By increasing the rail capacity between Newcastle and Edinburgh (see Section 7), more of the London – Edinburgh passenger market can be transferred from air to rail.

12: Impact on Rail Resilience

The re-opening of the route coupled with subsequent double tracking of the single-track sections, and electrification, creates a significant alternative route to the East Coast Main Line between Benton and Butterwell Junctions as described in Section 7.

13: Contribution to International Gateways

The freight route to Port of Blyth will be enhanced by upgrading the core AB&T route for passenger services. There would be passenger access to Newcastle Airport via the Metro interchange at Northumberland Park, coupled with future aspirations to run Metro services direct from the Coast branch to Airport.

14: Project Financing

NCC are the sponsoring local authority and will seek contributions from regional and national funds.

15: Project Downsides

None

16 Impact on Quality of Life

Quality of life is improved by increasing employment opportunities, economic regeneration of the area, better public transport to hospitals and improved health due to improvements in air quality.

Project f), New Rail Halt at Horden

This project is described elsewhere and is supported by NECA. It is therefore not discussed in detail here, but we reiterate our support for it as a strategic project with the potential to make a significant social and economic contribution, and support environmentally sustainable transport.

<http://www.durham.gov.uk/article/7707/Proposal-for-a-new-railway-station-at-Horden>

Project g) A new station at Ferryhill

1: Project Title

Ferryhill Proposed New Rail Station

2: Location

Ferryhill is a town in County Durham population 11,656 and is a rail junction between the East Coast Main Line and the branch line to Stockton on Tees. It is twelve rail miles from the towns of Stockton and Darlington and ten miles from Durham City.

3: Scheme History

Ferryhill railway station closed in 1967 and was demolished. The rail tracks in the Ferryhill area were rationalised and realigned in 1971 to provide higher line speeds, in 1990 the lines were electrified with overhead catenary.

A lot of employment was provided by coal mines in the area, these had all closed by 1968.

Alternative employment was provided by industrial estates in the locality but some people now work further afield.

There is scope to provide a new station at Ferryhill north of the road over bridge, which links Bishop Middleham with Ferryhill, known locally as Lough House Bank railway bridge.

Who would use this station? Within a four mile radius of the proposed station there are a number of towns and villages that have no rail provision, so it would make sense for them to use the new Ferryhill station. These settlements include Spennymoor, Middlestone Moor, Kirk Merrington, Tudhoe, Chilton, Cornforth, Bishop Middleham, Mainsforth and Sedgfield. From the population census of 2011, the total number of persons living within 4 miles of the proposed station is in the order of 45,000.

Which trains would serve the new station? Northern trains are to provide a new hourly connect service between Middlesbrough Newcastle and Carlisle, hopefully by the use of the rail route between Stockton and Ferryhill with suggested new platforms being provided on the slow lines at Ferryhill.

In addition to this, platforms should be provided on the main lines. These could comprise a new northbound platform and an island platform to serve both southbound mainline and the northbound line from Stockton. The platforms could be accessed by ramps with a slope of 1 in 20 from the north side of the existing bridge with an adjacent car park.

The main line service could be provided by the TPEX Manchester Airport to Newcastle service. This will be hourly from summer 2019 when new 5 car Hitachi 802 rolling stock is introduced.

Ferryhill station also has a number of bus services passing the site. For example service number 8 hourly frequency Darlington to Spennymoor, service 35A Bishop Auckland to Kirk Merrington evenings, service 56 Bishop Auckland to Durham half hourly, service 113 Sedgfield to Ferryhill hourly.

4: Economic Benefits and Tourism

Ferryhill and adjacent communities are former coal mining areas of County Durham and as such now experience a high degree of economic deprivation.

By providing a rail station at Ferryhill it would make travel to employment areas much easier and quicker, for example Darlington and Durham could be 10 minutes journey time. Newcastle could be reached in 25 minutes.

People may wish to come to Ferryhill to visit its weekly market. There are several walks in the area including former magnesium limestone quarries which are rich in flora and fauna. Thrislington national nature reserve is nearby and is the most valuable wildlife site on County Durham's magnesium limestone.

5: Impact on Employment and Education

A new station at Ferryhill would enable students to travel to Darlington College and Teeside university annex, which are both situated next to Darlington station. People could commute from Ferryhill to Durham and Newcastle where there are more job opportunities.

6: Mobility and Housing

The provision of a station at Ferryhill would stimulate house building in the area and improve the sustainability of the town.

7: Operational Advantages to Wider Rail Network

The station would provide new rail journey opportunities to Teeside and Tyneside and quicker journey times than present between these locations.

8: Contribution to Joined up Transport

As stated in section 3 there are 4 bus service that pass the station site plus there more services available by changing in Ferryhill town centre.

9: Contribution to Sustainability

No specific input

10: Impact on car Use

A new station at Ferryhill would remove the need to drive to either Durham or Darlington station to access rail services, thus reduce car usage on the A167 road.

11: Impact on Air Quality and Carbon Emissions

This will reduce in the A167 corridor between Darlington and Durham as people could drive to the new station at Ferryhill or use the existing bus services if convenient.

12: Impact on Rail Resilience

If a passenger service is routed from Ferryhill to Stockton then the line speed of this section of track needs to be raised from the present 50mph. This would benefit any planned diverted trains by speeding them up over this section of the track and impacting less on the timetable.

13: Contribution to International Gateways

No specific input

14: Project Financing

Money may be available from the new stations fund and or the local authority.

15: Project Downsides

None

16: Impact on Quality of Life

Quality of life is improved by increasing employment and learning opportunities, economic regeneration of the area, better public transport to hospitals and improved health due to improvements in air quality.

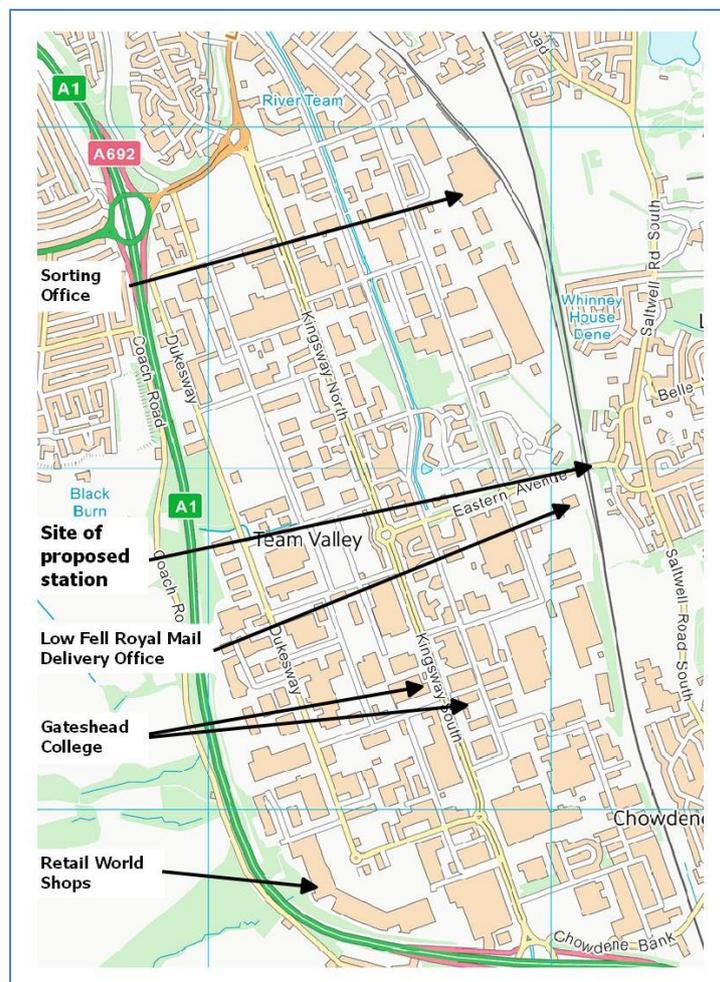

h) Station for Team Valley Trading Estate, Gateshead

1. Project Title:

Station for Team Valley Trading Estate, Gateshead

2. Location (see accompanying map):

Ordnance Survey grid reference NZ251600, site of old Low Fell station (closed 1952, now demolished), where Eastern Avenue passes over East Coast Main Line. The Team Valley Trading Estate (the Trading Estate) is a flat area measuring approximately three miles by three quarters of a mile. It contains a retail area called "Retail World" consisting of several large shops around a large car park, two departments of Gateshead College, the main regional Royal Mail sorting office, the letter delivery office for Low Fell postcodes and many factories and warehouses. These places are spread over a large area which is separated from the rest of the town by the East Coast Main Line. Over the railway line there are very few road or footpath crossings which makes it difficult to get here without a car both from outside Gateshead and even from within most of the town. It is easy to cycle on the Trading Estate (except Kingsway where traffic is fast moving) but difficult to cycle away from the estate because the valley has steep sides.

4, 5. Likely economic benefits and employment opportunities:

There are already many employers at the Trading Estate but for many people, access is very difficult without a car. Cars and buses can be held up in traffic on roads approaching the Trading Estate such as the A1 Western bypass and the Tyne crossings from Newcastle. Not every employer has a big enough car park and some of the roads within the Trading Estate are partially obstructed by parked cars. For job seekers, especially those without a car, there is a disincentive against seeking or

accepting employment here, particularly if it is low paid. Access by rail and linked buses would make commuting a reasonable prospect from north of Newcastle and from Durham.

6, 7. Mobility within the catchment area:

This station would directly serve the east side of the Trading Estate and the west of Low Fell, and a greater area if suitable bus links were provided. At present, the nearest railway station is at Newcastle, more than two miles away across the river Tyne. The nearest local railway station is Gateshead, on the Tyne and Wear Metro system, which is some 2km away from Team Valley at its nearest point. All road routes across the Tyne become congested at peak times. A railway station here would make journeys to the rest of the region, southbound journeys especially, much easier. If linking bus services were provided, it would become easier to reach this part of the Trading Estate from much of Gateshead. This should prove useful for those who need to visit their local letter delivery office, which is located adjacent to where the station would be, with no existing bus access.

8. Joined up transport (see accompanying map):

At present, no buses run on Eastern Avenue. They run north to south on Saltwell Road South, 200 yards to the east, and on Kingsway, 500 yards to the west. It would be physically possible to run buses from Kingsway via Eastern Avenue up to the A167 Durham Road and beyond. There are so few places where one can cross the East Coast Main Line, even on foot, that a bus route on this road should prove useful not only for reaching the station but also for travelling from Gateshead to the Trading Estate.

9, 10, 11. Car use and air quality:

The primary intention of the proposed station is to reduce car use within its catchment area. This should improve air quality both by reducing the number of motorised vehicles and by reducing the time which remaining vehicles spend in traffic queues with the engine idling. The Team Valley is flat at the bottom but the sides are steep. The ability to arrive and depart by train will enable more people to cycle in the valley without a strenuous return journey.

15. Downsides:

To be effective, the station would have to be a transport hub well served by buses reaching all parts of the TVTE, and providing good east to west links with places not reached by rail (including Low Fell, inner Gateshead and Birtley). The bus operators would have to co-operate. It is highly likely that most of the passengers would be too young to be eligible for free travel so fare income would probably be good.

Conclusion:

This station represents a fairly 'low-key' project, but in our opinion it would be enormously effective. It is difficult to believe that an industrial complex of the magnitude of the TVTE has remained 'rail less' for so long.

Project i) Newburn – Blaydon Foot/ Cycle Bridge

1. Project Title:

Newburn – Blaydon Foot/ Cycle Bridge

2. Location

In between Newburn Riverside and Blaydon, taking in the railway and bus stations.

3. Scheme History

The scheme was discussed within the 2005 report to Government Office North East, ONE North East, ANEC and the North East Assembly, “North East Prioritisation Framework” as an “emerging” scheme. At this point it was expected to cost £6m. The scheme featured in Regional Funding Allocation documents at the same time, with an expected price tag of £5-£10m. By the time ONE and NEA produced their final submission to government in Jan 2006, the scheme had apparently been reduced in status to one of the “current emerging schemes that could contribute towards delivering priority outcomes”.

The scheme then survived at least until the publication of the RSS in July 2008 where it is described in Section 3, part 3.302, Table 4 Page 181 as: New cross Tyne access to Newburn Riverside from Blaydon Station (Proposed Blaydon Newburn Pedestrian/Cycle bridge for investigation jointly by Newcastle City and Gateshead Councils).

ONE was abolished, along with other regional development agencies, in 2010; this, together with the financial crash of 2007-8, probably contributed to the slowdown in business development at Newburn Riverside, where ONE had been based.

In 2015, the undeveloped portion of the site was re-allocated for housing development in the Newcastle/Gateshead Core Strategy. This changes the likely usership of a bridge at this point: rather than being used by people working at Newburn Riverside and commuting to it via Blaydon, a bridge to be built alongside housing development on the Riverside would cater for residents accessing facilities and services in Blaydon, and commuting to Newcastle by rail from Blaydon.

4. Economic benefits and 5. Employment and education

The proposal could help residents on Newburn Riverside, Newburn and Lemington access employment in Newcastle via rail services from Blaydon. It could also help residents in Blaydon access employment on Newburn Riverside and Newburn Industrial Estate; the area currently has significant employment but poor public transport links. The scheme would also improve access to Blaydon station from the adjacent industrial area.

6. Mobility within the catchment area, 7. Operational advantages to wider network and 8. Joined-up transport

The timetable at Blaydon railway station saw a major improvement in December 2013, which has been rewarded by significant extra patronage. Improving links to the station and making it more accessible should result in greater use, and we would hope to see this reflected in the December 2017 timetable when there will be two trains per hour between Newcastle and Carlisle.

A cycle-accessible footbridge would provide an additional link in the network of good-quality cycle routes to the west of Newcastle, including Keelman’s Way and Hadrian’s Cycleway. It would provide access to rail services for residents of Newburn, Lemington and nearby settlements, which are within a few kilometres of Newburn Riverside. The scheme would also provide a better and more user-friendly link between bus and train services in Blaydon.

9. Sustainability, 10. Impact on car use, 11. Impact on Air Quality and Carbon Emissions

The scheme would provide access to local rail services for residents from Newburn, Lemington and Newburn Riverside, and adjacent suburbs, provide better linkages between bus and rail services in

Blaydon, and augment the existing pedestrian and cycle network in the area. This would provide a viable alternative to the private car for residents and employees on Newburn Riverside, where public transport services are poor, and would improve the convenience and attractiveness of non-car modes for residents in the other nearby settlements and suburbs.

12. Impact on Rail Resilience

The scheme could increase the viability of rail services at Blaydon by increasing its potential catchment to include nearby settlements and suburbs on the north bank of the river.

13. International gateways

No specific contribution.

14. Finance

The cost of the scheme was estimated at £6m in 2005 and £5-10m in 2006

15. Downsides

None.

16. Quality of Life

The scheme would link Newburn and Lemington with facilities and services in Blaydon, improve links from Blaydon railway station to the bus station and shopping centre, and provide step-free access to the eastbound platform at Blaydon. It would therefore increase local residents' access to facilities and services, and bring separated communities closer together.

A well-designed bridge at this location could also be an asset to the local landscape and townscape.

THE NATIONAL INFRASTRUCTURE ASSESSEMENT – CALL FOR EVIDENCE

This consultation response is made on behalf of Northampton Rail Users Group (NRUG).

NRUG campaign on behalf of rail users in Northampton, and through maintaining a high profile of the key issues for our members and other users, resulting in service improvements from Northampton to both London Euston and Birmingham New Street, the new Northampton railway station built, and, through proper use of the consultation channels, a good response for Northampton in the current refranchising round.

The over-arching response of our group to this call for evidence was the need for a good strategy for rail and rail freight, including the proper integration of freight with passenger traffic. Particular emphasis was put on not having a series of stop-gaps and short term measures presented as strategy in an industry that takes decades to expand effectively.

In principle we have limited our replies rail, as given in our response to the questions below.

13. How will travel pattern change between now and 2050? What will be the impact of the adoption of new technologies?

Note: travel patterns include both the frequency and distance of trips taken, as well as the mode of transport used. This covers both personal and commercial travel, including freight.

Concerning the introduction of new technologies this is very much looking into the “crystal ball”. However, our observations are that the change in working patterns, centralising jobs into the large urban areas and cities, particularly in the south east, and increased consumer spending on leisure travel, has to date resulted in greater needs for transport. There has been no net reduction through working at home and other such concepts that the information revolution was at one time said to bring. In fact, despite the rapid growth of new technologies, and the recession, rail passenger growth has been very strong over the past decade. Therefore, unless there is a major change in the way business operates, and decreased centralisation, particularly to the south east, we do not see any change to the current pattern.

Further, at local level, it is the case that small town local factories have gone, and employment is replaced by larger scale facilities in urban areas, again increasing the needs for transport. A similar pattern arises for health care and hospitals. The days of walking to the local factory are gone. In many ways the ability of IT to distribute jobs around the country, especially in financial services and administration, has been there for many years, but employers (including the public sector) choose not to do it.

Therefore we conclude that technology is not the driver, other employment and economic factors are driving a consistent growth in travel. However, we think that the current trend for longer distance commutes will continue, both as a function of house pricing and centralisation of business activity.

As regards freight, we think freight patterns are likely to be distorted by the nomination of rail freight interchanges as nationally important infrastructure, which coupled with the problems developers report with the planning system, is encouraging the application for facilities for

warehousing on rail connected sites that are not the best solution for rail or road capacity. In that context a proper strategy for freight is required, not a series of stop gaps.

14. What are the highest value transport investments to allow people and freight to get into, out of and around major urban areas?

Note: high value transport investments, in this context include those that enable agglomeration economies – the increase in productivity in firms locating close to one another.

Our only comment here is that as local economies stratify, and lose diversity, the need to travel to the places where similar activities are located increases as people travel further to work as their jobs relocate.

15. What are the highest value transport investments that can be used to connect people and places, as well as transport goods, outside of a single urban area?

Note: this includes travel in and between rural areas, as well as between urban areas and international travel.

There is a tension here between longer distances between set points that make rail the best option, and the need for local distribution of goods and movement of people. Rail is very good for moving vast numbers effectively between 2 locations, people or freight. However, since many rail journeys start and end with a journey to and from the station by car in rural areas or public transport in cities, there are local interactions. These usually pan out for passenger traffic due to the nature of commuting into the big cities, though commuter stations handling '000s or 10s of '000s per day put strain on local roads.

The case for freight needs much more careful consideration, as a policy of putting things onto rail entails by nature truck journeys to and from the rail head, which can considerably increase local road use, and if rail is used only for a short distance, increase truck traffic rather than decrease it. The effects on roads of rail freight are complex – it decreases long distance motorway freight, but increases local truck journeys. Multiple handling can also be expensive.

Co-location of manufacturing and rail freight is probably a good strategy.

See also our reply to 14 above.

16. What opportunities does “mobility as a service” create for road user charging? How would this affect road usage?

NRUG's only comment here is that town congestion charging should not add to the cost for commuters already facing heavy annual fares for going to work and parking at the station. This is a foreseeable rebound effect. People should not be forced out of their jobs by mobility pricing, unless such pricing is accompanied by a major restructure to enable them to work closer to home.

Further, our rural economies will suffer if too much is taken off those who live there in the name of mobility or congestion measures.

NRUG has been asked to campaign for low cost season tickets by care workers and other low paid people going to London. Capacity pricing has the rebound effect of making London too expensive for low paid health care workers, social care workers etc. If this is repeated on local roads the conditions for a backlash may be very high.

Cross cutting issues and Energy

The "Energy" section does not address this, but question 4 in "cross cutting issues touches on it:

NRUG would be concerned if demand management for energy forms a "double whammy" with demand management on rail capacity through peak fares, and even more concerned if road pricing turned that into a triple hit.

Lord Adonis
Chairman
National Infrastructure Commission
1 Horse Guards Road
London
SW1A 2HQ

10 February 2017

Dear Lord Adonis,

I am writing to respond to your call for evidence, to introduce Northern Gas Networks to you, and to highlight the work we are doing to help unlock the potential of the Northern energy economy.

By way of introducing Northern Gas Networks (NGN), we deliver gas to 2.7 million homes and businesses in the North of England. We employ over 2,000 people and generate on average around £330 million for the region's economy every year. We will be investing £1 billion to upgrade and replace our region's metal gas pipes with plastic equivalents by 2021, these pipes have a life span of 50 -70 years. With this continued investment we will have a gas network that will transport low cost, sustainable and low carbon gas for decades to come.

I would like to draw to your attention to work we have recently undertaken with KPMG to demonstrate the current and potential value of the Northern economy, specifically the energy economy.

I'd like to take this opportunity to share with you several notable conclusions from the report.

- The Northern Energy Economy is already making a substantial contribution towards the economic growth of the region. From 1997 to 2014 the North accounted for 23% of total UK economic value for the electricity, gas, steam and air conditioning supply sector. Indeed, the North West, the North East and Yorkshire and the Humber contributes to £3.5bn in GVA per year in the energy sector.
- Players in the region - from businesses to world class universities - are leading the way in developing transformative low-carbon technologies of the future, such as hydrogen networks. The region already plays a leadership role in areas including smart grids, decarbonised gas, offshore wind and transport.
- The North is well positioned to act as an 'energy champion' for the UK. There is potential for energy to increase GVA growth by £2.3bn by 2050 by building on existing strengths and exploiting opportunities in smart power, decarbonised gas and transport.

We are convinced that the development of the region is key to the future industrial success of the UK. We are therefore hugely supportive of the work the NIC is doing to support sustainable economic growth in the North and will be supporting your work where we can, beginning with our response to the National Infrastructure Assessment call for evidence:

1 What are the highest value infrastructure investments that would support long-term sustainable growth in your city or region?

Ongoing investment in the Gas Network in the UK already contributes a significant element to both the local and national economy through the strong economic multiplier effect this type of investment provides. In addition investment in programmes such as the Iron Mains Replacement Programme contributes significantly to the reduction in UK carbon emissions through reductions in the release of Methane to atmosphere through leakage from an ageing pipeline infrastructure. These significant shorter term benefits also play a role in allowing the gas network to play a key role in the transition to a low carbon economy in the medium term. But also provide policy makers with an economically viable component of a multi-vector energy system in the long term to 2050 and beyond.

Management of growth in a sustainable, secure and affordable way to 2050 and beyond will represent both a significant challenge and an opportunity. Currently, over 80% of peak energy demand is delivered by the gas grid and, with the UK population forecast to increase by 22% by 2050, energy demand is also likely to continue to move upwards. Although some interventions may mitigate the growth in demand (for example, improved building efficiency and the potential opportunities presented by linking smart metering technologies with reactive appliances and controls in the home) the challenge remains large if we want to keep our homes and businesses lit and warm in a safe, secure and affordable way whilst decarbonising our emissions as required by the Climate Change Act and the Paris Agreement.

Progress is being made to reduce carbon emissions from the electricity generation sector with the increase in renewables and the commissioning of new nuclear power; however, as mentioned above, at peak periods electricity supplies less than one-fifth of the country's total energy needs. Even if sufficient generating capacity could be built between now and 2050 (which is highly unlikely), the electricity transmission and distribution network would be completely incapable of transporting the required amount of energy.

Even though natural gas is the least carbon-intense fossil fuel, a key infrastructure investment for future sustainability would therefore be one that allowed for the reduction or elimination of carbon emitted due to the burning of gas. Hydrogen emits no carbon at the point of use and work is already underway, as part of Northern Gas Networks' and National Grid Gas' Hydeploy project, to examine the possibility of increasing the proportion of hydrogen in mains gas to up to as much as 20%. NGN has also recently produced the H21 Leeds City Gate report which demonstrates the feasibility and process to completely convert the Leeds gas supply network to 100% hydrogen. To deliver long-term sustainable growth it is essential that such initiatives have the support of industry, the regulators as well as local & central government.

Investment in and around research and development of alternative low carbon uses for this type of infrastructure can also provide a significant stimulus to economic growth. But also provide an opportunity to identify areas of international competitiveness for the UK

economy in the adoption and roll-out of new technologies and processes centred on the re-purposing of exiting energy/heat infrastructure.

2. How should infrastructure most effectively contribute to the UK's international competitiveness?

Continued access to efficient, safe, reliable and sustainable infrastructure that supports customers' heat and energy requirement must play a key role in ensuring that businesses and the wider economy remain competitive in the international marketplace.

However, the transition to a low carbon economy also presents significant opportunities for the UK to take a lead in the development of new technologies that give a significant 'first-mover' advantage. Investment in and around research and development of alternative low carbon uses for this type of infrastructure can also provide a significant stimulus to economic growth. But also provide an opportunity to identify areas of international competitiveness for the UK economy in the adoption and roll-out of new technologies and processes centred on the re-purposing of exiting energy/heat infrastructure.

5. How should the maintenance and repair of existing assets be most effectively balanced with the construction of new assets?

Effective asset management principles applied to a broader economic scenario can help identify the business case for maintenance/repair of existing assets or the development of new/additional infrastructure.

As indicated in the IMRP example above, opportunities exist to identify short, medium and long term benefits cases for investment in new infrastructure that address not only the current use of a particular infrastructure but also identify the role it can play in transitioning towards an alternative scenario and/or actively play a role in a particular energy future.

8. Are there circumstances where projects that can be funded will not be financed? What government interventions might improve financing without distorting well-functioning markets?

Funding/financing of investment in new/additional infrastructure can be impacted significantly by the associated risk profile of that investment and the availability and cost of access to funding for that level of risk.

The UK has been successful in providing significant and efficient levels of investment in infrastructure (Electricity, Gas, Water & Telecoms) in the UK through stable, low-risk regulatory frameworks. This type of framework should be considered in appropriate circumstances as an effective way of addressing access to low risk, low cost finance where this is believed to be a blocker to the timely and efficient development of infrastructure.

19. What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

Heat accounts for around 40% of UK energy demand (split approximately 60/40 between domestic and industrial/commercial respectively). If by 'value' we mean 'cost' then electrification of heat would be significantly higher cost (to factors of 10) than decarbonising the gas network and there are fundamental questions unanswered as to whether it would be technically possible. Moreover if electrification of heat was required it would involve generating vast amounts of clean electricity, which the UK already needs to do to displace oil in transport and currently electrical use. To put the scale of that

challenge into context, that would be the equivalent to building around 40 Hinckley point C size nuclear power stations.

Electrification of heat would also require fundamental changes to over 80% of UK households which currently use gas in addition to rebuilding of the electrical grid to allow transportation of this vast quantity of additional energy. Inter-seasonal storage would not be possible in an electric grid which would prevent this being practically and/or economically viable. A more realistic, cost effective and customer focused direction for heat would be to incrementally convert the UK gas networks to hydrogen as detailed in the H21 report. Additionally many industrial and commercial heat applications do not have an electrical alternative so a decarbonised gas grid with hydrogen has the potential to cover all users. Decisions must be made in the early 20s in order to give enough time to build the infrastructure incrementally to achieve decarbonisation targets in line with the Climate Change Act.

20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved?

Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

Currently electrical consumption accounts for around 20% of energy in the UK. A zero carbon power sector in 2050 would be heavily supported by a zero carbon hydrogen gas network and would be transporting more of the UKs end use requirement (maybe up to 40/50%). The hydrogen gas network would likely be providing the fuel for centralised power generation but also supporting decentralised power generation with micro CHP in the home removing 10% losses from the electrical distribution system. The power grid would also be supplied by growing renewable generation capacity and additional nuclear capacity. The electricity distribution grids would have undergone significant reinforcement and rebuilding to support both existing electrical demand and significant amounts of additional demand for electrical use for transport. The electricity network would be operating alongside the hydrogen gas grid taking advantage of system coupling opportunities between these two complementary energy vectors.

21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

Transportation currently accounts for around 40% of UK energy use and is almost entirely based on oil. Low carbon vehicles will be required to move away from oil and will likely be fuelled by a combination of gas (either methane and/or hydrogen) and electricity (which will only be low carbon if we have decarbonised the supply). To support and explore this potential NGN is partnering with Leeds City Council to construct a natural gas filling station which will initially be used to refuel the council’s waste disposal fleet. In order to fully displace oil significant additional energy production capacity will be required to meet the demand in the form of both gas (potentially hydrogen via steam methane reformers) and electricity. Additionally significant reinforcement of the electricity grid (transmission and distribution) will be required and extensive gas fuelling stations and electrical charging stations will need to be built. In reality, in order to meet the challenge, a combination of electrical vehicles (more likely in the domestic market) and gas vehicle in both the domestic and industrial markets (refuse trucks, HGVs, vans etc) will be required. The opportunity to utilise the UKs gas network for hydrogen would resolve any energy storage issues as gas can be stored indefinitely and managed to meet huge swings in demand as it does today.

26. What are the merits and limitations of natural flood management schemes and

innovative technologies and practices in reducing flood risk?

The impact of the Climate Change on the physical environment is a growing risk for infrastructure providers. The appropriate or efficient response to managing or mitigating these risks for existing infrastructure is, in many cases, multi-party. Without cooperation in addressing these risks, it could be envisaged that there may be multiple responses to the same risk with the potential for inefficient or over-investment.

'Up-stream' or 'natural' solutions to the impacts of climate change and flooding on the physical environment can be an effective and efficient way of managing these risks. However, this can only be confirmed when compared directly with the alternative investment or operational responses that manage the impact on infrastructure. There is therefore a requirement to ensure there is an effective means by which these comparisons can take place and how 'optimal' solutions can be identified and funded potentially across multiple agencies and industries.

Longer-term, it is clear that these impacts of climate change will need to become an important consideration in planning for investments in new infrastructure

May I draw your attention to three reports; the previously mentioned Energising the North, report, H21 Leeds City Gate and 2050 Future Energy Scenarios, which I hope you read with interest: <http://www.northerngasnetworks.co.uk/ngn-and-you/document-library/gearing-up-for-the-future>

It is our hope that the findings of the above reports and our direct response to your questions provide substantial evidence to help support the NIC in delivering a decarbonised energy sector.

I would be delighted to provide any further information for you and your team on Northern Gas Networks strategic priorities regarding delivering clean, secure, low cost energy for our customers. Please do let me know if this is of interest.

Yours sincerely,

Northern Gas Networks

[telephone number redacted]

[email redacted]

Northern Powergrid's response to the National Infrastructure Assessment Call for Evidence

Key Points

- **Moving towards 2050, networks are taking an increasingly central role in the energy system** due to the change in the generation mix, the growth in distributed energy, and the need to cost-effectively balance competing policy drivers and facilitate innovative approaches.
- **Electricity networks can be key enablers of growth, but maintaining resilience is critical to this.**
 - Managing the interdependencies between various parts of the energy supply chain, but also between different types of infrastructure is key to maintain or bolster the resilience of the energy system while allowing for innovation and change.
 - We need to consciously manage cross-network issues to ensure that investment builds resilience and mitigates against over-interdependence between systems.
- **DNOs have a critical role in supporting the roll-out of electric vehicles and they could provide a route for the rapid initial roll-out of a national network of charging infrastructure.**
- The Energy System is undergoing many changes and the future shape of the system is not clear. **Government has a clear role in ensuring that this transition is orderly:**
 - We believe that **particular weight should be given to innovations in the system that create flexibility, or those that create option value** – prioritising decisions (to either act or defer) that have low-or no-regret associated with them.
 - The broad structure of roles and responsibilities in the UK energy system works well, and the challenge is to allow for innovation, and flexibility at both national and local level, without introducing unnecessary risks and undermining investment in the sector.
 - **Ofgem needs to be a proactive regulator**, but it must also open and predictable; **we welcome the publication of its Regulatory Stances document¹.**
- Both third party and network companies should be allowed to deploy and operate distributed energy resources (like storage) - these types of asset could be vital tools in managing networks and network companies should be given some space to innovate.
 - **The *de-minimis* thresholds in the distribution licences could be calibrated to permit DNOs to take controlled but valuable steps towards becoming distribution system operators (DSOs)**, in doing so 'priming the pump' for technological and commercial innovations.
 - There needs to be a re-think of the funding routes available to support a 'whole energy system' approach for innovation projects widening the focus from the current 'network only' innovation. **Government should allow DNOs to be active players in networks innovation without crowding out third parties.**

¹ <https://www.ofgem.gov.uk/publications-and-updates/ofgems-regulatory-stances>

Overview

1. We welcome the Commission's call for evidence on the UK's infrastructure needs. The work is highly relevant to the recent call for evidence that we provided to the Department of Business, Energy and Industrial Strategy (BEIS) and Ofgem on a smart, flexible energy system². Many of the themes we raise here are explored in more detail in our response to that call for evidence³.
2. Further, we recognise a further important linkage – to the Government's green paper on the Industrial Strategy⁴. We are currently reviewing our response to that consultation along with our stakeholders.
3. Our submission is to be read in a wider context than simply Northern Powergrid as a distribution network operator (DNO). Our parent group has an appetite for further investment in energy infrastructure if the investment conditions are right.
4. We recognise that the National Infrastructure Commission (NIC) has already expressed an opinion on the future of energy infrastructure in the Smart Power report⁵, published in March 2016. We take the opportunity to return to some of the themes raised there in this response.

Northern Powergrid

5. Northern Powergrid is a wholly-owned subsidiary of Berkshire Hathaway Energy, one of the world's largest energy companies. Berkshire Hathaway Energy is an international group made up of integrated power companies; electricity transmission and distribution network companies and gas pipeline operators.
6. In the UK, Northern Powergrid runs the electricity distribution network that provides power to customers in the Northeast, Yorkshire and northern Lincolnshire. We are responsible for the safe, secure and cost-effective delivery of electricity to around eight million people in 3.9 million homes and businesses.
7. In practice we operate as one company, but we are regulated by the energy regulator, Ofgem, as two licensed businesses: Northern Powergrid (Northeast) Ltd. and Northern Powergrid (Yorkshire) plc.
8. We are one of the largest businesses in our region, directly employing over 2,200 people and a similar number of contractors. The majority of our annual investment in the UK is in regulated electricity networks - we typically invest £340m per annum.
9. Our network underpins the economy in Yorkshire, the Northeast and North Lincolnshire, connecting homes and businesses to transmission network and to generation; we also contact a full range of generating assets to the overall energy system. We are directly important to our local economies through our commitment to on-going investment in our network and see our role as facilitating the effective and efficient operation of the overall energy system and supporting growth in our region.

⁵ www.gov.uk/government/publications/smart-power-a-national-infrastructure-commission-report

Berkshire Hathaway Energy

10. While a separate regulated business Northern Powergrid benefits from being part of the Berkshire Hathaway Energy (Berkshire Hathaway Energy) group. Berkshire Hathaway Energy is a multinational energy company active across the entire energy supply chain through its various subsidiaries, most of which are in North America. Berkshire Hathaway Energy employs 21,000 employees worldwide, owns £53bn worth of assets, and invests more than £3bn per annum. Berkshire Hathaway Energy has 11.6 million customers and runs 34GW of generating assets. It operates 233 thousand miles of power transmission and distribution lines and 43 thousand miles of gas pipelines⁶. In addition to developing transmission and distribution networks we are also responsible for developing some of the largest wind and solar projects in North America as of early 2017 our parent owns 7% of US wind generation and 6% of US solar generation.
11. Northern Powergrid and the other Berkshire Hathaway Energy companies actively collaborate to ensure that lessons learnt in one business are shared across the group as part of a culture of continuous improvement.
12. We believe that the best way to protect and build the value of our business is to:
 - provide excellent customer service, with a commitment to continuous improvement;
 - strive to meet the highest standards of safety and (cyber) security; and
 - strategically invest for the long term.
13. Being part of Berkshire Hathaway Inc. means that we focus on building value rather than paying dividends. We believe that this long-term approach to investing and relatively conservative approach to running businesses is a powerful strategic fit with energy systems which require a lot of capital investment in assets that will last a long time.

Responses to the Commission's questions

14. Our detailed responses focus on those areas where we have the most evidence to provide from our position as a large energy utility centred in northern England and our appetite for infrastructure investment opportunities more widely. We are providing responses to five of the detailed questions. Our thinking is evolving in this space, particularly as we consider our response to the Industrial Strategy Green Paper.

Q9: How can we most effectively ensure that our infrastructure system is resilient to the risks arising from increasing interdependence across sectors?

15. From an energy perspective, it is vital that government takes a whole system approach, as there are interdependencies across the electricity transmission-distribution system as well as across vectors (electricity, heat and gas). We engage across these sectors with various industry parties and we believe that more whole energy system innovation is required to understand the cross-sector opportunities with their associated risks.

⁶ https://www.berkshirehathawayenergyco.com/assets/pdf/2016_corporate_brochure.pdf

-
16. In order to support innovation, there needs to be a re-think of the funding routes available to support 'whole energy system' trials that may deliver customer benefits (current projects in our sector are mostly focused 'network only' innovation).
 17. Cyber security is one such cross-sector risk, born from interconnectivity with data infrastructure, and the interconnectivity throughout the energy supply chain. As a member of the critical national infrastructure community we are engaged in dialogue with a range of organisations and Government. This collaboration is important in order to manage effectively what is arguably the most significant external risk facing the energy industry. The work is successfully identifying a number of routes by which parties may strengthen the energy system's resilience to this risk.
 18. The need to assess our exposure to climate change risks has led us to assess the interdependencies of our network assets with other infrastructure. Our adaptation strategy⁷ is in place and we have a plan on flood resilience whereby we are increasing the level of protection at substations dependent on a risk-based approach. Flood resilience is a part of our capital investment programme that attracts strong stakeholder support and interest. More widely, interaction with local authorities includes dialogue on blue-green infrastructure projects as well as emergency preparedness and response.
 19. Finally, a key area of inter-dependency is on telecommunications infrastructure where we use a mixture of private and public networks. We believe that smart systems offer opportunities towards increased resilience. **We have thoughts on this risks area that we would gladly discuss with the NIC.**

Q10: What changes could be made to the planning system and infrastructure governance arrangements to ensure infrastructure is delivered as efficiently as possible and on time?

20. The earlier Smart Power report highlighted the need for network companies to make long term strategic decisions, and work with third parties to help facilitate these investments (Recommendation 6). We agree with this vision, even more so in the context of the Government's Industrial Strategy which aims to stimulate pockets of economic growth with the likelihood of an associated increased in electrical demand. Engagement with our stakeholders indicates that they too support such a vision.
21. Government articulated in their response to Recommendation 6 that Ofgem's Quicker and More Efficient Connections (QMEC) was exploring the issue. We remain engaged with Ofgem and connections customers on this workstream. The priority here is for network operators to engage with local stakeholders and bring forward proposals to Ofgem where alternative or novel arrangements could reduce either or both of the timescales or the costs of connections. As such, we are discussing our customers' needs and exploring alternative arrangements where we can justifiably make efficient anticipatory investment to support regional economic development while also protecting the generality of our customers from increased costs from which they do not benefit.
22. There are some market distortions in the provision of electrical infrastructure that need closer scrutiny. We describe these further in our response to question 20 below.

⁷ www.northernpowergrid.com/asset/0/document/2032.pdf

-
23. We take note of the Commission's view, expressed in the Smart Power report, that the separation of the system operator (SO) function from the transmission operator function should not be a priority. Even with enhanced separation within National Grid, both running the SO as a truly independent function and credibly demonstrating that independence will be very challenging. Time will see if the new arrangements are sustainable.

Q19: What is the highest value solution for decarbonising heat, for both commercial and domestic consumers? When would decisions need to be made?

24. Across networks there is continuing uncertainty around how domestic heat will be decarbonised (and at what pace), with the prospect of potentially large-scale installation of domestic electric heat at some point in the next decade and, possibly, radical changes to how we use gas distribution networks (which might involve pairing them back or moving to grid hydrogen). This is detailed in the next steps for UK heat policy report by the Committee on Climate Change⁸.
25. The UK growth in heat pumps is well behind the forecasts from 2013. There were around 35,000 installations up to Q2 2016 versus a forecast of around 10 times that amount⁹.
26. Such equipment is more suited to new build, where the design of the heating system is an integral part of the design of the whole house (mainly for reasons of space and retrofit). We observe that the relatively low UK deployment of heat pumps is likely due to the practicalities of retrofit in addition to the subsidy not being sufficiently attractive to customers.
27. Northern Powergrid's Customer-Led Network Revolution (CLNR) project with 380 heat pump installations found that heat pumps were not as popular as expected with homeowners, due to the 'hassle factor' of installation, space constraints, requirement for low temperature radiator/underfloor heating and due to low levels of insulation in rural off-grid properties¹⁰. Some heat pump installations required planning permission from the local authority which caused delays.
28. Thermal storage enables the decoupling of electricity use and heat production, which means that this category of appliances can rank high in terms of flexibility of usage by consumers and thus of DSR potential¹¹.
- Trials of such heat pump combinations in the CLNR project showed that interruptions were successful for 67% of the time with the electricity consumption falling to zero during the control period, with no customer complaint about temperature fluctuations or report of inconvenience during the interruption event.
 - The heat pump was set to build a store of heat for up to two hours prior to an interruption, which meant that the trial participant had a supply of hot water to see them through the peak interruption because thermal storage enables the decoupling of electricity use and heat production, which means that this category of

⁹ 'Pathways to high penetration of heat pumps', Frontier Economics, October 2013

¹⁰ 'Customer experience of demand side response with smart appliances and heat pumps', available as report CLNR-L097 from the project library: www.networkrevolution.co.uk/resources/project-library/

¹¹ 'Future potential for DSR in GB', Frontier Economics, October 2015

appliances can rank high in terms of flexibility of usage by consumers and thus of DSR potential¹².

- As such, we would suggest that one way to increase customer engagement with this category of appliances is to add thermal storage to a heating or cooling system, thereby allowing for the consumer to remain comfortable, even when an appliance is switched off for DSR purposes.

29. The sector is still in a phase where it is exploring and comparing the costs, benefits and practicality of different solutions. As such, we believe that our role for now is to remain engaged with that diversity of solutions, and contribute to the assessment of demonstrator projects. For example we are engaged with the following heat projects:

- Customer-centric: a cross-utility project¹³ researching the attitude, needs and priorities of multi-storey tenants in terms of heat and other services;
- Stakeholder-led: smart systems and heat¹⁴ in Newcastle – a study by the Energy Systems Catapult of the potential heat solutions that would enable Newcastle City Council to meet its objectives for lowest cost decarbonisation of heat;
- Technology-centric: a report¹⁵ investigating the potential for electricity network operators to make a direct contribution to preventing fuel poverty, by investing in domestic energy efficiency improvements; and
- District heat deployment: being led by local authorities in our region to deliver affordable, low carbon heat and attract new businesses to deliver economic growth.

30. District heat is clearly an attractive solution for energy dense areas such as city centres and is being supported through the BEIS Heat Network Development Unit. However there are unintended consequences from these developments by local authorities that are leading in some instances to the inefficient development of energy systems. As they seek to maximise the revenue stream from the CHP system installed, local authorities in the Northern Powergrid region are implementing or considering the option to act as unlicensed energy suppliers over private wires.

- This option is currently the easiest in the current licensing framework, and the most appealing because it deducts from the electricity price the cost of the regulatory overhead and policy costs that would otherwise be levied (i.e. avoiding a “tax”).
- It means that development of the heating and electrical infrastructure takes place ‘behind the meter’. As such, an inefficient system is created with duplication of networks in the same streets and the cost recovery for assets then being avoided by those customers leaving the regulated network and placed on other consumers.
- Building a private wire to maximise income, to bypass the current unsatisfactory supply licence framework, is an infrastructure solution to a commercial and

¹⁵ More information on: www.northernpowergrid.com/news/new-research-highlights-potential-for-energy-system-win-win-win

regulatory issue. We believe that our stakeholders deserve a commercial solution to a commercial issue.

Q20. What does the most effective zero carbon power sector look like in 2050? How would this be achieved? Note: the “zero carbon power sector” includes the generation, transmission and distribution processes.

31. Energy systems across the world are experiencing changes on many fronts, uncertainty about how new technologies will be deployed and political uncertainty. Berkshire Hathaway Energy, of which Northern Powergrid is part, is seeing similar challenges everywhere it operates.
32. The changes in the UK are particularly acute: the future shape of the UK energy system is not clear. The broad structure of roles and responsibilities in the UK system works well; indeed, we see regulators in other jurisdictions moving towards the UK model.
33. The challenge is to manage the system to allow for innovation and flexibility of outcomes without introducing unnecessary risks and undermining investment in the sector. Government and regulatory policy needs to recognise this and facilitate innovation, diversity and experimentation while also maintaining the coherence and stability of the system overall. This is an obvious pillar of any Industrial Strategy.
34. In terms of policy development for BEIS and Ofgem, we believe that particular weight should be given to innovations in the system that create flexibility, or those that provide option value – prioritising decisions (to either act or defer) that have low- or no-regrets associated with them.
35. We believe that more customer engagement and regulatory innovation will be needed to unlock the potential of smart appliances and demand side response – applications are more advanced in some US states, in part, because there are fewer barriers to this.
36. The strategic priorities for the development of distribution charges need much clearer focus with an Ofgem-led review:
 - Ofgem should address the barriers and distortions that competition in distribution has introduced to ensure the appropriate socialisation of certain costs.
 - Network charging needs to be reformed to eliminate the scope that exists now for ‘free riders’ between customer groups and the perverse incentives that undermine fair cost recovery.
 - We see a future in which DNOs charge more active customers through bilateral contracts or market platforms, with traditional charging structures remaining for passive customers.
37. The review of charging should focus on the following¹⁶:
 - **Whole system cost-reflectivity and arbitrary distortions:** In future, it will be increasingly important that cost-reflectivity is considered from a ‘whole system’ perspective. Currently, there are different methods to derive grid charges for the transmission and distribution systems, and different methodologies employed at

¹⁶ For further detail see ‘Northern Powergrid’s response to ‘a smart, flexible energy system’ call for evidence from BEIS and Ofgem’ – paras 1.56-1.60 pp. 10-11 and paras 3.67-3.71 pp. 42-44, January 2017, <http://www.northernpowergrid.com/asset/0/document/3014.pdf>

different voltages within the distribution system. These create arbitrary boundaries across which tariffs vary significantly and in a way which does not reflect system cost.

- **Consistency across different areas of charging and the DSO role:** We potentially see three areas of charging that need to be considered simultaneously ensuring that relevant price signals are sent once and once only, namely: connection charges; DSO contracts; and use of system charges. Building in appropriate cost signals at this stage is the most likely means of influencing behaviours.
 - **Equity across consumer groups and avoiding the ‘free rider’ problem:** Outcomes must be good for consumers as a whole and not benefit one sector at the expense of material downside to another. Policy makers and companies need to consider any potentially disproportionate effects on the most vulnerable, and the problems that arise from ‘free rider’ issues need to be carefully considered and mitigated where possible.
38. Whatever generation and demand end up looking like, we see networks at the heart of the energy system. However exactly how technology will be used is not clear, but electricity networks and smart technology going to be key – the focus should be on building flexibility and option value. We think that the next five years is going to be a time of innovation and experimentation and so DNOs should be allowed to play fairly in this space as long as they don’t crowd third parties out.
39. As local networks take more central stage, system operation at distribution level will become essential. Such transition to more active Distribution System Operators (DSOs) merits careful consideration. At a high level we believe that the owner of a network is best placed to operate it, but there are clearly certain functions which sit between different players in the market.
40. We are supportive of the DSO work that Ofgem and the industry have carried out to date, and believe that we are the right party to provide local system balancing as a natural extension of the steps we are already taking to more actively manage our network and our knowledge of the local network requirements. However, clearly defining the scope of DSO activities is crucial as there is a need to ensure consistency and a common industry understanding.
41. Both third party and network companies should be allowed to deploy and operate distributed energy resources (like storage) - these types of asset could be vital tools in managing networks and network companies should be given some space to innovate.
- The *de-minimis* thresholds in the distribution licences could be calibrated to permit DNOs to take controlled but valuable steps towards becoming DSOs, ‘priming the pump’ for more widespread competitive market-based mechanisms to emerge over the medium- and long-term.
 - There needs to be a re-think of the funding routes available to support a ‘whole energy system’ approach for innovation projects that target the delivery of customer benefits from greater overall efficiency, widening the focus from the current ‘network only’ innovation.

-
42. More generally, Ofgem needs to be a proactive regulator - particularly in this space, but it must also open and predictable in order to maintain investor confidence; we welcome the publication of its Regulatory Stances document in that context¹⁷.
 43. We are committed to bringing our broad experience of running energy companies internationally to help the Government and regulators get the balance right and support economic growth.

Q21. What are the implications of low carbon vehicles for energy production, transmission, distribution, storage and new infrastructure requirements?

44. Evidence to date suggests that the more widespread charging of electric vehicles could have a significant impact on the distribution network with potentially high costs to absorb the new load. This is because charging of electric vehicles (EVs) unless managed is typically concentrated in the evening, coinciding with the household peak demand, as revealed by analysis from 160 EVs in the CLNR¹⁸ project and other trials. In these trials, time-of-use tariffs were not prevalent, and the EV charging curve closely followed the household demand curve, so we infer that it is strongly correlated with household occupancy.
45. In addition, Energy Networks Association members have worked collaboratively to carry out a high-level assessment of the potential impact of more widespread roll-out of electric vehicles and the associated charging smart-charging infrastructure. Part of that work included an analysis of the potential network investment cost to support charging infrastructure for EVs, which identified that under some relatively ambitious, but nevertheless plausible take-up scenarios, there would be a need for substantial investments between now and 2040.
46. There is evidence to support the fact that smart technology solutions can reduce the costs significantly. The My Electric Avenue project¹⁹ concluded that across Britain 32% of local electricity networks (312,000 circuits) will require intervention when the penetration rate of EVs reaches between 40% and 70%, but that new technology could reduce the cost by around £2.2 billion up to 2050.
47. Looking beyond the simple aspect of load growth we believe that electric vehicles could be a truly transformational technology that provide flexibility services to electricity suppliers or the network (known as 'vehicle to grid'). We supported the proposal in the BEIS and Ofgem call for evidence on a smart, flexible energy system for more demonstration projects in this area²⁰. It is an example of an opportunity to mitigate network capacity constraints, and its value may be maximised if used in combination with other network loads (such as heat).
48. We also welcome Government's continued focus on the issue, as demonstrated in the recent green paper on an Industrial Strategy and in its response to the Office for Low Emission

¹⁷ www.ofgem.gov.uk/publications-and-updates/ofgems-regulatory-stances

Vehicles and Department for Transport consultation on the 'Proposed ultra low emission vehicles measures for inclusion in the Modern Transport Bill'²¹.

49. We believe that there are two unresolved barriers to maximising the value from EVs for the energy industry:
- how a network company accesses services (i.e. either managed charging or vehicle-to-grid) from the end customer when the primary commercial relationship with the customer is through the supplier; and
 - the time and cost associated with the installation of fast-charger infrastructure.
50. We think DNOs could play an important role in rolling out EV charging infrastructure quickly. This could be achieved through the socialisation of the connection costs (i.e. transferring the cost from the connection customer to the entire customer base). Once this is secured, DNOs could invest in anticipatory reinforcement that supports the roll-out plans of stakeholders, such as housing developers or local councils. The DNO would continue to operate under their cost-efficiency, and non-discriminatory duties, and so act as advisors to stakeholders on preferred location, and suggest potential high-value combinations of solutions (i.e. matching complementary loads or generation in order to 'net off' and manage diversity for the benefit of all customers).

National Infrastructure Assessment – Call for Evidence

Friday 10 February 2017

NORTHUMBRIAN WATER GROUP

Introduction

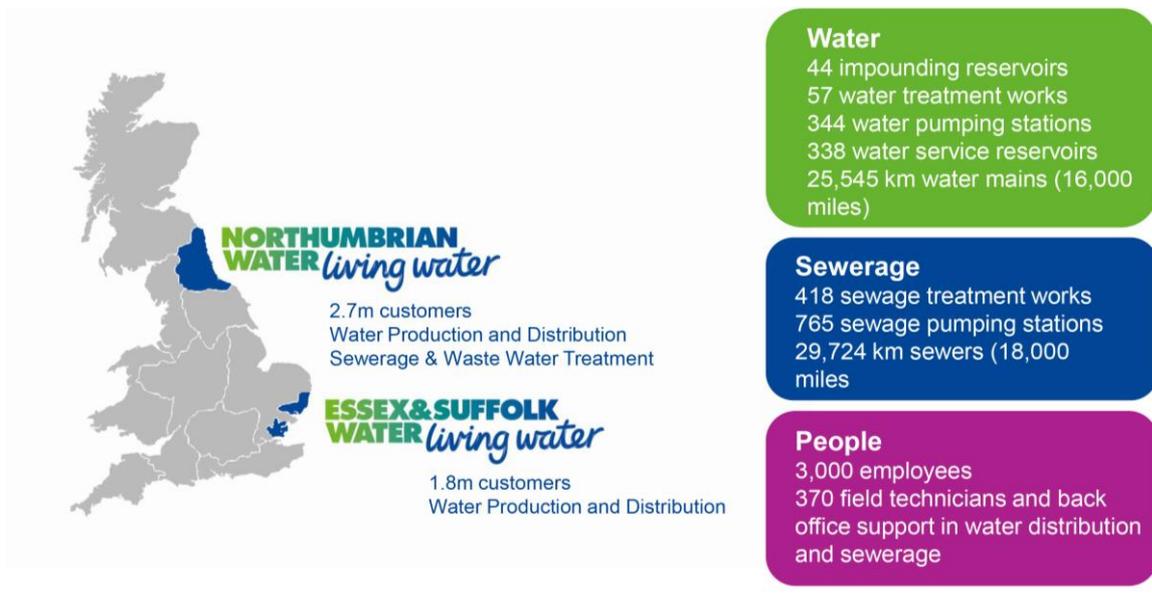

Northumbrian Water and Essex & Suffolk Water are part of Northumbrian Water Limited (NWL), which is a member of Northumbrian Water Group (NWG). We supply water and sewerage services to 4.5 million people. Every day we supply 1,104 megalitres (1.1 billion litres) of water.

North east England

Northumbrian Water provides water and sewerage services to 2.7 million people in the north east of England. The major population centres of Tyneside, Wearside and Teesside are in our area but we also serve large rural areas in Northumberland and County Durham (provision of waste water services only in Hartlepool).

South east England

Essex & Suffolk Water provides water services to two separate supply areas. Our Essex area, which has a population of 1.5 million, is part rural and part urban with the main areas of population being in Chelmsford, Southend and the London Boroughs of Barking and Dagenham, Havering and Redbridge. We serve a population of 0.3 million in our Suffolk area, which is mainly rural with the biggest towns being Great Yarmouth and Lowestoft.

Evidence

Having reviewed the questions put forward in the call for evidence, Northumbrian Water Group would like to put forward evidence for the following questions:

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?
22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?
23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?
24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?
25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?
26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?
27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?
28. What are the barriers to achieving a more circular economy? What would the costs and benefits (private and social) be?

Should you have any queries please contact:

4. What is the maximum potential for demand management, recognising behavioural constraints and rebound effects?

Note: “demand management” includes smart pricing, energy efficiency, water efficiency and leakage reduction. “Rebound effects” refer to the tendency for demand to increase when measures aimed at reducing or spreading demand also lead to lower prices or reduced congestion, undoing at least some of any demand reduction. For example, if smart meters reduce the cost of electricity in off-peak periods, this could lead to greater energy consumption overall, where a large number of individuals or firms take advantage of these lower prices by increasing their total usage

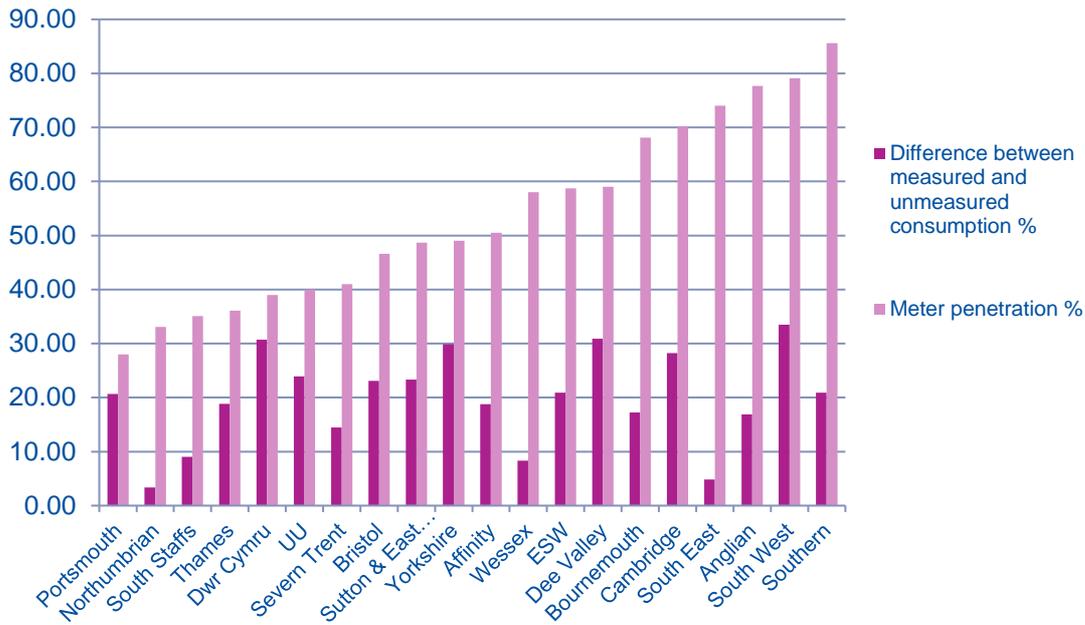

Water demand is the sum of a number of components, the more controllable component is leakage and significant reductions in leakage will require considerable funding. Reductions to consumption may be achieved through lower cost options although the results are less predictable. There is scope for further leakage reductions to be achieved nationwide but most companies focus on maintaining leakage at the sustainable economic level (SELL) through active leakage control (ALC). ALC involves finding and fixing leaks to counteract the increase in leakage through the effect of asset deterioration.

Reducing leakage beyond the SELL would need to be justified given the exponential rise in costs as leakage is driven down. Sustained, intensive ALC could theoretically reduce leakage as far as background leakage levels (around 60% of SELL). However, we estimate this would require five times the number of leak detectors required to maintain SELL. The number of leak repair jobs would increase by an even greater factor as identifiable leaks reduce in size as the level of leakage decreases. Additionally, we estimate that leakage occurring on customer pipework is 35% of overall leakage. It is very difficult to quantify and may be increasing, but identifying and addressing customer-side leakage will remain a big challenge without substantial investment into logging individual properties.

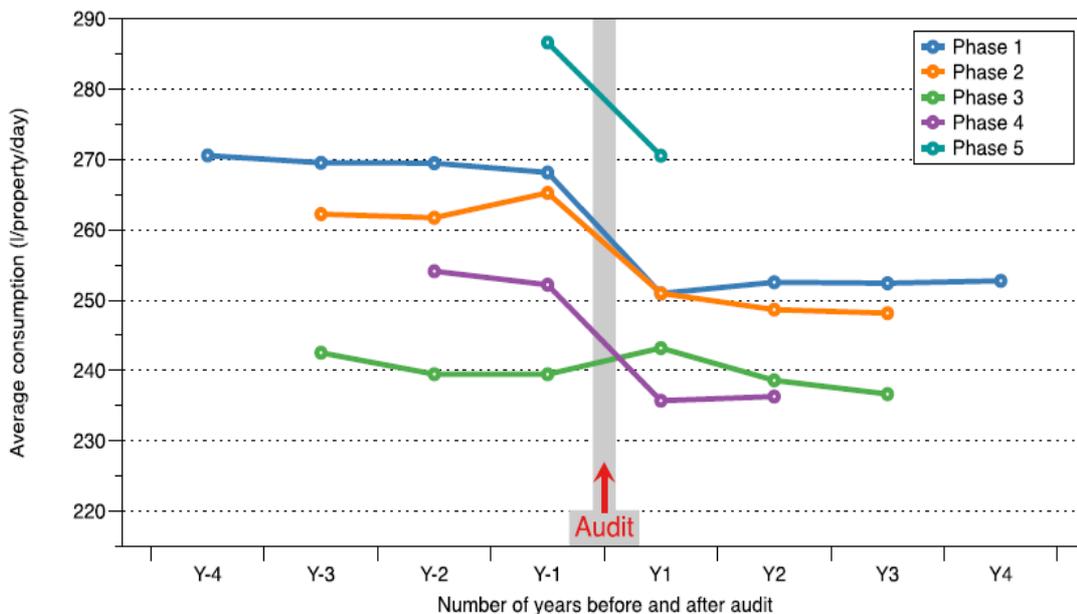

Renewing the water network has the effect of reducing background leakage levels and reducing the natural rate of rise (the rate at which new leaks appear) but the costs are high for the reduction achieved. Background leakage and the occurrence of bursts can be reduced with far less investment through reducing water pressure in the network. The maximum potential reductions that can be achieved with this can only be determined on a case by case basis. In Northumbrian Water (NW), early calculations are that up to a 20% leakage reduction might be achieved. In Essex & Suffolk Water (ESW), we have few remaining opportunities to optimise pressure management. Customer impacts of pressure changes also need to be considered.

Water consumption can be split into two categories – measured and unmeasured. Unmeasured consumption is difficult to quantify and water companies use different methods to estimate this. Based on the figures which are reported, customers with meters always have lower consumption per person than unmetered customers, although the difference on a company level can be as low as 3% or as high as 35%. This does not appear to correlate to the meter penetration level, as shown in the graph below.

Comparison of meter penetration and the difference between measured and unmeasured consumption in 2015/16

Metering alone does not deliver a consistent reduction to consumption. It is more effective when coupled with the promotion of water efficiency, which by itself can be a cost effective method of reducing consumption. The benefits are more easily measured with metered customers although there are often greater potential gains to be had from unmeasured customers. Analysis of eight phases of water efficiency audits over the past four years shows the reductions to consumption which can be achieved are highly variable and therefore uncertain. In the eight phases analysed (total of 4240 properties), average savings ranged from 4.9 litres/property/day to 48.1 litres/property/day. It can be seen from the four earlier phases that reductions have been sustained through time, as shown below.

Our experience shows that a combination of metering with water efficiency advice can lower consumption by 8 – 12% per property, although this only applies to unmetered properties which make up 67% of NW's properties and 41% of ESW's. Meter penetration has a ceiling of approximately 90% as a significant number of properties cannot currently be metered. While reductions in use are on average maintained, during dry weather periods metered customers increase their consumption and return to usage close to the dry year demand of unmeasured customers. This means water companies require the overall dry year water resources and associated treatment and distribution infrastructure to be able to meet these increased demands. More significant reductions to consumption might be achievable with greater grey water use either introduced through technology in the home or if water companies introduced a grey water supply stream. Either way, this would place a significant cost burden on customers and would rely heavily on changing customer attitudes and behaviour, reducing certainty in the effectiveness of a grey water strategy. There are also numerous water quality incidents where cross contamination has occurred between grey water and potable water systems. Appropriate regulation, training and competency is required here. Not just with companies installing this technology, but with the users.

22. What are most effective interventions to ensure the difference between supply and demand for water is addressed, particularly in those parts of the country where the difference will become most acute?

There are multiple approaches that may be taken to manage the supply-demand balance where current resources are short. In Northumbrian Water Group's regions (as in the rest of the UK) demand is gradually decreasing through reductions to leakage and customer consumption, and there is still scope for further reductions which should be pursued. However, there are limits to what can be achieved, as described in the response to Question 4. The costs of reducing leakage become increasingly high as it falls below the economic level – the level at which most companies are already managing leakage. Reducing customer demand substantially is also very costly and the effectiveness of investing in metering and/or efficiency promotion is variable and uncertain. At present, demand management measures are forecast to be sufficient to maintain the supply-demand balance for Northumbrian Water and Essex & Suffolk Water over the next 25 years.

Whilst demand management is important it cannot meet future forecast demands arising from population growth, climate change impacts and reductions in current abstractions for environmental reasons.

At present, population growth is not increasing demand to the point where the gains being achieved through leakage management and efficiency initiatives have no beneficial impact on the supply-demand balance, but this may change. In every situation where we have needed to rebalance supply and demand we have considered options on the basis of cost and certainty. As we were able to demonstrate in the case of Abberton reservoir expansion, in some cases it will be more effective for the long term to address a persistent supply-demand imbalance by investing in new or existing resources.

Some areas of the country have plentiful raw water resources which are not currently being used. Improving the connectivity between water resources nationally, enabling the transfer of water into water stressed areas, is likely to offer the most effective solution to chronic supply deficits. Building more treated water storage capacity would also offer greater security of supply and flexibility in the management of short-term supply-demand issues. Further into the future, if population growth or climate change puts strain on resources nationally then transferring water between regions may not be sufficient and it will then be necessary to invest in new dams, reservoirs, boreholes or even desalination plants. In that case, it will also be necessary to expand treatment and distribution capacity.

23. What are the most effective interventions to ensure that drainage and sewerage capacity is sufficient to meet future demand?

Note: this can include, but is not necessarily limited to, governance frameworks across the country.

The drainage system is complex with fragmented roles and responsibilities which can lead to sub-optimal interventions and solo working often driven in response to performance issues.

There are two types of potential interventions which are not mutually exclusive, reactive and proactive. We are largely focused on reactive interventions however we are exploring proactive flood risk reduction. In our experience the most effective interventions consider the following;

- **Partnership Working**

The Northumbria Integrated Drainage Partnership (NIDP) consists of 13 Lead Local Flood Authorities, the Environment Agency (EA) and Northumbrian Water (NW). The group aligns with and supports the Northumbria Regional Flood and Coastal Committee (NRFCC). The NIDP is successfully providing a link between reactive flood risk management and the desire for a proactive area based risk approach for the provision of integrated sustainable drainage. The outputs from the activities delivered through this group provide a robust evidence base for business planning and subsequent investment. This allows partners to align funding streams, develop schemes which are efficient, provide flood risk reduction from all sources, ensure future demands on the drainage network are mitigated and exceedance routes are created. A case study is located in appendix 1.

We are exploring partnership working with organisations which do not have flooding as a main objective but where working together could be mutually beneficial such as transport departments in Local Authorities. Together with Newcastle City Council (NCC) we were successfully awarded an Innovate UK grant to explore the feasibility of aligning various council programmes with the strategic surface water management plan for the city. This project has highlighted the difficulties in aligning multiple funding sources and programmes of work.

- **Risk Based Prioritisation**

Water and waste water companies face significant challenges relating to drainage such as flood risk reduction, reducing pollution, managing ageing assets, managing impacts of growth and urban creep etc. There is increasing pressure to keep water bills down and we must ensure our interventions provide the best possible outcomes for our customers. Therefore we must ensure that interventions in the drainage network maximise risk reduction. Risk based prioritisation is required for both partnership working and for sole responsibility interventions. NW have an internal risk based prioritisation for sole responsibility issues and have been instrumental in developing a regional risk based prioritisation for the NIDP.

- **Understanding of source/pathway/receptor**

Source control considers that prevention is better than cure. Slowing the flow of rainwater from entering streams, becks, rivers and sewerage systems can reduce the peak flow in the whole drainage system and reduce the risk of flooding to homes, businesses and communities. This approach advocates exploring the interdependencies of the drainage system and understanding that upstream catchment wide interventions can be most beneficial. An integrated catchment approach must consider practices within that catchment. This includes but is not limited to growth, land management, customer behaviours, urban creep, and community engagement.

- **Integrated catchment wide approach to the water cycle considering water quantity and quality**

It is also important to understand that the drainage system is part of the overall water system and that an integrated approach to include drainage issues should also include water quality and quantity issues. During the year we have made the first tentative steps towards aligning the aspirations of the NIDP and the Catchment Partnerships within the region. We believe this alignment of the flood risk and water quality and quantity agendas will provide even greater opportunities to deliver an integrated sustainable approach to water – see appendix 2.

24. How can we most effectively manage our water supply, wastewater and flood risk management systems using a whole catchment approach?

We recognise the need to take an integrated approach to water management. There is a need to balance efficient delivery of our services with risk/resilience and sustainability so that we can provide affordable solutions for customers. Understanding context and value, making environmentally sustainable decisions, striving for multiple benefits and working in partnership will allow us to be more integrated and take a whole catchment approach to deliver our Outcomes.

To take this approach partners must work together, this poses challenges as there are numerous bodies, companies and institutions with varying degrees of responsibility within catchments. NW have managed to take a catchment approach to flood risk management with our risk management partners and are attempting to develop this framework with other environmental partnerships such as the catchment based approach. With our partners we have taken the NIDP 3 stage process and applied stage 1, collection, collation and identification of partnership risks, to the Don River catchment widening the objectives from drainage flood risk to river water quality, habitat and health and wellbeing.

Although this approach is new, we have already recognised benefits, we better understand partner's objectives, and are developing a Don Partnership Vision. We believe this approach will be beneficial and our partners have expressed their aspirations of developing this approach for other water bodies. This type of approach delivers multiple benefits that are high priority to the community. However, most funding streams focus on one significant benefit with lesser benefits making up a small proportion of any funding bid. This makes multiple benefit schemes difficult to implement as multiple funding bids are required and aligning bids is complex. For example, do partners contribute proportionally? If so, how is the proportion assigned, which benefit is evaluated and over what timescale.

25. What level of flood resilience should the UK aim to achieve, balancing costs, development pressure and the long-term risks posed by climate change?

Within the water industry the term resilience incorporates the 4 Rs, resistance, resilience, redundancy and response & recovery and therefore a single measure or level is not the most appropriate item to consider. Instead a national threshold should be considered or a national aspiration that no properties should be at risk of internal flooding. Below this level or aspiration the 4 Rs would be used to determine the most cost beneficial technique for critical and non-critical infrastructure. This would allow companies to take a flexible approach to resilience and ensure the correct measures are taken for each piece of infrastructure balancing the risk, probability, cost and benefits to each intervention in relation to the 4 Rs. It would also ensure that the complexities of resilience were not distilled into a single measure which would stifle innovation and lead to an increase in customer water and waste water bills. It would ensure local conditions such as geography, could be taken into account and would also allow for multiple thresholds based on the criticality of assets.

We also consider that responses to Question 24 are relevant to this question – highlighting the role of land management in resilience, working in partnership and taking a pro-active integrated catchment based approach can deliver cost effective multi-beneficial solutions and ensuring source control techniques are implemented, dealing with the issues rather than the consequence, will help to reduce the long term risks posed by climate change.

The Environment Agency's fluvial and coastal flood maps passed the stress test which was carried out as part of the National Flood Resilience Review. Therefore there is a level of confidence of the fluvial and coastal flooding outline to 1:1000. However this review didn't take into account flooding from surface water or ground water. We welcome the development of enhanced, fully integrated and more accurate models and forecasts to predict rainfall patterns and the likelihood of future floods. Robust models would support future business planning in relation to supply and demand by assisting in the identification and prioritization of areas and projects for future investment, together with resilience and exceedance planning at high risk locations. We suggest that current models with a focus upon direct costs may not capture wider, indirect socio-economic costs associated with flooding.

We welcome the Environment Agency's flood risk awareness campaign committed to in the National Flood Resilience Review. Proactively working with homeowners and businesses at risk, both now and in the future, to assess their properties against the 4 Rs and offering incentives on the solutions could be the most cost effective way of making areas more resilient both now and in the future.

26. What are the merits and limitations of natural flood management schemes and innovative technologies and practices in reducing flood risk?

Note: “innovative technologies and practices” can include, but is not necessarily limited to, property level resistance and resilience, temporary defences, advances in predictive asset maintenance and innovative construction materials.

Natural Flood Management (NFM) is a tool which can be used to slow the flow of water and reduce the risk of flooding. There are other tools which in essence look to achieve the same objective in the same way such as Sustainable Drainage and Water Sensitive Urban Design etc. It is important that the language used does not fragment the message that all of these tools can be used to reduce the risk of flooding from all sources in a sustainable way which provides multiple benefits to society.

NFM, Sustainable Drainage, Water Sensitive Urban Drainage can be difficult to implement due to the fragmented roles and responsibilities for flooding within England. Northumbrian Water (NW) do not have the rights to construct NFM in and around water courses and therefore any scheme would have to be a partnership scheme. Partnerships are voluntary, it can be difficult to measure and apportion benefits for NFM schemes. NFM needs to have buy in from landowners, and it can be difficult to incentivise partnerships to work together and realise the benefits of innovative technologies. NFM may cause land to be flooded, we must realise that this land is someone’s business and we may need to consider compensation. There are real opportunities to incentivising environmental stewardship through landowners as we move from the Common Agricultural Policy. NFM has been successfully used in a number of projects in the North of England such as Pickering and Belford. It can be difficult to secure funding through Flood Defence Grant in Aid (FDGiA) as the tool used to calculate FDGiA was set up for coastal and fluvial flood defence work and can be very difficult to complete for partnership schemes and for schemes which use innovative technologies.

We consider that elements of our response to Question 24 are relevant to this question – highlighting the role of land management in resilience, working in partnership and taking a pro-active integrated catchment based approach can deliver cost effective multi-beneficial solutions and ensuring source control techniques are implemented, dealing with the issues rather than the consequence, will help to reduce the long term risks posed by climate change.

We also consider that elements of our response to Question 25 are relevant to this question – ensuring that the 4 Rs are considered when implementing property resilience and resistance to ensure the most effective solution, and the development of enhanced, fully integrated and more accurate models and forecasts to predict rainfall patterns and the likelihood of future floods.

NW have a statutory legal requirement to maintain the sewerage network, the highways agency have a legal duty to ensure highway drainage is maintained however the Environment Agency have no statutory obligation to maintain assets and therefore in times of austerity proactive maintenance may be reduced increasing the risk of flooding from the drainage network.

27. Are financial and regulatory incentives correctly aligned to provide sufficient long-term treatment capacity, to finance innovation, to meet landfill and recycling objectives and to assign responsibility for waste?

The water industry operates within the economic regulatory model overseen by Ofwat who set limits on prices charged for water and wastewater services. Price reviews are carried out every five years and importantly include expected operational efficiencies in protecting customers' bills. A total expenditure (TOTEX) approach was introduced at the 2014 price review to focus on efficient long-term delivery of investment and services, including energy use, waste management and maintenance, rather than capital costs alone. Alongside this was the introduction of Outcome measures instead of the previous approach which centered around meeting Outputs. This economic regulatory framework supports water companies in considering sustainable, resilient and innovative solutions, including effectively managing waste materials.
